Client Key Alias (clientKeyAlias): clientCert
Server Key Alias (serverKeyAlias): serverCert
SSL Type (type): [JSSE]
Client Authentication (clientAuthentication): [false]
Security Level of the SSL Configuration (securityLevel): [HIGH] HIGH
Enabled Ciphers SSL Configuration (enabledCiphers):
JSE Provider (jsseProvider): [IBMJSSE2]
Client Authentication Support (clientAuthenticationSupported): [false]
SSL Protocol (sslProtocol): [SSL_TLS] SSL_TLS
Trust Manager Object Names (trustManagerObjectNames):
*Trust Store Name (trustStoreName): testTrustStore
Trust Store Scope (trustStoreScopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
*Key Store Name (keyStoreName): testKeyStore
Key Store Scope Name (keyStoreScopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
Key Manager Name (keyManagerName): IbmX509
Key Manager Scope Name (keyManagerScopeName): (cell):HOSTNode01Cell:(node):HOSTNode01
```

Create SSL Configuration

F (Finish)

C (Cancel)

Select [F, C]: [F]

```
WASX7278I: Generated command line: $AdminTask createSSLConfig {-alias testSSLConfig
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01 -clientKeyAlias clientCert
-serverKeyAlias serverCert -trustStoreName testTrustStore
-trustStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyStoreName testKeyStore -keyStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyManagerName IbmX509 -keyManagerScopeName (cell):HOSTNode01Cell:(node):HOSTNode01 }
(cells/HOSTNode01Cell|security.xml#SSLConfig_1137687301834)
```

At the end of the output, the batch mode parameters are provided.

– Batch mode:

Using Jacl:

```
$AdminTask createSSLConfig {-alias testSSLConfig
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01 -clientKeyAlias clientCert
-serverKeyAlias serverCert -trustStoreName testTrustStore
-trustStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyStoreName testKeyStore -keyStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyManagerName IbmX509 -keyManagerScopeName (cell):HOSTNode01Cell:(node):HOSTNode01}
```

– Using Jython:

```
AdminTask.createSSLConfig ('[-alias testSSLConfig
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01 -clientKeyAlias clientCert
-serverKeyAlias serverCert -trustStoreName testTrustStore
-trustStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyStoreName testKeyStore -keyStoreScopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-keyManagerName IbmX509 -keyManagerScopeName (cell):HOSTNode01Cell:(node):HOSTNode01]')
```

Example output:

```
(cells/HOSTNode01Cell|security.xml#SSLConfig_1137687301834)
```

- **Key Stores and Trust Stores** The key store and trust store may already exist or a new one may need to be created. To create a new key store or trust store use the `createKeyStore` AdminTask. It will create a key store file and store the configuration object in the system configuration. A trust store is just a key store that usually only has signer certificates in it. To create a key store enter:

– Using Jacl:

```
$AdminTask createKeyStore {-keyStoreName testKeyStore -keyStoreType PKCS12
-keyStoreLocation $(USER_INSTALL_ROOT)\testKeyStore.p12 -keyStorePassword abcd
-keyStorePasswordVerify abcd -keyStoreIsFileBased true -keyStoreReadOnly false}
```

– Using Jython:

```
AdminTask.createKeyStore ('[-keyStoreName testKeyStore -keyStoreType PKCS12
-keyStoreLocation $(USER_INSTALL_ROOT)\testKeyStore.p12 -keyStorePassword abcd
-keyStorePasswordVerify abcd -keyStoreIsFileBased true -keyStoreReadOnly false]')
```

To populate the key store with certificates see “Managing Certificates using AdminConsole and Admin Task” The key store and trust store are required to create a SSL configuration. Use the ‘-keyStoreName’ and ‘-trustStoreName’ flags on the createSSLConfig. There scopes can be added with the ‘-keyStoreScope’ flag and ‘-trustStoreScope’ flags.

- Key Manager Key manager are used to determine how a certificate is selected. The IbmX509 key manager is in the security configuration by default. If a different key manager is needed then use createKeyManager AdminTask to create it. To create a key manager enter:

– Using Jacl:

```
$AdminTask createKeyManager {-name testKeyManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm }
```

– Using Jython:

```
AdminTask.createKeyManager ('[-name testKeyManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm]')
```

To supply a key manager on the createSSLConfig AdminTask use the ‘-keyManagerName’ along with the ‘-keyManagerScope’ flag.

- Trust Manager Trust managers are use to determine how trust is established during ssl communication. The IbmX509 and IbmPKIX are trust managers are in the security configuration by default. If a different or additional trust manager is needed then use the createTrustManger AdminTask to create it. To create a trust manager enter:

– Using Jacl:

```
$AdminTask createTrustManager {-name testTrustManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm }
```

– Using Jython:

```
AdminTask.createTrustManager ('[-name testTrustManager
-scopeName (cell):HOSTNode01Cell:(node):HOSTNode01
-provider IBMJSSE2 -algorithm specialAlgorithm]')
```

The SSL Configuration can have multiple trust managers. To supply multiple trust managers give a comma separated list of the trust managers configuration IDs with the -trustManagerObjectNames flag. When you create a trust manager the configuration object ID is returned. To get a list of trust managers object IDs use the **listTrustManagers** command of the AdminTask object with the -displayObjectName true flag. For example:

```
wsadmin>$AdminTask listTrustManagers -interactive
List Trust Managers
```

List trust managers.

```
Management Scope Name (scopeName):
Display list in ObjectName Format (displayObjectName): [false] true
```

List Trust Managers

```
F (Finish)
C (Cancel)
```

```
Select [F, C]: [F]
Inside generate script command
```

```
WASX7278I: Generated command line: $AdminTask listTrustManagers {-displayObjectName true }
IbmX509(cells/IBM-0AF8DABCF16Node01Cell|security.xml#TrustManager_IBM-0AF8DABCF16Node01_1)
IbmPKIX(cells/IBM-0AF8DABCF16Node01Cell|security.xml#TrustManager_IBM-0AF8DABCF16Node01_2)
```

Updating default key store passwords using scripting

Before starting this task, the wsadmin tool must be running. See the Starting the wsadmin scripting client article for more information.

When you install WebSphere Application Server, each server creates a key store and trust store for the default SSL configuration with the default password WebAS. To protect the security of the key store files and the SSL configuration, you must change the password. The following examples update the default password:

- Change multiple key stores passwords. The **changeMultipleKeyStorePasswords** command updates all of the key stores that have the same password. For example:

- Using Jacl:

```
$AdminTask changeMultipleKeyStorePasswords {-keyStorePassword WebAS
-newKeyStorePassword secretPwd -newKeyStorePasswordVerify secretPwd}
```

- Using Jython:

```
AdminTask.changeMultipleKeyStorePasswords ['-keyStorePassword WebAS
-newKeyStorePassword secretPwd -newKeyStorePasswordVerify secretPwd']
```

- Change the password of a single key store. The **changeKeyStorePassword** command updates the password of an individual key store. For example:

- Using Jacl:

```
$AdminTask changeKeyStorePassword {-keyStoreName testKS
-keyStoreScope (cell):localhost:(server):server1
-keyStorePassword WebAS -newKeyStorePassword secretPwd
-newKeyStorePasswordVerify secretPwd}
```

- Using Jython:

```
AdminTask.changeKeyStorePassword ('[-keyStoreName testKS
-keyStoreScope (cell):localhost:(server):server1
-keyStorePassword WebAS -newKeyStorePassword secretPwd
-newKeyStorePasswordVerify secretPwd]')
```

Commands for the IdMgrConfig group of the AdminTask object

Use the commands in the IdMgrConfig group to configure the virtual member manager. The commands for this group do not require a target object. To see the additional commands related to the virtual member manager, see the Commands for the IdMgrRepositoryConfig group of the AdminTask object and the Commands for the IdMgrRealmConfig group of the AdminTask object articles.

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the IdMgrConfig group of the AdminTask object:

Table 18.

Command name:	Description:	Parameters and return values:	Examples:
<p>createIdMgr Supported EntityType</p>	<p>The createIdMgr Supported EntityType command creates a supported entity type configuration. To validate the result, check for duplicate entity type names.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name of the supported entity type. (String, required) - defaultParent The default parent node for the supported entity type. (String, required) - rdnProperties The RDN attribute name for the supported entity type in the entity domain name. Separate the RDN properties with semicolons (;). (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createIdMgrSupported EntityType {-name <i>entity1</i> -defaultParent <i>node1</i>}</pre> • Using Jython string: <pre>AdminTask.createIdMgrSupported EntityType ('[-name <i>entity1</i> -defaultParent <i>node1</i>']')</pre> • Using Jython list: <pre>AdminTask.createIdMgrSupported EntityType (['-name', '<i>entity1</i>', '-defaultParent', '<i>node1</i>'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createIdMgrSupported EntityType {-interactive}</pre> • Using Jython string: <pre>AdminTask.createIdMgrSupported EntityType ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.createIdMgrSupported EntityType (['-interactive'])</pre>

Table 18. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>deleteIdMgr Supported EntityType</p>	<p>The deleteIdMgr Supported EntityType command deletes the supported entity type configuration that you specify.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name of the supported entity type. The value of this parameter must be one of the supported entity types. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrSupported EntityType {-name <i>entity1</i>} • Using Jython string: AdminTask.deleteIdMgrSupported EntityType ('[-name <i>entity1</i>']') • Using Jython list: AdminTask.deleteIdMgrSupportedEntityType (['-name', '<i>entity1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrSupportedEntityType {-interactive} • Using Jython string: AdminTask.deleteIdMgrSupportedEntityType ('[-interactive]') • Using Jython list: AdminTask.deleteIdMgrSupportedEntityType (['-interactive'])
<p>getIdMgr Supported EntityType</p>	<p>The getIdMgr Supported EntityType command returns the configuration of the supported entity type that you specify.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name of the supported entity type. The value of this parameter must be one of the supported entity types. (String, required) • Returns: A hash map that has the parameters of the createIdMgrSupportedEntityType command as keys. Since the rdnProperties parameter has multiple values, its values are returned in a list. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrSupported EntityType {-name <i>entity1</i>} • Using Jython string: AdminTask.getIdMgrSupported EntityType ('[-name <i>entity1</i>']') • Using Jython list: AdminTask.getIdMgrSupportedEntityType (['-name', '<i>entity1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrSupportedEntityType {-interactive} • Using Jython string: AdminTask.getIdMgrSupportedEntityType ('[-interactive]') • Using Jython list: AdminTask.getIdMgrSupportedEntityType (['-interactive'])

Table 18. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr Supported EntityTypes	The listIdMgr Supported EntityTypes command lists all of the supported entity types that are configured.	<ul style="list-style-type: none"> Parameters: None Returns: A list that contains the names of the supported entity types. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listIdMgr SupportedEntityTypes Using Jython string: AdminTask.listIdMgr SupportedEntityTypes() Using Jython list: AdminTask.listIdMgr SupportedEntityTypes() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listIdMgrSupported EntityTypes {-interactive} Using Jython string: AdminTask.listIdMgrSupported EntityTypes (['-interactive']) Using Jython list: AdminTask.listIdMgrSupported EntityTypes (['-interactive'])
resetId MgrConfig	The resetId MgrConfig command resets the current configuration to the last configuration that was saved.	<ul style="list-style-type: none"> Parameters: None Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask resetIdMgrConfig Using Jython string: AdminTask.resetIdMgrConfig() Using Jython list: AdminTask.resetIdMgrConfig() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask resetIdMgrConfig {-interactive} Using Jython string: AdminTask.resetIdMgrConfig (['-interactive']) Using Jython list: AdminTask.resetIdMgrConfig (['-interactive'])

Table 18. (continued)

Command name:	Description:	Parameters and return values:	Examples:
showId MgrConfig	The showId MgrConfig command returns the current configuration XML in string format.	<ul style="list-style-type: none"> • Parameters: None • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask showIdMgrConfig • Using Jython string: AdminTask.showIdMgrConfig() • Using Jython list: AdminTask.showIdMgrConfig() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask showIdMgrConfig {-interactive} • Using Jython string: AdminTask.showIdMgrConfig (['-interactive']) • Using Jython list: AdminTask.showIdMgrConfig (['-interactive'])
updateIdMgr Supported EntityType	The updateIdMgr Supported EntityType command updates the configuration that you specify for a supported entity type.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name of the supported entity type. The value of this parameter must be one of the supported entity types. (String, required) - defaultParent The default parent node for the supported entity type. (String, optional) - rdnProperties The RDN attribute name for the supported entity type in the entity domain name. To reset all the values of the rdnProperties parameter, specify a blank string (""). (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrSupported EntityType {-name <i>entity1</i>} • Using Jython string: AdminTask.updateIdMgrSupported EntityType ('[-name <i>entity1</i>']) • Using Jython list: AdminTask.updateIdMgrSupported EntityType (['-name', '<i>entity1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrSupported EntityType {-interactive} • Using Jython string: AdminTask.updateIdMgrSupported EntityType ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrSupported EntityType (['-interactive'])

Commands for the IdMgrRepositoryConfig group of the AdminTask object

Use the commands in the IdMgrRepositoryConfig to configure the virtual member manager. The commands for this group do not require a target object. To see the additional commands related to the virtual member manager, see the “Commands for the IdMgrConfig group of the AdminTask object” on page 676 and the “Commands for the IdMgrRealmConfig group of the AdminTask object” on page 770 articles.

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the IdMgrRepositoryConfig group of the AdminTask object:

Table 19.

Command name:	Description:	Parameters and return values:	Examples:
addIdMgrLDAPBackupServer	The addIdMgrLDAPBackupServer command adds or updates backup LDAP servers.	<ul style="list-style-type: none"> Parameters: - id The ID of the repository. (String, required) - primary_host The host name for the primary LDAP server. (String, required) - host The host name for the LDAP server. (String, required) - port The port number for the LDAP server. (Integer, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask addIdMgrLDAPBackupServer {-id <i>id1</i> -primary_host <i>myprimaryhost</i> -host <i>myhost.ibm.com</i>} Using Jython string: AdminTask.addIdMgrLDAPBackupServer ('[-id <i>id1</i> -primary_host <i>myprimaryhost</i> -host <i>myhost.ibm.com</i>']') Using Jython list: AdminTask.addIdMgrLDAPBackupServer (['-id', '<i>id1</i>', '-primary_host', '<i>myprimaryhost</i>', '-host', '<i>myhost.ibm.com</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask addIdMgrLDAPBackupServer {-interactive} Using Jython string: AdminTask.addIdMgrLDAPBackupServer ('[-interactive]') Using Jython list: AdminTask.addIdMgrLDAPBackupServer (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>addIdMgr LDAPEntity Type</p>	<p>The addIdMgr LDAPEntity Type command adds an LDAP entity type definition.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - name The name of the entity type. (String, required) - searchFilter The search filter that you want to use to search the entity type. (String, optional) - objectClasses One or more object classes for the entity type. (String, required) - objectClassesForCreate The object class to use when an entity type is created. If the value of this parameter is the same as the objectClass parameter, you do not need to specify this parameter. (String, optional) - searchBases The search base or bases to use while searching the entity type. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask addIdMgrLDAPEntity Type {-id <i>id1</i> -name <i>name1</i> -objectClasses <i>objectclass</i>}</code> • Using Jython string: <code>AdminTask.addIdMgrLDAPEntity Type ('[-id <i>id1</i> -name <i>name1</i> -objectClasses <i>objectclass</i>']')</code> • Using Jython list: <code>AdminTask.addIdMgrLDAPEntity Type (['-id', '<i>id1</i>', '-name', '<i>name1</i>', '-objectClasses', '<i>objectclass</i>'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask addIdMgrLDAPEntityType {-interactive}</code> • Using Jython string: <code>AdminTask.addIdMgrLDAPEntityType ('[-interactive]')</code> • Using Jython list: <code>AdminTask.addIdMgrLDAPEntityType (['-interactive'])</code>

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>addId MgrLDAP EntityType RDNAttr</p>	<p>The addId MgrLDAP EntityType RDNAttr command adds RDN attribute configuration to an LDAP entity type definition.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - entityTypeName The name of the entity type. (String, required) - name The attribute name that is used to build the relative distinguished name (RDN) for the entity type. (String, required) - objectClass The object class to use for the entity type for the relative distinguished name (RDN) attribute name that you specify. Use this parameter to map one entity type to multiple structural object classes. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask addIdMgrLDAPEntityTypeRDNAttr {-id <i>id1</i> -entityTypeName <i>entitytype</i> -name <i>name1</i>}</pre> • Using Jython string: <pre>AdminTask.addIdMgrLDAPEntityTypeRDNAttr ('[-id <i>id1</i> -entityTypeName <i>entitytype</i> -name <i>name1</i>']')</pre> • Using Jython list: <pre>AdminTask.addIdMgrLDAPEntityTypeRDNAttr (['-id', '<i>id1</i>', '-entityTypeName', '<i>entitytype</i>', '-name', '<i>name1</i>'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask addIdMgrLDAPEntityTypeRDNAttr {-interactive}</pre> • Using Jython string: <pre>AdminTask.addIdMgrLDAPEntityTypeRDNAttr ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.addIdMgrLDAPEntityTypeRDNAttr (['-interactive'])</pre>

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>addIdMgr LDAPGroup Dynamic Member Attr</p>	<p>The addIdMgr LDAPGroup Dynamic Member Attr command adds a dynamic member attribute configuration to an LDAP group configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - name The name of the LDAP attribute that is used as the group member attribute. For example, member or uniqueMember. (String, required) - objectClass The group object class that contains the member attribute. For example, groupOfNames or groupOfUniqueNames. If you do not define this parameter, the member attribute applies to all group object classes. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addIdMgrLDAPGroup DynamicMemberAttr {-id <i>id1</i> -name <i>name1</i> -objectClass <i>objectclass</i>} • Using Jython string: AdminTask.addIdMgrLDAPGroup DynamicMemberAttr ('[-id <i>id1</i> -name <i>name1</i> -objectClass <i>objectclass</i>']') • Using Jython list: AdminTask.addIdMgrLDAPGroup DynamicMemberAttr (['-id', '<i>id1</i>', '-name', '<i>name1</i>', '-objectClass', '<i>objectclass</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addIdMgrLDAPGroup DynamicMemberAttr {-interactive} • Using Jython string: AdminTask.addIdMgrLDAPGroup DynamicMemberAttr ('[-interactive]') • Using Jython list: AdminTask.addIdMgrLDAPGroup DynamicMemberAttr (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- scope</p> <p>The scope of the member attribute. The valid values for this parameter include the following:</p> <ul style="list-style-type: none"> • direct - The member attribute only contains direct members, therefore, this value refers to the member directly contained by the group and not contained through the nested group. For example, if Group1 contains Group2 and Group2 contains User1, then Group2 is a direct member of Group1 but User1 is not a direct member of Group1. Both member and uniqueMember are direct member attributes. • nested - The member attribute that contains the direct members and the nested members. 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> • all - The member attribute that contains the direct members, the nested members, and the dynamic members. For example, the <code>ibm-allMembers</code> attribute which is supported by the IBM Tivoli Directory Server. (String, optional) - dummyMember Indicates that if you create a group without specifying a member, a dummy member will be filled in to avoid creating an exception about missing a mandatory attribute. (String, optional) • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>addIdMgr LDAPGroup MemberAttr</p>	<p>The addIdMgr LDAPGroup MemberAttr command adds a member attribute configuration to an LDAP group configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. getIdMgr LDAPServer	The getIdMgr LDAPServer command returns the configuration for the LDAP server that you specify for the LDAP repository ID that you specify.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) - host The host name for the primary LDAP server. (String, required) • Returns: A hash map with the keys the same as the parameter names for the addIdMgr LDAPServer command. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPServer {-id <i>id1</i> -host <i>myhost.ibm.com</i>} • Using Jython string: AdminTask.getIdMgrLDAPServer ('[-id <i>id1</i> -host <i>myhost.ibm.com</i>]') • Using Jython list: AdminTask.getIdMgrLDAPServer (['-id', '<i>id1</i>', '-host', '<i>myhost.ibm.com</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrLDAPServer {-interactive} • Using Jython string: AdminTask.getIdMgrLDAPServer ('[-interactive]') • Using Jython list: AdminTask.getIdMgrLDAPServer (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getIdMgr Repository	<p>The getIdMgr Repository command returns the configuration of the specified repository.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map. The keys will vary depending on the type of repository. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask getIdMgrRepository {-id id1}</code> • Using Jython string: <code>AdminTask.getIdMgrRepository ('[-id id1]')</code> • Using Jython list: <code>AdminTask.getIdMgrRepository (['-id', 'id1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask getIdMgrRepository {-interactive}</code> • Using Jython string: <code>AdminTask.getIdMgrRepository (['-interactive'])</code> • Using Jython list: <code>AdminTask.getIdMgrRepository (['-interactive'])</code>
listIdMgr Custom Properties	<p>The listIdMgr Custom Properties command returns a list of custom properties for the repository that you specify.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map that contains keys as the custom property names and values as custom property values. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask listIdMgrCustomProperties {-id id1}</code> • Using Jython string: <code>AdminTask.listIdMgrCustomProperties ('[-id id1]')</code> • Using Jython list: <code>AdminTask.listIdMgrCustomProperties (['-id', 'id1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask listIdMgrCustomProperties {-interactive}</code> • Using Jython string: <code>AdminTask.listIdMgrCustomProperties (['-interactive'])</code> • Using Jython list: <code>AdminTask.listIdMgrCustomProperties (['-interactive'])</code>

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr LDAPBackupServers	The listIdMgr LDAPBackupServers command returns a list of the backup LDAP server or servers.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) - primary_host The host name for the primary LDAP server. (String, required) • Returns: A list of hash maps. The hash maps contains the names of the backup servers as the key and the port numbers as the value. Returning all the data in a hash map does not maintain the order of backup servers. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAPBackupServer {-id <i>id1</i> -primary_host <i>hostname</i>} • Using Jython string: AdminTask.listIdMgrLDAPBackupServer ('[-id <i>id1</i> -primary_host <i>hostname</i>]') • Using Jython list: AdminTask.listIdMgrLDAPBackupServer (['-id', '<i>id1</i>', '-primary_host', '<i>hostname</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAPBackupServer {-interactive} • Using Jython string: AdminTask.listIdMgrLDAPBackupServer ('[-interactive]') • Using Jython list: AdminTask.listIdMgrLDAPBackupServer (['-interactive'])
listIdMgr LDAPEntityTypeTypes	The listIdMgr LDAPEntityTypeTypes command lists the name of all of the configured LDAP entity type definitions.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A list that contains the names of the configured LDAP entity types. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAPEntityType {-id <i>id1</i>} • Using Jython string: AdminTask.listIdMgrLDAPEntityType ('[-id <i>id1</i>]') • Using Jython list: AdminTask.listIdMgrLDAPEntityType (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAPEntityType {-interactive} • Using Jython string: AdminTask.listIdMgrLDAPEntityType ('[-interactive]') • Using Jython list: AdminTask.listIdMgrLDAPEntityType (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr LDAP Servers	The listIdMgr LDAP Servers command lists all of the configured primary LDAP servers.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A list that contains the primary LDAP server names. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAP Servers {-id <i>id1</i>} • Using Jython string: AdminTask.listIdMgrLDAP Servers ('[-id <i>id1</i>']') • Using Jython list: AdminTask.listIdMgrLDAP Servers (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrLDAP Servers {-interactive} • Using Jython string: AdminTask.listIdMgrLDAP Servers ('[-interactive]') • Using Jython list: AdminTask.listIdMgrLDAP Servers (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr Repositories	<p>The listIdMgr Repositories command lists names and types of all configured repositories.</p>	<ul style="list-style-type: none"> • Parameters: None • Returns: A hash map with key as the name of the repository and value as another hash map that includes the following keys: <ul style="list-style-type: none"> – repositoryType - The type of repository. For example, File, LDAP, DB, and so on. – specificRepositoryType - The specific type of repository. For example, LDAP, IDS51, NDS, and so on. – host - The host name where the repository resides. For File, it is LocalHost and for DB it is dataSourceName. <p>This command will not return the Property Extension and Entry Mapping repository data.</p>	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listIdMgrRepositories</pre> • Using Jython string: <pre>AdminTask.listIdMgrRepositories()</pre> • Using Jython list: <pre>AdminTask.listIdMgrRepositories()</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listIdMgrRepositories {-interactive}</pre> • Using Jython string: <pre>AdminTask.listIdMgrRepositories (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.listIdMgrRepositories (['-interactive'])</pre>

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr Repository BaseEntries	The listIdMgr Repository BaseEntries command lists the base entries for a specified repository.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) • Returns: A hash map that contains base entry name as key and nameInRepository as value. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRepository BaseEntries {-id <i>id1</i>} • Using Jython string: AdminTask.listIdMgrRepository BaseEntries ('[-id <i>id1</i>']') • Using Jython list: AdminTask.listIdMgrRepository BaseEntries (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRepository BaseEntries {-interactive} • Using Jython string: AdminTask.listIdMgrRepository BaseEntries ('[-interactive]') • Using Jython list: AdminTask.listIdMgrRepository BaseEntries (['-interactive'])
listIdMgr Supported DBTypes	The listIdMgr Supported DBTypes command returns a list of supported database types.	<ul style="list-style-type: none"> • Parameters: None • Returns: A list of supported database types. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrSupportedDBTypes • Using Jython string: AdminTask.listIdMgrSupportedDBTypes () • Using Jython list: AdminTask.listIdMgrSupportedDBTypes () <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrSupported DBTypes {-interactive} • Using Jython string: AdminTask.listIdMgrSupported DBTypes ('[-interactive]') • Using Jython list: AdminTask.listIdMgrSupported DBTypes (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgr rSupported Message Digest Algorithms	The listIdMgr Supported Message Digest Algorithms command returns a list of supported message digest algorithms.	<ul style="list-style-type: none"> Parameters: None Returns: A list of supported message digest algorithms. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listIdMgrSupported MessageDigestAlgorithms Using Jython string: AdminTask.listIdMgrSupported MessageDigestAlgorithms () Using Jython list: AdminTask.listIdMgrSupported MessageDigestAlgorithms () <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listIdMgrSupportedMessageDigestAlgorithms {-interactive} Using Jython string: AdminTask.listIdMgrSupportedMessageDigestAlgorithms ('[-interactive]') Using Jython list: AdminTask.listIdMgrSupportedMessageDigestAlgorithms (['-interactive'])
listIdMgr Supported LDAPServerTypes	The listIdMgr Supported LDAP ServerTypes command returns a list of supported LDAP server types.	<ul style="list-style-type: none"> Parameters: None Returns: A list of supported LDAP server types. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listIdMgrSupported LDAPServerTypes Using Jython string: AdminTask.listIdMgrSupported LDAPServerTypes () Using Jython list: AdminTask.listIdMgrSupported LDAPServerTypes () <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listIdMgrSupported LDAPServerTypes {-interactive} Using Jython string: AdminTask.listIdMgrSupported LDAPServerTypes ('[-interactive]') Using Jython list: AdminTask.listIdMgrSupported LDAPServerTypes (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
removeIdMgr LDAPBackupServer	The removeIdMgr LDAPBackupServer command removes the backup LDAP server or servers.	<ul style="list-style-type: none"> • Parameters: <li style="padding-left: 20px;">- id The ID of the repository. (String, required) <li style="padding-left: 20px;">- primary_host The host name for the primary LDAP server. (String, required) <li style="padding-left: 20px;">- host The name of the backup host name. Use an asterisk (*) if you want to remove all backup servers. (String, required) <li style="padding-left: 20px;">- port The port number of the LDAP server. (Integer, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask removeIdMgrLDAPBackupServer {-id id1 -primary_host myprimaryhost.ibm.com -host myhost.ibm.com}</pre> • Using Jython string: <pre>AdminTask.removeIdMgrLDAPBackupServer ('[-id id1 -primary_host myprimaryhost.ibm.com -host myhost.ibm.com]')</pre> • Using Jython list: <pre>AdminTask.removeIdMgrLDAPBackupServer (['-id', 'id1', '-primary_host', 'myprimaryhost.ibm.com', '-host', 'myhost.ibm.com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask removeIdMgrLDAPBackupServer {-interactive}</pre> • Using Jython string: <pre>AdminTask.removeIdMgrLDAPBackupServer (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.removeIdMgrLDAPBackupServer (['-interactive'])</pre>

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>setIdMgr Custom Property</p>	<p>The setIdMgr Custom Property command adds the custom properties to a repository configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. Valid values include the existing repository IDs. (String, required) - name The name of the additional property for the repository that are not defined OOTB. (String, required) - value If this parameter is an empty string, the property will be deleted from the repository configuration. If this parameter is not an empty string and name does not exist, it will be added. If name is an empty string, all the custom properties will be deleted. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrCustomProperty {-id <i>id1</i> -name <i>name1</i> -value <i>value</i>} • Using Jython string: AdminTask.setIdMgrCustomProperty ('[-id <i>id1</i> -name <i>name1</i> -value <i>value</i>']') • Using Jython list: AdminTask.setIdMgrCustomProperty (['-id', '<i>id1</i>', '-name', '<i>name1</i>', '-value', '<i>value</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrCustomProperty {-interactive} • Using Jython string: AdminTask.setIdMgrCustomProperty ('[-interactive]') • Using Jython list: AdminTask.setIdMgrCustomProperty (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
setIdMgr LDAPA ttrCache	<p>The setIdMgr LDAPA ttrCache command configures the LDAP attribute cache configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - cachesDiskOffLoad (String, optional) - enabled Indicates if you want to enable attribute caching. The default value is true. (Boolean, optional) - cacheSize The maximum size of the attribute cache defined by the number of attribute objects that are permitted in the attribute cache. The minimum value of this parameter is 100. The default value is 4000. (Integer, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPAttr Cache {-id <i>id1</i>} • Using Jython string: AdminTask.setIdMgrLDAPAttr Cache ('[-id <i>id1</i>']') • Using Jython list: AdminTask.setIdMgrLDAPAttr Cache (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPAttr Cache {-interactive} • Using Jython string: AdminTask.setIdMgrLDAPAttr Cache ('[-interactive]') • Using Jython list: AdminTask.setIdMgrLDAPAttr Cache (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- cacheTimeOut The amount of time in seconds before the cached entries that are located in the attributes cache can be not valid. The minimum value of this parameter is 0. The attribute objects that are cached will remain in the attributes cache until the virtual member manager changes the attribute objects. The default value is 1200. (Integer, optional)</p> <p>- attributeSizeLimit An integer that represents the maximum number of attribute object values that can cache in the attributes cache.</p> <p>Some attributes, for example, the member attribute, contain many values. The attributeSizeLimit parameter prevents the attributes cache to cache large attributes. The default value is 2000. (Integer, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- serverTTLAttribute</p> <p>The name of the ttl attribute that is supported by the LDAP server. The attributes cache uses the value of this attribute to determine when the cached entries in the attributes cache will time out.</p> <p>The ttl attribute contains the time, in seconds, that any information from the entry should be kept by a client before it is considered stale and a new copy is fetched. A value of 0 implies that the object will not be cached.</p> <p>For more information about this attribute, go to: http://www.ietf.org/proceedings/98aug/I-D/draft-ietf-asid-ldap-cache-01.txt.</p> <p>The ttl attribute is not supported by all LDAP servers. If this attribute is supported by an LDAP server, you can set the value of the serverTTLAttribute parameter to the name of the ttl attribute in order to allow the value of the ttl attribute to determine when cached entries will time out. The time out value for different entries in attributes cache can be different.</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>For example, if the value of the <code>serverTTLAttribute</code> parameter is <code>ttl</code> and the <code>attributes cache</code> retrieves attributes of a user from an LDAP server, it will also retrieve the value of the <code>ttl</code> attribute of this user. If the value is 200, the WMM uses this value to set the time out for the attributes of the user in the <code>attributes cache</code> instead of using the value of <code>cacheTimeout</code>. You can set different <code>ttl</code> attribute values for different users.</p> <p>(String, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>setIdMgrLDAPContextPool</p>	<p>The setIdMgr LDAPContextPool command sets up the LDAP context pool configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - enabled By default, the context pool is enabled. If you set this parameter to false, the context pool is disabled. When the context pool is disabled, new context instances will be created for each request. The default value is true. (Boolean, optional) - initPoolSize The number of context instances that the the virtual member manager LDAP adapter creates when it creates the pool. The valid range for this parameter is 1 to 50. The default value is 1. (Integer, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPContextPool {-id <i>id1</i>} • Using Jython string: AdminTask.setIdMgrLDAPContextPool ('[-id <i>id1</i>']') • Using Jython list: AdminTask.setIdMgrLDAPContextPool (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPContextPool {-interactive} • Using Jython string: AdminTask.setIdMgrLDAPContextPool ('[-interactive]') • Using Jython list: AdminTask.setIdMgrLDAPContextPool (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- maxPoolSize</p> <p>The maximum number of context instances that the context pool will maintain. Context instances that are in use and those that are idle contribute to this number. When the pool size reaches this number, new context instances cannot be created for new requests. The new request is blocked until a context instance is released by another request or is removed. The request checks periodically if there are context instances available in the pool according to the amount of time that you specify using the poolWaitTime parameter.</p> <p>The minimum value for this parameter is 0. There is no maximum value. Setting the value of this parameter to 0 means that there is no maximum size and a request for a pooled context instance will use an existing pooled idle context instance or a newly created pooled context instance. The default value is 20. (Integer, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- prefPoolSize</p> <p>The preferred number of context instances that the context pool will maintain. Context instances that are in use and those that are idle contribute to this number. When there is a request for the use of a pooled context instance and the pool size is less than the preferred size, the context pool creates and uses a new pooled context instance regardless of whether an idle connection is available. When a request finishes with a pooled context instance and the pool size is greater than the preferred size, the context pool closes and removes the pooled context instance from the pool.</p> <p>The valid range for this parameter is from 0 to 100. Setting the value of this parameter to 0 means that there is no preferred size and a request for a pooled context instance results in a newly created context instance only if no idle ones are available. The default value is 3.(Integer, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- poolTimeout An integer that represents the number of milliseconds that an idle context instance may remain in the pool without being closed and removed from the pool. When a context instance is requested from the pool, if this context already exists in the pool for more than the time defined by poolTimeout, this connection will be closed no matter this context instance is stale or active. A new context instance will be created and put back to the pool after it has been released from the request.</p> <p>The minimum value for this parameter is 0. There is no maximum value. Setting the value of this parameter to 0 means that the context instances in the pool will remain in the pool until they are staled. The context pool catches the communication exception and recreates a new context instance. The default value is 0.(Integer, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- poolWaitTime The time interval in milliseconds that the request waits until the context pool rechecks if there are idle context instances available in the pool when the number of context instances reaches the maximum pool size. If no idle context instance, the request will continue waiting for the same period of time until next checking.</p> <p>The minimum value for the poolWaitout parameter is 0. There is no maximum value. A value of 0 for this parameter means that the context pool will not check if idle context exists. The request will be notified when a context instance releases from other requests. The default value is 3000.(Integer, optional)</p> <ul style="list-style-type: none"> Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>setIdMgr LDAPGroupConfig</p>	<p>The setIdMgr LDAPGroupConfig command sets up the LDAP group configuration.</p>	<ul style="list-style-type: none"> • Parameters: <li style="padding-left: 20px;">- id The ID of the repository. (String, required) <li style="padding-left: 20px;">- updateGroupMembership Updates the group membership if the member is deleted or renamed. Some LDAP servers, for example, Domino server, do not clean up the membership of the user when a user is deleted or renamed. If you choose these LDAP server types in the <code>ldapServerType</code> property, the value of this parameter is set to true. Use this parameter to change the value. The default value is false. (Boolean, optional) <li style="padding-left: 20px;">- name The name of the membership attribute. For example, <code>memberOf</code> in an active directory server and <code>ibm-allGroups</code> in IDS. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask setIdMgrLDAPGroupConfig {-id id1}</code> • Using Jython string: <code>AdminTask.setIdMgrLDAPGroupConfig ('[-id id1]')</code> • Using Jython list: <code>AdminTask.setIdMgrLDAPGroupConfig (['-id', 'id1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask setIdMgrLDAPGroupConfig {-interactive}</code> • Using Jython string: <code>AdminTask.setIdMgrLDAPGroupConfig ('[-interactive]')</code> • Using Jython list: <code>AdminTask.setIdMgrLDAPGroupConfig (['-interactive'])</code>

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- scope</p> <p>The scope of the membership attribute. The following are the possible values for this parameter:</p> <ul style="list-style-type: none"> • direct - The membership attribute only contains direct groups. Direct groups contain the member and are not contained through a nested group. For example, if group1 contains group2, group2 contains user1, then group2 is a direct group of user1, but group1 is not a direct group of user1. • nested - The membership attribute contains both direct groups and nested groups. • all - The membership attribute contains direct groups, nested groups, and dynamic members. <p>The default value is <code>direct</code>. (String, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>setIdMgr LDAPSearch ResultCache</p>	<p>The setIdMgr LDAPSearch ResultCache command sets up the LDAP search result cache configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - cachesDiskOffLoad Loads the attributes caches and the search results onto hard disk. By default, when the number of cache entries reaches the maximum size of the cache, cache entries are evicted to allow new entries to enter the caches. If you enable this parameter, the evicted cache entries will be copied to disk for future access. The default value is false. (Boolean, optional) - enabled Enables the search results cache. The default value is true. (Boolean, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPSearch ResultCache {-id <i>id1</i>} • Using Jython string: AdminTask.setIdMgrLDAPSearch ResultCache (['-id <i>id1</i>']) • Using Jython list: AdminTask.setIdMgrLDAPSearch ResultCache (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrLDAPSearch ResultCache {-interactive} • Using Jython string: AdminTask.setIdMgrLDAPSearch ResultCache (['-interactive']) • Using Jython list: AdminTask.setIdMgrLDAPSearch ResultCache (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- cacheSize The maximum size of the search results cache. The number of naming enumeration objects that can be put into the search results cache. The minimum value of this parameter is 100. The default value is 2000. (Integer, optional)</p> <p>- cacheTimeOut The amount of time in seconds before the cached entries in the search results cache can be not valid. The minimum value for this parameter is 0. A value of 0 means that the cached naming enumeration objects will stay in the search results cache until there are configuration changes. The default value is 600. (Integer, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- searchResultSizeLimit The maximum number of entries contained in the naming enumeration object that can be cached in the search results cache. For example, if the results from a search contains 2000 users, the search results will not cache in the search results cache if the value of the of this property is set to 1000. The default value is 1000. (Integer, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>setIdMgr Entry Mapping Repository</p>	<p>The setIdMgr Entry Mapping Repository command sets or updates an entry mapping repository configuration.</p>	<ul style="list-style-type: none"> • Parameters: - dataSourceName The name of the data source. The default value is jdbc/wimDS. The parameter is required if the property extension is not set. The parameter is not required if the command is used to update the existing configuration. (String) - databaseType The type of the database. The default value is DB2. The parameter is required if the property extension is not set. The parameter is not required if the command is used to update the existing configuration. (String) - dbURL The URL of the database. The parameter is required if the property extension is not set. The parameter is not required if the command is used to update the existing configuration. (String) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrEntry MappingRepository {-dbAdminId <i>dbid1</i> -dbAdminPassword <i>pw1</i>} • Using Jython string: AdminTask.setIdMgrEntry MappingRepository ('[-dbAdminId <i>dbid1</i> -dbAdminPassword <i>pw1</i>']') • Using Jython list: AdminTask.setIdMgrEntry MappingRepository (['-dbAdminId', '<i>dbid1</i>', '-dbAdmin Password', '<i>pw1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrEntryMapping Repository {-interactive} • Using Jython string: AdminTask.setIdMgrEntryMapping Repository ('[-interactive]') • Using Jython list: AdminTask.setIdMgrEntryMapping Repository (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - dbAdminId The database administrator ID. (String, required if database type is not Cloudscape.) - dbAdminPassword The database administrator password. (String, required if database type is not Cloudscape.) - JDBCDriverClass The JDBC driver class name. (String, optional) • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>setIdMgr Property Extension Repository</p>	<p>The setIdMgr Property Extension Repository command sets or updates the property extension repository configuration.</p>	<ul style="list-style-type: none"> • Parameters: - dataSourceName The name of the data source. The default value is jdbc/wimDS. The parameter is required if the property extension is not set. The parameter is not required if the command is used to update the existing configuration. (String) - databaseType The type of the database. The default value is DB2. The parameter is required if the property extension is not set. The parameter is not required if the command is used to update the existing configuration. (String) - dbURL The URL of the database. The parameter is required if the property extension is not set. The parameter is not required if the command is used to update the existing configuration. (String) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrProperty ExtensionRepository {-entity RetrievalLimit 10 -JDBC DriverClass classname} • Using Jython string: AdminTask.setIdMgrProperty ExtensionRepository ('[-entity RetrievalLimit 10 -JDBC DriverClass classname]') • Using Jython list: AdminTask.setIdMgrProperty ExtensionRepository (['-entity RetrievalLimit', '10', '-JDBCdriverClass', 'classname']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrProperty ExtensionRepository {-interactive} • Using Jython string: AdminTask.setIdMgrProperty ExtensionRepository (['-interactive']) • Using Jython list: AdminTask.setIdMgrPropertyExt ensionRepository (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - dbAdminId The database administrator ID. (String, required if database type is not Cloudscape.) - dbAdminPassword The database administrator password. (String, required if database type is not Cloudscape.) - entityRetrievalLimit The limit for the retrieval of entities. (Integer, required) - JDBCDriverClass The JDBC driver class name. (String, required) • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>updateId MgrDB Repository</p>	<p>The updateId MgrDB Repository command updates the configuration for the database repository that you specify.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - dataSourceName The name of the data source. The default value is jdbc/wimDS. (String, optional) - databaseType The type of the database. The default value is DB2. (String, optional) - dbURL The URL of the database. (String, optional) - dbAdminId The database administrator ID. (String, optional) - dbAdminPassword The database administrator password. (String, optional) - entityRetrievalLimit Indicates the value of the retrieval limit on database entries. The default value is 200. (Integer, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrDB Repository {-id <i>id1</i>} • Using Jython string: AdminTask.updateIdMgrDB Repository ('[-id <i>id1</i>']') • Using Jython list: AdminTask.updateIdMgrDB Repository (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrDB Repository {-interactive} • Using Jython string: AdminTask.updateIdMgrDB Repository ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrDB Repository (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - JDBCDriverClass The JDBC driver class name. (String, optional) - saltLength The salt length in bits. The default value is 12. (Integer, optional) - encryptionKey The default value is rZ15ws0e1y9yHk3zCs3sTMv/ho8fY17s. (String, optional) • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>updateId MgrFile Repository</p>	<p>The updateId MgrFile Repository command updates the configuration for the file repository that you specify. To update other properties of the file repository use the update IdMgr Repository command.</p>	<ul style="list-style-type: none"> • Parameters: <li style="padding-left: 20px;">- id The ID of the repository. (String, required) <li style="padding-left: 20px;">- messageDigest Algorithm The message digest algorithm that will be used for hashing the password. The default value is SHA-1. Valid values include the following: SHA-245, SHA-384, or SHA-512. (String, optional) <li style="padding-left: 20px;">- baseDirectory The base directory where the fill will be created in order to store the data. The default is to be dynamically built during run time using user.install.root and cell name. (String, optional) <li style="padding-left: 20px;">- fileName The file name of the repository. The default value is fileRegistry.xml. (String, optional) <li style="padding-left: 20px;">- saltLength The salt length of the randomly generated salt for password hashing. The default value is 12. (Integer, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrFile Repository {-id <i>id1</i>} • Using Jython string: AdminTask.updateIdMgrFile Repository ('[-id <i>id1</i>']') • Using Jython list: AdminTask.updateIdMgrFile Repository (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrFile Repository {-interactive} • Using Jython string: AdminTask.updateIdMgrFile Repository ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrFile Repository (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>updateId MgrLDAP AttrCache</p>	<p>The updateId MgrLDAP AttrCache command updates the LDAP attribute cache configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - cachesDiskOffLoad (String, optional) - enabled Indicates if you want to enable attribute caching. The default value is true. (Boolean, optional) - cacheSize The maximum size of the attribute cache defined by the number of attribute objects that are permitted in the attribute cache. The minimum value of this parameter is 100. The default value is 4000. (Integer, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAP AttrCache {-id <i>id1</i>} • Using Jython string: AdminTask.updateIdMgrLDAP AttrCache ('[-id <i>id1</i>']') • Using Jython list: AdminTask.updateIdMgrLDAP AttrCache (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAP AttrCache {-interactive} • Using Jython string: AdminTask.updateIdMgrLDAP AttrCache ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrLDAP AttrCache (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- cacheTimeOut The amount of time in seconds before the cached entries that are located in the attributes cache can be not valid. The minimum value of this parameter is 0. The attribute objects that are cached will remain in the attributes cache until the virtual member manager changes the attribute objects. The default value is 1200. (Integer, optional)</p> <p>- attributeSizeLimit An integer that represents the maximum number of attribute object values that can cache in the attributes cache.</p> <p>Some attributes, for example, the member attribute, contain many values. The attributeSizeLimit parameter prevents the attributes cache to cache large attributes. The default value is 2000. (Integer, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- serverTTLAttribute</p> <p>The name of the ttl attribute that is supported by the LDAP server. The attributes cache uses the value of this attribute to determine when the cached entries in the attributes cache will time out.</p> <p>The ttl attribute contains the time, in seconds, that any information from the entry should be kept by a client before it is considered stale and a new copy is fetched. A value of 0 implies that the object will not be cached.</p> <p>For more information about this attribute, go to:</p> <p>http://www.ietf.org/proceedings/98aug/I-D/draft-ietf-asid-ldap-cache-01.txt.</p> <p>The ttl attribute is not supported by all LDAP servers. If this attribute is supported by an LDAP server, you can set the value of the serverTTLAttribute parameter to the name of the ttl attribute in order to allow the value of the ttl attribute to determine when cached entries will time out. The time out value for different entries in attributes cache can be different.</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>For example, if the value of the serverTTLAttribute parameter is ttl and the attributes cache retrieves attributes of a user from an LDAP server, it will also retrieve the value of the ttl attribute of this user. If the value is 200, the WMM uses this value to set the time out for the attributes of the user in the attributes cache instead of using the value of cacheTimeout. You can set different ttl attribute values for different users. (String, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>updateId MgrLDAP ContextPool</p>	<p>The updateId MgrLDAP ContextPool command updates the LDAP context pool configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - enabled By default, the context pool is enabled. If you set the value of this parameter to false, the context pool is disabled which means that a new context instance will be created for each request. The default value is true. (Boolean, optional) - initPoolSize The number of context instances that the virtual member manager LDAP adapter creates when it creates the pool. The valid range for this parameter is 1 to 50. The default value is 1. (Integer, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrLDAP ContextPool {-id id1}</code> • Using Jython string: <code>AdminTask.updateIdMgrLDAP ContextPool ('[-id id1]')</code> • Using Jython list: <code>AdminTask.updateIdMgrLDAP ContextPool (['-id', 'id1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrLDAP ContextPool {-interactive}</code> • Using Jython string: <code>AdminTask.updateIdMgrLDAP ContextPool ('[-interactive]')</code> • Using Jython list: <code>AdminTask.updateIdMgrLDAP ContextPool (['-interactive'])</code>

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- maxPoolSize</p> <p>The maximum number of context instances that can be maintained concurrently by the context pool. Both in-use and idle context instances contribute to this number. When the pool size reaches this number, new context instances cannot be created for new requests. The new request is blocked until a context instance is released by another request or is removed. The request checks periodically if there are context instances available in the pool according to the value defined for the poolWaitTime parameter. The minimum value of the maxPoolSize parameter is 0. There is no maximum value. A maximum pool size of 0 means that there is no maximum size and that a request for a pooled context instance will use an existing pooled idle context instance or a newly created pooled context instance. The default value is 20. (Integer, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- prefPoolSize The preferred number of context instances that the Context Pool should maintain. Both in-use and idle context instances contribute to this number. When there is a request for the use of a pooled context instance and the pool size is less than the preferred size, Context Pool will create and use a new pooled context instance regardless of whether an idle connection is available. When a request is finished with a pooled context instance and the pool size is greater than the preferred size, the Context Pool will close and remove the pooled context instance from the pool. The valid range of the prefPoolSize parameter is 0 to 100. A preferred pool size of 0 means that there is no preferred size: A request for a pooled context instance will result in a newly created context instance only if no idle ones are available. The default value is 3. (Integer, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- poolTimeOut An integer that represents the number of milliseconds that an idle context instance may remain in the pool without being closed and removed from the pool. When a context instance is requested from the pool, if this context already exists in the pool for more than the time defined by poolTimeout, this connection will be closed no matter this context instance is stale or active. A new context instance will be created and put back to the pool after it has been released from the request. The minimum value of poolTimeout is 0. There is no maximum value. A poolTimeout of 0 means that the context instances in the pool will remain in the pool until they are staled. In this case, Context Pool will catch the communication exception and recreate a new context instance. The default value is 0. (Integer, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- poolWaitTime The time interval (in milliseconds) that the request will wait until the Context Pool checks again if there are idle context instance available in the pool when the number of context instances reaches the maximum pool size. If there is still no idle context instance, the request will continue waiting for the same period of time until next checking. The minimum value of poolWaitout is 0. There is no maximum value. A poolWaitTime of 0 means the Context Pool will not check if there are idle context. Instead, the request will be notified when there is a context instance is released from other requests. The default value is 3000. (Integer, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>updateId MgrLDAP EntityType</p>	<p>The updateId MgrLDAP EntityType command updates an existing LDAP entity type definition to LDAP repository configuration. You can use this command to add more values to multi-valued parameters. If the property already exists, the value of the property will be replaced. If the property does not exist, it will be added.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - name The name of the entity type. (String, required) - searchFilter The search filter that you want to use to search the entity type. (String, optional) - objectClasses One or more object classes for the entity type. (String, optional) - objectClassesForCreate The object class that will be when you create an entity type object. You do not have to specify the value of this parameter if it is the same as the value of the objectClasses parameter. (String, optional) - searchBases The search base or bases to use while searching the entity type. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrLDAPEntityType {-id <i>id1</i> -name <i>name1</i>}</code> • Using Jython string: <code>AdminTask.updateIdMgrLDAPEntityType ('[-id <i>id1</i> -name <i>name1</i>]')</code> • Using Jython list: <code>AdminTask.updateIdMgrLDAPEntityType (['-id', '<i>id1</i>', '-name', '<i>name1</i>'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrLDAPEntityType {-interactive}</code> • Using Jython string: <code>AdminTask.updateIdMgrLDAPEntityType ('[-interactive]')</code> • Using Jython list: <code>AdminTask.updateIdMgrLDAPEntityType (['-interactive'])</code>

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>updateIdMgr LDAPGroup Dynamic MemberAttr</p>	<p>The updateIdMgr LDAPGroup Dynamic MemberAttr command updates a dynamic member attribute configuration to an LDAP group configuration.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - id The ID of the repository. (String, required) - name The name of the LDAP attribute that is used as the group member attribute. For example, memberURL. (String, required) - objectClass The group object class that contains the dynamic member attribute. For example groupOfURLs. If you do not define this parameter, the dynamic member attribute will apply to all group object classes. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask updateIdMgrLDAPGroup DynamicMemberAttr {-id <i>id1</i> -name <i>name1</i> -objectClass groupOfURLs}</pre> • Using Jython string: <pre>AdminTask.updateIdMgrLDAPGroup DynamicMemberAttr (['-id <i>id1</i> -name <i>name1</i> -objectClass groupOfURLs'])</pre> • Using Jython list: <pre>AdminTask.updateIdMgrLDAPGroup DynamicMemberAttr (['-id', '<i>id1</i>', '-name', '<i>name1</i>', '-objectClass', '<i>groupOfURLs</i>'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask updateIdMgrLDAPGroup DynamicMemberAttr {-interactive}</pre> • Using Jython string: <pre>AdminTask.updateIdMgrLDAPGroup DynamicMemberAttr (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.updateIdMgrLDAPGroup DynamicMemberAttr (['-interactive'])</pre>

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgr LDAPGroup MemberAttr	<p>The updateIdMgr LDAPGroup MemberAttr command updates a member attribute configuration of an LDAP group configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - name The name of the LDAP attribute that is used as the group member attribute. For example, member or uniqueMember. (String, required) - objectClass The group object class that contains the member attribute. For example, groupOfNames or groupOfUniqueNames. If you do not define this parameter, the member attribute applies to all group object classes. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAPGroupMemberAttr {-id <i>id1</i> -name <i>name1</i>} • Using Jython string: AdminTask.updateIdMgrLDAPGroupMemberAttr ('[-id <i>id1</i> -name <i>name1</i>]') • Using Jython list: AdminTask.updateIdMgrLDAPGroupMemberAttr (['-id', '<i>id1</i>', '-name', '<i>name1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAPGroupMemberAttr {-interactive} • Using Jython string: AdminTask.updateIdMgrLDAPGroupMemberAttr ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrLDAPGroupMemberAttr (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- scope</p> <p>The scope of the member attribute. The following are the valid values:</p> <ul style="list-style-type: none"> • direct - The member attribute only contains direct members whereby the member is directly contained by the group and not contained in a nested group. For example, if group1 contains group2, group2 contains user1, then group2 is a direct member of group1 but user1 is not a direct member of group1. Both member and uniqueMember are direct member attributes. • nested - The member attribute contains both direct members and nested members. 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> • all - The member attribute contains direct members, nested members and dynamic members. One example is the <code>ibm-allMembers</code> attribute that IBM Tivoli Directory Server supports. <p>The default value is <code>direct</code>. (String, optional)</p> <p>- dummyMember When you create a group without specifying a member, a dummy member will be filled in automatically to avoid receiving an exception that indicates that there is a mandatory attribute missing. (String, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateId MgrLDAP Repository	The updateId MgrLDAP Repository command updates an LDAP repository configuration.	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - ldapServerType The type of LDAP server that is being used. The default value is <code>IDS51</code>. (String, optional) - adapterClassName The default value is <code>com.ibm.ws.wim.adapter.ldap.LdapAdapter</code>. (String, optional) - certificateMapMode Specifies whether to map X.509 certificates into a LDAP directory by exact distinguished name or by certificate filter. The default value is <code>exactdn</code>. To use the certificate filter for the mapping, specify <code>certificatefilter</code>. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrLDAP Repository {-id id1}</code> • Using Jython string: <code>AdminTask.updateIdMgrLDAP Repository ('[-id id1]')</code> • Using Jython list: <code>AdminTask.updateIdMgrLDAP Repository (['-id', 'id1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrLDAP Repository {-interactive}</code> • Using Jython string: <code>AdminTask.updateIdMgrLDAP Repository ('[-interactive]')</code> • Using Jython list: <code>AdminTask.updateIdMgrLDAP Repository (['-interactive'])</code>

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- certificateFilter If certificateMapMode has the value certificatefilter, then this property specifies the LDAP filter which maps attributes in the client certificate to entries in LDAP. (String, optional)</p> <p>- isExtIdUnique Specifies if the external ID is unique. The default value is true. (Boolean, optional)</p> <p>- loginProperties Indicates the property name used for login. (String , optional)</p> <p>-</p> <p>primaryServerQueryTimeInterval Indicates the polling interval for testing the primary server availability. The value of this parameter is specified in minutes. The default value is 15. (Integer, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - returnToPrimaryServer Indicates to return to the primary LDAP server when it is available. The default value is true. (Boolean, optional) - supportAsyncMode Indicates if the async mode is supported or not. The default value is false. (Boolean, optional) - supportSorting Indicates if sorting is supported or not. The default value is false. (Boolean, optional) - supportPaging Indicates if paging is supported or not. The default value is false. (Boolean, optional) - supportTransaction Indicates if transactions are supported or not. The default value is false. (Boolean, optional) 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - supportExternalName Indicates if external names are supported or not. The default value is <code>false</code>. (Boolean, optional) - sslConfiguration The SSL configuration. (String, optional) - translateRDN Indicates to translate RDN or not. The default value is <code>false</code>. (Boolean, optional) - searchTimeLimit The value of search time limit. (Integer, optional) - searchCountLimit The value of search count limit. (Integer, optional) - searchPageSize The value of search page size. (Integer, optional) • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgr LDAPSearch ResultCache	<p>The updateIdMgr LDAPSearch ResultCache command updates the LDAP search result cache configuration.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - cachesDiskOffLoad Loads the attributes caches and the search results onto hard disk. By default, when the number of cache entries reaches the maximum size of the cache, cache entries are evicted to allow new entries to enter the caches. If you enable this parameter, the evicted cache entries will be copied to disk for future access. The default value is false. (Boolean, optional) - enabled Enables the search results cache. The default value is true. (Boolean, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAP SearchResultCache {-id id1} • Using Jython string: AdminTask.updateIdMgrLDAPSearch ResultCache ('[-id id1]') • Using Jython list: AdminTask.updateIdMgrLDAPSearch ResultCache (['-id', 'id1']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrLDAP SearchResultCache {-interactive} • Using Jython string: AdminTask.updateIdMgrLDAPSearch ResultCache ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrLDAPSearch ResultCache (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- cacheSize The maximum size of the search results cache. The number of naming enumeration objects that can be put into the search results cache. The minimum value of this parameter is 100. The default value is 2000. (Integer, optional)</p> <p>- cacheTimeOut The amount of time in seconds before the cached entries in the search results cache can be not valid. The minimum value for this parameter is 0. A value of 0 means that the cached naming enumeration objects will stay in the search results cache until there are configuration changes. The default value is 600. (Integer, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- searchResultSizeLimit The maximum number of entries contained in the naming enumeration object that can be cached in the search results cache. For example, if the results from a search contains 2000 users, the search results will not cache in the search results cache if the value of the of this property is set to 1000. The default value is 1000. (Integer, optional)</p> <ul style="list-style-type: none"> • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgr LDAPServer	<p>The updateIdMgr LDAPServer command updates an LDAP server configuration for the LDAP repository ID that you specify.</p>	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - host The host name for the LDAP server that contains the properties that you want to modify. (String, required) - port The port number for the LDAP server. (Integer, optional) - authentication Indicates the authentication method to use. The default value is simple. Valid values include: none or strong. (String, optional) - bindDN The binding domain name for the LDAP server. (String, optional) - bindPassword The binding password. The password is encrypted before it is stored. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrLDAPServer {-id <i>id1</i> -host <i>myhost.ibm.com</i>}</code> • Using Jython string: <code>AdminTask.updateIdMgrLDAPServer ('[-id <i>id1</i> -host <i>myhost.ibm.com</i>]')</code> • Using Jython list: <code>AdminTask.updateIdMgrLDAPServer (['-id', '<i>id1</i>', '-host', '<i>myhost.ibm.com</i>'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrLDAPServer {-interactive}</code> • Using Jython string: <code>AdminTask.updateIdMgrLDAPServer ('[-interactive]')</code> • Using Jython list: <code>AdminTask.updateIdMgrLDAPServer (['-interactive'])</code>

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>-</p> <p>certificateMapMode Specifies whether to map X.509 certificates into a LDAP directory by exact distinguished name or by certificate filter. The default value is exactdn. To use the certificate filter for the mapping, specify certificatefilter. (String, optional)</p> <p>- certificateFilter If certificateMapMode has the value certificatefilter, then this property specifies the LDAP filter which maps attributes in the client certificate to entries in LDAP. (String, optional)</p> <p>- connectTimeout The connection timeout measured in seconds. The default value is 0. (Integer, optional)</p> <p>- connectionPool The connection pool. The default value is false. (Boolean, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<p>- derefAliases Controls how aliases are dereferenced. The default value is always. Valid values include:</p> <ul style="list-style-type: none"> • never - never deference aliases • finding - deferences aliases only during name resolution • searching - deferences aliases only after name resolution <p>(String, optional)</p> <p>- IdapServerType The type of LDAP server being used. The default value is IDS51. (String, optional)</p> <p>- primary_host The host name for the primary LDAP server. (String, optional)</p> <p>- referral The LDAP referral. The default value is ignore. Valid values include: follow, throw, or false. (String, optional)</p>	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - sslConfiguration The SSL configuration. (String, optional) - sslEnabled Indicates to enable SSL or not. The default value is false. (Boolean, optional) • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgr Repository	The updateIdMgr Repository command updates the common repository configuration.	<ul style="list-style-type: none"> • Parameters: - id The ID of the repository. (String, required) - adapterClassName The implementation class name for the repository adapter. (String, optional) - EntityTypesNotAllowCreate The name of the entity type that should not be created in this repository. (String, optional) - EntityTypesNotAllowUpdate The name of the entity type that should not be updated in this repository. (String, optional) - EntityTypesNotAllowRead The name of the entity type that should not be read from this repository. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrRepository {-id <i>id1</i>} • Using Jython string: AdminTask.updateIdMgrRepository ('[-id <i>id1</i>']') • Using Jython list: AdminTask.updateIdMgrRepository (['-id', '<i>id1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrRepository {-interactive} • Using Jython string: AdminTask.updateIdMgrRepository ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrRepository (['-interactive'])

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - EntityTypesNotAllowDelete The name of the entity type that should not be deleted from this repository. (String, optional) - loginProperties (String, optional) - readOnly Indicates if this is a read only repository. The default value is false. (Boolean, optional) - repositoriesForGroups The repository ID where group data is stored. (String, optional) - supportPaging Indicates if the repository supports paging or not. (Boolean, optional) - supportSorting Indicates if the repository supports sorting or not. (Boolean, optional) 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - supportTransaction Indicates if the repository supports transaction or not. (Boolean, optional) - isExtIdUnique Specifies if the external ID is unique or not. (Boolean, optional) - supportedExternalName Indicates if the repository supports external names or not. (Boolean, optional) - supportAsyncMode Indicates if the adapter supports async mode or not. The default value is false. (Boolean, optional) <ul style="list-style-type: none"> • Returns: None 	

Table 19. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgr Repository BaseEntry	The updateIdMgr Repository BaseEntry command updates a base entry to the specified repository.	<ul style="list-style-type: none"> • Parameters: <li style="padding-left: 20px;">- id The ID of the repository. (String, required) <li style="padding-left: 20px;">- name The distinguished name of a base entry. (String, required) <li style="padding-left: 20px;">- nameInRepository The distinguished name in the repository that uniquely identifies the base entry name. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrRepositoryBaseEntry {-id <i>id1</i> name <i>name1</i>}</code> • Using Jython string: <code>AdminTask.updateIdMgrRepositoryBaseEntry ('[-id <i>id1</i> name <i>name1</i>]')</code> • Using Jython list: <code>AdminTask.updateIdMgrRepositoryBaseEntry (['-id', '<i>id1</i>', 'name', '<i>name1</i>'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateIdMgrRepositoryBaseEntry {-interactive}</code> • Using Jython string: <code>AdminTask.updateIdMgrRepositoryBaseEntry ('[-interactive]')</code> • Using Jython list: <code>AdminTask.updateIdMgrRepositoryBaseEntry (['-interactive'])</code>

Commands for the IdMgrRealmConfig group of the AdminTask object

Use the commands in the IdMgrConfig group to configure the member manager realm and realms. The commands for this group do not require a target object. To see the additional commands related to the member manager, see the `Commands for the IdMgrRepositoryConfig group of the AdminTask object` and the `Commands for the IdMgrConfig group of the AdminTask object` articles.

For more information about the AdminTask object, see the `Commands for the AdminTask object` article.

The following commands are available for the IdMgrRealmConfig group of the AdminTask object:

Table 20.

Command name:	Description:	Parameters and return values:	Examples:
addIdMgrRealmBaseEntry	<p>The addIdMgrRealmBaseEntry command adds a base entry to a specified realm configuration.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) - baseEntry The name of a base entry. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask addIdMgrRealmBaseEntry {-name realm1 -baseEntry entry1}</pre> • Using Jython string: <pre>AdminTask addIdMgrRealmBaseEntry (['-name realm1 -baseEntry entry1'])</pre> • Using Jython list: <pre>AdminTask addIdMgrRealmBaseEntry (['-name', 'realm1', '-base Entry', 'entry1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask addIdMgrRealm BaseEntry {-interactive}</pre> • Using Jython string: <pre>AdminTask.addIdMgrReaIbmBase Entry ('-interactive')</pre> • Using Jython list: <pre>AdminTask.addIdMgrReaIbmBase Entry (['-interactive'])</pre>

Table 20. (continued)

Command name:	Description:	Parameters and return values:	Examples:
createIdMgrRealm	<p>The createIdMgrRealm command creates a realm configuration.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) - securityUse A string that indicates if this virtual realm will be used in security now, later, or never. The default value is active. Additional values includes: inactive and nonSelectable. (String, optional) - delimiter The delimiter used for this realm. The default value is @. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createIdMgrRealm {-name realm1} • Using Jython string: AdminTask.createIdMgrRealm ('[-name realm1]') • Using Jython list: AdminTask.createIdMgrRealm (['-name', 'realm1']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createIdMgrRealm {-interactive} • Using Jython string: AdminTask.createIdMgrRealm ('[-interactive]') • Using Jython list: AdminTask.createIdMgrRealm (['-interactive'])
deleteIdMgrRealm	<p>The deleteIdMgrRealm command deletes the realm configuration that you specified.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrRealm {-name realm1} • Using Jython string: AdminTask.deleteIdMgrRealm ('[-name realm1]') • Using Jython list: AdminTask.deleteIdMgrRealm (['-name', 'realm1']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteIdMgrRealm {-interactive} • Using Jython string: AdminTask.deleteIdMgrRealm ('[-interactive]') • Using Jython list: AdminTask.deleteIdMgrRealm (['-interactive'])

Table 20. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>deleteIdMgr RealmBaseEntry</p>	<p>The deleteIdMgr RealmBaseEntry command deletes a base entry from a realm configuration that you specified.</p> <p>The realm must always contain at least one base entry, thus you cannot remove every entry.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) - baseEntry The name of a base entry. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteIdMgrRealmBaseEntry {-name realm1 -baseEntry entry1}</pre> • Using Jython string: <pre>AdminTask.deleteIdMgrRealmBaseEntry (['-name realm1 -baseEntry entry1'])</pre> • Using Jython list: <pre>AdminTask.deleteIdMgrRealmBaseEntry (['-name', 'realm1', '-base Entry', 'entry1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteIdMgrRealm BaseEntry {-interactive}</pre> • Using Jython string: <pre>AdminTask.deleteIdMgrRealm BaseEntry ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.deleteIdMgrRealm BaseEntry (['-interactive'])</pre>
<p>getIdMgrDefaultRealm</p>	<p>The getIdMgrDefaultRealm command returns the default realm name.</p>	<ul style="list-style-type: none"> • Parameters: None • Returns: The name of the default realm. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrDefaultRealm</pre> • Using Jython string: <pre>AdminTask.getIdMgrDefaultRealm()</pre> • Using Jython list: <pre>AdminTask.getIdMgrDefaultRealm()</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrDefault Realm {-interactive}</pre> • Using Jython string: <pre>AdminTask.getIdMgrDefault Realm ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getIdMgrDefault Realm (['-interactive'])</pre>

Table 20. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>getIdMgrRepositories ForRealm</p>	<p>The getIdMgrRepositories ForRealm command returns repository specific details for the repositories configured for a specified realm.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) • Returns: A hash map with the following keys: <ul style="list-style-type: none"> - id - The repository ID. - repositoryType - The type of repository, for example, File, LDAP, DB, and so on. - specificRepositoryType - The specific type of repository, for example, for LDAP, IDS51, NDS, and so on. - host - The host name where the repository resides. For example, for File, LocalHost or for DB, dataSourceName. - port - The port number. This only applies to LDAP. - name - The name of the base entry. - nameInRepository - The name in repository for the base entry. <p>This command will not return the property extension and entry mapping repository data.</p>	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrRepositories ForRealm {-name realm1}</pre> • Using Jython string: <pre>AdminTask.getIdMgrRepositories ForRealm ('[-name realm1]')</pre> • Using Jython list: <pre>AdminTask.getIdMgrRepositories ForRealm (['-name', 'realm1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getIdMgrRepositories ForRealm {-interactive}</pre> • Using Jython string: <pre>AdminTask.getIdMgrRepositories ForRealm (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.getIdMgrRepositories ForRealm (['-interactive'])</pre>

Table 20. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getIdMgrRealm	The getIdMgrRealm command returns the configuration parameters for the realm that you specified.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) • Returns: A hash map that contains keys as the parameters of the createIdMgrRealm command. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrRealm {-name <i>realm1</i>} • Using Jython string: AdminTask.getIdMgrRealm ('[-name <i>realm1</i>']') • Using Jython list: AdminTask.getIdMgrRealm (['-name', '<i>realm1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getIdMgrRealm {-interactive} • Using Jython string: AdminTask.getIdMgrRealm ('[-interactive]') • Using Jython list: AdminTask.getIdMgrRealm (['-interactive'])
listIdMgrRealms	The listIdMgrRealms command returns all of the names of the configured realms.	<ul style="list-style-type: none"> • Parameters: None • Returns: A list that contains the name of the configured realms. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRealms • Using Jython string: AdminTask.listIdMgrRealms() • Using Jython list: AdminTask.listIdMgrRealms() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRealms {-interactive} • Using Jython string: AdminTask.listIdMgrRealms ('[-interactive]') • Using Jython list: AdminTask.listIdMgrRealms (['-interactive'])

Table 20. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listIdMgrRealmBaseEntries	The listIdMgrRealmBaseEntries command returns all of the names of the configured realms.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) • Returns: A list of all the base entries of the specified realm. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRealmBaseEntries {-name <i>realm1</i>} • Using Jython string: AdminTask.listIdMgrRealmBaseEntries ('[-name <i>realm1</i>']') • Using Jython list: AdminTask.listIdMgrRealmBaseEntries (['-name', '<i>realm1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listIdMgrRealmBaseEntries {-interactive} • Using Jython string: AdminTask.listIdMgrRealmBaseEntries ('[-interactive]') • Using Jython list: AdminTask.listIdMgrRealmBaseEntries (['-interactive'])
renameIdMgrRealm	The renameIdMgrRealm command renames the name of the realm that you specified.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The realm name. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask renameIdMgrRealm {-name <i>realm1</i>} • Using Jython string: AdminTask.renameIdMgrRealm ('[-name <i>realm1</i>']') • Using Jython list: AdminTask.renameIdMgrRealm (['-name', '<i>realm1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask renameIdMgrRealm {-interactive} • Using Jython string: AdminTask.renameIdMgrRealm ('[-interactive]') • Using Jython list: AdminTask.renameIdMgrRealm (['-interactive'])

Table 20. (continued)

Command name:	Description:	Parameters and return values:	Examples:
setIdMgrDefaultRealm	The setIdMgrDefaultRealm command sets up the default realm configuration.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name of the realm that is used as a default realm when the caller does not specify any in context. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrDefaultRealm {-name <i>realm1</i>} • Using Jython string: AdminTask.setIdMgrDefaultRealm ('[-name <i>realm1</i>']') • Using Jython list: AdminTask.setIdMgrDefaultRealm (['-name', '<i>realm1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask setIdMgrDefaultRealm {-interactive} • Using Jython string: AdminTask.setIdMgrDefaultRealm ('[-interactive]') • Using Jython list: AdminTask.setIdMgrDefaultRealm (['-interactive'])

Table 20. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateIdMgrRealm	The updateIdMgrRealm command updates the configuration for a realm that you specify.	<ul style="list-style-type: none"> • Parameters: - name The realm name. (String, required) - securityUse A string that indicates if this realm will be used in security now, later, or never. The default value is active. Additional values includes: inactive and nonSelectable. (String, optional) - delimiter The delimiter used for this realm. The default value is @. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrRealm {-name <i>realm1</i>} • Using Jython string: AdminTask.updateIdMgrRealm ('[-name <i>realm1</i>']') • Using Jython list: AdminTask.updateIdMgrRealm (['-name', '<i>realm1</i>']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateIdMgrRealm {-interactive} • Using Jython string: AdminTask.updateIdMgrRealm ('[-interactive]') • Using Jython list: AdminTask.updateIdMgrRealm (['-interactive'])

Commands for the WIMManagementCommands group of the AdminTask object

Use the commands in the WIMManagementCommands group to configure the virtual member manager. The commands for this group do not require a target object. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the WIMManagementCommands group of the AdminTask object:

Table 21.

Command name:	Description:	Parameters and return values:	Examples:
addMemberToGroup	<p>The addMemberToGroup command adds a user or a group to a group.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - memberUniqueName Specifies the unique name value for the user or group that you want to add to the specified group. This parameter maps to the uniqueName property in the virtual member manager. (String, required) - groupUniqueName Specifies the unique name value for the group to which you want to add the user or group that you specified in the memberUniqueName parameter. This parameter maps to the uniqueName property in virtual member manager. (String, required) • Returns: Void if the command is successful. Returns an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask addMemberToGroup {-memberUniqueName uid= meyersd,cn=users,dc=yourco, dc=com -groupUniqueName cn=admins,cn=groups, dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.addMemberToGroup ('[-memberUniqueName uid=meyersd,cn=users, dc=yourco,dc=com -group UniqueName cn=admins, cn=groups,dc=yourco, dc=com]')</pre> • Using Jython list: <pre>AdminTask.addMemberToGroup (['-memberUniqueName', 'uid=meyersd,cn=users,dc= yourco,dc=com', '-group UniqueName', 'cn=admins, cn=groups,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask addMemberToGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.addMemberToGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.addMemberToGroup (['-interactive'])</pre>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
createGroup	<p>The createGroup command creates a new group in the virtual member manager. After the command completes, the new group will appear in the repository. For LDAP, a group must contain a member. The <code>memberUniqueName</code> parameter is optional in this case. If you set the <code>memberUniqueName</code> parameter to the unique name of a group or a user, the group or user will be added as a member of the group.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - cn Specifies the common name for the group that you want to create. This parameter maps to the <code>cn</code> property in virtual member manager. (String, required) - description Specifies additional information about the group that you want to create. This parameter maps to the <code>description</code> property in a virtual member manager object. (String, optional) - parent Specifies the repository in which you want to create the group. This parameter maps to the <code>parent</code> property in the virtual member manager. (String, optional) - memberUniqueName Specifies the unique name value for the user or group that you want to add to the new group. This parameter maps to the <code>uniqueName</code> property in the virtual member manager. (String, optional) • Returns: The unique name of the group that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createGroup {-cn groupA -description a group of admins}</code> • Using Jython string: <code>AdminTask.createGroup (['-cn groupA -description a group of admins'])</code> • Using Jython list: <code>AdminTask.createGroup (['-cn', 'groupA', '-description', 'a group of admins'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createGroup {-interactive}</code> • Using Jython string: <code>AdminTask.createGroup (['-interactive'])</code> • Using Jython list: <code>AdminTask.createGroup (['-interactive'])</code>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
createUser	<p>The createUser command creates a new user in the default repository or a repository that the parent command parameter specifies. This command creates a person entity and a login account entity in the virtual member manager.</p>	<ul style="list-style-type: none"> • Parameters: - uid Specifies the unique ID for the user that you want to create. Virtual member manager then creates a uniqueId value and a uniqueName value for the user. This parameter maps to the uid property in the virtual member manager. (String, required) - password Specifies the password for the user. This parameter maps to the password property in the virtual member manager. (String, required) - confirmPassword Specifies the password again to validate how it was entered for the password parameter. This parameter maps to the password property in virtual member manager. (String, optional) - cn Specifies the first name or given name of the user. This parameter maps to the cn property in virtual member manager. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createUser {-uid 123 -password tempPass -confirmPassword tempPass -cn Jane -surname Doe -ibm-primaryEmail janedoe@acme.com}</pre> • Using Jython string: <pre>AdminTask.createUser ('[-uid 123 -password tempPass -confirmPassword tempPass -cn Jane -surname Doe -ibm-primaryEmail janedoe@acme.com]')</pre> • Using Jython list: <pre>AdminTask.createUser (['-uid', '123', '-password', 'tempPass', '-confirmPassword', 'tempPass', '-cn', 'Jane', '-surname', 'Doe', '-ibm-primaryEmail', 'janedoe@acme.com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createUser {-interactive}</pre> • Using Jython string: <pre>AdminTask.createUser ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.createUser (['-interactive'])</pre>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> <li data-bbox="732 302 1008 562"> <p>- surname Specifies the last name or family name of the user. This parameter maps to the sn property in virtual member manager. (String, optional)</p> <li data-bbox="732 579 1008 840"> <p>- ibm-primaryEmail Specifies the e-mail address of the user. This parameter maps to the ibm-PrimaryEmail property in the virtual member manager. (String, optional)</p> <li data-bbox="732 856 1008 1117"> <p>- parent Specifies the repository in which you want to create the user. This parameter maps to the parent property in the virtual member manager. (String, optional)</p> <li data-bbox="732 1134 1008 1207"> <p>• Returns: The unique name of the user that you created.</p> 	

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
deleteGroup	<p>The deleteGroup command deletes a group in the virtual member manager. You cannot use this command to delete descendants. When this command completes, the group will be deleted from the repository.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the group that you want to delete. This parameter maps to the <code>uniqueName</code> property in virtual member manager. (String, required) • Returns: Void if the command is successful. Returns an error if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteGroup {-uniqueName cn=opera tors,cn=users,dc=yourco, dc=com}</pre> • Using Jython string: <pre>AdminTask.deleteGroup (['-uniqueName cn=ope rators,cn=users,dc=you rco,dc=com']')</pre> • Using Jython list: <pre>AdminTask.deleteGroup (['-uniqueName', 'cn =operators,cn=users,dc =yourco,dc=com']')</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.deleteGroup (['-interactive']')</pre> • Using Jython list: <pre>AdminTask.deleteGroup (['-interactive']')</pre>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
deleteUser	<p>The deleteUser command deletes a user from the virtual member manager. This includes a person object and an account object in the non-merged repositories.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the user that you want to delete. This parameter maps to the uniqueName property in virtual member manager. (String, required) • Returns: Void if the command is successful and an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteUser {-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.deleteUser ('[-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.deleteUser (['-uniqueName', 'uid=dmeyers,cn=users,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteUser {-interactive}</pre> • Using Jython string: <pre>AdminTask.deleteUser ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.deleteUser (['-interactive'])</pre>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>duplicate MembershipOfGroup</p>	<p>Use the duplicate MembershipOfGroup command to make a one group a member of all of the same groups as another group. For example, group A is in group B and group C. To add group D to the same groups as group A, use the duplicate MembershipOfGroup command.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - copyToName Specifies the name of the group to which you want to add the memberships of the group specified in the copyFromName parameter. (String, required) - copyFromName Specifies the name of the group from which you want to copy the group memberships for another group to use. (String, required) • Returns: Void if the command is successful. Returns an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask duplicateMembershipOfGroup {-copyToName cn=operators,cn=groups,dc=yourco,dc=com -copyFromName cn=admins,cn=groups,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.duplicateMembershipOfGroup ('[-copyToName cn=operators,cn=groups,dc=yourco,dc=com -copyFromName cn=admins,cn=groups,dc=yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.duplicateMembershipOfGroup (['-copyToName', 'cn=operators,cn=groups,dc=yourco,dc=com', '-copyFromName', 'cn=admins,cn=groups,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask duplicateMembershipOfGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.duplicateMembershipOfGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.duplicateMembershipOfGroup (['-interactive'])</pre>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
duplicate Membership OfUser	<p>Use the duplicate Membership OfUser command to make a one user a member of all of the same groups as another user. For example, user 1 is in group B and group C. To add user 2 to the same groups as user 1, use the duplicate Membership OfUser command.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - copyToName Specifies the name of the user to which you want to add the memberships of the user specified in the copyFromName parameter. (String, required) - copyFromName Specifies the name of the user from which you want to copy the group memberships for another user to use. (String, required) • Returns: Void if the command is successful. Returns an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask duplicateMembershipOfUser {-copyToName uid=meyersd,cn=users,dc=yourco,dc=com -copyFromName uid=jhart,cn=users,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.duplicateMembershipOfUser ('[-copyToName uid=meyersd,cn=users,dc=yourco,dc=com -copyFromName uid=jhart,cn=users,dc=yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.duplicateMembershipOfUser (['-copyToName', 'uid=meyersd,cn=users,dc=yourco,dc=com', '-copyFromName', 'uid=jhart,cn=users,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask duplicateMembershipOfUser {-interactive}</pre> • Using Jython string: <pre>AdminTask.duplicateMembershipOfUser (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.duplicateMembershipOfUser (['-interactive'])</pre>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getGroup	The getGroup command retrieves the common name and description of a group.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the group that you want to view. This parameter maps to the uniqueName property in virtual member manager. (String, required) • Returns: A map of common name and description properties. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getGroup {-uniqueName cn=operators, cn=groups,dc=yourco,dc=com} • Using Jython string: AdminTask.getGroup ('[-uniqueName cn=operators, cn=groups,dc=yourco, dc=com]') • Using Jython list: AdminTask.getGroup (['-uniqueName', 'cn=operators, cn=groups,dc=yourco,dc=com']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getGroup {-interactive} • Using Jython string: AdminTask.getGroup ('[-interactive]') • Using Jython list: AdminTask.getGroup (['-interactive'])

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getMembership OfGroup	The getMembership OfGroup command retrieves the groups of which a group is a member.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the group whose group memberships you want to view. This parameter maps to the uniqueName property in virtual member manager. (String, required) • Returns: A list of unique names of each of the groups of which the group is a member. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMebmership OfGroup {-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.getMebmership OfGroup ('[-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.getMebmership OfGroup (['-uniqueName', 'uid=dmeyers,cn=users,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMembership OfGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.getMembership OfGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getMembership OfGroup (['-interactive'])</pre>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getMembershipOfUser	<p>The getMembershipOfUser command retrieves the groups of which a user is a member.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the user whose group memberships you want to view. This parameter maps to the uniqueName property in virtual member manager. (String, required) • Returns: A list of unique names for each group of which the user is a member. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMembershipOfUser {-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.getMembershipOfUser ('[-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.getMembershipOfUser (['-uniqueName', 'uid=dmeyers,cn=users,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMembershipOfUser {-interactive}</pre> • Using Jython string: <pre>AdminTask.getMembershipOfUser ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getMembershipOfUser (['-interactive'])</pre>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getMembers OfGroup	<p>The getMembers OfGroup command retrieves the members of a group.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the group whose members you want to view. This parameter maps to the uniqueName property in virtual member manager. (String, required) • Returns: The unique name of each of the members of the group and the type of each member. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMembersOfGroup {-uniqueName cn=operators,cn=groups ,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.getMembersOfGroup [('-uniqueName cn=operators,cn=groups ,dc=yourco,dc=com')]</pre> • Using Jython list: <pre>AdminTask.getMembersOfGroup [('-uniqueName', 'cn=operators,cn=groups ,dc=yourco,dc=com')]</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getMembersOfGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.getMembersOfGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getMembersOfGroup (['-interactive'])</pre>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>getUser</p>	<p>The getUser command retrieves information about a user in the virtual member manager.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the user that you want to view. This parameter maps to the uniqueName property in the virtual member manager. (String, required) • Returns: A map that contains the following properties: uniqueName, cn, sn, uid, and ibm-primaryEmail. These attributes are fixed and you cannot change them. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getUser {-user Name uid=dmeyers,cn=users,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.getUser ('[-use rName uid=dmeyers,cn=users,dc=yourco,dc=com]')</pre> • Using Jython list: <pre>AdminTask.getUser (['-use rName', 'uid=dmeyers,cn=users,dc=yourco,dc=com'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getUser {-interactive}</pre> • Using Jython string: <pre>AdminTask.getUser (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.getUser (['-interactive'])</pre>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>removeMemberFromGroup</p>	<p>The removeMemberFromGroup command removes a user or a group from a group.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - memberUniqueName Specifies the unique name value for the user or group that you want to remove from the specified group. This parameter maps to the <code>uniqueName</code> property in virtual member manager. (String, required) - groupUniqueName Specifies the unique name value for the group from which you want to remove the user or group that you specified with the <code>memberUniqueName</code> parameter. This parameter maps to the <code>uniqueName</code> property in virtual member manager. (String, required) • Returns: Void if the command is successful. Returns an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask removeMemberFromGroup {-memberUniqueName uid=meyersd,cn=users,dc=yourco,dc=com -groupUniqueName cn=admins,cn-groups,dc=yourco,dc=com}</pre> • Using Jython string: <pre>AdminTask.removeMemberFromGroup (['-memberUniqueName uid=meyersd,cn=users,dc=yourco,dc=com -groupUniqueName cn=admins,cn-groups,dc=yourco,dc=com']')</pre> • Using Jython list: <pre>AdminTask.removeMemberFromGroup (['-memberUniqueName', 'uid=meyersd,cn=users,dc=yourco,dc=com', '-groupUniqueName', 'cn=admins,cn-groups,dc=yourco,dc=com']')</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask removeMemberFromGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.removeMemberFromGroup (['-interactive']')</pre> • Using Jython list: <pre>AdminTask.removeMemberFromGroup (['-interactive']')</pre>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
searchGroups	<p>Use the searchGroups command to find groups in the virtual member manager that match criteria that you provide. For example, you can use the searchGroups command to find all of the groups with a common name that begins with IBM. You can search for any virtual member manager property because the command is generic.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - cn The first name or given name of the user. This parameter maps to the cn property in the virtual member manager. You must set this parameter or the description parameter, but not both. (String, optional) - description Specifies information about the group. This parameter maps to the description entity in a virtual member manager object. You must set this parameter or the cn parameter, but not both. (String, optional) - timeLimit Specifies the maximum amount of time in milliseconds that the search can run. The default value is no time limit. (String, optional) - countLimit Specifies the maximum number of results that you want returned from the search. By default, all groups found in the search are returned. (String, optional) • Returns: A list of unique names of all of the groups that match the search criteria that you provided. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask searchGroups {cn *IBM*}</code> • Using Jython string: <code>AdminTask.searchGroups ('[cn *IBM*]')</code> • Using Jython list: <code>AdminTask.searchGroups (['cn', '*IBM*'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask searchGroups {-interactive}</code> • Using Jython string: <code>AdminTask.searchGroups (['-interactive'])</code> • Using Jython list: <code>AdminTask.searchGroups (['-interactive'])</code>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
searchUsers	<p>Use the searchUsers command to find users in the virtual member manager that match criteria that you provide. For example, you can use the searchUsers command to find all of the telephone numbers that contain 919. You can search for any virtual member manager property because the command is generic.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - principalName Specifies the principal name of the user that is used as the logon ID for the user in the system. This parameter maps to the <code>principalName</code> property in virtual member manager. You must specify only one of the following parameters: <code>principalName</code>, <code>uid</code>, <code>cn</code>, <code>sn</code>, or <code>ibm-primaryEmail</code>. (String, optional) - uid Specifies the unique ID value for the user for whom you want to search. This parameter maps to the <code>uid</code> property in virtual member manager. You must specify only one of the following parameters: <code>principalName</code>, <code>uid</code>, <code>cn</code>, <code>sn</code>, or <code>ibm-primaryEmail</code>. (String, optional) - cn Specifies the first name or given name of the user. This parameter maps to the <code>cn</code> property in virtual member manager. You must specify only one of the following parameters: <code>principalName</code>, <code>uid</code>, <code>cn</code>, <code>sn</code>, or <code>ibm-primaryEmail</code>. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask searchUsers {-principalName */IBM/US*}</code> • Using Jython string: <code>AdminTask.searchUsers ('[-principalName */IBM/US*]')</code> • Using Jython list: <code>AdminTask.searchUsers (['-principalName', '*/IBM/US*'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask searchUsers {-interactive}</code> • Using Jython string: <code>AdminTask.searchUsers (['-interactive'])</code> • Using Jython list: <code>AdminTask.searchUsers (['-interactive'])</code>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> <li data-bbox="764 306 1047 709"> <p>- sn Specifies the last name or family name of the user. This parameter maps to the sn property in virtual member manager. You must specify only one of the following parameters: principalName, uid, cn, sn, or ibm-primaryEmail. (String, optional)</p> <li data-bbox="764 726 1047 1161"> <p>- ibm-primaryEmail Specifies the email address of the user. This parameter maps to the ibm-PrimaryEmail property in the virtual member manager. You must specify only one of the following parameters: principalName, uid, cn, sn, or ibm-primaryEmail. (String, optional)</p> <li data-bbox="764 1178 1047 1409"> <p>- timeLimit Specifies the maximum amount of time in milliseconds that the search can run. The default is not time limit. (String, optional)</p> <li data-bbox="764 1425 1047 1686"> <p>- countLimit Specifies the maximum number of results that you want returned from the search. By default, all users found in the search are returned. (String, optional)</p> <li data-bbox="764 1703 1047 1835"> <ul style="list-style-type: none"> <li data-bbox="764 1703 1047 1835">• Returns: A list of unique names of all of the users that match the search criteria that you provided. 	

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateGroup	<p>The updateGroup command updates the common name or the description of a group.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - uniqueName Specifies the unique name value for the group for which you want to modify the properties. This parameter maps to the uniqueName property in virtual member manager. (String, required) - cn Specifies the new common name used for the group. This parameter maps to the cn property in virtual member manager. (String, optional) - description Specifies the new information about the group. This parameter maps to the description entity in a virtual member manager object. (String, optional) • Returns: Void if the command is successful. Returns an exception if the command fails. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateGroup {-uniqueName cn=opera tors,cn=groups,dc=yourco ,dc=com -cn groupA} • Using Jython string: AdminTask.updateGroup ('[-uniqueName cn=oper ators,cn=groups,dc=your co,dc=com -cn groupA]') • Using Jython list: AdminTask.updateGroup (['-uniqueName', 'cn=oper ators,cn=groups,dc=yourco, dc=com', '-cn', 'groupA']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask updateGroup {-interactive} • Using Jython string: AdminTask.updateGroup ('[-interactive]') • Using Jython list: AdminTask.updateGroup (['-interactive'])

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
updateUser	<p>The updateUser command updates the following properties: uniqueName, uid, password, cn, sn, or ibm-primaryEmail.</p>	<ul style="list-style-type: none"> • Parameters: - uniqueName Specifies the unique name value for the user for which you want to modify the properties. This parameter maps to the uniqueName property in virtual member manager. (String, required) - uid Specifies the new unique ID value for the user. This parameter maps to the uid property in virtual member manager. (String, optional) - password Specifies the new password for the user. This parameter maps to the password property in virtual member manager. (String, optional) - confirmPassword Specifies the password again to validate how it was entered on the password parameter. This parameter maps to the password property in virtual member manager. (String, optional) - cn Specifies the new first name or given name of the user. This parameter maps to the cn property in virtual member manager. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateUser {-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com -uid 123}</code> • Using Jython string: <code>AdminTask.updateUser ('[-uniqueName uid=dmeyers,cn=users,dc=yourco,dc=com -uid 123]')</code> • Using Jython list: <code>AdminTask.updateUser (['-uniqueName', 'uid=dmeyers,cn=users,dc=yourco,dc=com', '-uid', '123'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask updateUser {-interactive}</code> • Using Jython string: <code>AdminTask.updateUser (['-interactive'])</code> • Using Jython list: <code>AdminTask.updateUser (['-interactive'])</code>

Table 21. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - surname Specifies the new last name or family name of the user. This parameter maps to the sn property in virtual member manager. (String, optional) - ibm-primaryEmail Specifies the new e-mail address of the user. This parameter maps to the mail property in virtual member manager. (String, optional) • Returns: Void if the command is successful. Returns an exception if the command fails. 	

Commands for the KeyStoreCommands group of the AdminTask object

Use the commands in the KeyStoreCommands group to create or delete key stores. The commands for this group do not require a target object. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the KeyStoreCommands group of the AdminTask object:

Table 22.

Command name:	Description:	Parameters and return values:	Examples:
<p>changeKey Store Password</p>	<p>The changeKey Store Password command changes the password on the key store.</p>	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - keyStorePassword The password that protects the key store that you want to change. (String, required) - newkeyStorePassword The new password that protects the key store. (String, required) - newkeyStorePassword Verify The new password that protects the key store. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask changeKeyStore Password {-keyStoreName testKS -keyStorePassword testpwd -newKeyStorePassword keyPWD -newKeyStorePasswordVerify keyPWD}</pre> • Using Jython string: <pre>AdminTask.changeKeyStore Password ('[-keyStoreName testKS -keyStorePassword testpwd -newKeyStorePassword keyPWD -newKeyStorePassword Verify keyPWD]')</pre> • Using Jython list: <pre>AdminTask.changeKeyStore Password (['-keyStoreName', 'testKS', '-keyStorePassword', 'testpwd', '-newKeyStorePassword', 'keyPWD', '-newKeyStorePasswordVerify', 'keyPWD'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask changeKeyStore Password {-interactive}</pre> • Using Jython string: <pre>AdminTask.changeKeyStore Password ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.changeKeyStore Password (['-interactive'])</pre>

Table 22. (continued)

Command name:	Description:	Parameters and return values:	Examples:
<p>change Multiple KeyStore Passwords</p>	<p>The change Multiple KeyStore Passwords command updates all of the key stores in the configuration that have a give password and changed them to a new password. This is useful because when you create key store files on the system, they will have WebAS as a password by default.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStorePassword Specifies the name of the password that you want to change. (String, required) - newKeyStorePassword Specifies the new password that you will use to access the key store. (String, required) - newKeyStorePassword Verify Confirms the new key store password. (String, required) • Returns: A list of key store aliases that where changed 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask changeMultipleKeyStorePasswords {-keyStorePassword WebAS -newKeyStorePassword newpwd -verify newpwd}</pre> • Using Jython string: <pre>AdminTask.changeMultipleKeyStorePasswords ('[-keyStorePassword WebAS -newKeyStorePassword newpwd -newKeyStorePasswordVerify newpwd]')</pre> • Using Jython list: <pre>AdminTask.changeMultipleKeyStorePasswords (['-keyStorePassword', 'WebAS', '-newKeyStorePassword', 'newpwd', '-newKeyStorePasswordVerify', 'newpwd'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask changeMultipleKeyStorePasswords {-interactive}</pre> • Using Jython string: <pre>AdminTask.changeMultipleKeyStorePasswords (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.changeMultipleKeyStorePasswords (['-interactive'])</pre>

Table 22. (continued)

Command name:	Description:	Parameters and return values:	Examples:
createKeyStore	The createKeyStore command creates the key store settings in the configuration and the key store database.	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreType The implementation of the key store management. (String, required) - keyStoreLocation The location of the key store. For file based, the location is the files system path to the key store database. For hardware key store, the location is the path to the token library. (String, required) - keyStorePassword The password that protects the key store. (String, required) - keyStorePasswordVerify The password that protects the key store. (String, required) - keyStoreProvider The provider used to implement the key store. (String, optional) - isKeyStoreFileBased Set the value of this parameter to true if the key store is file based. Set the value of this parameter to false for hardware crypto key stores. (Boolean, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeyStore {-keyStoreName testKS -location c:\temp\test KeyFile.p12 keyStorePass word testpwd -keyStore PasswordVerify testpwd -isKeyStoreFileBased true -keyStoreInitAtStartup true -keyStoreReadOnly false}</pre> • Using Jython string: <pre>AdminTask.createKeyStore (['-keyStoreName testKS -location c:\temp\testKey File.p12 keyStorePass word testpwd -keyStorePass wordVerify testpwd -isKey StoreFileBased true -key StoreInitAtStartup true -keyStoreReadOnly false'])</pre> • Using Jython list: <pre>AdminTask.createKeyStore (['-keyStoreName', 'testKS', '-location', 'c:\temp\test KeyFile.p12', 'keyStorePass word', 'testpwd', '-keySto rePasswordVerify', 'testpwd', '-isKeyStoreFileBased', 'true', '-keyStoreInitAt Startup', 'true', '-key StoreReadOnly', 'false'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKey Store {-interactive}</pre> • Using Jython string: <pre>AdminTask.createKeySt ore ['-interactive']</pre> • Using Jython list: <pre>AdminTask.createKeyS tore (['-interactive'])</pre>

Table 22. (continued)

Command name:	Description:	Parameters and return values:	Examples:
		<ul style="list-style-type: none"> - keyStoreHostList A list of host names that indicate from where the key store is remotely managed, separated by commas. (String, optional) - keyStoreInitAtStartup Set the value of this parameter to true if the key store is initialized at startup. Otherwise, set the value of this parameter to false. (Boolean, optional) - keyStoreReadOnly Set the value of this parameter to true if you cannot write to the key store. Otherwise, set the value of this parameter to false. (Boolean, optional) - keyStoreStashFile Set the value of this parameter to true if you want to create stash files for CMS type key store. Otherwise, set the value of this parameter to false. (Boolean, optional) - scopeName The name of the scope. (String, optional) - - enableCryptoOperations Specifies if the key store object will be used for hardware cryptographic operations or not. The default value is false. (Boolean, optional) • Returns: The configuration object name of the key store object that you created. 	

Table 22. (continued)

Command name:	Description:	Parameters and return values:	Examples:
createCMSKeyStore	<p>The createCMSKeyStore command creates a CMS key store database and the key store settings in the configuration.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - cmsKeyStoreURI The URI of the CMS key store. (String, required) - pluginHostName The host name of the plug-in. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createCMSKeyStore • Using Jython: AdminTask.createCMSKeyStore() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createCMSKeyStore {-interactive} • Using Jython string: AdminTask.createCMSKeyStore ('[-interactive]') • Using Jython list: AdminTask.createCMSKeyStore (['-interactive'])
deleteKeyStore	<p>The deleteKeyStore command deletes the settings of a key store from the configuration and the key store file.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key store that you want to delete. (String, required) - scopeName The name of the scope. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeyStore {-name testKS} • Using Jython string: AdminTask.deleteKeyStore ('[-name testKS]') • Using Jython list: AdminTask.deleteKeyStore (['-name', 'testKS']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeyStore {-interactive} • Using Jython string: AdminTask.deleteKeyStore ('[-interactive]') • Using Jython list: AdminTask.deleteKeyStore (['-interactive'])

Table 22. (continued)

Command name:	Description:	Parameters and return values:	Examples:
exchangeSigners	The exchangeSigners command exchange signer certificate between key stores.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName1 The name that uniquely identifies a key store. You must specify a second key store name using the <code>keyStoreName2</code> parameter. (String, required) - keyStoreScope1 The scope name of the key store that you specified with the <code>keyStoreName1</code> parameter. (String, required) - certificateAlaisList1 A list of aliases separated by a comma. (String, optional) - keyStoreName2 The name that uniquely identifies a key store. You must specify a second key store name using the <code>keyStoreName1</code> parameter. (String, required) - keyStoreScope2 The scope name of the key store that you specified with the <code>keyStoreName2</code> parameter. (String, required) - certificateAliasList2 A list of aliases separated by a comma. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask exchangeSigners {-keyStoreName1 testKS -certificateAliasList1 testCert1 -keyStoreName2 secondKS -certificate AlaisList2 certAlis}</pre> • Using Jython string: <pre>AdminTask.exchangeSigners ('[-keyStoreName1 testKS -certificateAliasList1 testCert1 -keyStoreName2 secondKS -certificateAlais List2 certAlis]')</pre> • Using Jython list: <pre>AdminTask.exchangeSigners (['-keyStoreName1', 'testKS', '-certificateAliasList1', 'testCert1', '-keyStoreName 2', 'secondKS', '-certifica teAlaisList2', 'certAlis'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask exchangeSigners {-interactive}</pre> • Using Jython string: <pre>AdminTask.exchangeSigners ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.exchangeSigners (['-interactive'])</pre>

Table 22. (continued)

Command name:	Description:	Parameters and return values:	Examples:
getKeyStoreInfo	The getKeyStoreInfo command displays the settings of a particular key store.	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key store. (String, required) - scopeName The name of the scope. (String, optional) • Returns: The settings of the key store that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeyStore {-name testKS} • Using Jython string: AdminTask.getKeyStore ('[-name testKS]') • Using Jython list: AdminTask.getKeyStore (['-name', 'testKS']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeyStore Info {-interactive} • Using Jython string: AdminTask.getKeyStore Info ('[-interactive]') • Using Jython list: AdminTask.getKeyStore Info (['-interactive'])

Table 22. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listKeyFileAliases	<p>The listKeyFileAliases command lists the certificates in a key store file.</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyFilePath The path of the key file. (String, required) - keyFilePassword The password for the key file. (String, required) - keyFileType The key file type. (String, required) • Returns: A list of certificate aliases. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listKeyFileAliases {-keyFilePaht c:\temp\testKeyFile.p12 -keyFilePassword testPwd -keyFileType PKCS12}</pre> • Using Jython string: <pre>AdminTask.listKeyFileAliases ('[-keyFilePaht c:\temp\testKeyFile.p12 -keyFilePassword testPwd -keyFileType PKCS12]')</pre> • Using Jython list: <pre>AdminTask.listKeyFileAliases (['-keyFilePaht', 'c:\temp\testKeyFile.p12', '-keyFilePassword', 'testPwd', '-keyFileType', 'PKCS12'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listKeyFileAliases {-interactive}</pre> • Using Jython string: <pre>AdminTask.listKeyFileAliases ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.listKeyFileAliases (['-interactive'])</pre>

Table 22. (continued)

Command name:	Description:	Parameters and return values:	Examples:
listKeyStores	The listKeyStores command lists the key store for a particular scope.	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - displayObjectName Set the value of this parameter to true to list the key store configuration objects within a scope. Set the value of this parameter to false to list the strings that contain the key store name and management scope. (String, optional) - scopeName The name of the scope. (String, optional) Returns: A list of key stores. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listKeyStores</code> Using Jython: <code>AdminTask.listKeyStores()</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listKeyStores {-interactive}</code> Using Jython string: <code>AdminTask.listKeyStores ('[-interactive]')</code> Using Jython list: <code>AdminTask.listKeyStores (['-interactive'])</code>
listKeyStoresTypes	The listKeyStoresTypes command lists all valid key store types.	<ul style="list-style-type: none"> Parameters: None Returns: A list of key store types. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listKeyStoreTypes</code> Using Jython: <code>AdminTask.listKeyStoreTypes()</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listKeyStores Types {-interactive}</code> Using Jython string: <code>AdminTask.listKeyStores Types ('[-interactive]')</code> Using Jython list: <code>AdminTask.listKeyStores Types (['-interactive'])</code>

Commands for the SSLConfigCommands group of the AdminTask object

Use the commands in the SSLConfigCommands group to create and delete SSL configurations. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SSLConfigCommands group of the AdminTask object:

Table 23.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createSSLConfig	<p>The createSSLConfig command creates an SSL configuration that is based on key store and trust store settings. You can use the SSL configuration settings to make the SSL connections.</p>	None	<ul style="list-style-type: none"> • Parameters: - alias The name of the alias. (String, required) - scopeName The name of the scope. (String, optional) - clientKeyAlias The certificate alias name for the client. (String, optional) - serverKeyAlias The certificate alias name for the server. (String, optional) - type The type of SSL configuration. (String, optional) - clientAuthentication Set the value of this parameter to true to request client authentication. Otherwise, set the value of this parameter to false. (Boolean, optional) - securityLevel The cipher group that you want to use. Valid values include: HIGH, MEDIUM, LOW, and CUSTOM. (String, optional) - enabledCiphers A list of ciphers used during SSL handshake. (String, optional) - jsseProvider One of the JSSE providers. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createSSLConfig {-alias testSSLCfg -clientKeyAlias key1 -serverKeyAlias key2 -trustStoreName trustKS -keyStoreName testKS -keyManagerName testKeyMgr} • Using Jython string: AdminTask.createSSLConfig ('[-alias testSSLCfg -clientKeyAlias key1 -serverKeyAlias key2 -trustStoreName trustKS -keyStoreName testKS -keyManagerName testKeyMgr]') • Using Jython list: AdminTask.createSSLConfig (['-alias', 'testSSLCfg', '-clientKeyAlias', 'key1', '-serverKeyAlias', 'key2', '-trustStoreName', 'trustKS', '-keyStoreName', 'testKS', '-keyManagerName', 'testKeyMgr']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createSSLConfig {-interactive} • Using Jython string: AdminTask.createSSLConfig ('[-interactive]') • Using Jython list: AdminTask.createSSLConfig (['-interactive'])

Table 23. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<p>-</p> <p>clientAuthenticationSupported Set the value of this parameter to true to support client authentication. Otherwise, set the value of this parameter to false. (Boolean, optional)</p> <p>- sslProtocol The protocol type for the SSL handshake. Valid values include: SSL_TLS, SSL, SSLv2, SSLv3, TLS, TLSv1. (String, optional)</p> <p>-</p> <p>trustManagerObjectName A list of trust managers separated by commas. (String, optional)</p> <p>- trustStoreNames The key store that holds trust information used to validate the trust from remote connections. (String, required)</p> <p>-</p> <p>trustStoreScopeName The management scope name of the trust store. (String, optional)</p>	

Table 23. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - keyStoreName The key store that holds the personal certificates that provide identity for the connection. (String, required) - keyStoreScopeName The management scope name of the key store. (String, optional) - ssslKeyRingName Specifies a system SSL (SSSL) key ring name. The value for this parameter has no affect unless the SSL configuration type is SSSL. (String, optional) • Returns: The configuration object name of the SSL configuration object that you created. 	

Table 23. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createSSL Config Property	The createSSL Config Property command creates a property for an SSL configuration. Use this command to set SSL configuration settings that are different than the settings in the SSL configuration object.	None	<ul style="list-style-type: none"> • Parameters: - sslConfigAliasName The alias name of the SSL configuration. (String, required) - scopeName The name of the scope. (String, optional) - propertyName The name of the property. (String, required) - propertyValue The value of the property. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createSSLConfigProperty {-sslConfigAliasName NodeDefaultSSLSettings -scopeName (cell):localhostNode01Cell:(node):localhostNode01 -propertyName test.property -propertyValue testValue} • Using Jython string: AdminTask.createSSLConfigProperty ('[-sslConfigAliasName NodeDefaultSSLSettings -scopeName (cell):localhostNode01Cell:(node):localhostNode01 -propertyName test.property -propertyValue testValue]') • Using Jython list: AdminTask.createSSLConfigProperty (['-sslConfigAliasName', 'NodeDefaultSSLSettings', '-scopeName', '(cell):localhostNode01Cell:(node):localhostNode01', '-propertyName', 'test.property', '-propertyValue', 'testValue']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createSSLConfigProperty {-interactive} • Using Jython string: AdminTask.createSSLConfigProperty ('[-interactive]') • Using Jython list: AdminTask.createSSLConfigProperty (['-interactive'])

Table 23. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteSSLConfig	The deleteSSLConfig command deletes the SSL configuration object that you specify from the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - alias The name of the alias. (String, required) - scopeName The name of the scope. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteSSLConfig {-alias NodeDefaultSSL Settings -scopeName (cell):localhostNode01Cell:(no de):localhostNode01}</pre> • Using Jython string: <pre>AdminTask.deleteSSLConfig (['-alias NodeDefaultSSL Settings -scopeName (cell):localhostNode01Cell:(no de):localhostNode01'])</pre> • Using Jython list: <pre>AdminTask.deleteSSLConfig (['-alias', 'NodeDefault SSLSettings', '-scopeName', '(cell):localhostNode01 Cell:(node):localhost Node01'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteSSLConfig {-interactive}</pre> • Using Jython string: <pre>AdminTask.deleteSSLConfig (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.deleteSSLConfig (['-interactive'])</pre>

Table 23. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getSSLConfig	The getSSLConfig command obtains information about an SSL configuration and displays the settings.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - alias The name of the alias. (String, required) - scopeName The name of the scope. (String, optional) • Returns: Information about the SSL configuration that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getSSLConfig {-alias NodeDefaultSSL Settings -scopeName (cell):localhostNode01 Cell:(node):localhost Node01 }</pre> • Using Jython string: <pre>AdminTask.getSSLConfig (['-alias NodeDefault SSLSettings -scopeName (cell):localhostNode01 Cell:(node):localhost Node01'])</pre> • Using Jython list: <pre>AdminTask.getSSLConfig (['-alias', 'Node DefaultSSLSettings', '-scopeName', '(cell): localhostNode01Cell: (node):localhostNode01'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getSSLConfig {-interactive}</pre> • Using Jython string: <pre>AdminTask.getSSLConfig (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.getSSLConfig (['-interactive'])</pre>

Table 23. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getSSLConfig Properties	The getSSLConfig Properties command obtains information about SSL configuration properties.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - alias The name of the alias. (String, required) - scopeName The name of the scope. (String, optional) • Returns: Information about SSL configuration properties. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getSSLConfig Properties {-sslConfig AliasName NodeDefault SSLSettings -scopeName (cell):localhostNode01 Cell:(node):localhostNode01}</pre> • Using Jython string: <pre>AdminTask.getSSLConfig Properties ('[-sslConfigAliasName NodeDefaultSSLSettings -scopeName (cell):localhostNode01Cell:(node):localhostNode01]')</pre> • Using Jython list: <pre>AdminTask.getSSLConfig Properties (['-sslConfigAliasName', 'NodeDefaultSSLSettings', '-scopeName', '(cell):localhostNode01Cell:(node):localhostNode01'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getSSLConfig Properties {-interactive}</pre> • Using Jython string: <pre>AdminTask.getSSLConfig Properties ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getSSLConfig Properties (['-interactive'])</pre>

Table 23. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listSSLCiphers	The listSSLCiphers command lists the SSL ciphers.	None	<ul style="list-style-type: none"> • Parameters: - sslConfigAliasName The alias name of the SSL configuration. (String, required) - scopeName The name of the scope. (String, optional) - securityLevel The cipher group that you want to use. Valid values include: HIGH, MEDIUM, LOW, and CUSTOM. (String, required) - provider (String, optional) • Returns: A list of SSL ciphers. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listSSLCiphers {-sslConfigAliasName test SSLCfg -securityLevel HIGH} • Using Jython string: AdminTask.listSSLCiphers ('[-sslConfigAliasName testSSLCfg -securityLevel HIGH]') • Using Jython list: AdminTask.listSSLCiphers (['-sslConfigAliasName', 'testSSLCfg', '-securityLevel', 'HIGH']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listSSLCiphers {-interactive} • Using Jython string: AdminTask.listSSLCiphers ('[-interactive]') • Using Jython list: AdminTask.listSSLCiphers (['-interactive'])

Table 23. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listSSLConfig	The listSSLConfig command lists the defined SSL configurations within a management scope.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name of the scope. (String, optional) - displayObjectName Set the value of this parameter to true to list the SSL configuration objects within the scope. Set the value of this parameter to false to list the strings that contain the SSL configuration alias and management scope. (Boolean, optional) • Returns: A list of the defined SSL configurations. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listSSLConfig {-scopeName (cell): localhostNode01Cell:(node): localhostNode01 -displayObjectName true}</pre> • Using Jython string: <pre>AdminTask.listSSLConfig (['-scopeName (cell): localhostNode01Cell:(node):localhostNode01 -displayObjectName true'])</pre> • Using Jython list: <pre>AdminTask.listSSLConfig (['-scopeName', '(cell):localhostNode01Cell:(node):localhostNode01', '-displayObjectName', 'true'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listSSLConfig {-interactive}</pre> • Using Jython string: <pre>AdminTask.listSSLConfig (['-interactive'])</pre> • Using Jython list: <pre>AdminTask.listSSLConfig (['-interactive'])</pre>

Table 23. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listSSLConfig Properties	The listSSLConfig Properties command lists the properties for a SSL configuration.	None	<ul style="list-style-type: none"> • Parameters: - • sslConfigAliasName The alias name of the SSL configuration. (String, required) - • scopeName The name of the scope. (String, optional) - • displayObjectName Set the value of this parameter to true to list the SSL configuration objects within the scope. Set the value of this parameter to false to list the strings that contain the SSL configuration alias and management scope. (Boolean, optional) • Returns: A list of properties. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listSSLConfig Property {-alias No deDefaultSSLSettings -scope Name (cell):localhostNode01:(node):localhostNode01 -displayObjectName true} • Using Jython string: AdminTask.listSSLConfig Property ('[-alias No deDefaultSSLSettings -scopeName (cell):localhostNode01Cell:(node):localhostNode01 -displayObjectName true]') • Using Jython list: AdminTask.listSSLConfigProperty (['-alias', 'No', 'deDefaultSSLSettings', '-scopeName', '(cell):localhostNode01Cell:(node):localhostNode01', '-displayObjectName', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listSSLConfig Properties {-interactive} • Using Jython string: AdminTask.listSSLConfig Properties ('[-interactive]') • Using Jython list: AdminTask.listSSLConfig Properties (['-interactive'])

Table 23. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>modifySSLConfig</p>	<p>The modifySSLConfig command modifies the settings of an existing SSL configuration.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - alias The name of the alias. (String, required) - scopeName The name of the scope. (String, optional) - clientKeyAlias The certificate alias name for the client. (String, optional) - serverKeyAlias The certificate alias name for the server. (String, optional) - type The type of SSL configuration. (String, optional) - clientAuthentication Set the value of this parameter to true to request client authentication. Otherwise, set the value of this parameter to false. (Boolean, optional) - securityLevel The cipher group that you want to use. Valid values include: HIGH, MEDIUM, LOW, and CUSTOM. Commands for the DescriptivePropCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the DescriptivePropCommands group of the AdminTask object:

Table 24.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createDescriptiveProp	The createDescriptiveProp command creates key manager settings in the configuration. Use this command during SSL handshake to determine which certificate to use.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - parentDataType (String, required) - parentClassName (String, required) - parentScopeName (String, optional) - name (String, required) - value (String, required) - type (String, required) - displayNameKey (String, required) - nlsRangeKey (String, optional) - hoverHelpKey (String, optional) - range (String, optional) - inclusive (Boolean, optional) - firstClass (Boolean, optional) Returns: The configuration object name of the key manager object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask createKeyManager {-name testKM -keyManager Class com.ibm.ws.security. ltpa.LTPAKeyPairGenerator}</pre> Using Jython string: <pre>AdminTask.createKeyManager (['-name testKM -keyManag erClass com.ibm.ws.securi ty.ltpa.LTPAKeyPairGenera tor']')</pre> Using Jython list: <pre>AdminTask.createKeyManager (['-name', 'testKM', '-key ManagerClass', 'com.ibm.ws .security.ltpa.LTPAKeyPair Generator'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask createDescrip tiveProp {-interactive}</pre> Using Jython string: <pre>AdminTask.createDescripti veProp (['-interactive']')</pre> Using Jython list: <pre>AdminTask.createDescripti veProp (['-interactive'])</pre>
deleteDescriptiveProp	The deleteDescriptiveProp command deletes key manager settings from the configuration.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - parentDataType (String, required) - parentClassName (String, required) - parentScopeName (String, optional) - name (String, required) Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask deleteDescrip tiveProp {-interactive}</pre> Using Jython string: <pre>AdminTask.deleteDescrip tiveProp (['-interactive']')</pre> Using Jython list: <pre>AdminTask.deleteDescrip tiveProp (['-interactive'])</pre>

Table 24. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getDescriptiveProp	The getDescriptiveProp command obtains information about key manager settings.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - parentDataType (String, required) - parentClassName (String, required) - parentScopeName (String, optional) - name (String, required) Returns: Information about key manager settings. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask getDescriptiveProp {-interactive}</pre> Using Jython string: <pre>AdminTask.getDescriptiveProp ('[-interactive]')</pre> Using Jython list: <pre>AdminTask.getDescriptiveProp (['-interactive'])</pre>
listDescriptiveProp	The listDescriptiveProp command lists the key managers within a particular management scope.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - parentDataType (String, required) - parentClassName (String, required) - parentScopeName (String, optional) - displayObjectName Set the value of this parameter to true to list the key manager objects within the scope. Set the value of this parameter to false to list the strings that contain the key manager name and management scope. (Boolean, optional) Returns: A list of key managers. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask listDescriptiveProp {-interactive}</pre> Using Jython string: <pre>AdminTask.listDescriptiveProp ('[-interactive]')</pre> Using Jython list: <pre>AdminTask.listDescriptiveProp (['-interactive'])</pre>

Table 24. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifyDescriptiveProp	The modifyDescriptiveProp command modifies the settings of an existing key manager.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - parentDataType (String, required) - parentClassName (String, required) - parentScopeName (String, optional) - name (String, required) - value (String, optional) - type (String, optional) - displayNameKey (String, optional) - nlsRangeKey (String, optional) - hoverHelpKey (String, optional) - range (String, optional) - inclusive (Boolean, optional) - firstClass (Boolean, optional) Returns: None 	Interactive mode example usage: <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask modifyDescriptiveProp {-interactive}</pre> Using Jython string: <pre>AdminTask.modifyDescriptiveProp ('[-interactive]')</pre> Using Jython list: <pre>AdminTask.modifyDescriptiveProp (['-interactive'])</pre>

Commands for the TrustManagerCommands group of the AdminTask object

Use the commands in the TrustManagerCommands group to create and delete a trust manager. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the TrustManagerCommands group of the AdminTask object:

Table 25.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createTrustManager	<p>The createTrustManagerInfo command creates trust manager settings in the configuration. Use this command during SSL handshake to make trust decisions about remote endpoints.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the trust manager. (String, required) - scopeName The name of the scope. (String, optional) - provider The provider name of the trust manager. (String, optional) - algorithm The algorithm name of the trust manager. (String, optional) - trustManagerClass Specifies a class that implements the <code>javax.net.ssl.X509TrustManager</code> interface. You cannot use this parameter with the provider or algorithm parameters. (String, optional) • Returns: The configuration object name of the trust manager object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createTrustManager {-name testTM -provider IBMJSSE2 -algorithm IbmX509}</pre> • Using Jython string: <pre>AdminTask.createTrustManager ('[-name testTM -provider IBMJSSE2 -algorithm IbmX509]')</pre> • Using Jython list: <pre>AdminTask.createTrustManager (['-name', 'testTM', '-provider', 'IBMJSSE2', '-algorithm', 'IbmX509'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createTrustManager {-interactive}</pre> • Using Jython string: <pre>AdminTask.createTrustManager ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.createTrustManager (['-interactive'])</pre>

Table 25. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteTrustManager	The deleteTrustManager command deletes the trust manager settings from the configuration.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the trust manager. (String, optional) - scopeName The name of the scope. (String, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask deleteTrustManager {-name testTM} Using Jython string: AdminTask.deleteTrustManager (['-name testTM']) Using Jython list: AdminTask.deleteTrustManager (['-name', 'testTM']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask deleteTrustManager {-interactive} Using Jython string: AdminTask.deleteTrustManager (['-interactive']) Using Jython list: AdminTask.deleteTrustManager (['-interactive'])
getTrustManager	The getTrustManager command obtains the setting of a trust manager.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the trust manager. (String, optional) - scopeName The name of the scope. (String, optional) Returns: The settings of the trust manager group that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask getTrustManager {-name testTM} Using Jython string: AdminTask.getTrustManager (['-name testTM']) Using Jython list: AdminTask.getTrustManager (['-name', 'testTM']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask getTrustManager {-interactive} Using Jython string: AdminTask.getTrustManager (['-interactive']) Using Jython list: AdminTask.getTrustManager (['-interactive'])

Table 25. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listTrustManagers	The listTrustManagers command lists the trust managers within a particular management scope.	None	<ul style="list-style-type: none"> • Parameters: - scopeName The name of the scope. (String, optional) - displayObjectName Set the value of this parameter to true to list the trust manager objects within a scope. Set the value of this parameter to false to list the strings that contain the trust manager name and management scope. (Boolean, optional) • Returns: A list of trust managers that are found within the management scope that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listTrustManagers {-displayObjectName true} • Using Jython string: AdminTask.listTrustManagers ('[-displayObjectName true]') • Using Jython list: AdminTask.listTrustManagers (['-displayName', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listTrustManagers {-interactive} • Using Jython string: AdminTask.listTrustManagers ('[-interactive]') • Using Jython list: AdminTask.listTrustManagers (['-interactive'])

Table 25. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifyTrustManager	The modifyTrustManager command changes existing trust manager settings.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the trust manager. (String, required) - scopeName The name of the scope. (String, optional) - provider The provider name of the trust manager. (String, optional) - algorithm The algorithm name of the trust manager. (String, optional) - trustManagerClass Specifies a class that implements the <code>javax.net.ssl.X509TrustManager</code> interface. You cannot use this parameter with the provider or algorithm parameters. (String, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask modifyTrustManager {-name testTM -trustManagerClass test.trust.manager}</pre> Using Jython string: <pre>AdminTask.modifyTrustManager (['-name testTM -trustManagerClass test.trust.manager'])</pre> Using Jython list: <pre>AdminTask.modifyTrustManager (['-name', 'testTM', '-trustManagerClass', 'test.trust.manager'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask modifyTrustManager {-interactive}</pre> Using Jython string: <pre>AdminTask.modifyTrustManager (['-interactive'])</pre> Using Jython list: <pre>AdminTask.modifyTrustManager (['-interactive'])</pre>

Commands for the keyManagerCommands group of the AdminTask object

Use the commands in the keyManagerCommands group to manage key managers. You can use these commands to create, modify, list, or obtain information about key managers. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the keyManagerCommands group of the AdminTask object:

Table 26.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createKeyManager	<p>The createKeyManager command creates the key manager settings in the configuration. Use this command during SSL handshake to determine which certificate alias to use.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key manager. (String, required) - scopeName The name of the scope. (String, optional) - provider The provider name of the key manager. (String, optional) - algorithm The algorithm name of the key manager. (String, optional) - keyManagerClass The name of the key manager implementation class. You can not use this parameter with the provider or the algorithm parameter. (String, optional) • Returns: The configuration object name of the key manager object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeyManager {-name testKM -keyManagerClass com.ibm.ws.security.ltpa.LTPAKeyPairGenerator}</pre> • Using Jython string: <pre>AdminTask.createKeyManager ('[-name testKM -keyManagerClass com.ibm.ws.security.ltpa.LTPAKeyPairGenerator]')</pre> • Using Jython list: <pre>AdminTask.createKeyManager (['-name', 'testKM', '-keyManagerClass', 'com.ibm.ws.security.ltpa.LTPAKeyPairGenerator'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeyManager {-interactive}</pre> • Using Jython string: <pre>AdminTask.createKeyManager ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.createKeyManager (['-interactive'])</pre>

Table 26. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteKeyManager	The deleteKeyManager command deletes the key manager settings from the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key manager. (String, optional) - scopeName The name of the scope. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeyMa nager {-name testKM} • Using Jython string: AdminTask.deleteKeyMa nager ('[-name testKM]') • Using Jython list: AdminTask.deleteKeyMa nager (['-name', 'testKM']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeyM anager {-interactive} • Using Jython string: AdminTask.deleteKeyMa nager ('[-interactive]') • Using Jython list: AdminTask.deleteKeyM anager (['-interactive'])
getKeyManager	The getKeyManager command obtains the settings of a key manager.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key manager. (String, optional) - scopeName The name of the scope. (String, optional) • Returns: The settings of the key manager that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeyMana ger {-name testKM} • Using Jython string: AdminTask.getKeyMana ger ('[-name testKM]') • Using Jython list: AdminTask.getKeyMana ger (['-name', 'testKM']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeyManag er {-interactive} • Using Jython string: AdminTask.getKeyManag er ('[-interactive]') • Using Jython list: AdminTask.getKeyManag er (['-interactive'])

Table 26. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listKeyManagers	The listKeyManagers command lists the key managers within a particular management scope.	None	<ul style="list-style-type: none"> • Parameters: - scopeName The name of the scope. (String, optional) - - displayObjectName Set the value of this parameter to true to list the key manager objects within the scope. Set the value of this parameter to false to list the strings that contain the key manager name and the management scope. (Boolean, optional) • Returns: A list of key managers. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeyManagers • Using Jython: AdminTask.listKeyManagers() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeyManagers {-interactive} • Using Jython string: AdminTask.listKeyManagers ('[-interactive]') • Using Jython list: AdminTask.listKeyManagers (['-interactive'])

Table 26. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifyKeyManagers	The modifyKeyManagers command changes existing key manager settings.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key manager. (String, required) - scopeName The name of the scope. (String, optional) - provider The provider name of the key manager. (String, optional) - algorithm The algorithm name of the key manager. (String, optional) - keyManagerClass The name of the key manager implementation class. You can not use this parameter with the provider or the algorithm parameter. (String, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask modifyKeyManagers {-name testKM -provider IBMJSSE2 -algorithm IbmX509} Using Jython string: AdminTask.modifyKeyManagers ('[-name testKM -provider IBMJSSE2 -algorithm IbmX509]') Using Jython list: AdminTask.modifyKeyManagers (['-name', 'testKM', '-provider', 'IBMJSSE2', '-algorithm', 'IbmX509']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask modifyKeyManagers {-interactive} Using Jython string: AdminTask.modifyKeyManagers ('[-interactive]') Using Jython list: AdminTask.modifyKeyManagers (['-interactive'])

Commands for the SSLConfigGroupCommands group of the AdminTask object

Use the commands in the SSLConfigGroupCommands group to create or delete a SSL configuration group. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SSLConfigGroupCommands group of the AdminTask object:

Table 27.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createSSLConfigGroup	<p>The createSSLConfigGroup command creates a SSL configuration group.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the SSL configuration group. (String, required) - direction The direction to which the SSL configuration applies. Valid values include inbound or outbound. (String, required) - certificateAlias (String, required) - scopeName The name of the scope. (String, optional) - sslConfigAliasName The alias that uniquely identifies the SSL configurations in the group. (String, required) - sslConfigScopeName The scope that uniquely identifies the SSL configurations in the group. (String, optional) • Returns: The configuration object name of the SSL configuration group object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createSSLConfigGroup { -name testSSLCfgGrp -direction inbound -certificateAlias alias1 -sslConfigAliasName testSSLCfg}</pre> • Using Jython string: <pre>AdminTask.createSSLConfigGroup [('-name testSSLCfgGrp -direction inbound -certificateAlias alias1 -sslConfigAliasName testSSLCfg)']</pre> • Using Jython list: <pre>AdminTask.createSSLConfigGroup [('-name', 'testSSLCfgGrp', '-direction', 'inbound', '-certificateAlias', 'alias1', '-sslConfigAliasName', 'testSSLCfg)']</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createSSLConfigGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.createSSLConfigGroup ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.createSSLConfigGroup (['-interactive'])</pre>

Table 27. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteSSLConfigGroup	The deleteSSLConfigGroup command deletes a SSL configuration group from the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the SSL configuration group. (String, required) - direction The direction to which the SSL configuration applies. Valid values include inbound or outbound. (String, required) - scopeName The name of the scope. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteSSLConfigGroup {-name createSSLCfgGrp -direction inbound} • Using Jython string: AdminTask.deleteSSLConfigGroup [('-name createSSLCfgGrp -direction inbound)'] • Using Jython list: AdminTask.deleteSSLConfigGroup [('-name', 'createSSLCfgGrp', '-direction', 'inbound)'] <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteSSLConfigGroup {-interactive} • Using Jython string: AdminTask.deleteSSLConfigGroup ('[-interactive]') • Using Jython list: AdminTask.deleteSSLConfigGroup (['-interactive'])

Table 27. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getSSLConfigGroup	The getSSLConfigGroup command returns information about a SSL configuration setting.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the SSL configuration group. (String, required) - direction The direction to which the SSL configuration applies. Valid values include inbound or outbound. (String, required) - scopeName The name of the scope. (String, optional) • Returns: The settings of the SSL configuration group that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getSSLConfig Group {-name createSSLCfgGrp -direction inbound} • Using Jython string: AdminTask.getSSLConfig Group ['-name createSSLCfgGrp -direction inbound'] • Using Jython list: AdminTask.getSSLConfig Group [('-name', 'createSSLCfgGrp', '-direction', 'inbound')] <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getSSLConfig Group {-interactive} • Using Jython string: AdminTask.getSSLConfig Group ('[-interactive]') • Using Jython list: AdminTask.getSSLConfig Group (['-interactive'])

Table 27. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listSSLConfigGroups	<p>The listSSLConfigGroups command lists the SSL configuration groups within a scope and a direction.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - direction The direction to which the SSL configuration applies. Valid values include inbound or outbound. (String, optional) - scopeName The name of the scope. (String, optional) - displayObjectName If you set this parameter to true, the command returns a list of all of the SSL configuration group objects within the scope. If you set this parameter to false, the command returns a list of strings that contain the SSL configuration name and management scope. (Boolean, optional) • Returns: A list of SSL configuration groups. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask -listSSLConfigGroups {-displayObjectName true}</code> • Using Jython string: <code>AdminTask.listSSLConfigGroups [('-displayObjectName true)']</code> • Using Jython list: <code>AdminTask.listSSLConfigGroups [('-displayObjectName' 'true')]</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask listSSLConfigGroups {-interactive}</code> • Using Jython string: <code>AdminTask.listSSLConfigGroups ('[-interactive]')</code> • Using Jython list: <code>AdminTask.listSSLConfigGroups (['-interactive'])</code>

Table 27. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifySSLConfigGroup	The modifySSLConfigGroup command modifies the setting of an existing SSL configuration group.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the SSL configuration group. (String, required) - direction The direction to which the SSL configuration applies. Valid values include inbound or outbound. (String, required) - certificateAlias (String, optional) - scopeName The name of the scope. (String, optional) - sslConfigAliasName The alias that uniquely identifies the SSL configurations in the group. (String, optional) - sslConfigScopeName The scope that uniquely identifies the SSL configurations in the group. (String, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask modifySSLConfigGroup {-name createSSLCfgGrp -direction inbound -certificateAlias alias2} Using Jython string: AdminTask.modifySSLConfigGroup ['(-name createSSLCfgGrp -direction inbound -certificateAlias alias2)'] Using Jython list: AdminTask.modifySSLConfigGroup [('-name', 'createSSLCfgGrp', '-direction', 'inbound', '-certificateAlias', 'alias2')] <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask modifySSLConfigGroup {-interactive} Using Jython string: AdminTask.modifySSLConfigGroup ('[-interactive]') Using Jython list: AdminTask.modifySSLConfigGroup (['-interactive'])

Commands for the DynamicSSLConfigSelections group of the AdminTask object

Use the commands in the DynamicSSLConfigSelections group to create or delete a dynamic SSL configuration selection. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the DynamicSSLConfigSelections group of the AdminTask object:

Table 28.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>createDynamic SSLConfig Selection</p>	<p>The createDynamic SSLConfig Selection command creates the configuration settings for the dynamic SSL configuration selection.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - dynSSLConfigSelectionName The name that uniquely identifies the dynamic SSL configuration selection. (String, required) - scopeName The name of the scope. (String, optional) - dynSSLConfigSelectionDescription The description of the dynamic SSL configuration selection. (String, optional) - dynSSLConfigSelectionInfo The information for the dynamic SSL configuration selection. (String, required) - sslConfigName The name of the SSL configuration. (String, required) - sslConfigScope The scope of the SSL configuration. (String, optional) - certificateAlias The alias name to identify the certificate. (String, required) • Returns: The configuration object name of the dynamic SSL configuration selection object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createDynamicSSLConfigSelection</code> • Using Jython: <code>AdminTask.createDynamicSSLConfigSelection()</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createDynamicSSLConfigSelection {-interactive}</code> • Using Jython string: <code>AdminTask.createDynamicSSLConfigSelection (['-interactive'])</code> • Using Jython list: <code>AdminTask.createDynamicSSLConfigSelection (['-interactive'])</code>

Table 28. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>deleteDynamic SSLConfig Selection</p>	<p>The deleteDynamic SSLConfig Selection command deletes the dynamic SSL configuration selection from the configuration.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: None • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteDynamic SSLConfigSelection</pre> • Using Jython: <pre>AdminTask.deleteDynamic SSLConfigSelection()</pre> • <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask deleteDynamic SSLConfigSelection {-interactive}</pre> • Using Jython string: <pre>AdminTask.deleteDynamicSSLConfigSelection ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.deleteDynamic SSLConfigSelection (['-interactive'])</pre>
<p>getDynamic SSLConfig Selection</p>	<p>The getDynamic SSLConfig Selection command obtains information about a particular dynamic SSL configuration selection.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: None • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getDynamicSSLConfigSelection</pre> • Using Jython: <pre>AdminTask.getDynamicSSLConfigSelection()</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask getDynamicSSLConfigSelection {-interactive}</pre> • Using Jython string: <pre>AdminTask.getDynamicSSLConfigSelection ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.getDynamicSSLConfigSelection (['-interactive'])</pre>

Table 28. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listDynamic SSLConfig Selections	The listDynamic SSLConfig Selections command lists the configuration objects name for a dynamic SSL configuration selection.	None	<ul style="list-style-type: none"> Parameters: None Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listDynamic SSLConfigSelection Using Jython: AdminTask.listDynamic SSLConfigSelection() <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listDynamicSSL ConfigSelections {-inter active} Using Jython string: AdminTask.listDynamicSSL ConfigSelections ('[-inte ractive]') Using Jython list: AdminTask.listDynamicSSL ConfigSelections (['-int eractive'])

Commands for the ManagementScopeCommands group of the AdminTask object

Use the commands in the ManagementScopeCommands group to create or delete a management scope. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the ManagementScopeCommands group of the AdminTask object:

Table 29.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createManagementScope	The createManagementScope command creates a management scope setting in the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name that uniquely identifies the management scope. (String, required) - scopeType The type of the management scope. Valid types include cell, node, nodegroup, cluster, server, and endpoint. (String, optional) • Returns: The configuration object name of the management scope object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createManagementScope {-name (cell):localhostNode01Cell -scopeType cell} • Using Jython string: AdminTask.createManagementScope [('-name (cell):localhostNode01Cell -scopeType cell)'] • Using Jython list: AdminTask.createManagementScope [('-name', '(cell):localhostNode01Cell', '-scopeType', 'cell')] <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createManagementScope {-interactive} • Using Jython string: AdminTask.createManagementScope ('[-interactive]') • Using Jython list: AdminTask.createManagementScope (['-interactive'])

Table 29. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteManagementScope	The deleteManagementScope command deletes a management object from the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name that uniquely identifies the management scope. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteManagementScope {-scopeName (cell):localhostNode01Cell} • Using Jython string: AdminTask.deleteManagementScope ('[-scopeName (cell):localhostNode01Cell]') • Using Jython list: AdminTask.deleteManagementScope (['-scopeName', '(cell):localhostNode01Cell']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteManagementScope {-interactive} • Using Jython string: AdminTask.deleteManagementScope ('[-interactive]') • Using Jython list: AdminTask.deleteManagementScope (['-interactive'])

Table 29. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getManagementScope	The getManagementScope command displays the setting of a management scope object.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name that uniquely identifies the management scope. (String, required) • Returns: The settings of the management scope object. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getManagementScope {-scopeName (cell):localhostNode01Cell} • Using Jython string: AdminTask.getManagementScope ('[-scopeName (cell):localhostNode01Cell]') • Using Jython list: AdminTask.getManagementScope (['-scopeName', '(cell):localhostNode01Cell']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getManagementScope {-interactive} • Using Jython string: AdminTask.getManagementScope ('[-interactive]') • Using Jython list: AdminTask.getManagementScope (['-interactive'])

Table 29. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listManagementScopes	The listManagementScopes command lists the management scopes in the configuration.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - displayObjectName Set the value to true to display the object names of the management scope. (Boolean, optional) Returns: A list that contains all of the management scope names. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask listManagementScopes { -name testKM -provider IBMJSSE2 -algorithm IbmX509}</pre> Using Jython string: <pre>AdminTask.listManagementScopes ('[-name testKM -provider IBMJSSE2 -algorithm IbmX509]')</pre> Using Jython list: <pre>AdminTask.listManagementScopes (['-name', 'testKM', '-provider', 'IBMJSSE2', '-algorithm', 'IbmX509'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask listManagementScopes {-interactive}</pre> Using Jython string: <pre>AdminTask.listManagementScopes (['-interactive'])</pre> Using Jython list: <pre>AdminTask.listManagementScopes (['-interactive'])</pre>

Commands for the WSCertExpMonitorCommands group of the AdminTask object

Use the commands in the WSCertExpMonitorCommands group to start or update the certificate expiration monitor. For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the WSCertExpMonitorCommands group of the AdminTask object:

Table 30.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createWSCert ExpMonitor	The createWSCert ExpMonitor command creates the certificate expiration monitor settings in the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the certificate expiration monitor. (String, required) - autoReplace Set the value of this parameter to true if you want to replace a certificate within a certificate expiration date. If not, set the value of this parameter to false. (Boolean, required) - deleteOld Set the value of this parameter to true if you want to delete an old certificate during certificate expiration monitoring. If not, set the value of this parameter to false. (Boolean, required) - daysBeforeNotification The number of days before a certificate expires that you want to be notified of the expiration. (Integer, required) - wsScheduleName The name of the scheduler to use for certificate expiration. (String, required) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createWSCert ExpMonitor {-name test CertMon -autoReplace true -deleteOld true -days BeforeNotification 30 -wsScheduleName testSch edule -wsNotificationName testNotifier -isEnabled false}</pre> • Using Jython string: <pre>AdminTask.createWSCert ExpMonitor ('[-name tes tCertMon -autoReplace true -deleteOld true -daysBeforeNotification 30 -wsScheduleName test Schedule -wsNotificati onName testNotifier -isEnabled false]')</pre> • Using Jython list: <pre>AdminTask.createWSCert ExpMonitor (['-name', 'testCertMon', '-autoRe place', 'true', '-delete Old', 'true', '-daysBe foreNotification', '30', '-wsScheduleName', 'te stSchedule', '-wsNotifi cationName', 'testNotif ier', '-isEnabled', 'false'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createWSCert ExpMonitor {-interactive}</pre> • Using Jython string: <pre>AdminTask.createWSCert ExpMonitor ('[-interac tive]')</pre> • Using Jython list: <pre>AdminTask.createWSCert ExpMonitor (['-interac tive'])</pre>

Table 30. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - wsNotificationName The name of the notifier to use for certificate expiration. (String, required) - isEnabled Set the value of this parameter to true if the certificate expiration monitor is enabled. If not, set the value of this parameter to false. (Boolean, optional) • Returns: The configuration object name of the certificate expiration monitor object that you created. 	
<p>deleteWSCertExpMonitor</p>	<p>The deleteWSCertExpMonitor command deletes the settings of a scheduler from the configuration.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the certificate expiration monitor. (String, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask deleteWSCertExpMonitor {-name test CertMon}</code> • Using Jython string: <code>AdminTask.deleteWSCertExpMonitor ('[-name test CertMon]')</code> • Using Jython list: <code>AdminTask.deleteWSCertExpMonitor (['-name', 'testCertMon'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask deleteWSCertExpMonitor {-interactive}</code> • Using Jython string: <code>AdminTask.deleteWSCertExpMonitor ('[-interactive]')</code> • Using Jython list: <code>AdminTask.deleteWSCertExpMonitor (['-interactive'])</code>

Table 30. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getWSCertExpMonitor	The getWSCertExpMonitor command displays the settings of a particular scheduler. Command name:	Description:	Target object:	Parameters and return values:	Examples:
listWSCertExpMonitor	The listWSCertExpMonitor command lists the scheduler in the configuration.	None	<ul style="list-style-type: none"> • Parameters: - displayObjectNames If you set the value of this parameter to true, the command returns the certificate expiration monitor configuration object. If you set the value of this parameter to false, the command returns the name of the certificate expiration monitor. (Boolean, optional) • Returns: The scheduler in the configuration. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listWSCertExpMonitor {-displayObjectName false} • Using Jython string: AdminTask.listWSCertExpMonitor ('[-displayObjectName false]') • Using Jython list: AdminTask.listWSCertExpMonitor (['-displayObjectName', 'false']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listWSCertExpMonitor {-interactive} • Using Jython string: AdminTask.listWSCertExpMonitor ('[-interactive]') • Using Jython list: AdminTask.listWSCertExpMonitor (['-interactive'])

Table 30. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>modifyWSCert ExpMonitor</p>	<p>The modifyWSCert ExpMonitor command changes the setting of an existing scheduler.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - name The name that uniquely identifies the certificate expiration monitor. (String, required) - autoReplace Set the value of this parameter to true if you want to replace a certificate within a certificate expiration date. If not, set the value of this parameter to false. (Boolean, required) - deleteOld Set the value of this parameter to true if you want to delete an old certificate during certificate expiration monitoring. If not, set the value of this parameter to false. (Boolean, required) - daysBeforeNotification The number of days before a certificate expires that you want to be notified of the expiration. (Integer, required) - wsScheduleName The name of the scheduler to use for certificate expiration. (String, required) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask modifyWSCert ExpMonitor {-name testCertMon -autoReplace false -deleteOld false -daysBeforeNotification 20 -isEnabled true}</code> • Using Jython string: <code>AdminTask.modifyWSCert ExpMonitor ('[-name testCertMon -autoReplace false -deleteOld false -daysBeforeNotification 20 -isEnabled true]')</code> • Using Jython list: <code>AdminTask.modifyWSCert ExpMonitor (['-name', 'testCertMon', '-autoReplace', 'false', '-deleteOld', 'false', '-daysBeforeNotification', '20', '-isEnabled', 'true'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask modifyWSCert ExpMonitor {-interactive}</code> • Using Jython string: <code>AdminTask.modifyWSCert ExpMonitor ('[-interactive]')</code> • Using Jython list: <code>AdminTask.modifyWSCert ExpMonitor (['-interactive'])</code>

Table 30. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - wsNotificationName The name of the notifier to use for certificate expiration. (String, required) - isEnabled Set the value of this parameter to true if the certificate expiration monitor is enabled. If not, set the value of this parameter to false. (Boolean, optional) <ul style="list-style-type: none"> • Returns: None 	
startCertificateExpMonitor	The startCertificateExpMonitor command performs certificate monitoring. This command visits all key stores and checks to see if they are within certificate expiration range.	None	<ul style="list-style-type: none"> • Parameters: None • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask startCertificateExpMonitor</code> • Using Jython: <code>AdminTask.startCertificateExpMonitor()</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask startCertificateExpMonitor {-interactive}</code> • Using Jython string: <code>AdminTask.startCertificateExpMonitor ('[-interactive]')</code> • Using Jython list: <code>AdminTask.startCertificateExpMonitor (['-interactive'])</code>

Commands for the KeySetGroupCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the KeySetGroupCommands group of the AdminTask object:

Table 31.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createKeySetGroup	<p>The createKeySetGroup command creates the key set group settings in the configuration. Use this command to manage groups of public, private, and shared keys.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set group. (String, required) - scopeName The name of the scope. (String, optional) - autoGenerate Set the value of this parameter to true if you want to automatically generate keys. If not, set the value to false. (Boolean, optional) - wsScheduleName The name of the scheduler to use to perform key generation. (String, required) - keySetObjectNames A list of key set configuration names separated by colons (:). (String, required) • Returns: The configuration object name of the key set group object that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeySetGroup {-name keySetGrp -autoGenerate true -wsScheduleName testSchedule -keySetObjectNames testKeySet(cells/localhostNode01Cell security.xml#KeySet_1130354347825)}</pre> • Using Jython string: <pre>AdminTask.createKeySetGroup(['-name keySetGrp -autoGenerate true -wsScheduleName testSchedule -keySetObjectNames testKeySet(cells/localhostNode01Cell security.xml#KeySet_1130354347825)'])</pre> • Using Jython list: <pre>AdminTask.createKeySetGroup(['-name', 'keySetGrp', '-autoGenerate', 'true', '-wsScheduleName', 'testSchedule', '-keySetObjectNames', 'testKeySet(cells/localhostNode01Cell security.xml#KeySet_1130354347825)'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeySetGroup {-interactive}</pre> • Using Jython string: <pre>AdminTask.createKeySetGroup(['-interactive'])</pre> • Using Jython list: <pre>AdminTask.createKeySetGroup(['-interactive'])</pre>

Table 31. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteKeySetGroup	The deleteKeySetGroup command deletes the settings of a key set group from the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set group. (String, required) - scopeName The name of the scope. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeySet Group {-name keySetGrp } • Using Jython string: AdminTask.deleteKeySet Group ('[-name keySetGrp]') • Using Jython list: AdminTask.deleteKeySet Group (['-name', 'key SetGrp']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKey SetGroup {-interactive} • Using Jython string: AdminTask.deleteKeySet Group ('[-interactive]') • Using Jython list: AdminTask.deleteKeySet Group (['-interactive'])

Table 31. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
generateKeys ForKey SetGroup	The generateKeys ForKey SetGroup command generates keys for all of the keys in the key sets that make up the key set group.	None	<ul style="list-style-type: none"> • Parameters: - keySetGroupName The name of the key set group. (String, required) - keySetGroupScope The scope of the key set group. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask generateKey ForKeySetGroup {-keySetGroupName keySetGrp} • Using Jython string: AdminTask.generateKey ForKeySetGroup ('[-keySetGroupName keySetGrp]') • Using Jython list: AdminTask.generateKey ForKeySetGroup (['-keySetGroupName', 'keySetGrp']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask generateKeys ForKeySetGroup {-interactive} • Using Jython string: AdminTask.generateKeys ForKeySetGroup ('[-interactive]') • Using Jython list: AdminTask.generateKeys ForKeySetGroup (['-interactive'])

Table 31. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getKeySetGroups	<p>The getKeySetGroups command displays the settings of a particular key set group.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set group. (String, required) - scopeName The name of the scope. (String, optional) • Returns: The settings of the specified key set group. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeySetGroup { -name keySetGrp } • Using Jython string: AdminTask.getKeySetGroup ('[-name keySetGrp]') • Using Jython list: AdminTask.getKeySetGroup (['-name', 'keySetGrp']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getKeySetGroups {-interactive} • Using Jython string: AdminTask.getKeySetGroups (['-interactive']) • Using Jython list: AdminTask.getKeySetGroups (['-interactive'])

Table 31. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listKeySetGroups	The listKeySetGroups command lists the key set groups for a particular scope.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name of the scope. (String, optional) - displayObjectNames If you set the value of this parameter to true, the command returns a list of all of the key set group objects within a scope. If you set the value of this parameter to false, the command returns a list of strings that contain the key set group name and management scope. (Boolean, optional) • Returns: A list of key set groups. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeySetGroup {-displayObjectName true} • Using Jython string: AdminTask.listKeySetGroup ('[-displayObjectName true]') • Using Jython list: AdminTask.listKeySetGroup (['-displayObjectName', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeySetGroups {-interactive} • Using Jython string: AdminTask.listKeySetGroups ('[-interactive]') • Using Jython list: AdminTask.listKeySetGroups (['-interactive'])

Table 31. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifyKeySetGroup	The modifyKeySetGroup command changes the settings of an existing key set group.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set group. (String, required) - scopeName The name of the scope. (String, optional) - autoGenerate Set the value of this parameter to true if you want to automatically generate keys. If not, set the value to false. (Boolean, optional) - wsScheduleName The name of the scheduler to use to perform key generation. (String, optional) - keySetObjectNames A list of key set configuration names separated by colons (:). (String, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask modifyKeySet Group {-name keySetGrp -autoGenerate false} Using Jython string: AdminTask.modifyKeySet Group ('[-name keySetGrp -autoGenerate false]') Using Jython list: AdminTask.modifyKeySet Group (['-name', 'keySetGrp', '-autoGenerate', 'false']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask modifyKeySet Group {-interactive} Using Jython string: AdminTask.modifyKeySet Group ('[-interactive]') Using Jython list: AdminTask.modifyKeySet Group (['-interactive'])

Commands for the KeySetCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the KeySetCommands group of the AdminTask object:

Table 32.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
createKeySet	The createKeySet command creates the key set settings in the configuration. Use this command to control key instances that have the same type.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set. (String, required) - scopeName The name of the scope. (String, optional) - aliasPrefix The prefix for the key alias when a new key generates. (String, required) - password The password that protects the key in the key store. (String, required) - maxKeyReferences The maximum number of key references returned keys from this key set. (Integer, required) - deleteOldKeys Set the value of this parameter to true to delete old keys when new keys are generated. Otherwise, set the value of this parameter to false. (Boolean, optional) - keyGenerationClass The class that is used to generate new keys in the key set. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeySet {-name testKeySet -alias Prefix test -password pwd -maxKeyReferences 2 -del eteOldKeys true -keyStor eName testKeyStore -isK eyPair false}</pre> • Using Jython string: <pre>AdminTask.createKeySet(' [-name testKeySet -alias Prefix test -password pwd -maxKeyReferences 2 -deleteOldKeys true -key StoreName testKeyStore -isKeyPair false]')</pre> • Using Jython list: <pre>AdminTask.createKeySet (['-name', 'testKeySet', '-aliasPrefix', 'test', '-password', 'pwd', '-max KeyReferences', '2', '-deleteOldKeys', 'true', '-keyStoreName', 'test KeyStore', '-isKeyPair', 'false'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createKeySet {-interactive}</pre> • Using Jython string: <pre>AdminTask.createKeySet ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.createKeySet (['-interactive'])</pre>

Table 32. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - keyStoreName The key store that contains the keys. (String, required) - - keyStoreScopeName The management scope where the key store is located. (String, optional) - isKeyPair Set the value of this parameter to true if the keys in the key set are key pairs. Otherwise, set the value of this parameter to false. (Boolean, optional) • Returns: The configuration object name of the key set object that you created. 	
deleteKeySet	The deleteKeySet command deletes the settings of a key set from the configuration.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set. (String, required) - scopeName The name of the scope. (String, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeySet {-name testKeySet} • Using Jython string: AdminTask.deleteKeySet (['-name testKeySet']) • Using Jython list: AdminTask.deleteKeySet (['-name', 'testKeySet']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteKeySet {-interactive} • Using Jython string: AdminTask.deleteKeySet (['-interactive']) • Using Jython list: AdminTask.deleteKeySet (['-interactive'])

Table 32. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
generateKeyForKeySet	The generateKeyForKeySet command generates keys for the keys in the key set.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - keySetName The name of the key set. (String, required) - keySetScope The scope of the key set. (String, optional) - keySetSaveConfig Set the value of this parameter to true to save the configuration of the key set. Otherwise, set the value of this parameter to false. (Boolean, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask generateKeyForKeySet { -keySetName testKeySet } Using Jython string: AdminTask.generateKeyForKeySet ('[-keySetName testKeySet]') Using Jython list: AdminTask.generateKeyForKeySet (['-keySetName', 'testKeySet']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask generateKeyForKeySet {-interactive} Using Jython string: AdminTask.generateKeyForKeySet ('[-interactive]') Using Jython list: AdminTask.generateKeyForKeySet (['-interactive'])
getKeySet	The getKeySet command displays the settings of a particular key set.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set. (String, required) - scopeName The name of the scope. (String, optional) Returns: The settings of the specified key set group. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask getKeySet {-name testKeySet} Using Jython string: AdminTask.getKeySet ('[-name testKeySet]') Using Jython list: AdminTask.getKeySet (['-name', 'testKeySet']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask getKeySet {-interactive} Using Jython string: AdminTask.getKeySet ('[-interactive]') Using Jython list: AdminTask.getKeySet (['-interactive'])

Table 32. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listKeySets	The listKeySets command lists the key sets in a particular scope.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - scopeName The name of the scope. (String, optional) - displayObjectNames Set the value of this parameter to true to list the key set configuration objects within the scope. Set the value of this parameter to false if you want to list the strings that contain the key set group name and management scope. (Boolean, optional) • Returns: The key sets for the scope that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeySets {-displayObjectName true} • Using Jython string: AdminTask.listKeySets ('[-displayObjectName true]') • Using Jython list: AdminTask.listKeySets (['-displayObjectName', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listKeySets {-interactive} • Using Jython string: AdminTask.listKeySets ('[-interactive]') • Using Jython list: AdminTask.listKeySets (['-interactive'])

Table 32. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
modifyKeySet	The modifyKeySet command changes the settings of an existing key set.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - name The name that uniquely identifies the key set. (String, required) - scopeName The name of the scope. (String, optional) - aliasPrefix The prefix for the key alias when a new key generates. (String, optional) - password The password that protects the key in the key store. (String, optional) - maxKeyReferences The maximum number of key references returned keys from this key set. (Integer, optional) - deleteOldKeys Set the value of this parameter to true to delete old keys when new keys are generated. Otherwise, set the value of this parameter to false. Commands for the securityEnablement group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the securityEnablement group of the AdminTask object:

Table 34.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
GlobalSettings		None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - secureApps Enables application security. The default value is true. (Boolean, required) - secureLocalResources Enables Java 2 Security. The default value is true. (Boolean, required) - ltpaPassword Defines the LTPA password. Valid values include the password used by LTPA. (String, required) - userRegistryType Defines the type of user registry to use. Valid values include: Embedded, LDAP, LocalOS, or Custom. (String, required) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask GlobalSettings {-interactive} • Using Jython string: AdminTask.GlobalSettings ('[-interactive]') • Using Jython list: AdminTask.GlobalSettings (['-interactive'])

Table 34. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
CustomRegistry	The CustomRegistry command checks that the specified name for the primary administrator does not already exist in the custom registry.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - primaryAdminName Represents a name of the primary administrator. The value must be a valid administrator name. (String, required) - serverUserName Represents the user name used to connect to internal security routines. The value must be a valid user name. (String, required) - customRegistryClass Represents the class name of the custom user registry implementation of the UserRegistry. The value must be a valid class name for a custom registry. (String, required) - customProperties Custom user registry properties. An array or name-value properties. (String, required) - customName The custom user registry property name. (String, required) - customValue The custom user registry property value that is associated with the property name. (String, required) • Returns: A value of true if the primary administrator does not already exist in the custom registry. Otherwise, returns a value of false. 	Interactive mode example usage: <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask CustomRegistry {-interactive}</code> • Using Jython string: <code>AdminTask.CustomRegistry ('[-interactive]')</code> • Using Jython list: <code>AdminTask.CustomRegistry (['-interactive'])</code>

Table 34. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
EmbeddedRegistry	<p>The EmbeddedRegistry command checks that the specified name for the primary administrator does not already exist in the WIM file-based registry. Returns true if it does not; false, otherwise.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - primaryAdminName This string represents a name of the primary administrator. The value must be a valid administrator name. (String, required) - adminPassword The password associated with the primary administrator. The value must be a valid administrator password. (String, required) - serverUserName This string represents the user name used to connect to internal security routines. The value must be a valid user name. (String, required) • Returns: A value of true if the specified name for the primary administrator does not already exist in the WIM file-based registry. Otherwise, returns a value of false. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask EmbeddedRegistry {-interactive} • Using Jython string: AdminTask.EmbeddedRegistry ('[-interactive]') • Using Jython list: AdminTask.EmbeddedRegistry (['-interactive'])

Table 34. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
LDAPRegistry	<p>The LDAPRegistry command checks, after all the inputs for the LDAP registry have been defined, that a connection can be made successfully to the LDAP server. An SSL connection test to LDAP is also supported using this command.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - IdapServerType The type of LDAP user registry to be connected to WebSphere Application Server. Valid values include: IBM Tivoli Directory Server, SecureWay, Sun ONE, Domino, Active Directory, eDirectory, Custom. (String, required) - IdapHostname The host name for the LDAP server. (String, required) - IdapPort The port to connect to the LDAP server. (Integer, required) - IdapBaseDN The base distinguished name of the directory service, the starting point for searches. (String, required) - IdapBindDN The bind distinguished name, used to bind to the directory server. (String, required) 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask LDAPRegistry {-interactive} • Using Jython string: AdminTask.LDAPRegistry ('[-interactive]') • Using Jython list: AdminTask.LDAPRegistry (['-interactive'])

Table 34. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - IdapBindPassword The password for the application server, used to bind to the directory service (String, required) - IdapServerUserName The user ID that is used to run WebSphere Application Server for security purposes. (String, required) • Returns: A value of true if the connection was successful. Otherwise, returns a value of false. 	
LocalOSRegistry	The LocalOSRegistry command checks that the specified name for the primary administrator does not already exist in the LocalOS registry.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - primaryAdminName This string represents a name of the primary administrator. The value must be a valid administrator name. (String, required) - serverUserName This string represents the user name used to connect to internal security routines. The value must be a valid user name. (String, required) • Returns: A value of true if the specified name for the primary administrator does not already exist in the LocalOS registry. Otherwise, returns a value of false. 	Interactive mode example usage: <ul style="list-style-type: none"> • Using Jacl: \$AdminTask LocalOSRegistry {-interactive} • Using Jython string: AdminTask.LocalOSRegistry ('[-interactive]') • Using Jython list: AdminTask.LocalOSRegistry (['-interactive'])

Table 34. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
CurrentSettings	The CurrentSettings command returns a string that represents all of the existing settings set by the wizard that will be read from the workspace instead of from the configuration repository of the <code>security.xml</code> file.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - currentWizardSettings A properties object that contains all the current settings selected through the wizard. (Properties, required) Returns: A string of security settings as name-value pairs. 	Interactive mode example usage: <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask CurrentSettings {-interactive}</code> Using Jython string: <code>AdminTask.CurrentSettings ('[-interactive]')</code> Using Jython list: <code>AdminTask.CurrentSettings (['-interactive'])</code>

Commands for the CertificateRequestCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the CertificateRequestCommands group of the AdminTask object:

Table 35.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>createCertificateRequest</p>	<p>The createCertificateRequest command creates a certificate request that is associated with a particular key store.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - certificateVersion The certificate version. (String, required) - certificateSize (Integer, required) - certificateCommonName (String, required) - certificateOrganization (String, optional) - certificateOrganizationUnit (String, optional) - certificateLocality (String, optional) - certificateState The state code for the certificate. (String, optional) - certificateZip The zip code for the certificate. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createCertificateRequest {-keyStoreName testKeyStore -certificateAlias certReq -certificateSize 1024 -certificateCommonName localhost -certificateOrganization testing -certificateRequestFilePath c:\temp\testCertReq.arm} • Using Jython string: AdminTask.createCertificateRequest ('[-keyStoreName testKeyStore -certificateAlias certReq -certificateSize 1024 -certificateCommonName localhost -certificateOrganization testing -certificateRequestFilePath c:\temp\testCertReq.arm] • Using Jython list: AdminTask.createCertificateRequest (['-keyStoreName', 'testKeyStore', '-certificateAlias', 'certReq', '-certificateSize', '1024', '-certificateCommonName', 'localhost', '-certificateOrganization', 'testing', '-certificateRequestFilePath', 'c:\temp\testCertReq.arm']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createCertificateRequest {-interactive} • Using Jython string: AdminTask.createCertificateRequest ('[-interactive]') • Using Jython list: AdminTask.createCertificateRequest (['-interactive'])

Table 35. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - certificateCountry The country for the certificate. (String, optional) - certificateValidDays The amount of time in days for which the certificate is valid. (Integer, optional) - - certificateRequestFilePath The file location of the certificate request that can be sent to a certificate authority. (String, required) • Returns: The configuration object name of the key store object that you created. 	
deleteCertificate Request	The deleteCertificateRequest command deletes a certificate request from a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask deleteCertificateRequest {-interactive}</code> • Using Jython string: <code>AdminTask.deleteCertificateRequest ('[-interactive]')</code> • Using Jython list: <code>AdminTask.deleteCertificateRequest (['-interactive'])</code>

Table 35. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
extractCertificateRequest	The extractCertificateRequest command extracts a certificate request to a file.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - certificateRequestFilePath The file location of the certificate request that can be sent to a certificate authority. (String, required) • Returns: A certificate request file is created that contains the extracted certificate. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask extractCertificateRequest {-interactive}</code> • Using Jython string: <code>AdminTask.extractCertificateRequest ('[-interactive]')</code> • Using Jython list: <code>AdminTask.extractCertificateRequest (['-interactive'])</code>

Table 35. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getCertificateRequest	The getCertificateRequest command obtains information about a particular certificate request in a key store.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) Returns: Information about the certificate request. 	Interactive mode example usage: <ul style="list-style-type: none"> Using Jacl: \$AdminTask getCertificateRequest {-interactive} Using Jython string: AdminTask.getCertificateRequest ('[-interactive]') Using Jython list: AdminTask.getCertificateRequest (['-interactive'])
listCertificateRequest	The listCertificateRequest command lists all the certificate requests associated with a particular key store.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) Returns: An attribute list for each certificate request in a key store. 	Interactive mode example usage: <ul style="list-style-type: none"> Using Jacl: \$AdminTask listCertificateRequest {-interactive} Using Jython string: AdminTask.listCertificateRequest ('[-interactive]') Using Jython list: AdminTask.listCertificateRequest (['-interactive'])

Commands for the SignerCertificateCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SignerCertificateCommands group of the AdminTask object:

Table 36.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
addSignerCertificate	The addSignerCertificate command adds a signer certificate from a certificate file to a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, optional) - certificateFilePath The full path name of the file that contains the signer certificate. (String, required) - certificateAlias The alias name of the signer certificate in the key store. (String, required) - base64Encoded Set the value of this parameter to true if the certificate is ascii base 64 encoded. Set the value of this parameter to false if the certificate is binary. (String, required) • Returns: The configuration object name of the key store object that you created. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask addSignerCertificate {-interactive} • Using Jython string: AdminTask.addSignerCertificate ('[-interactive]') • Using Jython list: AdminTask.addSignerCertificate (['-interactive'])

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
deleteSignerCertificate	The deleteSignerCertificate command deletes a signer certificate from a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, optional) - certificateAlias The alias name of the signer certificate in the key store. (String, required) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteSignerCertificate {-interactive} • Using Jython string: AdminTask.deleteSignerCertificate ('[-interactive]') • Using Jython list: AdminTask.deleteSignerCertificate (['-interactive'])

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
extractSignerCertificate	The extractSignerCertificate command extracts a signer certificate from a key store to a file.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, optional) - certificateAlias The alias name of the signer certificate in the key store. (String, required) - certificateFilePath The full path name of the file that contains the signer certificate. (String, required) - base64Encoded Set the value of this parameter to true if the certificate is ascii base 64 encoded. Set the value of this parameter to false if the certificate is binary. (String, required) • Returns: The certificate file is created and contains the signer certificate. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask extractSignerCertificate {-interactive} • Using Jython string: AdminTask.extractSignerCertificate ('[-interactive]') • Using Jython list: AdminTask.extractSignerCertificate (['-interactive'])

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getSignerCertificate	The getSignerCertificate command obtains information about a signer certificate from a key store.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, optional) - certificateAlias The alias name of the signer certificate in the key store. (String, required) Returns: Information about a signer certificate. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask getSignerCertificate {-interactive} Using Jython string: AdminTask.getSignerCertificate ('[-interactive]') Using Jython list: AdminTask.getSignerCertificate (['-interactive'])
listSignerCertificates	The listSignerCertificates command lists all signer certificates in a particular key store.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, optional) Returns: A list of signer certificate aliases. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask listSignerCertificates {-interactive} Using Jython string: AdminTask.listSignerCertificates ('[-interactive]') Using Jython list: AdminTask.listSignerCertificates (['-interactive'])

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
retrieveSignerFromPort	The retrieveSignerFromPort command retrieves a signer from a remote host and stores the signer in a key store.	None	<ul style="list-style-type: none"> • Parameters: - host The host name of the system from where the signer certificate will be retrieved. (String, required) - port The port of the remote system from where the signer certificate will be retrieved. (Integer, required) - keyStoreName The name of the key store where the signer certificate is located. (String, required) - keyStoreScope The management scope of the key store. (String, required) - sslConfigName The name of the SSL configuration object. (String, optional) - sslConfigScopeName The management scope where the SSL configuration object is located. (String, optional) • Returns: The signer certificate is created in the key store file. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask retrieveSignerFromPort {-host serverHost -port 443 -keyStoreName testKeyStore -certificateAlias serverHostSigner} • Using Jython string: AdminTask.retrieveSignerFromPort ('[-host serverHost -port 443 -keyStoreName testKeyStore -certificateAlias serverHostSigner]') • Using Jython list: AdminTask.retrieveSignerFromPort (['-host', 'serverHost', '-port', '443', '-keyStoreName', 'testKeyStore', '-certificateAlias', 'serverHostSigner']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask retrieveSignerFromPort {-interactive} • Using Jython string: AdminTask.retrieveSignerFromPort ('[-interactive]') • Using Jython list: AdminTask.retrieveSignerFromPort (['-interactive'])

Table 36. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
retrieveSigner InfoFromPort	The retrieveSigner InfoFromPort command retrieves signer information from a port on a remote host.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - host The host name of the system from where the signer certificate will be retrieved. (String, required) - port The port of the remote system from where the signer certificate will be retrieved. (Integer, required) - sslConfigName The name of the SSL configuration object. (String, optional) - sslConfigScopeName The management scope where the SSL configuration object is located. (String, optional) Returns: Information about the signer certificate from the remote host port. 	Interactive mode example usage: <ul style="list-style-type: none"> Using Jacl: \$AdminTask retrieveSigner InfoFromPort {-interactive} Using Jython string: AdminTask.retrieveSigner InfoFromPort ('[-interactive]') Using Jython list: AdminTask.retrieveSigner InfoFromPort (['-interactive'])

Commands for the PersonalCertificateCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the personalCertificateCommands group of the AdminTask object:

Table 37.

Command name:	Description:	Target object:	Parameters and return values:	Examples:
<p>createSelfSignedCertificate</p>	<p>The createSelfSignedCertificate command creates a personal certificate in a key store.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - certificateVersion The version of the certificate. (String, required) - certificateSize The size of the certificate. (Integer, required) - certificateCommonName The common name of the certificate. (String, required) - certificateOrganization The organization of the certificate. (String, optional) - certificateOrganizationUnit The organizational unit of the certificate. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createSelfSignedCertificate {-keyStoreName testKeyStore -certificateAlias default -certificateCommonName localhost -certificateOrganization ibm} • Using Jython string: AdminTask.createSelfSignedCertificate (['-keyStoreName testKeyStore -certificateAlias default -certificateCommonName localhost -certificateOrganization ibm']) • Using Jython list: AdminTask.createSelfSignedCertificate (['-keyStoreName', 'testKeyStore', '-certificateAlias', 'default', '-certificateCommonName', 'localhost', '-certificateOrganization', 'ibm']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask createSelfSignedCertificate {-interactive} • Using Jython string: AdminTask.createSelfSignedCertificate (['-interactive']) • Using Jython list: AdminTask.createSelfSignedCertificate (['-interactive'])

Table 37. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
			<ul style="list-style-type: none"> - certificateLocality The locality of the certificate. (String, optional) - certificateState The state of the certificate. (String, optional) - certificateZip The zip code of the certificate. (String, optional) - certificateCountry The country of the certificate. (String, optional) - certificateValidDays The amount of time in days for which the certificate is valid. (Integer, optional) • Returns: None 	
deleteCertificate	The deleteCertificate command deletes a personal certificate from a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask deleteCertificate {-interactive} • Using Jython string: AdminTask.deleteCertificate ('[-interactive]') • Using Jython list: AdminTask.deleteCertificate (['-interactive'])

Table 37. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
exportCertificate	<p>The exportCertificate command exports a personal certificate from one key store to another.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - keyStorePassword The password to the key store. (String, required) - keyFilePath The full path to a key store file that is located in a file system. The store from where a certificate will be imported or exported. (String, required) - keyFilePassword The password to the key store file. (String, required) - keyFileType The type of the key file. (String, required) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - aliasInKeyStore (String, optional) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask exportCertificate {-interactive}</code> • Using Jython string: <code>AdminTask.exportCertificate ('[-interactive]')</code> • Using Jython list: <code>AdminTask.exportCertificate (['-interactive'])</code>

Table 37. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
extractCertificate	<p>The extractCertificate command extracts the signer part of a personal certificate to a file.</p>	None	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - certificateRequestFilePath The full path of the request file that contains the certificate. (String, required) - base64Encoded Set the value of this parameter to true if the certificate is ascii base 64 encoded. Set the value of this parameter to false if the certificate is binary. (Boolean, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask extractCertificate {-keyStoreName testKeyStore -certificateFilePath c:\temp\CertFile.arm -certificateAlias testCertificate} • Using Jython string: AdminTask.extractCertificate (['-keyStoreName testKeyStore -certificateFilePath c:\temp\CertFile.arm -certificateAlias testCertificate']) • Using Jython list: AdminTask.extractCertificate (['-keyStoreName', 'testKeyStore', '-certificateFilePath', 'c:\temp\CertFile.arm', '-certificateAlias', 'testCertificate']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask extractCertificate {-interactive} • Using Jython string: AdminTask.extractCertificate (['-interactive']) • Using Jython list: AdminTask.extractCertificate (['-interactive'])

Table 37. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
getCertificate	The getCertificate command obtains information about a particular personal certificate in a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) • Returns: Information about the certificate request. 	Interactive mode example usage: <ul style="list-style-type: none"> • Using Jacl: \$AdminTask getCertificate {-interactive} • Using Jython string: AdminTask.getCertificate ('[-interactive]') • Using Jython list: AdminTask.getCertificate (['-interactive'])

Table 37. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
importCertificate	The importCertificate command imports a personal certificate from a key store.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - keyFilePath The full path to a key store file that is located in a file system. The store from where a certificate will be imported or exported. (String, required) - keyFilePassword The password to the key store file. (String, required) - keyFileType The type of the key file. (String, required) - - certificateAliasFromKeyFile The certificate alias in the key file from which the certificate is being imported. (String, required) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask importCertificate {-interactive} • Using Jython string: AdminTask.importCertificate ('[-interactive]') • Using Jython list: AdminTask.importCertificate (['-interactive'])

Table 37. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
listPersonalCertificates	<p>The listPersonalCertificates command lists the personal certificates in a particular key store.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) • Returns: A list of attributes for each personal certificate in a key store. 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask listPersonalCertificates {-interactive} • Using Jython string: AdminTask.listPersonalCertificates ('[-interactive]') • Using Jython list: AdminTask.listPersonalCertificates (['-interactive'])

Table 37. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
receiveCertificate	<p>The receiveCertificate command receives a signer certificate from a file to a personal certificate.</p>	None	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - certificateFilePath The full path of the file that contains the certificate. (String, required) - base64Encoded Set the value of this parameter to true if the certificate is ascii base 64 encoded. Set the value of this parameter to false if the certificate is binary. (Boolean, required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask receiveCertificate {-keyStoreName testKeyStore -certificateFilePath c:\temp\CertFile.arm} • Using Jython string: AdminTask.receiveCertificate (['-keyStoreName testKeyStore -certificateFilePath c:\temp\CertFile.arm']) • Using Jython list: AdminTask.receiveCertificate (['-keyStoreName', 'testKeyStore', '-certificateFilePath', 'c:\temp\CertFile.arm']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask receiveCertificate {-interactive} • Using Jython string: AdminTask.receiveCertificate (['-interactive']) • Using Jython list: AdminTask.receiveCertificate (['-interactive'])

Table 37. (continued)

Command name:	Description:	Target object:	Parameters and return values:	Examples:
replaceCertificate	<p>The replaceCertificate command replaces a personal certificate with a new one. Replaces all signer certificates from the personal certificate.</p>	None	<ul style="list-style-type: none"> • Parameters: - keyStoreName The name that uniquely identifies the key store configuration object. (String, required) - keyStoreScope The scope name of the key store. (String, optional) - certificateAlias The name that uniquely identifies the certificate request in a key store. (String, required) - replacementCertificateAlias The alias of the certificate that is used to replace a different certificate. (String, required) - deleteOldCert Set the value of this parameter to true if you want to delete the old signer certificates during certificate replacement. Otherwise, set the value of this parameter to false. (Boolean, optional) - deleteOldSigners Set the value of this parameter to true if you want to delete the old certificates during certificate replacement. Otherwise, set the value of this parameter to false. (Boolean, optional) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask replaceCertificate {-keyStoreName testKeyStore -certificateAlias default -replacementCertificateAlias replaceCert -deleteOldCert true -deleteOldSigners true} • Using Jython string: AdminTask.replaceCertificate ('[-keyStoreName testKeyStore -certificateAlias default -replacementCertificateAlias replaceCert -deleteOldCert true -deleteOldSigners true]') • Using Jython list: AdminTask.replaceCertificate (['-keyStoreName', 'testKeyStore', '-certificateAlias', 'default', '-replacementCertificateAlias', 'replaceCert', '-deleteOldCert', 'true', '-deleteOldSigners', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: \$AdminTask replaceCertificate {-interactive} • Using Jython string: AdminTask.replaceCertificate ('[-interactive]') • Using Jython list: AdminTask.replaceCertificate (['-interactive'])

Commands for the SPNEGO TAI group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the SPNEGO TAI group of the AdminTask object:

Command name:	Description:	Target object:	Parameters and return values:	Examples:
addSpnegoTAI Properties	The addSpnegoTAI Properties command adds properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.	None	<ul style="list-style-type: none"> Parameters: - spnld This is the SPN identifier for the group of custom properties that are to be defined with this command. If you do not specify this parameter, an unused SPN identifier is assigned. (String, optional) - host Specifies the host name portion in the SPN used by the SPNEGO TAI to establish a Kerberos secure context. (String, required) - filter Defines the filtering criteria used by the class specified with the above attribute. If no filter is specified, all HTTP requests are subject to SPNEGO authentication. (String, optional) - filterClass Specifies the name of the Java class used by the SPNEGO TAI to select which HTTP requests will be subject to SPNEGO authentication. If no filter class is specified, the default filter class, <code>com.ibm.ws.security.spnego.HTTPHeaderFilter</code>, is used. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask addSpnegoTAIProperties -host myhost.ibm.com -filter user-agent%=IE 6</code> Using Jython string: <code>AdminTask.addSpnegoTAIProperties ('[-host myhost.ibm.com -filter user-agent%=IE 6]')</code> Using Jython list: <code>AdminTask.addSpnegoTAIProperties (['-host', 'myhost.ibm.com', '-filter', 'user-agent%=IE', '6'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask addSpnegoTAIProperties -interactive</code> Using Jython string: <code>AdminTask.addSpnegoTAIProperties (['-interactive'])</code> Using Jython list: <code>AdminTask.addSpnegoTAIProperties ['-interactive'])</code>

			<p>- noSpnegoPage Specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application if it does not support SPNEGO authentication. (String, optional).</p> <p>If you do not specify the noSpnegoPage attribute then the default is used:</p> <pre>"<html><head><title> SPNEGO authentication is not supported. </title></head>" + "<body>SPNEGO authe ntication is not supported on this client.</body> </html>";</pre> <p>- ntlmTokenPage Specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application when the SPNEGO token received by the interceptor after the challenge-response handshake contains a NT LAN manager (NTLM) token instead of the expected SPNEGO token. (String, optional).</p> <p>If you do not specify the ntlmTokenPage attribute then the default is used:</p> <pre>"<html><head><title> An NTLM Token was received.</title> </head>" + "<body>Your bro wser configuration is correct, but you have not logged into a supported Windows Domain." + "<p>Please login to the application using the normal login page.</html>";</pre>	
--	--	--	--	--

			<p>- trimUserName Specifies whether (true) or not (false) the SPNEGO TAI is to remove the suffix of the principal user name, starting from the @ that precedes the Kerberos realm name. If this attribute is set to true, the suffix of the principal user name is removed. If this attribute is set to false, the suffix of the principal name is retained. The default value used is true. (String, optional)</p> <ul style="list-style-type: none">• Returns: None	
--	--	--	--	--

<p>createKrb ConfigFile</p>	<p>The createKrb ConfigFile command creates the Kerberos configuration file for use with the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - krbPath Provides the fully qualified file system location of the Kerberos configuration (krb5.ini or krb5.conf) file. (String, required) - realm Provides the Kerberos realm name. The value of this attribute is used by the SPNEGO TAI to form the Kerberos service principal name for each of the hosts specified with the property <code>com.ibm.ws.security.spnego.SPN<id>.hostname</code> (String, required) - kdcHost Provides the host name of the Kerberos Key Distribution Center (KDC). (String, required) - kdcPort Provides the port number of the KDC. The default value, if not specified, is 88. (String, optional) - dns Provides the default domain name service (DNS) that is used to produce a fully qualified host name. (String, required) - keytabPath Provides the file system location of the Kerberos keytab file. (String, required) - encryption Identifies the list of supported encryption types, separated by a space. The specified value is used for the <code>default_tkt_encytypes</code> and <code>default_tgs_encytypes</code>. The default encryption types, if not specified, are <code>des-cbc-md5</code> and <code>rc4-hmac</code>. (String, optional) • Returns: None 	<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask createKrbConfigFile -interactive</code> • Using Jython string: <code>AdminTask.createKrbConfigFile ('[-interactive]')</code> • Using Jython list: <code>AdminTask.createKrbConfigFile ['-interactive']</code>
---------------------------------	---	-------------	--	---

deleteSpnego TAIProperties	The deleteSpnegoTAIProperties command deletes properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - spnId The SPN identifier for the group of custom properties that are to be deleted with this command. If you do not specify this parameter, all SPNEGO TAI custom properties are deleted. (String, optional) • Returns: None 	Batch mode example usage: <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask deleteSpnegoTAIProperties {-spnId 2}</code> • Using Jython string: <code>AdminTask.deleteSpnegoTAIProperties ('[-spnId 2]')</code> • Using Jython list: <code>AdminTask.deleteSpnegoTAIProperties (['-spnId', '2'])</code> Interactive mode example usage: <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask deleteSpnegoTAIProperties -interactive</code> • Using Jython string: <code>AdminTask.deleteSpnegoTAIProperties (['-interactive'])</code> • Using Jython list: <code>AdminTask.deleteSpnegoTAIProperties ['-interactive'])</code>
-------------------------------	---	------	---	---

<p>modifySpnegoTAIProperties</p>	<p>The modifySpnegoTAIProperties command modifies the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: - spnId The SPN identifier for the group of custom properties that are to be defined with this command. (String, required) - host Specifies the host name portion in the SPN used by the SPNEGO TAI to establish a Kerberos secure context. (String, optional) - filter Defines the filtering criteria used by the class specified with the above attribute. (String, optional) - filterClass Specifies the name of the Java class used by the SPNEGO TAI to select which HTTP requests will be subject to SPNEGO authentication. If no class is specified, all HTTP requests will be subject to SPNEGO authentication. (String, optional) - noSpnegoPage Specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application if it does not support SPNEGO authentication. (String, optional) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask modifySpnegoTAI PROPERTIES -spnId 1 -filter host==myhost.company.com</code> • Using Jython string: <code>AdminTask.modifySpnegoTAI PROPERTIES (['-spnId 1 -filter host==myhost.com pany.com']')</code> • Using Jython list: <code>AdminTask.modifySpnegoTAI PROPERTIES (['-spnId', '1', '-filter', 'host==my host.company.com']')</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask modifySpnegoTAI Properties -interactive</code> • Using Jython string: <code>AdminTask.modifySpnegoTAI Properties (['-interactive']')</code> • Using Jython list: <code>AdminTask.modifySpnegoTAI Properties ['-interactive']')</code>
----------------------------------	---	-------------	---	--

			<p>- ntlmTokenPage Specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application when the SPNEGO token received by the interceptor after the challenge-response handshake contains a NT LAN manager (NTLM) token instead of the expected SPNEGO token. (String, optional)</p> <p>- trimUserName Specifies whether (true) or not (false) the SPNEGO TAI is to remove the suffix of the principal user name, starting from the "@" that precedes the Kerberos realm name. If this attribute is set to true, the suffix of the principal user name is removed. If this attribute is set to false, the suffix of the principal name is retained. The default value used is true. (String, optional)</p> <ul style="list-style-type: none"> • Returns: None 	
--	--	--	--	--

showSpnegoTAI Properties	The showSpnegoTAI Properties command displays the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - spnid The service principal name (SPN) identifier for the group of custom properties that are to be displayed with this command. If you do not specify this parameter, all SPNEGO TAI custom properties are displayed. (String, optional) Returns: A list of properties. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask showSpnegoTAI Properties -spnid 1</code> Using Jython string: <code>AdminTask.showSpnegoTAI Properties (['-spnid 1'])</code> Using Jython list: <code>AdminTask.showSpnegoTAI Properties (['-spnid', '1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask showSpnegoTAI Properties -interactive</code> Using Jython string: <code>AdminTask.showSpnegoTAI Properties (['-interactive'])</code> Using Jython list: <code>AdminTask.showSpnegoTAI Properties ['-interactive'])</code>
--------------------------	---	------	---	---

Commands for the AuthorizationGroupCommands group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the AuthorizationGroupCommands group of the AdminTask object:

Command name:	Description:	Target object:	Parameters and return values:	Examples:
---------------	--------------	----------------	-------------------------------	-----------

<p>addResourceToAuthorizationGroup</p>	<p>The addResourceToAuthorizationGroup command adds a resource instance to an existing authorization group. A resource instance cannot belong to more than one authorization group.</p>	<p>None</p>	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. (String, required) - resourceName The name of the resource instance that you want to add to an authorization group. (String, required) <p>The resourceName parameter should be in the following format: ResourceType= ResourceName</p> <p>where ResourceType is one of the following values: Application, Server, ServerCluster, Node, NodeGroup</p> <p>ResourceName is the name of the resource instance, for example, server1.</p> <p>The following are example uses of the resourceName parameter:</p> <ul style="list-style-type: none"> - Node=node1:Server=server1 <p>This example uniquely identifies server1. node1 is required if another server1 exists on a different node.</p> <ul style="list-style-type: none"> - Application=app1 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask addResourceToAuthorizationGroup {-authorizationGroupName groupName -resourceName Application=app1}</code> Using Jython string: <code>AdminTask.addResourceToAuthorizationGroup(['-authorizationGroupName groupName -resourceName Application=app1'])</code> Using Jython list: <code>AdminTask.addResourceToAuthorizationGroup(['-authorizationGroupName', 'groupName', '-resourceName', 'Application=app1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask addResourceToAuthorizationGroup {-interactive}</code> Using Jython string: <code>AdminTask.addResourceToAuthorizationGroup (['-interactive'])</code> Using Jython list: <code>AdminTask.addResourceToAuthorizationGroup (['-interactive'])</code>
			<ul style="list-style-type: none"> Returns: None 	

<p>createAuthorizationGroup</p>	<p>The createAuthorizationGroup command creates a new authorization group. When you create a new authorization group, no members are associated with it. Also, no user to administrative role mapping for the authorization table is associated with the authorization group.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group that you want to create. (String, required) • Returns: The configuration ID of the authorization group that you created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createAuthorizationGroup {-authorizationGroupName <i>groupName</i>}</pre> • Using Jython string: <pre>AdminTask.createAuthorizationGroup(['-authorizationGroupName <i>groupName</i>'])</pre> • Using Jython list: <pre>AdminTask.createAuthorizationGroup(['-authorizationGroupName', '<i>groupName</i>'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask createAuthorizationGroup -interactive</pre> • Using Jython string: <pre>AdminTask.createAuthorizationGroup(['-interactive'])</pre> • Using Jython list: <pre>AdminTask.createAuthorizationGroup(['-interactive'])</pre>
---------------------------------	--	-------------	--	--

deleteAuthorizationGroup	The deletes an existing authorization group. When you delete an authorization group, the authorization table that corresponds is also deleted.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - authorizationGroup Name The name of the authorization group that you want to delete. (String, required) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask deleteAuthorizationGroup {-authorizationGroupName groupName}</code> Using Jython string: <code>AdminTask.deleteAuthorizationGroup('[-authorizationGroupName groupName]')</code> Using Jython list: <code>AdminTask.deleteAuthorizationGroup(['-authorizationGroupName', 'groupName'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask deleteAuthorizationGroup {-interactive}</code> Using Jython string: <code>AdminTask.deleteAuthorizationGroup ('[-interactive]')</code> Using Jython list: <code>AdminTask.deleteAuthorizationGroup (['-interactive'])</code>
	The command lists the existing authorization groups.	None	<ul style="list-style-type: none"> Parameters: None Returns: A list of short names of all existing authorization groups. (String []) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroups</code> Using Jython: <code>AdminTask.listAuthorizationGroups()</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroups {-interactive}</code> Using Jython string: <code>AdminTask.listAuthorizationGroups ('[-interactive]')</code> Using Jython list: <code>AdminTask.listAuthorizationGroups (['-interactive'])</code>

<p>listAuthorizationGroupsForGroupID</p>	<p>The listAuthorizationGroupsForGroupID command lists all of the authorization groups to which a given user group has access. This command lists the authorization groups and the granted roles for each authorization group. The group ID can be a short name or a fully qualified domain name if the LDAP user registry is being used. This command will list cell as a group if the user has cell level access.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - groupid The ID of the user group. (String, required) • Returns: The map of the authorization group and granted roles. (Map[String=String[]]) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listAuthorizationGroupsForGroupID {-groupid <i>userGroupName</i>}</pre> • Using Jython string: <pre>AdminTask.listAuthorizationGroupsForGroupID(['-groupid <i>userGroupName</i>'])</pre> • Using Jython list: <pre>AdminTask.listAuthorizationGroupsForGroupID(['-groupid', '<i>userGroupName</i>'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listAuthorizationGroupsForGroupID {-interactive}</pre> • Using Jython string: <pre>AdminTask.listAuthorizationGroupsForGroupID ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.listAuthorizationGroupsForGroupID (['-interactive'])</pre>
--	--	-------------	---	---

listAuthorizationGroupsForUser ID	The listAuthorizationGroupsForUser ID command lists all of the authorization groups to which a given user has access. This command lists the authorization groups and the granted roles for each authorization group. The user ID and the group ID can be a short name or a fully qualified domain name if the LDAP user registry is being used. This command will list cell as a group if the user has cell level access.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - userid The ID of the user. (String, required) Returns: The map of the authorization group and granted roles. (Map[String=String[]]) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroupsForUserID{-userid userName}</code> Using Jython string: <code>AdminTask.listAuthorizationGroupsForUserID(['-userid userName'])</code> Using Jython list: <code>AdminTask.listAuthorizationGroupsForUserID(['-userid', 'userName'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroupsForUserID {-interactive}</code> Using Jython string: <code>AdminTask.listAuthorizationGroupsForUserID (['-interactive'])</code> Using Jython list: <code>AdminTask.listAuthorizationGroupsForUserID (['-interactive'])</code>
-----------------------------------	---	------	--	---

listAuthorizationGroupsOfResource	The listAuthorizationGroupsOfResource command lists authorization groups for a given resource. If the value of the <code>traverseContainedObjects</code> parameter is false, only the authorization group of the resource is returned. If the value of the <code>traverseContainedObjects</code> parameter is true, it returns the authorization group of the resource and the authorization groups of all the parent resources in the containment tree.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - resourceName The name of the resource. (String, required) The <code>resourceName</code> parameter must be in the following format: ResourceType=ResourceName where <code>ResourceType</code> can be any one of the following values: Application, Server, ServerCluster, Node, or NodeGroup. <code>ResourceName</code> is the name of the resource instance, for example, <code>server1</code>. The following are examples of the <code>resourceName</code> parameter: Node=node1: Server=server This example uniquely identifies <code>server1</code>. The name of the node is required if a server on a different node uses the same server name. Application=app1 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroupsOfResource {-resourceName Application=app1}</code> Using Jython string: <code>AdminTask.listAuthorizationGroupsOfResource(['-resourceName Application=app1'])</code> Using Jython list: <code>AdminTask.listAuthorizationGroupsOfResource(['-resourceName', 'Application=app1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask listAuthorizationGroupsOfResource {-interactive}</code> Using Jython string: <code>AdminTask.listAuthorizationGroupsOfResource(['-interactive'])</code> Using Jython list: <code>AdminTask.listAuthorizationGroupsOfResource(['-interactive'])</code>
-----------------------------------	---	------	---	--

			<p>- traverseContainedResources</p> <p>Finds the authorization groups of all the parent resources by traversing the resource containment tree upwards. The default value is false. (Boolean, optional)</p> <ul style="list-style-type: none"> Returns: The short names of all of the authorization groups for which the resource belongs. If you do not specify the <code>traverseContainedResources</code> parameter, the result of this command will only contain one value because a resource instance can only belong to one authorization group. (String[]) 	
listResourcesOfAuthorizationGroup	The listResourcesOfAuthorizationGroup command lists all of the resources within the given authorization group.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. (String, required) Returns: The configuration IDs of all of the resource instances within the authorization group. (String[]) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask listResourcesOfAuthorizationGroup {-authorizationGroupName groupName}</pre> Using Jython string: <pre>AdminTask.listResourcesOfAuthorizationGroup(['-authorizationGroupName groupName'])</pre> Using Jython list: <pre>AdminTask.listResourcesOfAuthorizationGroup(['-authorizationGroupName', 'groupName'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask listResourcesOfAuthorizationGroup {-interactive}</pre> Using Jython string: <pre>AdminTask.listResourcesOfAuthorizationGroup(['-interactive'])</pre> Using Jython list: <pre>AdminTask.listResourcesOfAuthorizationGroup(['-interactive'])</pre>

listResourcesForGroupID	<p>The listResourcesForGroupID command lists all the objects that a given group has access to. This command lists the resources and the granted roles for each resource. The resources that this command returns include the resources from the authorization groups to which the user group is granted roles and the resources that are descendants of the resources with in authorization groups to which the user group is granted access to any role. The group ID can be a short name or fully qualified domain name if a LDAP user registry is used.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - groupid The ID of the user group. (String, required) • Returns: The map of the granted role and resources. (Map[String=String[]]) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listResourcesForGroupID {-groupid <i>userGroup</i> <i>groupName</i>}</pre> • Using Jython string: <pre>AdminTask.listResourcesForGroupID(['-groupid <i>userGroup</i> <i>groupName</i>'])</pre> • Using Jython list: <pre>AdminTask.listResourcesForGroupID(['-groupid', 'userGroupName'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listResourcesForGroupID {-interactive}</pre> • Using Jython string: <pre>AdminTask.listResourcesForGroupID ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.listResourcesForGroupID (['-interactive'])</pre>
-------------------------	---	------	--	--

listResourcesForUserID	<p>The listResourcesForUserID command lists all the objects that a given user has access to. This command lists the resources and the granted roles for each resource. The resources that this command returns include the resources from the authorization groups to which the user is granted roles and the resources that are descendants of the resources with in authorization groups to which the user is granted access to any role. The user ID can be a short name or fully qualified domain name if a LDAP user registry is used.</p>	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - userid The ID of the user. (String, required). • Returns: The map of granted role and resources. (Map[String=String[]]) 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask listResourcesForUserID {-userid userName }</code> • Using Jython string: <code>AdminTask.listResourcesForUserID('[-userid userName]')</code> • Using Jython list: <code>AdminTask.listResourcesForUserID(['-userid', 'userName'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <code>\$AdminTask listResourcesForUserID {-interactive}</code> • Using Jython string: <code>AdminTask.listResourcesForUserID ('[-interactive]')</code> • Using Jython list: <code>AdminTask.listResourcesForUserID (['-interactive'])</code> <p>Example output:</p> <pre>{deployer=[], operator=[], administrator=[cells/IBM-LP16L31HVE8Cell107/clusters/C1 cluster.xml, cells/IBM-LP16L31HVE8Cell107/nodes/IBM-LP16L31HVE8Node05/servers/cm1 server.xml], monitor=[], configurator=[]}</pre>
------------------------	--	------	--	---

mapGroupsToAdminRole	<p>The mapGroupsToAdminRole command maps group IDs in an administrative roles in an authorization group. The name of the authorization group that you provide determines which authorization table will be used. If you do not specify an authorization group name, the mapping is done to the cell level authorization table. The group ID can be a short name or a fully qualified domain name if the LDAP user registry is used.</p>	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. If you do not specify this parameters, the cell level authorization group is assumed. (String, optional) - roleName The name of the administrative role. (String, required) - groupids The list of group IDs that will mapped to the administrative role. (String[], required) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask mapGroupsToAdminRole {-authorizationGroupName group Name - roleName administrator -groupids group1}</pre> Using Jython string: <pre>AdminTask.mapGroupsToAdminRole ('[-authorizationGroupName group Name -roleName administrator -groupids group1]')</pre> Using Jython list: <pre>AdminTask.mapGroupsToAdminRole (['-authorizationGroupName', 'groupName', '-roleName', 'administrator', '-groupids', 'group1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask mapGroupsToAdminRole {-interactive}</pre> Using Jython string: <pre>AdminTask.mapGroupsToAdminRole ('[-interactive]')</pre> Using Jython list: <pre>AdminTask.mapGroupsToAdminRole (['-interactive'])</pre>
----------------------	--	------	---	---

<p>mapUsersToAdminRole</p>	<p>The mapUsersToAdminRole command maps user IDs to one or more administrative roles in the authorization group. The name of the authorization group that you provide determines the authorization table. If you do not specify the name of the authorization group, the mapping is done to the cell level authorization table. The user ID can be a short name or fully qualified domain name in case LDAP user registry is used.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. If you do not specify this parameter, the cell level authorization group is assumed. (String, optional) - roleName The name of the administrative role. (String, required) - userids The list of user IDs that will be mapped to the administrative role (String[], required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask mapUsersToAdminRole {-authorizationGroupName group Name - roleName administrator -userids user1}</pre> • Using Jython string: <pre>AdminTask.mapUsersToAdminRole ('[-authorizationGroupName groupName -roleName administ rator -userids user1]')</pre> • Using Jython list: <pre>AdminTask.mapUsersToAdminRole (['-authorizationGroupName', 'groupName', '-roleName', 'administrator', '-userids', 'user1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask mapUsersToAdmin Role {-interactive}</pre> • Using Jython string: <pre>AdminTask.mapUsersToAdmin Role ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.mapUsersToAdmin Role (['-interactive'])</pre>
----------------------------	---	-------------	--	--

<p>removeGroupsFromAdminRole</p>	<p>The removeGroupsFromAdminRole command removes previously mapped group IDs from administrative roles in the authorization group. The name of the authorization group that you provide determines which authorization table is involved. If you do not specify an authorization group name, the group IDs are removed from the cell level authorization table. The group ID can be a short name or fully qualified domain name if a LDAP user registry is used.</p>	<p>None</p>	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. If you do not specify this parameter, the cell level authorization group is assumed. (String, optional) - roleName The name of the administrative role. (String, required) - userids A list of group IDs that you want to remove from the administrative role. (String[], required) • Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask removeGroupsFromAdminRole {-authorizationGroupName groupName - roleName administrator -groupids group1}</pre> • Using Jython string: <pre>AdminTask.removeGroupsFromAdminRole('[-authorizationGroupName groupName -roleName administrator -groupids group1]')</pre> • Using Jython list: <pre>AdminTask.removeGroupsFromAdminRole(['-authorizationGroupName', 'groupName', '-roleName', 'administrator', '-groupids', 'group1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask removeGroupsFromAdminRole {-interactive}</pre> • Using Jython string: <pre>AdminTask.removeGroupsFromAdminRole ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.removeGroupsFromAdminRole (['-interactive'])</pre>
----------------------------------	---	-------------	--	---

<p>removeResourceFromAuthorizationGroup</p>	<p>The removeResourceFromAuthorizationGroup command removes resources from an existing authorization group. If you do not specify the authorization group, it will be determined and the resource will be removed from that authorization group.</p>	<p>None</p>	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. (String, optional) - resourceName The name of the resource instance that you want to remove from the authorization group. (String, required) <p>The resourceName parameter must be in the following format:</p> <pre>ResourceType=ResourceName</pre> <p>where the ResourceType can be any of the following: Application, Server, ServerCluster, Node, or NodeGroup.</p> <p>The ResourceName is the name of the resource instance, for example, server1.</p> <p>The following are examples of the resourceName parameter:</p> <pre>Node=node1: Server=server1</pre> <p>This example uniquely identifies server1. node1 is required if the name of the server exists on multiple nodes.</p> <pre>Application=app1</pre> Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask removeResourceFromAuthorizationGroup {-authorizationGroupName groupName -resourceName Application=app1}</pre> Using Jython string: <pre>AdminTask.removeResourceFromAuthorizationGroup(['-authorizationGroupName groupName -resourceName Application=app1'])</pre> Using Jython list: <pre>AdminTask.removeResourceFromAuthorizationGroup(['-authorizationGroupName', 'groupName', '-resourceName', 'Application=app1'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask removeResourceFromAuthorizationGroup {-interactive}</pre> Using Jython string: <pre>AdminTask.removeResourceFromAuthorizationGroup (['-interactive'])</pre> Using Jython list: <pre>AdminTask.removeResourceFromAuthorizationGroup (['-interactive'])</pre>
---	---	-------------	--	--

removeUsersFromAdminRole	The removeUsersFromAdminRole command removes previously mapped user IDs from administrative roles in the authorization group. The name of the authorization group that you provide determines which authorization table is involved. If you do not specify an authorization group name, the user ID from the cell level authorization table will be used. The user ID can be a short name or a fully qualified domain name if a LDAP user registry is used.	None	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - authorizationGroupName The name of the authorization group. If you do not specify this parameter, the cell level authorization group is assumed. (String, optional) - roleName The name of the administrative role. (String, required) - userids A list of user IDs that you want to remove from the administrative role. (String[], required) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask removeUsersFromAdminRole {-authorizationGroupName groupName - roleName administrator -userids user1}</code> Using Jython string: <code>AdminTask.removeUsersFromAdminRole('[-authorizationGroupName groupName -roleName administrator -userids user1]')</code> Using Jython list: <code>AdminTask.removeUsersFromAdminRole(['-authorizationGroupName', 'groupName', '-roleName', 'administrator', '-userids', 'user1'])</code> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <code>\$AdminTask removeUsersFromAdminRole {-interactive}</code> Using Jython string: <code>AdminTask.removeUsersFromAdminRole ('[-interactive]')</code> Using Jython list: <code>AdminTask.removeUsersFromAdminRole (['-interactive'])</code>
--------------------------	--	------	---	---

Commands for the ChannelFrameworkManagement group of the AdminTask object

For more information about the AdminTask object, see the Commands for the AdminTask object article.

The following commands are available for the ChannelFrameworkManagement group of the AdminTask object:

Command name:	Description:	Target object:	Parameters and return values:	Examples:
---------------	--------------	----------------	-------------------------------	-----------

createChain	The createChain command creates a new chain of transport channels that are based on a chain template.	The instance of the transport channel service under which the new chain is created. (ObjectName, required)	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - template The chain template on which to base the new chain. (ObjectName, required) - name The name of the new chain. (String, required) - endPoint The name of the end point to be used by the instance of the TCP inbound channel in the new chain if the chain is an inbound chain. (ObjectName, optional) Returns: The object name of the channel chain that was created. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask createChain (cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1) {-template WebContainer(templates/chains webcontainer-chains.xml#Chain_1) -name trialChain1} \$AdminTask createChain (cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1) {-template WebContainer(templates/chains webcontainer-chains.xml#Chain_1) -name trialChain1 -endPoint (cells/rohitbuildCell01/nodes/rohitbuildCellManager01 serverindex.xml#EndPoint_3) }</pre> Using Jython string: <pre>AdminTask.createChain('cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1', '[-template "WebContainer(templates/chains webcontainer-chains.xml#Chain_1)" -name trialChain]')</pre> <pre>AdminTask.createChain('cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1', '[-template "WebContainer(templates/chains webcontainer-chains.xml#Chain_1)" -name trialChain -endPoint "(cells/rohitbuildCell01/nodes/rohitbuildCellManager01 serverindex.xml#EndPoint_3)"]')</pre> Using Jython list: <pre>AdminTask.createChain('cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1', ['-template', "WebContainer(templates/chains webcontainer-chains.xml#Chain_1)", '-name', 'trialChain']) AdminTask.createChain('cells/rohitbuildCell01/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1', ['-template', "WebContainer(templates/chains webcontainer-chains.xml#Chain_1)", '-name', 'trialChain', '-endPoint', "(cells/rohitbuildCell01/nodes/rohitbuildCellManager01 serverindex.xml#EndPoint_3)"])</pre>
-------------	--	--	---	---

				<p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask createChain {-interactive} Using Jython string: AdminTask.createChain ('[-interactive]') Using Jython list: AdminTask.createChain (['-interactive'])
deleteChain	The deleteChain command deletes an existing chain and, optionally, the transport channels in the chain.	The chain to be deleted. (Object name, required)	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - deleteChannels If the value of this attribute is true, non-shared transport channels used by the specified chain will be deleted. (Boolean, optional) Returns: None 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask deleteChain trialChain1 (cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#Chain_1093554462922) \$AdminTask deleteChain trialChain1 (cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#Chain_1093554378078) {-deleteChannels true} Using Jython string: AdminTask.deleteChain('trialChain1(cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1)') AdminTask.deleteChain('trialChain1(cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1)', '[-deleteChannels true]') Using Jython list: AdminTask.deleteChain('trialChain1(cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1)') AdminTask.deleteChain('trialChain1(cells/rohitbuildCell101/nodes/rohitbuildCellManager01/servers/dmgr server.xml#TransportChannelService_1)', ['-deleteChannels', 'true']) <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> Using Jacl: \$AdminTask deleteChain {-interactive} Using Jython string: AdminTask.deleteChain ('[-interactive]') Using Jython list: AdminTask.deleteChain (['-interactive'])

listChain Templates	The listChain Templates command displays a list of templates that you can use to create chains in this configuration. All templates have a certain type of transport channel as the last transport channel in the chain.	None	<ul style="list-style-type: none"> • Parameters: <ul style="list-style-type: none"> - acceptorFilter The templates returned by this method all have a transport channel instance of the specified type as the last transport channel in the chain. (String, optional) • Returns: A list of all the chain template object names. If you specify the <code>acceptorFilter</code> parameter, the list that returns is filtered to match the filter that you specified. 	<p>Batch mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listChainTemplates {} \$AdminTask listChainTemplates "-acceptorFilter WebContainer InboundChannel"</pre> • Using Jython string: <pre>AdminTask.listChainTemplates() AdminTask.listChainTemplates (['-acceptorFilter WebContainerInboundChannel'])</pre> • Using Jython list: <pre>AdminTask.listChainTemplates() AdminTask.listChainTemplates (['-acceptorFilter', 'WebContainerInboundChannel'])</pre> <p>Interactive mode example usage:</p> <ul style="list-style-type: none"> • Using Jacl: <pre>\$AdminTask listChainTemplates {-interactive}</pre> • Using Jython string: <pre>AdminTask.listChainTemplates ('[-interactive]')</pre> • Using Jython list: <pre>AdminTask.listChainTemplates (['-interactive'])</pre>
---------------------	---	------	--	---

listChains	The listChains command lists all the chains that are configured under a particular instance of the transport channel service.	The instance of the transport channel service under which the chains are configured. (ObjectName, required)	<ul style="list-style-type: none"> Parameters: <ul style="list-style-type: none"> - acceptorFilter The chains that are returned by this parameter will have a transport channel instance of the type that you specify as the last transport channel in the chain. (String, optional) - endPointFilter: The chains returned by this parameter will have a TCP inbound channel using an end point with the name that you specify.(String, optional) Returns: A list of all the channel chain object names that match the specified filters. If no you do not specify any parameters, all of the channel chains that are configured under the particular instance of transport channel service are returned. 	Batch mode example usage: <ul style="list-style-type: none"> Using Jacl: <pre>\$AdminTask listChains (cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328) \$AdminTask listChains (cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328) {-acceptorFilter WebContainerInboundChannel} \$AdminTask listChains (cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328) {-endPointFilter WC_adminhost}</pre> Using Jython string: <pre>AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)') AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)', '[-acceptorFilter WebContainerInboundChannel]') AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)', '[-endPointFilter WC_adminhost]')</pre> Using Jython list: <pre>AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)') AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)', ['-acceptorFilter', 'WebContainerInboundChannel']) AdminTask.listChains('(cells/rohitbuildCell101/nodes/rohitbuildNode01/servers/server2 server.xml#TransportChannelService_1093445762328)', ['-endPointFilter', 'WC_adminhost'])</pre>
------------	--	---	--	---

				<p>Interactive mode example usage:</p> <ul style="list-style-type: none">• Using Jacl: <code>\$AdminTask listChains {-interactive}</code>• Using Jython string: <code>AdminTask.listChains ('[-interactive]')</code>• Using Jython list: <code>AdminTask.listChains (['-interactive'])</code>
--	--	--	--	--

Chapter 10. Granting authority to a profile using the i5/OS command line

To grant authority to objects and directories in a profile, run the **grtwasaut** command from the Qshell command line.

To run the script, perform the following steps:

1. On the i5/OS command line, run the STRQSH (Start Qshell) command.
2. On the Qshell command line, use the cd command to change to the directory that contains the script:

```
cd app_server_root/bin
```

3. Run the **grtwasaut** command:

```
grtwasaut -profileName profile [ -user usrprf | -authlist authlist ]  
-dtaaut dataAuth -objaut objAuth
```

where *profile* is the profile to which you are granting authority, *usrprf* is the user profile to which you are granting authority, *authlist* is the authorization list to which you are granting authority, *dataAuth* specifies the data authorities that you are granting to the user specified by the *-user* parameter and *objAuth* specifies the object authorities that you are granting to the user specified by the *-user* parameter. You do not need to specify both the *-user* and *-authlist* parameters, but you must specify at least one of them. For more information on the **grtwasaut** command and additional parameters, see the **grtwasaut** command article. Examples

In the following example, the user profiles johndoe and jsmith are granted rwx authority to the profile devinst and the associated objects.

```
grtwasaut -profileName devinst -user "johndoe jsmith" -dtaaut rwx -recursive
```

In the following example, the user profiles johndoe and jsmith are granted rwx authority to the installedApps subdirectory and all nested objects in the installedApps subdirectory.

```
grtwasaut -profileName devinst -object installedApps -user "johndoe jsmith" -dtaaut rwx -recursive
```

Chapter 11. Revoking authority to a profile using the i5/OS command line

To revoke authority to objects and directories in a profile, run the `rvkwasaut` script from the Qshell command line.

To run the script, follow these steps:

1. On the i5/OS command line, run the STRQSH (Start Qshell) command.
2. On the Qshell command line, use the `cd` command to change to the directory that contains the script:

```
cd app_server_root/bin
```

3. Run the `rvkwasaut` script:

```
rvkwasaut -profileName profile [-user usrprf | -authlist authlist]
```

where *profile* is the *profile* to which you want are revoking authority, *usrprf* is the user profile from which you are revoking authority, and *authlist* is the authorization list from which you are revoking authority. You do not need to specify both the `-user` and `-authlist` parameters, but you must specify at least one of them. For more information on the `rvkwasaut` script and additional parameters, see the `rvkwasaut` command article.

In the following example, the user profile `jsmith` no longer has authority to the profile `devinst`:

```
rvkwasaut -profileName devinst -user jsmith -recursive
```

In the example, the user profile `jsmith` no longer has authority to the `installedApps` subdirectory and all nested objects in the `installedApps` subdirectory.

```
rvkwasaut -profileName devinst -object installedApps -user jsmith -recursive
```

Chapter 12. Web applications

Securing Web applications using an assembly tool

You can use three types of Web login authentication mechanisms to configure a Web application: basic authentication, form-based authentication and client certificate-based authentication. Protect Web resources in a Web application by assigning security roles to those resources.

To secure Web applications, determine the Web resources that need protecting and determine how to protect them.

Note: This procedure might not match the steps that are required when using your assembly tool, or match the version of the assembly tool that you are using. You should follow the instructions for the tool and version that you are using.

The following steps detail securing a Web application using an assembly tool:

1. In an assembly tool, import your Web archive (WAR) file or an application archive (EAR) file that contains one or more Web modules.
For more information, see "Importing Web archive (WAR) files" and "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.
2. In the Project Explorer folder, locate your Web application.
3. Right-click the deployment descriptor and click **Open With > Deployment Descriptor Editor**. The Deployment Descriptor window opens. To see online information about the editor, press F1 and click the editor name. If you select a Web archive (WAR) file, a Web deployment descriptor editor opens. If you select an enterprise application (EAR) file, an application deployment descriptor editor opens.
4. Create security roles either at the application level or at the Web module level. If a security role is created at the Web module level, the role also displays in the application level. If a security role is created at the application level, the role does not display in all of the Web modules. You can copy and paste a security role at the application level to one or more Web module security roles.
 - Create a role at a Web-module level. In a Web deployment descriptor editor, click the Security tab. Under **Security Roles**, click **Add**. Enter the security role name, describe the security role, and click **Finish**.
 - Create a role at the application level. In an application deployment descriptor editor, click the Security tab. Under the list of security roles, click **Add**. In the Add Security Role wizard, name and describe the security role and then click **Finish**.
5. Create security constraints. Security constraints are a mapping of one or more Web resources to a set of roles.
 - a. On the Security tab of a Web deployment descriptor editor, click **Security Constraints**. On the Security Constraints tab, you can do the following actions:
 - Add or remove security constraints for specific security roles.
 - Add or remove Web resources and their HTTP methods.
 - Define which security roles are authorized to access the Web resources.
 - Specify None, Integral, or Confidential constraints on user data.
 - None** The application does not require transport guarantees.
 - Integral**
Data cannot be changed in transit between the client and the server.
 - Confidential**
Data content cannot be observed while it is in transit.Integral and Confidential usually require the use of SSL.
 - b. Under Security Constraints, click **Add**.
 - c. Under Constraint name, specify a display name for the security constraint and click **Next**.
 - d. Type a name and description for the Web resource collection.

- e. Select one or more HTTP methods. The HTTP method options are: GET, PUT, HEAD, TRACE, POST, DELETE, and OPTIONS.
 - f. Beside the Patterns field, click **Add**.
 - g. Specify a URL Pattern. For example, type - /*, *.jsp, /hello. Consult the Servlet specification Version 2.4 for instructions on mapping URL patterns to servlets. The security runtime uses the exact match first to map the incoming URL with URL patterns. If the exact match is not present, the security runtime uses the longest match. The wild card (*.*,*.jsp) URL pattern matching is used last.
 - h. Click **Finish**.
 - i. Repeat these steps to create multiple security constraints.
6. Map security-role-ref and role-name elements to the role-link element. During the development of a Web application, you can create the security-role-ref element. The security-role-ref element contains only the role-name field. The role-name field contains the name of the role that is referenced in the servlet or JavaServer Pages (JSP) code to determine if the caller is in a specified role. Because security roles are created during the assembly stage, the developer uses a logical role name in the Role-name field and provides enough description in the Description field for the assembler to map the role actual. The Security-role-ref element is at the servlet level. A servlet or JavaServer Pages (JSP) file can have zero or more security-role-ref elements.
 - a. Go to the References tab of a Web deployment descriptor editor. On the References tab, you can add or remove the name of an enterprise bean reference to the deployment descriptor. You can define five types of references on this tab:
 - EJB reference
 - Service reference
 - Resource reference
 - Message destination reference
 - Security role reference
 - Resource environment reference
 - b. Under the list of Enterprise JavaBeans (EJB) references, click **Add**.
 - c. Specify a name and a type for the reference in the **Name** and **Ref Type** fields.
 - d. Select either **Enterprise Beans in the workplace** or **Enterprise Beans not in the workplace**.
 - e. **Optional:** If you select **Enterprise Beans not in the workplace**, select the type of enterprise bean in the **Type** field. You can specify either an entity bean or a session bean.
 - f. **Optional:** Click **Browse** to specify values for the local home and local interface in the **Local home** and **Local** fields before you click **Next**.
 - g. Map every role-name that is used during development to the role using the previous steps. Every role name that is used during development maps to the actual role.
 7. Specify the RunAs identity for servlets and JSP files. The RunAs identity of a servlet is used to invoke enterprise beans from within the servlet code. When enterprise beans are invoked, the RunAs identity is passed to the enterprise bean for performing an authorization check on the enterprise beans. If the RunAs identity is not specified, the client identity is propagated to the enterprise beans. The RunAs identity is assigned at the servlet level.
 - a. On the Servlets tab of a Web deployment descriptor editor, under **Servlets and JSP**, click **Add**. The Add Servlet or JSP wizard opens.
 - b. Specify the servlet or JavaServer Pages (JSP) file settings, including the name, initialization parameters, and URL mappings and click **Next**.
 - c. Specify the class file destination.
 - d. Click **Next** to specify additional settings or click **Finish**.
 - e. Click **Run As** on the **Servlets** tab, select the security role and describe the role.
 - f. Specify a RunAs identity for each servlet and JSP file that is used by your Web application.
 8. Configure the login mechanism for the Web module. This configured login mechanism applies to all the servlets, JavaServer Pages (JSP) files and HTML resources in the Web module.

- a. Click the **Pages** tab of a Web deployment descriptor editor and click **Login**. Select the required authentication method. Available method values include: Unspecified, Basic, Digest, Form, and Client-Cert.
 - b. Specify a realm name.
 - c. If you select the Form authentication method, select a login page and an error page Web address. For example, you might use `/login.jsp` or `/error.jsp`. The specified login and error pages are present in the `.war` file.
 - d. Install the client certificate on the browser or Web client and place the client certificate in the server trust keyring file, if `ClientCert` is selected.
9. Close the deployment descriptor editor and, when prompted, click **Yes** to save the changes.

After securing a Web application, the resulting Web archive (WAR) file contains security information in its deployment descriptor. The Web module security information is stored in the `web.xml` file. When you work in the Web deployment descriptor editor, you also can edit other deployment descriptors in the Web project, including information on bindings and IBM extensions in the `ibm-web-bnd.xmi` and `ibm-web-ext.xmi` files.

After using an assembly tool to secure a Web application, you can install the Web application using the administrative console. During the Web application installation, complete the steps in “Deploying secured applications” on page 937 to finish securing the Web application.

Security constraints

Security constraints determine how Web content is to be protected.

These properties associate security constraints with one or more Web resource collections. A constraint consists of a Web resource collection, an authorization constraint and a user data constraint.

- A Web resource collection is a set of resources (URL patterns) and HTTP methods on those resources. All requests that contain a request path that matches the URL pattern described in the Web resource collection are subject to the constraint. If no HTTP methods are specified, then the security constraint applies to all HTTP methods.
- An authorization constraint is a set of roles that users must be granted in order to access the resources described by the Web resource collection. If a user who requests access to a specified Uniform Resource Identifier (URI) is not granted at least one of the roles specified in the authorization constraint, the user is denied access to that resource.
- A user data constraint indicates that the transport layer of the client or server communications process must satisfy the requirement of either guaranteeing content integrity (preventing tampering in transit) or guaranteeing confidentiality (preventing reading while in transit).

Security settings

Use the administrative console to modify the security settings for all applications. You can enable security for applications by enabling the **Enable application security** option on the Secure administration, applications, and infrastructure panel.

Note that:

- Global settings apply to existing and future applications and cannot be customized.
- Default settings apply only to future applications and can be customized.

The default settings are used as a template or starting point for configuring individual applications. The administrator should still explicitly configure security settings for each application.

The following security settings are specified during application assembly:

Security role settings

When using the Assembly Toolkit at an application level (Enterprise Archive (EAR) file), security roles are synchronized with the security roles defined for the embedded modules of the application.

If a security role is manually added to the EAR file, it can be automatically removed when the file is saved if an embedded module does not reference the role, or the role is in conflict with an existing role. In this case, remove the manually added role, but then all roles with the same name are removed.

The role is automatically added again when the file is saved if it is still referenced in an embedded module file. If a duplicate role is added in an embedded module file, delete all roles with the same name and manually read the correct role.

Security constraints

Security constraints declare how to protect Web content. These properties associate security constraints with one or more Web resource collections. A *constraint* consists of a Web resource collection, an authorization constraint, and a user data constraint.

Security constraints are set when configuring a Web application in the Assembly Toolkit.

Security role references

Web application developers or Enterprise JavaBeans (EJB) providers must use a role-name in the code when using the available programmatic security Java 2 Platform, Enterprise Edition (J2EE) application programming interfaces (APIs) `isUserInRole(String roleName)` and `isCallerInRole(String roleName)`.

The roles used in the deployed run-time environment might not be known until the Web application and EJB components (for example, Web archive (WAR) files and `ejb-jar.xml` files) are assembled into an enterprise archive (EAR) file. Therefore, the role names used in the Web application or EJB component code are logical role names which the application assembler maps to the actual run-time environment roles during application assembly. The security role references provide a level of indirection that insulate Web application component and EJB developers from having to know the actual roles in the run-time environment.

The definition of the logical roles and the mapping to the actual run-time environment roles are specified in the `security-role-ref` element of both the Web application and the EJB JAR file deployment descriptors, `web.xml` and `ejb-jar.xml` respectively. Use the assembly tools to define the role names and map them to the actual run-time roles in the environment with the `role-link` element.

The following code sample is an example of a `security-role-ref` from an EJB `ejb-jar.xml` deployment descriptor.

```
... <enterprise-beans>
... <entity>
<ejb-name>AardvarkPayroll</ejb-name>
<ejb-class>com.aardvark.payroll.PayrollBean</ejb-class>
...
<security-role-ref>
<description>
```

This role should be assigned to the employees of the payroll department. Members of this role have access to the payroll record of everyone. The role has been linked to the payroll-department role. This role should be assigned to the employees of the payroll department. Members of this role have access to all payroll records. The role has been linked to the payroll-department role.

```
</description> <role-name>payroll</role-name>
<role-link>payroll-department</role-link>
</security-role-ref>
...
</entity>
...
</enterprise-beans>
```

In the previous example, the string `payroll`, which appears in the `<role-name>` element, is what the EJB provider uses as the argument to the `isCallerInRole()` API. The `<role-link>` element is what ties the logical role to the actual role used in the run-time environment.

Note that for enterprise beans, the `security-role-ref` element must appear in the deployment descriptor even if the logical role name is the same as the actual role name in the environment.

The rules Web application components are slightly different. If no `security-role-ref` element matching a `security-role` element is declared, the container must default to checking the `role-name` element argument against the list of `security-role` elements for the Web application. The `isUserInRole` method references the list to determine whether the caller is mapped to a security role. The developer must be aware that the use of this default mechanism can limit the flexibility in changing role names in the application without having to recompile the servlet making the call.

See the EJB Version 2.0 and Servlet Version 2.3 specification in the Security: Resources for Learning article for complete details on this specification.

Securing applications during assembly and deployment

Several assembly tools exist that are graphical user interfaces for assembling enterprise or Java 2 Platform, Enterprise Edition (J2EE) applications. You can use these tools to assemble an application and secure Enterprise JavaBeans (EJB) and Web modules in that application.

An EJB module consists of one or more beans. You can enforce security at the EJB method level. A Web module consists of one or more Web resources: an HTML page, a JavaServer Pages (JSP) file, or a servlet. You can also enforce security for each Web resource.

Note: For information about the tools that WebSphere Application Server supports, see Assembly tools.

To secure an EJB module, a Java archive (JAR) file, a Web module, a Web archive (WAR) file, or an application enterprise archive (EAR) file, you can use an assembly tool. You can create an application, an EJB module, or a Web module and secure them using an assembly tool or development tools such as the IBM Rational Application Developer.

1. Secure EJB applications using an assembly tool. For more information, see “Securing enterprise bean applications” on page 943.
2. Secure Web applications using an assembly tool. For more information, see “Securing Web applications using an assembly tool” on page 923.
3. Add users and groups-to-roles while assembling a secured application using an assembly tool. For more information, see “Adding users and groups to roles using an assembly tool” on page 929.
4. Map users to RunAs roles using an assembly tool. For more information, see “Mapping users to RunAs roles using an assembly tool” on page 933.
5. “Adding the `was.policy` file to applications” on page 540.
6. Assemble the application components that you secured using an assembly tool. For more information, see Assembling applications.

After securing an application, the resulting `.ear` file contains security information in its deployment descriptor. The EJB module security information is stored in the `ejb-jar.xml` file and the Web module security information is stored in the `web.xml` file. The `application.xml` file of the application EAR file contains all the roles that are used in the application. The user and group-to-roles mapping is stored in the `ibm-application-bnd.xmi` file of the application EAR file.

The `was.policy` file of the application EAR contains the permissions granted for the application to access system resources protected by Java 2 security.

This task is required to secure EJB modules and Web modules in an application. This task is also required for applications to run properly when Java 2 security is enabled. If the `was.policy` file is not created and it does not contain required permissions, the application might not be able to access system resources.

After securing an application, you can install an application using the administrative console. When you install a secured application, refer to “Deploying secured applications” on page 937 to complete this task.

Assigning users and groups to roles

This topic describes how to assign users and groups to roles if you are using WebSphere Application Server authorization for Java 2 Platform, Enterprise Edition (J2EE) roles.

Before you perform this task:

- Secure the Web applications and Enterprise JavaBeans (EJB) applications where new roles are created and assigned to Web and enterprise bean resources.
- Create all the roles in your application.
- Verify that you have properly configured the user registry that contains the users that you want to assign. It is preferable to have security turned on with the user registry of your choice before beginning this process.
- Make sure that if you change anything in the security configuration you save the configuration and restart the server before the changes become effective. For example, enable security or change the user registry.

These steps are common for both installing an application and modifying an existing application. If the application contains roles, you see the Security role to user/group mapping link during application installation and also during application management, as a link in the Additional properties section.

1. Access the administrative console.

Type `http://server_name:port_number/ibm/console` in a Web browser.

2. Click **Applications > Enterprise applications > application_name**.
3. Under Detail properties, click **Security role to user/group mapping**. A list of all the roles that belong to this application is displayed. If the roles already have users or All Authentication or Everyone special subjects assigned, they display here.
4. To assign the special subjects, select either the **Everyone** or the **All Authenticated** option for the appropriate roles.
5. To assign users or groups, select the role. You can select multiple roles at the same time, if the same users or groups are assigned to all the roles.
6. Click **Look up users** or **Look up groups**.
7. Get the appropriate users and groups from the user registry by completing the Limit and the Search string fields and by clicking **Search**. The Limit field limits the number of users that are obtained and displayed from the user registry. The pattern is a searchable pattern matching one or more users and groups. For example, `user*` lists users like `user1`, `user2`. A pattern of asterisk (*) indicates all users or groups.

Use the limit and the search strings cautiously so as not to overwhelm the user registry. When you use large user registries such as Lightweight Directory Access Protocol (LDAP) where information on thousands of users and groups resides, a search for a large number of users or groups can make the system slow and can make it fail. When more entries exist than requests for entries, a message displays on top of the panel. You can refine your search until you have the required list.

8. Select the users and groups to include as members of these roles from the **Available** field and click **>>** to add them to the roles.
9. To remove existing users and groups, select them from the **Selected** field and click **<<**. When removing existing users and groups from roles, use caution if those same roles are used as RunAs roles.

For example, if the user1 user is assigned to the role1 RunAs role and you try to remove the user1 user from the role1 role, the administrative console validation does not delete the user. A user can only be part of a RunAs role if the user is already in a role either directly or indirectly through a group. In this case, the user1 user is in the role1 role. For more information on the validation checks that are performed between RunAs role mapping and user and group mapping to roles, see “Assigning users to RunAs roles” on page 932.

10. Click **OK**. If any validation problems exist between the role assignments and the RunAs role assignments, the changes are not committed and an error message that indicates the problem displays at the top of the panel. If a problem exists, make sure that the user in the RunAs role is also a member of the regular role. If the regular role contains a group that contains the user in the RunAs role, make sure that the group is assigned to the role using the administrative console. Follow steps 4 and 5. Avoid using the Application Server Toolkit or any other manual process where the complete name of the group, host name, group name, or distinguished name (DN) is not used.

The user and group information is added to the binding file in the application. This information is used later for authorization purposes.

This task is required to assign users and groups to roles, which enables the correct users and groups to access a secured application. If you are installing an application, complete your installation. After the application is installed and running you can access your resources according to the user and group mapping that you did in this task. If you manage applications and modify the users and groups to role mapping, make sure you save, stop, and restart the application so that the changes become effective. Try accessing the J2EE resources in the application to verify that the changes are effective.

Adding users and groups to roles using an assembly tool

After creating new roles and assigning them to enterprise bean and Web resources, use this task to add users and groups to roles with an assembly tool.

Before you perform this task, you already completed the steps in “Securing Web applications using an assembly tool” on page 923 and “Securing enterprise bean applications” on page 943 where you created new roles and assigned those roles to enterprise bean and Web resources. Complete these steps during application installation. The environment user registry under which the application is running is not known until deployment.

If you already know the environment in which the application is running and the user registry that is used, you can use an assembly tool to assign users and groups to roles. Using the administrative console to assign users and groups to roles is recommended.

Note: This procedure might not match the steps that are required when using your assembly tool, or match the version of the assembly tool that you are using. You should follow the instructions for the tool and version that you are using.

To add users and groups to roles using an assembly tool, follow these steps:

1. In the Project Explorer view of an assembly tool, right-click an enterprise application project, or Enterprise Archive (EAR) file, and click **Open With > Deployment Descriptor Editor**. An application deployment descriptor editor opens on the EAR file. To access information about the editor, press F1 and click **Application deployment descriptor editor**.
2. Click the **Security** tab and, under the main panel, click **Add**.
3. In the Add Security Role wizard, name and describe the security role. Click **Finish**.
4. Under WebSphere Bindings, select the user or group extension properties for the security role. Available values include: Everyone, All authenticated users, and Users/Groups.
5. If you selected Users/Groups, click **Add** beside the Users or Groups panes. In the wizard that opens, specify a user or group name and click **Finish**. Repeat this step until you added all the users and groups to which the security role applies.

6. Close the application deployment descriptor editor and, when prompted, click **Yes** to save the changes.

The `ibm-application-bnd.xml` file in the application contains the users and groups-to-roles mapping table, which is the *authorization table*.

After securing an application, install the application using the administrative console.

Mapping users to roles

Use this page to specify the users and groups that are mapped to the security roles that are used with the enterprise application.

To view this administrative console page, click **Application > Install new application**.

While using the Install New Application Wizard, prompts appear to help you map security roles to users. You also can configure security roles to user mappings of deployed applications. Different roles can have different security authorizations. Mapping users or groups to a role authorizes those users or groups to access applications defined by the role. Users, groups, and roles are defined when an application is installed or configured.

You also can select role to user and group mappings while you are deploying applications. After deployment, click **Security role to user/group mapping** under Detailed properties to change user and group mappings to a role.

Look up users:

Enables the server to locate the users that you can define for a particular security role.

Select the check box beside the role and click **Look up users**. Complete the Limit and the Search string fields. The Limit field contains the number of entries that the search function returns. The Search string field contains the search pattern used for searching entries. For example, `bob*` searches all users or groups starting with bob. A limit of zero returns all the entries that match the pattern. Use this value only when a small number of users or groups match this pattern in the registry. If the registry contains more entries that match the pattern than requested, a message appears in the console to indicate that there are more entries in the registry. You can either increase the limit or refine the search pattern to get all the entries.

Look up groups:

Enables the server to locate the groups that you can define for a particular security role.

Select the check box beside the role and click **Look up groups**. Complete the Limit and the Search string fields. The Limit field contains the number of entries that the search function returns. The Search string field contains the search pattern used for searching entries. For example, `bob*` searches all users or groups starting with bob. A limit of zero returns all the entries that match the pattern. Use this value only when a small number of users or groups match this pattern in the registry. If the registry contains more entries that match the pattern than requested, a message appears in the console to indicate that there are more entries in the registry. You can either increase the limit or refine the search pattern to get all the entries.

Role:

Maps specific capabilities to a user. Role privileges give users and groups permission to run as specified.

Select the check boxes to choose a role or a set of roles. Click **Look up users** to map users to the roles that you have selected. Click **Look up groups** to map groups to the selected roles. Use the check boxes to map roles to **EVERYONE** or **ALL AUTHENTICATED** special subject.

For example, you might map the user Joe to the administrator role, which enables user Joe to perform all of the tasks associated with the administrator role.

The authorization policy is only enforced when global security is enabled.

Everyone:

Specifies whether to map everyone to a specified role. When you map everyone to a role, anyone can access the resources that are protected by this role and, essentially, there is no security.

All authenticated:

Specifies whether to map all of the authenticated users to a specified role. When you map all authenticated users to a specified role, all of the valid users in the current registry who have been authenticated can access resources that are protected by this role.

Mapped users:

Lists the users that are mapped to the specified role within this application.

Mapped groups:

Lists the groups that are mapped to this specified role within this application.

Look up users and groups settings

Use this page to select users and groups for security roles.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Detail properties, click **Security role to user/group mapping**.
3. Select the role and click either **Look up users** or **Look up groups**.

Different roles can have different security authorizations. Mapping users or groups to a role authorizes those users or groups to access applications defined by the role. Users and groups are associated with roles defined in an application when the application is installed or configured. Use the Search pattern field to display users in the Available list. Click >> to add users from the Available list to the Selected list.

Limit:

Specifies the maximum number of users or groups that can be returned when assigning users/groups to roles.

A value of 0 implies a return of all users or groups that match the pattern. You can either increase the limit or refine the search pattern to get all the entries.

Data type	Integer
Units	User name
Default	20
Range	0 or more

Search string:

Indicates the search pattern used to search for the entries in a user registry.

The Search string field contains the search pattern that is used to search for the user or group entries. For example, bob* will search all users or groups starting with bob. A limit of zero (0) retrieves all of the entries that match the pattern. Use a limit of zero (0) only when a small number users or groups match that pattern in the user registry. If the user registry contains more entries that match the pattern than requested for, a message shows in the administrative console to indicate that there are more entries in the user registry.

Data type	String
Units	Number of users
Default	20
Range	A-Z with *

Assigning users to RunAs roles

This article explains how to assign users to the RunAs roles for your application.

Complete the following tasks:

- Secure the Web applications and the EJB applications where new RunAs roles are created and assigned to Web and EJB resources.
- Create all the RunAs roles in your application. The user in the RunAs role can only be entered if that user or a group to which that user belongs is already part of the regular role.
- Assign users and groups to security roles. Refer to “Assigning users and groups to roles” on page 928 for more information.
- Verify that the user registry requirements are met. These requirements are the same as those discussed in “Assigning users and groups to roles” on page 928. For example, if the role1 role is a role that is also used as a RunAs role, then the user1 user can be added to the RunAs role. The administrative console checks this logic when **Apply** or **OK** is clicked. If the check fails, the change is not made and an error message is displayed at the top of the panel.

When a user ID and password is assigned to a RunAs role, validation occurs using the current active user registry that is configured. By default, the local operating system registry is set as the active user registry. Therefore, when an application is installed and security is disabled on the server, the local operating system registry is used to validate the user ID and password that is assigned to the RunAs Role. If the intended registry for the application is not local operative system, the validation fails. Therefore, map RunAs roles to users when the security is enabled on the server. However, if the active user registry and the intended registry after enabling security are the same, you can assign the user to a RunAs role when security is disabled.

If the Everyone or All Authenticated special subjects are assigned to a role, validation does not occur for that role.

Validation is done every time you click **Apply** in this panel or when you click **OK** in the Security role to user/group mapping panel. The check verifies that all the users in all the RunAs roles do exist directly or indirectly through a group in those roles in the Security role to user/group mappings panel. If a role is assigned both a user and a group to which that user belongs, you can delete either the user or the group from the Security role to user/group mapping panel.

If the RunAs role user belongs to a group and if that group is assigned to that role, make sure that the assignment of this group to the role is done through the administrative console and not through an assembly tool or other method. When using the administrative console, the full name of the group is used (for example, hostname\groupName in Windows systems and distinguished names (DN) in Lightweight Directory Access Protocol (LDAP)). During the check, all the groups to which the RunAs role user belongs are obtained from the user registry. Because the list of groups that are obtained from the user registry are the full names of the groups, the check works correctly. If the short name of a group is entered using an assembly tool, for example group1 instead of CN=group1, o=myCompany.com, this check fails.

These steps are common to both installing an application and modifying an existing application. If the application contains RunAs roles, you see the User RunAs roles link during application installation and also during managing applications as a link in the Additional properties section.

1. Click **Applications > Enterprise Applications > *application_name***.
2. Under Additional properties, click **User RunAs roles**. A list of all the RunAs roles that belong to this application display. If the roles already have users assigned, they display here.
3. To assign a user, select the role. You can select multiple roles at the same time if the same user is assigned to all the roles.
4. Enter the user's name and password in the designated fields. The user name entered can be either the short name, which is preferred, or the full name, as seen when getting users and groups from the user registry.
5. Click **Apply**. The user is authenticated using the active user registry. If authentication is successful, a check is made to verify that this user or group is mapped to the role in the Map security roles to users and groups panel. If authentication fails, verify that the user and password are correct and that the active registry configuration is correct.
6. To remove a user from a RunAs role, select the roles and click **Remove**.

The RunAs role user is added to the binding file in the application. This file is used for delegation purposes when accessing J2EE resources. This step is required to assign users to RunAs roles so that during delegation the appropriate user is used to invoke the EJB methods.

If you are installing the application, complete installation. After the application is installed and running, you can access your resources according to the RunAS role mapping. Save the configuration.

If you manage applications and modify User RunAs roles, make sure you save, stop, and restart the application so that the changes become effective. Try accessing your Java 2 Platform, Enterprise Edition (J2EE) resources to verify that the new changes are in effect.

Mapping users to RunAs roles using an assembly tool:

RunAs roles are used for delegation. A servlet or enterprise bean component uses the RunAs role to invoke another enterprise bean by impersonating that role.

Before you perform this task:

- Secure the Web application and enterprise bean applications, including creating and assigning new roles to enterprise bean and Web resources. For more information, see “Securing Web applications using an assembly tool” on page 923 and “Securing enterprise bean applications” on page 943.
- Assign users and groups to roles. For more information, see “Adding users and groups to roles using an assembly tool” on page 929. Complete this step during the installation of the application. The environment or user registry under which the application is going to run is not known until deployment. If you already know the environment in which the application is going to run and you know the user registry, then you can use an assembly tool to assign users to RunAs roles.

Note: This procedure might not match the steps that are required when using your assembly tool, or match the version of the assembly tool that you are using. You should follow the instructions for the tool and version that you are using.

To define RunAs roles when a servlet or an enterprise bean in an application is configured with RunAs settings, perform these steps:

1. In the Project Explorer view of an assembly tool, right-click an enterprise application project or Enterprise Archive (EAR) file and click **Open With > Deployment Descriptor Editor**. An application deployment descriptor editor opens on the EAR file. To access information about the editor, press F1 and click **Application deployment descriptor editor**.
2. On the Security tab, under Security Role Run As Bindings, click **Add**.

3. Click **Add** under RunAs Bindings.
4. In the Security Role wizard, select one or more roles and click **Finish**.
5. Repeat steps 3 through 5 for all the RunAs roles in the application.
6. Close the application deployment descriptor editor and, when prompted, click **Yes** to save the changes.

The `ibm-application-bnd.xml` file in the application contains the user to RunAs role mapping table.

After securing an application, you can install the application using the administrative console. You can change the RunAs role mappings of an installed application. For more information, see “User RunAs collection” on page 936.

Ensure all unprotected 1.x methods have the correct level of protection:

Use this page to verify that the unprotected Enterprise JavaBeans (EJB) Version 1.x methods have the correct level of protection before you map users to roles.

This administrative console panel is displayed during the application deployment process. To access the administrative console panel, click **Application > Install new application > application_name**. The panel is displayed as *Ensure all unprotected 1.x methods have the correct level of protection* in the application deployment steps. On this administrative console panel, you can specify whether users can access specific EJB modules.

EJB module:

Specifies the EJB module name.

URI:

Specifies the Uniform Resource Identifier (URI) that is used to locate the Java archive (JAR) file for the EJB module.

Deny all access:

Select this option to protect this EJB module by making it inaccessible to users regardless of their access permissions.

Default: Cleared

Ensure all unprotected 2.x methods have the correct level of protection:

Use this page to verify that the unprotected Enterprise JavaBeans (EJB) Version 2.x methods have the correct level of protection before you map users to roles.

This administrative console panel is displayed during the application deployment process. To access the administrative console panel, click **Application > Install new application > application_name**. The panel is displayed as *Ensure all unprotected 2.x methods have the correct level of protection* in the application deployment steps. On this administrative console panel, you can specify whether users can access specific EJB modules.

To use this administrative console page, select the **Uncheck**, **Exclude**, or **Role** option, the check box next to the EJB module, and click **Apply**. If you select **Role** option, select the appropriate role for the EJB module before you click **Apply**.

Uncheck:

Select this option if you do not want the application server to verify the access permissions for the EJB module. Everyone can access the EJB module.

Default: Selected

Exclude:

Select this option to protect this EJB module by making it inaccessible to users regardless of their access permissions.

Default: Deselected

Role:

Specifies the EJB level of protection based on the security role.

The roles listed in this menu are obtained from the application scope. If the selected role is not in the module, then it is added to the modules or Java archive (JAR) files.

Default: Deselected

EJB module:

Specifies the name of the module.

If a module name appears in this list, then the module contains unprotected EJB methods.

URI:

Specifies the Uniform Resource Identifier (URI) that is used to locate the Java archive (JAR) file for the EJB module.

Protection type:

Specifies the level of protection that is assigned to a particular module name.

After you select the **Uncheck**, **Exclude**, or **Role** option and click **Apply**, the selected protection option is displayed in this column.

Correct use of the system identity:

Use this page to manage the system identity properties for the Enterprise JavaBeans (EJB) method in your application.

This administrative console panel is displayed during the application deployment process. To access the administrative console panel, click **Applications > Install new application > application_name**. The panel is displayed as *Correct use of System Identity* in the application deployment steps.

To use this panel, complete the following steps:

1. Select the check box next to the EJB method.
2. Select a role that is defined for this enterprise bean.
3. Specify a user name and password for the RunAs role. The user name must be defined in your user registry.
4. Click **Apply**.

The specified user will be assigned to the specified RunAs role for the EJB method that you selected.

Role:

Specifies the RunAs role that is used for this EJB method.

Username:

Specifies the user name that is assigned to the RunAs role for this EJB method.

The user name is used in conjunction with the RunAs role that you select for the Role.

Password:

Specifies the password that is associated with the user name in the user registry.

User RunAs collection:

Use this page to map a specified user identity and password to a RunAs role. This panel enables you to specify application-specific privileges for individual users to run specific tasks using another user identity.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Detail properties, click **User RunAs roles**.

The enterprise beans that you install contain predefined RunAs roles. RunAs roles are used by enterprise beans that need to run as a particular role for recognition while interacting with another enterprise bean.

Username:

Specifies a user name for the RunAs role user.

This user already maps to the role specified in the Mapping users and groups to roles panel. You can map the user to its appropriate role by either mapping the user to that role directly or mapping a group that contains the user to that role. After you specify the user name and password for the user and select a RunAs role, click **Apply**.

Data type: String

Password:

Specifies the password for the RunAs user.

Data type: String

Role:

Maps specific capabilities to a user.

The authorization policy is only enforced when global security is enabled.

Updating and redeploying secured applications

This section addresses the way to update existing applications.

Before you perform this task, secure Web applications, secure Enterprise JavaBeans (EJB) applications, and deploy them in WebSphere Application Server.

1. Use the administrative console to modify the existing users and groups mapping to roles. For information on the required steps, see “Assigning users and groups to roles” on page 928.
2. Use the administrative console to modify the users for the RunAs roles. For information on the required steps, see “Assigning users to RunAs roles” on page 932.
3. Complete and save the changes.
4. Stop and restart the application for the changes to become effective.
5. Use an assembly tool. For more information, see Assembling applications.
6. Use an assembly tool to modify roles, method permissions, auth-constraints, data-constraints and so on. For more information, see Assembling applications.
7. Save the enterprise archive (EAR) file, uninstall the old application, deploy the modified application and start the application to make the changes effective.

The applications are modified and redeployed. This step is required to modify existing secured applications.

If information about roles is modified, make sure that you update the user and group information using the administrative console. After the secured applications are modified and either restarted or redeployed, verify that the changes are effective by accessing the resources in the application.

Deploying secured applications

Deploying applications that have security constraints (secured applications) is not much different than deploying applications that do not contain any security constraints. The only difference is that you might need to assign users and groups to roles for a secured application. The secured application requires that you have the correct active user registry.

Before you perform this task, verify that you already designed, developed, and assembled an application with all the relevant security configurations. For more information on these tasks refer to “Developing applications that use programmatic security” on page 525 and “Securing applications during assembly and deployment” on page 927. In this context, deploying and installing an application are considered the same task.

To deploy a newly secured application click **Applications > Install New Application** and follow the prompts to complete the installation steps. One of the required steps to deploy secured applications is to assign users and groups to roles that are defined in the application.

- If you are installing a secured application, roles will be defined in the application.
- If delegation is required in the application, you will be defining RunAs roles also.

During the installation of a new application, the role definition is completed as part of the step that maps security roles to users and groups. If this assignment has already been completed by using an assembly tool, you can still confirm the mapping by going through this installation step. You can add new users and groups and modify existing information during this step.

If the application supports delegation, a RunAs role will already be defined in the application. If the delegation policy is set to `Specified Identity` during assembly, the intermediary invokes a method by using an identity setup during deployment. Use the RunAs role to specify the identity under which the downstream invocations are made. For example, if the RunAs role is assigned user `bob` and the client `alice` is invoking a servlet, with delegation set that calls the enterprise beans, the method on the enterprise beans is invoked with `bob` as the identity.

As part of the new application installation and deployment process, one of the steps is to map or modify users to the RunAs roles. Use this step to assign new users or modify existing users to RunAs roles when the delegation policy is set to Specified Identity.

Note that the steps are common whether you are installing an application or modifying an existing application.

To install and deploy the application, complete the following steps.

1. Click **Applications > Install New Application**. Complete the required steps until you see the step for mapping security roles to users and groups.
2. If the application contains roles, assign users and groups to roles. At this step during the installation, under Additional Properties, click **Map security roles to users and groups**. For more information, see “Assigning users and groups to roles” on page 928.
3. If RunAs roles exist in the application, assign users to RunAs roles. At this step during the installation, under Additional Properties, click **Map RunAs roles to users**. For more information, see “Assigning users to RunAs roles” on page 932.
4. **Optional:** Click **Correct use of System Identity** to specify RunAs roles, if needed. Complete this action if the application has delegation set to use system identity, which is applicable to enterprise beans only. System identity uses the WebSphere Application Server security server ID to invoke downstream methods. Using system identity is not recommended as this ID has more privileges than other identities in accessing WebSphere Application Server internal methods. This task is provided to make sure that the deployer is aware that the methods listed in the panel have system identity set up for delegation and to correct them if necessary. When the internalServerId feature is used, runAs with system identity is not supported; you must specify RunAs roles here.
5. Complete the remaining non-security related steps to finish installing and deploying the application.

After a secured application is deployed, verify that you can access the resources in the application with the correct credentials. For example, if your application has a protected Web module, make sure only the users that you assigned to the roles can use the application.

Chapter 13. SIP applications

Securing SIP applications

You can apply digest authentication and Trust Association Interceptor (TAI) for a SIP application by applying Lightweight Directory Access Protocol (LDAP) security to the application.

Before you can apply security, you must first deploy an application that has been developed to support security (with the web.xml file configured for security) and roles. The following software must also be installed:

1. Install Tivoli Directory Server version 5.2
2. Set up and activate Lightweight Third Party Authentication. For more information, see the Lightweight Third Party Authentication section.

To apply LDAP security to a SIP application, click **Applications** → **Enterprise Applications** → **applicationName** and complete the following steps:

1. Click **Detail Properties** → **Security role to user/group mapping**.
2. Check **All Authenticated**.
3. Save all changes.
4. Restart the server.

Configuring security for the SIP container

This section provides instructions specific to security for the SIP container, employed with software such as Tivoli Directory Server or Oracle Internet Directory.

Before you can configure security for your SIP container, you will need to:

1. Set up and activate Lightweight Third Party Authentication. For more information, see the Lightweight Third Party Authentication section.
2. Install Oracle Internet Directory or Tivoli Directory Server.

You may also need to:

- Adjust key group settings. Refer to Lightweight Third Party Authentication key sets and key set groups for LTPA key information.
- Establish and configure Trust Association Interceptor (TAI) settings. Refer to Trust association interceptor settings.

You must know the name of the key set group and the management scope where the key set group is defined in order to activate and secure LTPA with keys. Refer to Activating Lightweight Third Party Authentication key versions for the setup and activation procedures.

To configure security based on the Lightweight Directory Access Protocol (LDAP), you can configure digest authentication by using either Tivoli Directory Server or Oracle Internet Directory.

- To configure digest authentication and TAI on WebSphere Application Server for Tivoli, select “Configuring digest authentication and TAI for Tivoli Directory Server” on page 940.
- For configuring digest authentication on WebSphere Application Server for Oracle Internet Directory, select “Configuring digest authentication for Oracle Internet Directory” on page 941.

If setting up a TAI you will need to specify the trust information for any reverse security proxy servers. See “Trust association interceptor settings” on page 225 to configure TAI settings.

Configuring digest authentication and TAI for Tivoli Directory Server

You can configure digest authentication and Trust Association Interceptor (TAI) for IBM Tivoli Directory Server.

To configure digest authentication and TAI on WebSphere Application Server, you will need to:

- Install Tivoli Directory Server version 5.2
- Set up and activate Lightweight Third Party Authentication. For more information, see the Lightweight Third Party Authentication section.
- You also may want to refer to the section Configuring a custom trust association interceptor for more TAI information.

Complete the following procedure to configure digest authentication and TAI on WebSphere Application Server:

1. To set up digest authentication, verify that **Lightweight Third Party Authentication (LTPA)** is configured for use on your server by selecting **Security** → **Secure administration, applications, and infrastructure** → **Authentication mechanisms**. In the **Configuration** tab on the **Authentication mechanisms and expiration** page you should see the **Password** field already filled in.
2. In the administrative console, click **Security** → **Secure administration, applications, and infrastructure**.
 - a. Under **Authentication**, expand **Web security** and click on **Trust association**.
 - b. On the **Configuration** tab, under **General properties**, make sure the **Enable trust association** box is checked. Then click **Apply**.
3. On the **Interceptors** page of the administration console look for `com.ibm.ws.sip.security.digest.DigestTAI` in the **Interceptor class name** list:
 - a. If this class name is not present, click **New** to open the Configuration tab and enter `com.ibm.ws.sip.security.digest.DigestTAI` in the **Interceptor class name** field and click **Apply**. Then proceed to the following steps.
 - b. If this interceptor class is present, you may proceed to set up a realm in digest authentication. To do this, click **com.ibm.ws.sip.security.digest.DigestTAI** → **Custom Properties**:
 - c. Click **OK**.
4. Navigate through **Security** → **Secure administration, applications, and infrastructure** → **Authentication mechanisms and expiration** to the **Configuration** tab.
 - a. In the **Key generation** section, click **Generate Keys**. (No import or export of the key is necessary.)
 - b. Under the Cross-cell single sign-on section fill in the **Password** fields.
 - c. Fill in the **Internal server ID** field.
 - d. Click **OK**.
5. Click to **Security** → **Secure administration, applications, and infrastructure**.
 - a. If the box **Use Java 2 security to restrict application access to local resources** is checked, click to deselect it.
 - b. In the **User account repository** section of the page, select your LDAP registry from the **Available realm definitions** drop-down box.
 - c. Click **Set as current** and then click **Apply**.
6. Save all changes.
7. Restart the server.
8. Be sure you see the following message appear in the SystemOut.log after the server has restarted:
`SECJ0121I: Trust Association Init class com.ibm.ws.sip.security.digest.DigestTAI loaded successfully`

If this message does not appear in the log, digest authentication has not been activated.

Configuring digest authentication for Oracle Internet Directory

You can configure digest authentication for Oracle Internet Directory, an implementation of the Lightweight Directory Access Protocol (LDAP) that uses the Oracle database as a repository for directory entries.

To configure digest authentication for Oracle Internet Directory, you will need to:

- Install Oracle Internet Directory version 9.0.2.
- Set up and activate Lightweight Third Party Authentication. For more information, see the Lightweight Third Party Authentication section.
- You also may want to refer to the section Configuring a custom trust association interceptor for more TAI information.

Complete the following procedure to configure digest authentication for Oracle Internet Directory on WebSphere Application Server:

1. To set up digest authentication, verify that **Lightweight Third Party Authentication (LTPA)** is configured for use on your server by selecting **Security** → **Secure administration, applications, and infrastructure** → **Authentication mechanisms**. In the **Configuration** tab on the **Authentication mechanisms and expiration** page you should see the **Password** field already filled in.
2. In the administrative console, click **Security** → **Secure administration, applications, and infrastructure**.
 - a. Under **Authentication**, expand **Web security** and click on **Trust association**.
 - b. On the **Configuration** tab, under **General properties**, make sure the **Enable trust association** box is checked. Then click **Apply**.
3. On the **Interceptors** page of the administration console look for `com.ibm.ws.sip.security.digest.SIPDigestOID` in the **Interceptor class name** list:
 - a. If this class name is not present, click **New** to open the Configuration tab and enter `com.ibm.ws.sip.security.digest.SIPDigestOID` in the **Interceptor class name** field and click **Apply**. Then proceed to the following steps.
 - b. If this interceptor class is present, you may set up custom properties for it. To do this, click **com.ibm.ws.sip.security.digest.SIPDigestOID** → **Custom Properties**:
 - c. Click **OK**.
4. Navigate through **Security** → **Secure administration, applications, and infrastructure** → **Authentication mechanisms and expiration** to the **Configuration** tab.
 - a. In the **Key generation** section, click **Generate Keys**. (No import or export of the key is necessary.)
 - b. Under the Cross-cell single sign-on section fill in the **Password** fields.
 - c. Fill in the **Internal server ID** field.
 - d. Click **OK**.
5. Click to **Security** → **Secure administration, applications, and infrastructure**.
 - a. If the box **Use Java 2 security to restrict application access to local resources** is checked, click to deselect it.
 - b. In the **User account repository** section of the page, select your LDAP registry from the **Available realm definitions** drop-down box.
 - c. Click **Set as current** and then click **Apply**.
6. Save all changes.
7. Restart the server.
8. Be sure you see the following message appear in the SystemOut.log after the server has restarted:

```
SECJ0121I: Trust Association Init class  
com.ibm.ws.sip.security.digest.SIPDigestOID loaded successfully
```

If this message does not appear in the log, digest authentication has not been activated.

Configuring a custom trust association interceptor

How to configure a custom trust association interceptor (TAI).

Before you can configure a custom TAI, you must enable global security after you install the following software:

1. WebSphere Application Server version 6.1
2. Tivoli Directory Server version 5.2
3. Verify that **Lightweight Third Party Authentication (LTPA)** is configured for use on your server by selecting **Security** → **Secure administration, applications, and infrastructure** → **Authentication mechanisms**. In the **Configuration** tab on the **Authentication mechanisms and expiration** page you should see the **Password** field already filled in.

To configure a custom TAI, you may want to familiarize yourself with the general TAI information contained in the Trust Associations documentation. You also may want to refer to the Developing a custom trust association interceptor topic for information about the Java class extensions.

The JAR file that contains your custom TAI should be deployed in the application server environment in a location that is accessible by the security portions of the application server runtime. They reside in the *WASProductDir*/plugins directory for the application server nodes. You may encounter problems if you try to place your TAI under a shared library for just the application server.

To configure your custom TAI, complete the following steps (for more details, see the “TAI usage” section of IBM WebSphere Developer Technical Journal: Advanced authentication in WebSphere Application Server):

1. Install your TAI JAR file in the *WASProductDir*/plugins directory.
2. From the WebSphere Application Server administrative console, navigate to **Security** → **Secure administration, applications, and infrastructure**
3. Under **Authentication**, expand **Web security** and click on **Trust association**.
4. On the **Configuration** tab, under **General properties**, make sure the **Enable trust association** box is checked. Then click **Apply**.
5. To create the new custom class, navigate to **Trust association** → **Configuration** tab (see step 4 above) and under **Additional properties**, click **Interceptors**.
6. Click **New** and enter the fully qualified class name to your custom TAI class, and click **Apply**.
7. If your TAI depends on custom properties, navigate to **Trust association** → **Configuration** tab (see step 4 above) and under **Additional properties**, click **Interceptors**. Select your Interceptor class name list. In the **Configuration** tab that opens, click on **Custom properties** Type the name and value pairs for the properties on which your TAI depends, and click **Apply**.
8. Save your configuration, and then restart your server to make your TAI fully operational.

Chapter 14. EJB applications

Securing enterprise bean applications

You can protect enterprise bean methods by assigning security roles to them. Before you assign security roles, you need to know which Enterprise JavaBeans (EJB) methods need protecting and how to protect them.

Note: This procedure might not match the steps that are required when using your assembly tool, or match the version of the assembly tool that you are using. You should follow the instructions for the tool and version that you are using.

To secure enterprise bean applications, follow these steps:

1. In an assembly tool, import your Enterprise JavaBean (EJB) Java Archive (JAR) file or an application archive (EAR) file that contains one or more Web modules.
See the information about importing an EJB JAR file or importing an enterprise application EAR file in the Application Server Toolkit (AST) documentation.
2. In the Project Explorer, click **EJB Projects** directory and click the name of your application.
3. Right-click the deployment descriptor and click **Open with > Deployment Descriptor Editor**. If you selected an enterprise bean .jar file, an EJB deployment descriptor editor opens. If you select an application .ear file, an application deployment descriptor editor opens. To see online information about the editor, press **F1** and click the editor name.
4. Create security roles. You can create security roles at the application level or at the EJB module level. If you create a security role at the EJB module level, the role displays in the application level. If a security role is created at the application level, the role does not display in all the EJB modules. You can copy and paste one or more EJB module security roles that you create at application level:
 - Create a role at an EJB module level. In an EJB deployment descriptor editor, click the **Assembly** tab. Under Security Roles, click **Add**. In the Add Security Role wizard, name and describe the security role and click **Finish**.
 - Create a role at the application level. In an application deployment descriptor editor, select the **Security** tab. Under the list of security roles, click **Add**. In the Add Security Role wizard, name and describe the security role; then click **Finish**.
5. Create method permissions. Method permissions map one or more methods to a set of roles. An enterprise bean has four types of methods: home methods, remote methods, LocalHome methods and local methods. You can add permissions to enterprise beans on the method level. You cannot add a method permission to an enterprise bean unless you already have one or more security roles defined. For Version 2.0 EJB projects, an unselected option specifies that the selected methods from the selected beans do not require authorization to run. To add a method permission to an enterprise bean:
 - a. On the **Assembly** tab of an EJB deployment descriptor editor, under **Method Permissions**, click **Add**. The Add Method Permission wizard is opened.
 - b. Select a security role from the list of roles found and click **Next**.
 - c. Select one or more enterprise beans from the list of beans found. You can click **Select All** or **Deselect All** to select or clear all of the enterprise beans in the list. Click **Next**.
 - d. Select the methods that you want to bind to your security role. The Method elements page lists all the methods that are associated with the enterprise beans. You can click **Apply to All** or **Deselect All** to quickly select or clear multiple methods. The selection affects the default (*) method for each bean only. Creating a method permission for the exact method signature overrides the default (*) method permission setting. The default (*) method represents all the methods within the bean. There are default (*) methods for each interface as well. By not selecting all of the individual methods in the tree, you can set other permissions on the remaining methods.
 - e. Click **Finish**.

After the method permission is created, you can see the new method permission in the tree. Expand the tree to see the bean and the methods that are defined in the method permission.

6. Exclude user access to methods. Users cannot access excluded methods. Any method in the enterprise beans that is not assigned to a role or that is not excluded, is cleared during the application installation by the deployer.
 - a. On the **Assembly** tab of an EJB deployment descriptor editor, under **Excludes List**, click **Add**. The Exclude List wizard is opened.
 - b. Select one or more enterprise beans from the list of beans found and click **Next**.
 - c. Select one or more of the method elements for the security identity and click **Finish**.
7. Map the security-role-ref and role-name to the role-link. When developing enterprise beans, you can create the security-role-ref element. The security-role-ref element contains only the role-name field. The role-name field determines if the caller is in a specified role(isCallerInRole()) role and contains the name of the role that is referenced in the code. Because you create security roles during the assembly stage, the developer uses a *logical role name* in the **role-name** field and provides enough information in the **Description** field for the assembler to map the actual role (role-link). The security-role-ref element is located at the EJB level. Enterprise beans can have zero or more security-role-ref elements.
 - a. On the **Reference** tab of an EJB deployment descriptor editor, under the list of references, click **Add**. The Add Reference wizard is opened.
 - b. Select **Security role reference** and click **Next**.
 - c. Name the security role reference, select a security role to link the reference to, describe the security role reference, and click **Finish**.
 - d. Map every role-name that is used during development to the role (role-link) using the previous steps.
8. Specify the RunAs identity for enterprise bean components. The RunAs identity of the enterprise bean is used to invoke the next enterprise beans in the chain of EJB invocations. When the next enterprise beans are invoked, the RunAsIdentity identity passes to the next enterprise beans for performing an authorization check on the next enterprise bean. If the RunAs identity is not specified, the client identity is propagated to the next enterprise bean. The RunAs identity can represent each of the enterprise beans or can represent each method in the enterprise beans.
 - a. On the **Access** tab of an EJB deployment descriptor editor, next to the **Security Identity (Bean Level)** field, click **Add**. The Add Security Identity wizard is opened.
 - b. Select the appropriate run as mode, describe the security identity, and click **Next**. Select the **Use identity of caller** mode to instruct the security service to not make changes to the credential settings for the principal. Select the **Use identity assigned to specific role (below)** mode to use a principal that is assigned to the specified security role for running the bean methods. This association is part of the application binding in which the role is associated with the user ID and password of a user who is granted that role. If you select the **Use identity assigned to specific role (below)** mode , you must specify a role name and role description.
 - c. Select one or more enterprise beans from the list of beans found and click **Next**. If Next is unavailable, click **Finish**.
 - d. **Optional:** On the Method elements page, select one or more of the method elements for the security identity and click **Finish**.
9. Close the deployment descriptor editor and, when prompted, click **Yes** to save the changes.

After securing an EJB application, the resulting .jar file contains security information in its deployment descriptor. The security information of the EJB modules is stored in the ejb-jar.xml file.

After securing an EJB application using an assembly tool, you can install the EJB application using the administrative console. During the installation of a secured EJB application, follow the steps in the “Deploying secured applications” on page 937 article to complete the task of securing the EJB application.

Configuring security for EJB 2.1 message-driven beans

Use this task to configure resource security and security permissions for Enterprise JavaBeans (EJB) Version 2.1 message-driven beans.

The association between connection factories, destinations, and message-driven beans is provided by listener ports. A listener port allows a deployed message-driven bean associated with the port to retrieve messages from the associated destination. You create listener ports by specifying their administrative name, the connection factory JNDI name, and the destination name (other optional properties are also configurable). Listener ports provide simplified administration of the associations between connection factories, destinations and message-driven beans, and are managed by a listener manager. The listener manager is provided by the message listener service to control and monitor the JMS listeners that are monitoring JMS destinations on behalf of deployed message-driven beans. For more information about listener ports, see *Message-driven beans - listener port components*

Messages handled by message-driven beans have no client credentials associated with them. The messages are anonymous.

To call secure enterprise beans from a message-driven bean, the message-driven bean needs to be configured with a RunAs Identity deployment descriptor. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component.

For more information about EJB security, see *EJB component security*. For more information about configuring security for your application, see *Assembling secured applications*.

Connections used by message-driven beans can benefit from the added security of using J2C container-managed authentication. To enable the use of J2C container authentication aliases and mapping, define an authentication alias on the J2C activation specification that the message-driven bean is configured with. If defined, the message-driven bean uses the authentication alias for its JMSConnection security credentials instead of any application-managed alias.

To set the authentication alias, you can use the administrative console to complete the following steps. This task description assumes that you have already created an activation specification. If you want to create a new activation specification, see the related tasks.

- For a message-driven bean listening on a JMS destination of the default messaging provider, set the authentication alias on a JMS activation specification.
 1. To display the JMS activation specification settings, click **Resources** → **JMS Providers** → **Default messaging** → **[Activation Specifications] JMS activation specification**
 2. If you have already created a JMS activation specification, click its name in the list displayed. Otherwise, click **New** to create a new JMS activation specification.
 3. Set the **Authentication alias** property.
 4. Click **OK**
 5. Save your changes to the master configuration.
- For a message-driven bean listening on a destination (or endpoint) of another JCA provider, set the authentication alias on a J2C activation specification.
 1. To display the J2C activation specification settings, click **Resources** → **Resource Adapters** → **adapter_name** → **J2C Activation specifications** → **activation_specification_name**
 2. Set the **Authentication alias** property.
 3. Click **OK**
 4. Save your changes to the master configuration.

Chapter 15. Client applications

Accessing secure resources using SSL and applet clients

By default, the applet client is configured to have security enabled. If you have administrative security turned on at the server from which you are accessing resources, then you can use secure sockets layer (SSL) when needed.

If you decide that the security requirements for the applet differ from other application client types, then create a new version of the `sas.client.props` and `ssl.client.props` files.

1. Make a copy of the following files so that you can use them for an applet:
 - `<app_client_root>\properties\sas.client.props`
 - `<app_client_root>\properties\ssl.client.props`
2. Edit the copies of the `sas.client.props` and `ssl.client.props` files that you made with your changes.
3. Click **Start > Control panel** > select the product Java plug-in to open the Java control panel. To use the files you created in step 1, modify the following values:
 - `-Dcom.ibm.CORBA.ConfigURL=file:<app_client_root>\properties\sas.client.props`
 - `-Dcom.ibm.SSL.ConfigURL=file:<app_client_root>\properties\ssl.client.props`

For more information on the `sas.client.props` and `ssl.client.props` files and WebSphere Application Server security, see the Security section of the information center.

Applet client security requirements

When code is loaded, it is assigned permissions based on the security policy in effect. This policy specifies the permissions that are available for code from various locations. You can initialize this policy from an external policy file.

By default, the client uses the `<app_server_root>/properties/client.policy` file. You must update this file with the following permission:

SocketPermission grants permission to open a port and make a connection to a host machine, which is your WebSphere Application Server. In the following example, `yourserver.yourcompany.com` is the complete host name of your WebSphere Application Server:

```
permission java.util.PropertyPermission "*", "read";
permission java.net.SocketPermission "yourserver.yourcompany.com", "connect";
```

Chapter 16. Web services

Configuring HTTP outbound transport level security with the administrative console

This topic explains how to configure HTTP outbound transport level security with the administrative console.

This task is one of several ways that you can configure the HTTP outbound transport level security for a Web service acting as a client to another Web service server. You can also configure the HTTP outbound transport level security with an assembly tool or by using the Java properties. If you do not configure the HTTP outbound transport level security, the Web services runtime defers to the Java 2 Platform, Enterprise Edition (J2EE) security runtime in the WebSphere product for an effective Secure Sockets Layer (SSL) configuration. If there is no SSL configuration with the J2EE security runtime in the WebSphere product, the Java Secure Socket Extension (JSSE) system properties are used.

If you choose to configure the HTTP outbound transport level security with the administrative console or an assembly tool, the Web services security binding information is modified. You can use the administrative console to configure the Web services client security bindings if you have deployed or installed the Web services application into WebSphere Application Server. If you have not installed the Web services application, you can configure the HTTP SSL configuration with an assembly tool. This task assumes that you have deployed the Web services application into the WebSphere product.

If you configure the HTTP outbound transport level security using the standard Java properties for JSSE, the properties are configured as system properties. The configuration specified in the binding takes precedence over the Java properties. However, the configurations that are specified by the J2EE security programming model, or that are associated the Dynamic selection, have higher precedence.

Review the topic Secure communications using Secure Sockets Layer for more information.

Configure the HTTP outbound transport level security with the following steps provided in this task section.

1. Open the administrative console.
2. Click **Applications > Enterprise Applications > *application_instance* > Manage Modules > *module_instance* > Web Services Client Security Bindings.**
3. Click **HTTP SSL Configuration** to access the HTTP SSL configuration panel. Select the **Centrally-managed** radio button so that the system runtime chooses the SSL configuration that is based on the current context. Select the **Specific to this Web service port** radio button if you want to choose the SSL configuration in the HTTP SSL configuration drop down box.

You have configured the HTTP outbound transport level security for a Web service acting as a client to another Web service with the administrative console.

HTTP SSL Configuration collection

Use this page to configure transport-level Secure Sockets Layer (SSL) security. You can use this configuration when a Web service is a client to another Web service.

You can use transport-level security to enable HTTP SSL (or HTTPS). Transport-level security can be enabled or disabled independently from message-level security. Because transport-level security provides minimal security, use message-level security when security is essential to the Web service application.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > *application_instance*.**
2. Click **Manage modules > *URI_file_name* > Web Services: Client Security Bindings.**

3. Under HTTP SSL Configuration, click **Edit**.

SSL configuration

Select the **Centrally-managed** radio button so that the system runtime chooses the SSL configuration that is based on the current context. Select the **Specific to this Web service port** radio button if you want to choose the SSL configuration in the **HTTP SSL configuration** drop down box.

HTTP SSL configuration

The **HTTP SSL configuration** drop down box lists the SSL configurations used with the HTTP transport for a port. Use this drop down box if you want to select the SSL configuration rather than using the SSL configuration that the runtime automatically selects. To use the drop down box, select the **Specific to the Web service port** radio button that is located in the **SSL configuration** field. After you select the radio button, you can click the drop down box to view and select an SSL configuration.

Configuring HTTP outbound transport level security with an assembly tool

This topic explains how to configure the HTTP outbound transport level security with an assembly tool.

You can configure HTTP outbound transport level security with assembly tools provided with WebSphere Application Server.

This task is one of several ways that you can configure the HTTP outbound transport level security for a Web Service acting as a client to another Web service server. You can also configure the HTTP outbound transport level security with the administrative console or by using the Java properties. If you do not configure the HTTP outbound transport level security, the Web services runtime defers to the Java 2 Platform, Enterprise Edition (J2EE) security runtime in the WebSphere product for an effective Secure Sockets Layer (SSL) configuration. If there is no SSL configuration with the J2EE security runtime in the WebSphere product, the Java Secure Socket Extension (JSSE) system properties are used.

If you configure the HTTP outbound transport level security with assembly tool or with the administrative console, the Web services security binding information is modified. If you have not yet installed the Web services application into WebSphere Application Server, you can configure the HTTP SSL configuration with an assembly tool. This task assumes that you have not deployed the Web services application into the WebSphere product.

If you configure the HTTP outbound transport level security using the standard Java properties for JSSE, the properties are configured as system properties. The configuration that is specified in the binding takes precedence over the Java properties. However, the configurations that are specified by the J2EE security programming model, or are associated with the Dynamic selection, have a higher precedence.

Review the topic [Secure communications using Secure Sockets Layer](#) for more information.

Configure the HTTP outbound transport level security with the following steps provided in this task section.

1. Start an assembly tool. See "Starting WebSphere Application Server Toolkit" in the Application Server Toolkit documentation for more information.
2. If you have not done so already, configure the assembly tool to work on J2EE modules. Make sure that the **J2EE** and **Web** categories are enabled. See "Configuring WebSphere Application Server Toolkit" in the Application Server Toolkit documentation for more information.
3. Migrate the Web archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an AST or Rational Web Developer assembly tool. To migrate files, import your WAR files to the assembly tool. See "Importing Web archive (WAR) files" in the Application Server Toolkit documentation for more information.
4. Configure the HTTP outbound transport level security. See "Enabling Web service endpoints" in the Application Server Toolkit documentation for more information.

You have configured the HTTP outbound transport level security for a Web Service acting as a client to another Web service with an assembly tool.

Configuring HTTP outbound transport-level security using Java properties

This topic explains how to configure the HTTP outbound transport level security for a Web service using Java properties

This task is one of three ways that you can configure HTTP outbound transport-level security for a Web service that is acting as a client to another Web service. You can also configure the HTTP outbound transport level security with the administrative console or an assembly tool. However, you can also use this task to configure the HTTP outbound transport-level security for a Web service client.

If you choose to configure the HTTP outbound transport-level security with the administrative console or an assembly tool, the Web services security binding information is modified.

If you configure the HTTP outbound transport-level security using Java properties, the properties are configured as system properties. However, the configuration specified in the binding takes precedence over the Java properties.

You can configure the HTTP outbound transport-level security using WebSphere SSL properties or JSSE SSL properties. However, the WebSphere SSL properties take precedence over the JSSE SSL properties.

Configure the HTTP outbound transport-level security with the following steps provided in this task section.

1. Create a property file that includes the following properties:

```
com.ibm.ssl.protocol
com.ibm.ssl.keyStoreType
com.ibm.ssl.keyStore
com.ibm.ssl.keyStorePassword
com.ibm.ssl.trustStoreType
com.ibm.ssl.trustStore
com.ibm.ssl.trustStorePassword
```

2. Set the `com.ibm.webservices.sslConfigURL` Java system property to the absolute path of the created property file. If no WebSphere SSL properties are defined, the JSSE SSL properties are used. Set the JSSE SSL properties as JVM custom properties. See “Secure transports with JSSE and JCE programming interfaces” on page 607 for more information about setting the JSSE SSL properties.

You have configured the HTTP outbound transport-level security for a Web service acting as a client to another Web service.

Transport level security

Transport level security is based on Secure Sockets Layer (SSL) or Transport Layer Security (TLS) that runs beneath HTTP.

Transport level security can be used to secure Web services messages. However, transport-level security functionality is independent from functionality that is provided by WS-Security or HTTP Basic Authentication.

SSL and TLS provide security features including authentication, data protection, and cryptographic token support for secure HTTP connections. To run with HTTPS, the service port address must be in the form `https://`.

The integrity and confidentiality of transport data, including SOAP messages and HTTP basic authentication, is confirmed when you use SSL and TLS.

WebSphere Application Server uses the Java Secure Sockets Extension (JSSE) package to support SSL and TLS.

HTTP basic authentication

HTTP basic authentication uses a user name and password to authenticate a service client to a secure endpoint.

WebSphere Application Server can have several resources, including Web services, protected by a Java 2 Platform, Enterprise Edition (J2EE) security model.

HTTP basic authentication is orthogonal to the security support provided by WS-Security or HTTP Secure Sockets Layer (SSL) configuration.

A simple way to provide authentication data for the service client is to authenticate to the protected service endpoint using HTTP basic authentication. The basic authentication is encoded in the HTTP request that carries the SOAP message. When the application server receives the HTTP request, the user name and password are retrieved and verified using the authentication mechanism specific to the server.

Although the basic authentication data is base64-encoded, sending data over HTTPS is recommended. The integrity and confidentiality of the data can be protected by the SSL protocol.

In some cases, a firewall is present using a pass-thru HTTP proxy server. The HTTP proxy server forwards the basic authentication data into the J2EE application proxy server. The proxy server can also be protected. Applications can specify the proxy data by setting properties in a stub object.

Configuring HTTP basic authentication with the administrative console

This topic explains how to configure HTTP basic authentication with the administrative console.

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with an assembly tool or by modifying the HTTP properties programmatically.

If you choose to configure HTTP basic authentication with the administrative console or an assembly tool, the Web services security binding information is modified. You can use the administrative console to configure HTTP basic authentication if you have deployed or installed the Web services application into WebSphere Application Server. If you have not installed the Web services application, then you can configure the security bindings with an assembly tool. This task assumes that you have deployed the Web services application into the WebSphere product.

If you configure HTTP basic authentication programmatically, the properties are configured in the Stub or Call instance. The values set programmatically take precedence over the values defined in the binding. However, you only can programmatically configure HTTP proxy authentication.

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

Configure HTTP basic authentication with the following steps provided in this task section.

Open the administrative console.

1. Click **Applications > Enterprise Applications > *application_instance* > Manage Modules > *module_instance* > Web services: Client security bindings.**
2. Click **HTTP Basic Authentication** to access the HTTP basic authentication panel. Enter the values in the HTTP Basic Authentication panel.

You have configured the HTTP basic authentication.

HTTP basic authentication collection

Use this page to specify a user name and password for transport-level basic authentication security for this port. You can use this configuration when a Web service is a client to another Web service.

You can use transport-level security to enable basic authentication. Transport-level security can be enabled or disabled independently from message-level security. Because transport-level security provides minimal security, use message-level security when security is essential to the Web service application.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > *application_instance***.
2. Click **Manage modules > *URI_file_name* > Web Services: Client Security Bindings**.
3. Under HTTP basic authentication, click **Edit**.

Basic authentication ID

The user name for the HTTP basic authentication for this port is set in this field.

Basic authentication password

The password for the HTTP basic authentication for this port is set in this field.

Configuring HTTP basic authentication with an assembly tool

This topic explains how to configure HTTP basic authentication with an assembly tool.

You can configure HTTP basic authentication with assembly tools provided with WebSphere Application Server.

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with the administrative console or by modifying the HTTP properties programmatically.

If you choose to configure the HTTP basic authentication with an assembly tool or with the administrative console, the Web services security binding information is modified. You can use an assembly tool to configure HTTP basic authentication before you deploy or install the Web services application into WebSphere Application Server. This task assumes that you have not deployed the Web services application into the WebSphere product.

If you configure HTTP basic authentication programmatically, the properties are configured in the Stub or Call instance. The values set programmatically take precedence over the values defined in the binding. However, you only can programmatically configure HTTP proxy authentication.

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

To configure HTTP basic authentication, use the WebSphere Application Server tools to modify the binding information.

1. Start an assembly tool. See "Starting WebSphere Application Server Toolkit" in the Application Server Toolkit documentation for more information.
2. If you have not done so already, configure the assembly tool to work on J2EE modules. Make sure that the **J2EE** and **Web** categories are enabled. See "Configuring WebSphere Application Server Toolkit" in the Application Server Toolkit documentation for more information.

3. Migrate the Web archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an AST or Rational Web Developer assembly tool. To migrate files, import your WAR files to the assembly tool. See "Importing Web archive (WAR) files" in the Application Server Toolkit documentation for more information.
4. Configure the HTTP basic authentication in the Web Services Client Port Binding page for a Web service or a Web service client. The Web Services Client Port Binding page is available after double-clicking the client deployment descriptor file.

Configuring HTTP basic authentication programmatically

This topic explains how to configure HTTP basic authentication by programmatically modifying HTTP properties.

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with an assembly tool or with the administrative console.

If you programmatically configure HTTP basic authentication, the properties are configured in the Stub or Call instance. If you choose to configure HTTP basic authentication with the administrative console or an assembly tool, the Web services security binding information is modified. The values that are set programmatically take precedence over the values defined in the binding. However, you can only configure HTTP proxy authentication programmatically.

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

Configure HTTP basic authentication programmatically with the following steps provided in this task section.

1. Set the properties in the Stub or Call instance for a Web service or a Web service client. You can set the following properties:

```
javax.xml.rpc.Call.USERNAME_PROPERTY  
javax.xml.rpc.Call.PASSWORD_PROPERTY  
javax.xml.rpc.Stub.USERNAME_PROPERTY  
javax.xml.rpc.Stub.PASSWORD_PROPERTY
```

2. Set the properties in the Stub or Call instance to configure the HTTP proxy authentication.

- a. You can set the following properties for HTTP:

```
com.ibm.wsspi.webservices.HTTP_PROXYHOST_PROPERTY  
com.ibm.wsspi.webservices.HTTP_PROXYPORT_PROPERTY  
com.ibm.wsspi.webservices.HTTP_PROXYUSER_PROPERTY  
com.ibm.wsspi.webservices.HTTP_PROXYPASSWORD_PROPERTY
```

3. You can set the following properties for HTTPS:

```
com.ibm.wsspi.webservices.HTTPS_PROXYHOST_PROPERTY  
com.ibm.wsspi.webservices.HTTPS_PROXYPORT_PROPERTY  
com.ibm.wsspi.webservices.HTTPS_PROXYUSER_PROPERTY  
com.ibm.wsspi.webservices.HTTPS_PROXYPASSWORD_PROPERTY
```

Configuring additional HTTP transport properties using the JVM custom property panel in the administrative console

This topic explains how to configure additional HTTP transport properties with the JVM custom properties panel in the administrative console.

This task is one of three ways that you can configure additional HTTP transport properties for a Web Service acting as a client to another Web service. You can also configure the additional HTTP transport properties in the following ways:

- Configure the properties with an assembly tool
- Configure the properties using the **wsadmin** command-line tool

If you want to programmatically configure the properties using the Java API XML-based Remote Procedure Call (JAX-RPC) programming model, review the JAX-RPC specification that is available through Web services: Resources for learning.

See Additional HTTP transport properties for Web services applications for more information about the following properties that you can configure:

- `com.ibm.websphere.webservices.http.requestContentEncoding`
- `com.ibm.websphere.webservices.http.responseContentEncoding`
- `com.ibm.websphere.webservices.http.connectionKeepAlive`
- `com.ibm.websphere.webservices.http.requestResendEnabled`
- `http.proxyHost`
- `http.proxyPort`
- `https.proxyHost`
- `https.proxyPort`

These additional properties are configured for Web services applications that use the HTTP protocol. The properties affect the content encoding of the message in the HTTP request, the HTTP response, the HTTP connection persistence and the behavior of an HTTP request that is resent after a `java.net.ConnectException` error occurs when there is a read time-out.

Configure the additional HTTP properties with the administrative console with the following steps provided in this task section:

1. Open the administrative console.
 - a. Click **Servers > Application Servers > server > Java and Process Management > Process Definition > Java Virtual Machine > Custom Properties**.
2. (Optional) If the property is not listed, create a new property name.
3. Enter the name and value.
4. (Optional) Accept the redirection of the HTTP request to a different URI in HTTPS.

A redirection of the HTTP request to a different URI in HTTPS can occur if the transport guarantee of CONFIDENTIAL or INTEGRAL is configured in the application. To accept the redirection, you can do either of the following tasks:

 - Set the `com.ibm.ws.webservices.HttpRedirectEnabled` Java system property to true.
 - Programmatically set the `com.ibm.wsspi.webservices.Constants.HTTP_REDIRECT_ENABLED` property to true in the stub or call object before invoking the service.

You have configured HTTP transport properties for a Web services application.

Configuring additional HTTP transport properties with an assembly tool

This topic explains how to configure additional HTTP transport properties with an assembly tool. The assembly tool is used to configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor binding file.

You can configure additional HTTP transport properties with assembly tools provided with WebSphere Application Server.

This task is one of three ways that you can configure additional HTTP transport properties for a Web Service acting as a client to another Web service. You can also configure the additional HTTP transport properties in the following ways:

- Configuring additional HTTP transport properties using the JVM custom property panel in the administrative console
- Configure the properties using the **wsadmin** command-line tool.

If you want to programmatically configure the properties using the Java API XML-based Remote Procedure Call (JAX-RPC) programming model, review the JAX-RPC specification that is available through Web services: Resources for learning.

See Additional HTTP transport properties for Web services applications for more information about the following properties that you can configure:

- com.ibm.websphere.webservices.http.requestContentEncoding
- com.ibm.websphere.webservices.http.responseContentEncoding
- com.ibm.websphere.webservices.http.connectionKeepAlive
- com.ibm.websphere.webservices.http.requestResendEnabled
- http.proxyHost
- http.proxyPort
- https.proxyHost
- https.proxyPort

These additional properties are configured for Web services applications that use the HTTP protocol. The properties affect the content encoding of the message in the HTTP request, the HTTP response, the HTTP connection persistence and the behavior of an HTTP request that is resent after a `java.net.ConnectException` error occurs when there is a read time-out.

Configure the additional HTTP properties with an assembly tool with the following steps provided in this task section:

1. The assembly tools, Application Server Toolkit (AST) and Rational Web Developer, provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring related Java 2 Platform, Enterprise Edition (J2EE) Version 1.2, 1.3 or 1.4 compliant deployment descriptors.
2. Start an assembly tool. See "Starting WebSphere Application Server Toolkit" in the Application Server Toolkit documentation for more information.
3. If you have not done so already, configure the assembly tool to work on J2EE modules. Make sure that the **J2EE** and **Web** categories are enabled. See "Configuring WebSphere Application Server Toolkit" in the Application Server Toolkit documentation for more information.
4. Migrate the Web archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an AST or Rational Web Developer assembly tool. To migrate files, import your WAR files to the assembly tool. See "Importing Web archive (WAR) files" in the Application Server Toolkit documentation for more information.
5. Configure the additional HTTP transport properties. Create and specify the name/value pair in the **Web Services Client Port Binding** page for a Web service client. The Web Services Client Port Binding page is available after double-clicking the client deployment descriptor file.

You have configured additional HTTP transport properties for a Web services application.

Configuring additional HTTP transport properties using the wsadmin command-line tool

This topic explains how to configure additional HTTP transport properties with the **wsadmin** command-line tool.

The WebSphere Application Server wsadmin tool provides the ability to run scripts. You can use the wsadmin tool to manage a WebSphere Application Server installation, as well as configuration, application deployment, and server run-time operations. The WebSphere Application Server only supports the Jacl and Jython scripting languages. For more information about the wsadmin tool options, review Options for the AdminApp object install, installInteractive, edit, editInteractive, update, and updateInteractive commands

This task is one of three ways that you can configure additional HTTP transport properties for a Web Service acting as a client to another Web service. You can also configure the additional HTTP transport properties in the following ways:

- Configure the properties with an assembly tool
- Configuring additional HTTP transport properties using the JVM custom property panel in the administrative console

If you want to programmatically configure the properties using the Java API XML-based Remote Procedure Call (JAX-RPC) programming model, review the JAX-RPC specification that is available through Web services: Resources for learning.

See Additional HTTP transport properties for Web services applications for more information about the following properties that you can configure:

- com.ibm.websphere.webservices.http.requestContentEncoding
- com.ibm.websphere.webservices.http.responseContentEncoding
- com.ibm.websphere.webservices.http.connectionKeepAlive
- com.ibm.websphere.webservices.http.requestResendEnabled
- http.proxyHost
- http.proxyPort
- https.proxyHost
- https.proxyPort

These additional properties are configured for Web services applications that use the HTTP protocol. The properties affect the content encoding of the message in the HTTP request, the HTTP response, the HTTP connection persistence and the behavior of an HTTP request that is resent after a `java.net.ConnectException` error occurs when there is a read time-out.

Configure the additional HTTP properties with the wsadmin tool by following steps provided in this task section:

1. Launch a scripting command.
2. At the **wsadmin** command prompt, enter the command syntax. You can use `install`, `installInteractive`, `edit`, `editInteractive`, `update`, and `updateInteractive` commands.
3. If you are configuring the `com.ibm.websphere.webservices.http.responseContentEncoding` property, use the **WebServicesServerCustomProperty** command option.
4. Configure all other properties using the **WebServicesClientCustomProperty** command option.
5. Save the configuration changes with the **\$AdminConfig save** command.

You have configured HTTP transport properties for a Web services application.

The following illustrates an example of the Jython script syntax:

```
AdminApp.edit ( 'PlantsByWebSphere', '[ -WebServicesClientCustomProperty [[PlantsByWebSphere.war ""  
service/FrontGate_SEIService FrontGate http.proxyHost+http.proxyPort myhost+80]]]' )  
AdminConfig.save()
```

```
AdminApp.edit ( 'WebServicesSamples', '[ -WebServicesServerCustomProperty  
[[AddressBookW2JE.jarAddressBookService AddressBook http.proxyHost+http.proxyPort myhost+80]]]' )  
AdminConfig.save()
```

The following illustrates an example of the Jacly script syntax:

```
$AdminApp edit PlantsByWebSphere { -WebServicesClientCustomProperty {{PlantsByWebSphere.war {  
service/FrontGate_SEIService FrontGate http.proxyHost+http.proxyPort myhost+80 }}}  
$AdminConfig save
```

```
$AdminApp edit WebServicesSamples {-WebServicesServerCustomProperty {{AddressBookW2JE.jar  
AddressBookService AddressBook http.proxyHost+http.proxyPort myhost+80}}}  
$AdminConfig save
```

To convert these examples from **edit** to **install**, add `.ear` to form a file name, and add any extra keywords for deployment, like `-usedefaultbindings` and `-deployejb`.

Provide HTTP endpoint URL information

Use this page to specify endpoint URL prefix information for Web services accessed by HTTP. Prefixes are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications >Enterprise Applications >application_instance > Provide HTTP endpoint URL information**.

You can specify a portion of the endpoint URL to be used in each Web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the `port's soap:address` element.

Specify endpoint URL prefixes for Web services

Specifies the *protocol* (either `http` or `https`), *host_name*, and *port_number* to be used in the endpoint URL.

You can select a prefix from a predefined list using the **HTTP URL prefix** or **Custom HTTP URL prefix** field.

The URL prefix format is *protocol://host_name:port_number*, for example, `http://myHost:9045`. The actual endpoint URL that appears in a published WSDL file consists of the prefix followed by the module's context-root and the Web service url-pattern, for example, `http://myHost:9045/services/myService`.

Select default HTTP URL prefix

Specifies the drop down list associated with a default list of URL prefixes. This list is the intersection of the set of ports for the module's virtual host and the set of ports for the module's application server. Use items from this list if the Web services application server is accessed directly.

To set an HTTP endpoint URL prefix, select **Select default HTTP URL prefix** and select a value from the drop down list. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP URL prefix** field of any module whose check box is selected.

Select custom HTTP URL prefix

Specifies the *protocol*, *host*, and *port_number* of the intermediate service if the Web services in a module are accessed through an intermediate node, for example the Web services gateway or an IHS server.

To set a custom HTTP endpoint URL prefix, select **Select custom HTTP URL prefix** and enter a value. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP endpoint URL prefix** field of any module whose check box is selected.

Publish WSDL zip files settings

Use this page to publish Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications >Enterprise Applications > application_instance > Publish WSDL zip files**.

When you click **OK**, a panel showing one or several zip file names displays. Each zip file contains a WSDL file that represents the Web services-enabled modules in the application. When you select a zip file to publish, a dialogue displays from which you can choose where to create the zip file. Within the published zip files, the directory structure is *application_name/module_name/[META-INF|WEB-INF]/wsdl/wsdl_file_name*.

In a published WSDL file, the location attribute of a port's `soap:address` element contains the endpoint URL through which the Web service is accessed. Using the **Provide HTTP endpoint URL information** and the **Provide JMS and EJB endpoint URL information** panels, configure the endpoint URLs to be used for the Web services in each module.

application_name_WSDLFiles.zip

Specifies the *application_name_WSDLFiles.zip* file containing the WSDL that describes Web services that are accessible by standard SOAP-based ports.

application_name_ExtendedWSDLFiles.zip

Specifies the *application_name_ExtendedWSDLFiles.zip* file containing the WSDL file that describes the Web services available, including SOAP-based and non-SOAP based (for example, EJB) ports.

If there are no Web services configured for direct EJB access, this zip file name does not appear. Do not use this zip file if you want to produce a WSDL file compliant to standards.

Securing Web services for Version 6 and later applications based on WS-Security

Web services security for WebSphere Application Server is based on standards included in the Organization for the Advancement of Structured Information Standards (OASIS) Web services security (WSS) Version 1.0 specification, the Username token Version 1.0 profile, and the X.509 token Version 1.0 profile.

These standards and profiles address how to provide protection for messages exchanged in a Web service environment. The specification defines the core facilities for protecting the integrity and confidentiality of a message and provides mechanisms for associating security-related claims with the message. Web services security is a message-level standard based on securing SOAP messages through XML digital signature, confidentiality through XML encryption, and credential propagation through security tokens.

To secure Web services, you must consider a broad set of security requirements, including authentication, authorization, privacy, trust, integrity, confidentiality, secure communications channels, federation, delegation, and auditing across a spectrum of application and business topologies. One of the key requirements for the security model in today's business environment is the ability to inter-operate between formerly incompatible security technologies (such as public key infrastructure, Kerberos and so on) in heterogeneous environments (such as Microsoft .NET and Java 2 Platform, Enterprise Edition (J2EE)). The complete Web services security protocol stack and technology roadmap is described in Security in a Web Services World: A Proposed Architecture and Roadmap.

The Web Services Security: SOAP Message Security 1.0 specification outlines a standard set of SOAP extensions that you can use to build secure Web services. These standards confirm integrity and confidentiality, which are generally provided with digital signature and encryption technologies. In addition, Web services security provides a general purpose mechanism for associating security tokens with messages. A typical example of the security token is a username token, in which a user name and password are included as text. Web services security defines how to encode binary security tokens using methods such as X.509 certificates and Kerberos tickets. However, the required security tokens are not defined in the Web service security Version 1.0 specification. Instead, the tokens are defined in separate profiles such as the Username token profile, the X.509 token profile, the Security Assertion Markup Language (SAML) profile, the Kerberos profile, the eXtensible rights Markup Language (XrML) profile and so on.

Web service security is supported in the managed Web service container. To establish a managed environment and to enforce constraints for Web services security, you must perform a Java Naming and Directory Interface (JNDI) lookup on the client to resolve the service reference.

Compatibility between WebSphere Application Server Version 6.1 and Version 5.x

In WebSphere Application Server Version 6.1, you can run a Version 5.x Web services-secured application on a Version 6.1 application server. However, when you use a Web services-secured application, the client and the server must use the same version of the application server. For example, a Web services-secured application does not work properly when the client uses WebSphere Application Server Version 6.1 and the server uses Version 5.x. Conversely, a Web services-secured application does not work properly when the client uses WebSphere Application Server Version 5.x and the server uses Version 6.1. This issue occurs because the SOAP message format is different between a Version 5.x application and a Version 6 or later application.

Configurations

To secure Web services with WebSphere Application Server, you must specify several different configurations. Although there is not a specific sequence in which you must specify these different configurations, some configurations reference other configurations. You can configure Web services security on the application level, server level, and the cell level. The following table shows an example of the relationships between each of the configurations that apply to just the application, to an entire server, or to the entire cell. However, the requirements for the bindings depend upon the deployment descriptor. Some binding information depends upon other information in the binding or server and cell-level configuration. Within the table, the configurations in the Referenced configurations column are referenced by the configuration listed in the Configuration name column. For example, the token generator on the application-level for the request generator references the collection certificate store, the nonce, time stamp, and callback handler configurations.

Table 38. The relationship between the configurations.

Configuration level	Configuration name	Referenced configurations
Application-level request generator	Token generator	<ul style="list-style-type: none"> Collection certificate store Nonce Timestamp Callback handler
Application-level request generator	Key information	<ul style="list-style-type: none"> Key locator Key name Token
Application-level request generator	Signing information	<ul style="list-style-type: none"> Key information
Application-level request generator	Encryption information	<ul style="list-style-type: none"> Key information
Application-level request consumer	Token consumer	<ul style="list-style-type: none"> Trust anchor Collection certificate store Trusted ID evaluators Java Authentication and Authorization Service (JAAS) configuration
Application-level request consumer	Key information	<ul style="list-style-type: none"> Key locator Token
Application-level request consumer	Signing information	<ul style="list-style-type: none"> Key information
Application-level request consumer	Encryption information	<ul style="list-style-type: none"> Key information
Application-level response generator	Token generator	<ul style="list-style-type: none"> Collection certificate store Callback handler
Application-level response generator	Key information	<ul style="list-style-type: none"> Key locator Token
Application-level response generator	Signing information	<ul style="list-style-type: none"> Key information
Application-level response generator	Encryption information	<ul style="list-style-type: none"> Key information
Application-level response consumer	Token consumer	<ul style="list-style-type: none"> Trust anchor Collection certificate store JAAS configuration
Application-level response consumer	Key information	<ul style="list-style-type: none"> Key locator Key name Token
Application-level response consumer	Signing information	<ul style="list-style-type: none"> Key information
Application-level response consumer	Encryption information	<ul style="list-style-type: none"> Key information
Server-level default generator bindings	Token generator	<ul style="list-style-type: none"> Collection certificate store Callback handler
Server-level default generator bindings	Key information	<ul style="list-style-type: none"> Key locator Token
Server-level default generator bindings	Signing information	<ul style="list-style-type: none"> Key information

Table 38. The relationship between the configurations. (continued)

Configuration level	Configuration name	Referenced configurations
Server-level default generator bindings	Encryption information	<ul style="list-style-type: none"> • Key information
Server-level default consumer bindings	Token consumer	<ul style="list-style-type: none"> • Trust anchor • Collection certificate store • Trusted ID evaluator • JAAS configuration
Server-level default consumer bindings	Key information	<ul style="list-style-type: none"> • Key locator • Token
Server-level default consumer bindings	Signing information	<ul style="list-style-type: none"> • Key information
Server-level default consumer bindings	Encryption information	<ul style="list-style-type: none"> • Key information
Cell-level default generator bindings	Token generator	<ul style="list-style-type: none"> • Collection certificate store • Callback handler
Cell-level default generator bindings	Key information	<ul style="list-style-type: none"> • Key locator • Token
Cell-level default generator bindings	Signing information	<ul style="list-style-type: none"> • Key information
Cell-level default generator bindings	Encryption information	<ul style="list-style-type: none"> • Key information
Cell-level default consumer bindings	Token consumer	<ul style="list-style-type: none"> • Trust anchor • Collection certificate store • Trusted ID evaluator • JAAS configuration
Cell-level default consumer bindings	Key information	<ul style="list-style-type: none"> • Key locator • Token
Cell-level default consumer bindings	Signing information	<ul style="list-style-type: none"> • Key information
Cell-level default consumer bindings	Encryption information	<ul style="list-style-type: none"> • Key information

When multiple applications will use the same binding information, consider configuring the binding information on the server or cell level. For example, you might have a global key locator configuration that is used by multiple applications. Configuration information for the application-level precedes similar configuration information on the server-level and the cell level.

Because of the relationship between the different Web services security configurations, it is recommended that you specify the configurations on each level of the configuration in following order. You can choose to configure Web services security for the application level, the server level or the cell level as it depends upon your environment and security needs.

- Assemble your Web services security-enabled application using an assembly tool. Prior to modifying a Web services security-enabled application in the WebSphere Application Server administrative console, you must assemble your application using an assembly tool. Although you can modify some of the application settings using the administrative console, you must configure the generator and the consumer security constraints using an assembly tool such as the Application Server Toolkit or the Rational Application Developer. For information on the assembly tools, see *Assembly tools*. For information on how to add Web services security to an application using an assembly tool, see

“Configuring an application for Web services security with an assembly tool” on page 1014. Return to this article after you have assembled your application and imported it into the administrative console.

- Modify the application-level configurations in the administrative console.
 1. Configure the trust anchors for the generator binding. For more information, see “Configuring trust anchors for the generator binding on the application level” on page 1108.
 2. Configure the collection certificate store for the generator binding. For more information, see “Configuring the collection certificate store for the generator binding on the application level” on page 1113.
 3. Configure the token for the generator binding. For more information, see “Configuring the token generator on the application level” on page 1125.
 4. Configure the key locators for the generator binding. For more information, see “Configuring the key locator for the generator binding on the application level” on page 1142.
 5. Configure the key information for the generator binding. For more information, see “Configuring the key information for the generator binding on the application level” on page 1148.
 6. Configure the signing information for the generator binding. For more information, see “Configuring the signing information for the generator binding on the application level” on page 1160.
 7. Configure the encryption information for the generator binding. For more information, see “Configuring the encryption information for the generator binding on the application level” on page 1176.
 8. Configure the trust anchors for the consumer binding. For more information, see “Configuring trust anchors for the consumer binding on the application level” on page 1188.
 9. Configure the collection certificate store for the consumer binding. For more information, see “Configuring the collection certificate store for the consumer binding on the application level” on page 1189.
 10. Configure the token for the consumer binding. For more information, see “Configuring token consumer on the application level” on page 1191.
 11. Configure the key locators for the consumer binding. For more information, see “Configuring the key locator for the consumer binding on the application level” on page 1203.
 12. Configure the key information for the consumer binding. For more information, see “Configuring the key information for the consumer binding on the application level” on page 1204.
 13. Configure the signing information for the consumer binding. For more information, see “Configuring the signing information for the consumer binding on the application level” on page 1207.
 14. Configure the encryption information for the consumer binding. For more information, see “Configuring the encryption information for the consumer binding on the application level” on page 1211.
- Specify the server-level configurations.
 1. Configure the trust anchors for the server level. For more information, see “Configuring trust anchors on the server or cell level” on page 1217
 2. Configure the collection certificate store for the server level. For more information, see “Configuring the collection certificate store for the server or cell-level bindings” on page 1218
 3. Configure a token generator. For more information, see “Configuring token generators on the server or cell level” on page 1222.
 4. Configure a nonce for the server level. For more information, see “Configuring a nonce on the server or cell level” on page 1221.
 5. Configure the key locators for the generator binding. For more information, see “Configuring the key locator on the server or cell level” on page 1234.
 6. Configure the key information for the generator binding. For more information, see “Configuring the key information for the generator binding on the server or cell level” on page 1236.
 7. Configure the signing information for the generator binding. For more information, see “Configuring the signing information for the generator binding on the server or cell level” on page 1238.

8. Configure the encryption information for the generator binding. For more information, see “Configuring the encryption information for the generator binding on the server or cell level” on page 1241.
 9. Configure the trusted ID evaluators for the server level. For more information, see “Configuring trusted ID evaluators on the server or cell level” on page 1242.
 10. Configure a token consumer. For more information, see “Configuring token consumers on the server or cell level” on page 1246.
 11. Configure the key information for the consumer binding. For more information, see “Configuring the key information for the consumer binding on the server or cell level” on page 1254.
 12. Configure the signing information for the consumer binding. For more information, see “Configuring the signing information for the consumer binding on the server or cell level” on page 1255.
 13. Configure the encryption information for the consumer binding. For more information, see “Configuring the encryption information for the consumer binding on the server or cell level” on page 1258.
- Specify the cell-level configuration.
 1. Configure the trust anchors for the cell level. For more information, see “Configuring trust anchors on the server or cell level” on page 1217.
 2. Configure the collection certificate store for the cell level. For more information, see “Configuring the collection certificate store for the server or cell-level bindings” on page 1218.
 3. Configure a token generator. For more information, see “Configuring token generators on the server or cell level” on page 1222.
 4. Configure a nonce for the cell level. For more information, see “Configuring a nonce on the server or cell level” on page 1221.
 5. Configure the key locators for the generator binding. For more information, see “Configuring the key locator on the server or cell level” on page 1234.
 6. Configure the key information for the generator binding. For more information, see “Configuring the key information for the generator binding on the server or cell level” on page 1236.
 7. Configure the signing information for the generator binding. For more information, see “Configuring the signing information for the generator binding on the server or cell level” on page 1238.
 8. Configure the encryption information for the generator binding. For more information, see “Configuring the encryption information for the generator binding on the server or cell level” on page 1241.
 9. Configure the trusted ID evaluators for the cell level. For more information, see “Configuring trusted ID evaluators on the server or cell level” on page 1242.
 10. Configure a token consumer. For more information, see “Configuring token consumers on the server or cell level” on page 1246.
 11. Configure the key information for the consumer binding. For more information, see “Configuring the key information for the consumer binding on the server or cell level” on page 1254.
 12. Configure the signing information for the consumer binding. For more information, see “Configuring the signing information for the consumer binding on the server or cell level” on page 1255.
 13. Configure the encryption information for the consumer binding. For more information, see “Configuring the encryption information for the consumer binding on the server or cell level” on page 1258.

After completing these steps on the appropriate level of WebSphere Application Server, you have secured Web services.

What is new for securing Web services

In WebSphere Application Server Version 6.0.x, and later there are many security enhancements for Web services. The enhancements include supporting sections of the Web services security specifications and providing architectural support for plugging in and extending the capabilities of security tokens.

Enhancements from the supported Web services security specifications

Since September 2002, the Organization for the Advancement of Structured Information Standards (OASIS) has been developing the Web Services Security (WSS) for SOAP message standard. In April 2004, OASIS released the Web Services security Version 1.0 specification, which is a major milestone for securing Web services. This specification is the foundation for other Web services security specifications and is also the basis for the Basic Security Profile (WS-I BSP) Version 1.0 work, which is a working draft. See Basic Security Profile for more information. Web services security Version 1.0 is a strategic move towards Web services security interoperability, and it is the first step in the Web services security roadmap. For more information on the Web services security roadmap, see *Security in a Web Services World: A Proposed Architecture and Roadmap*.

WebSphere Application Server Version 6.0.x and later support the following specifications and profiles:

- OASIS: Web Services Security: SOAP Message Security 1.0 (WS-Security 2004)
- OASIS: Web Services Security: UsernameToken Profile 1.0
- OASIS: Web Services Security X.509 Certificate Token Profile 1.0
- New in Version 6.1: Basic Security Profile (WS-I BSP)

For details on what parts of the previous specifications are supported in WebSphere Application Server Version 6.0.x and later, see “Supported functionality from OASIS specifications” on page 973.

High level features overview in WebSphere Application Server Version 6.0.x and later

The Web Services Security for SOAP Message Version 1.0 specification is designed to be flexible and accommodate the requirements of Web services. For example, the specification does not have a mandatory security token definition in the Web services security Version 1.0 specification. Rather the specification defines a generic mechanism to associate the security token with a SOAP message. The use of security tokens is defined in the various security token profiles such as:

- The username token profile
- The X.509 token profile
- The WS-Security Kerberos token profile
- The Security Assertion Markup Language (SAML) token profile
- The Rights Express Language (REL) token profile

For more information on security token profile development at OASIS, see Organization for the Advancement of Structured Information Standards.

Important: The wire format in the Web services security Version 1.0 specification changed and is not compatible with the previous drafts of the Web services security specification. It is not possible to make an implementation of the wire format using a previous draft of the Web services security specification to interoperate with the Web Services Security Version 1.0 specification.

Support for pluggable security tokens has been available since WebSphere Application Server Version 5.0.2. However, in WebSphere Application Server Version 6.0.x and later, the pluggable architecture is enhanced to support the Web services security Version 1.0 specification, other profiles, and other Web services security specifications. WebSphere Application Server Version 6 and later include the following key enhancements:

- Support for the client (sender or generator) to send multiple security tokens in a SOAP message.
- Ability to derive keys from a security token for digital signature (verification) and encryption (decryption).
- Support to sign or encrypt any element in a SOAP message. However, some limitations exist. For example, encrypting some parts of a message might break the SOAP message format. If you encrypt the SOAP body element, the SOAP message format breaks.

- Support for signing the SOAP envelope, the SOAP header, and the Web services security header.
- Ability to configure the order of the digital signature and encryption.
- Support for various mechanisms to reference the security tokens such as direct references, key identifiers, key names, and embedded references.
- Support for the PKCS#7 format certificate revocation list (CRL) encoding for an X.509 security token.
- Support for CRL verification.
- Ability to insert nonce and time stamps into elements within the Web services security header, into signed elements, or into encrypted elements.
- Support for identity assertion using the Run As (invocation) identity in the current security context for WebSphere Application Server.
- Support for a default binding, which is a set of default Web services security bindings for applications.
- Ability to use pluggable digital signature (verification) and encryption (decryption) algorithms.
- Support for the acceleration of hardware cryptographic devices.
- Support for secure keys.
- Support for the Basic Security Profile (WS-I BSP).

For more information on some of these enhancements, see “Web services security enhancements” on page 979.

Configuration

WebSphere Application Server Version 6 uses the deployment model for implementing the Web services security Version 1.0 specification, the Username token Version 1.0 profile, and the X.509 token Version 1.0 profile. The deployment model is an extension of the Web services deployment model for Java 2 Platform, Enterprise Edition (J2EE). The Web services security constraints are defined in the IBM extension deployment descriptor and the binding file based on the Web service port.

The format of the deployment descriptor and the binding file is IBM proprietary material and is not available. However, WebSphere Application Server provides the following tools that you can use to edit the deployment descriptor and the binding file:

Rational Application Developer Version 6.0.x

You can use Rational Application Developer Version 6.0.x to develop Web services and configure the deployment descriptor and the binding file for Web services security. The Rational Application Developer enables you to assemble both Web and Enterprise JavaBeans™ (EJB) modules.

Rational Web Developer Version 6.0.x

You can use Rational Web Developer Version 6.0.x to develop Web services and configure the deployment descriptor and the binding file for Web services security. However, you cannot assemble Enterprise JavaBeans modules using this tool. Instead, use the Application Server Toolkit or the Rational Application Developer.

Application Server Toolkit

You can use the Application Server Toolkit (AST), which is an assembly tool designer for WebSphere Application Server Version 6.0.x and later, to specify the deployment descriptor and the binding file for Web services security.

WebSphere Application Server administrative console

You can use the administrative console to configure the Web services security binding of a deployed application with Web services security constraints that are defined in the deployment descriptor.

Important: The format of the deployment descriptor and the binding file for Web services security in WebSphere Application Server Version 6.0.x and later is different from WebSphere Application Server Versions 5.0.2, 5.1, and 5.1.1. Web services security support in WebSphere Application

Server Versions 5.0.2, 5.1, and 5.1.1 is based on the Web services security draft 13 specification and the Username token draft 2 profile. Thus, this support is deprecated. However, applications that you configured using the Web service security Versions 5.0.2, 5.1, and 5.1.1 deployment descriptor and binding file can work with WebSphere Application Server Version 6 and later. These applications use a deployment descriptor and binding file that emit SOAP message security using the draft 13 specification format. The Web services security deployment descriptor and binding file for WebSphere Application Server Version 6.0.x and later is available for a J2EE Version 1.4 application only. Therefore, the Web services security Version 1.0 specification is supported for a J2EE Version 1.4 application only.

To take advantage of implementations associated with the Web services security Version 1.0 specification, you must:

- Migrate existing applications to J2EE Version 1.4
- Re-configure the Web services security constraints in the new deployment descriptor and binding format

Important: An automatic process does not exist for migrating the deployment descriptor and the binding file for Web services security from the Version 5.0.2, 5.1, and 5.1.1 format to the new Version 6.0.x and later format using the Rational Web Developer and Application Server Toolkit. You must migrate the configuration manually.

Important: The Web services security support in WebSphere Application Server Version 6.0 is based in part on the OASIS specification titled *Web Services Security: X.509 Token Profile 1.0* plus the first errata (*Errata 1.0*).

In the first errata, the URIs for the X.509 token type and the X.509 Subject Key Identifier value type were modified. WebSphere Application Server Version 6.0 was based on these modified URIs. After WebSphere Application Server Version 6.0 shipped, the OASIS Technical Committee reversed those changes, reverting back to the original 1.0 profile URIs.

There could be interoperability problems between WebSphere Application Server Version 6.0 and other vendor's Web services products that are based on the current version of the profile. WebSphere Application Server was fixed in Versions 6.0.2 and 6.0.1.2 to comply with the latest version of the profile. If WebSphere Application Server Version 6.0 is used in a heterogeneous environment with other vendor's Web services products, it is recommended that the server be upgraded to Version 6.0.1.2, 6.0.2, or later, or to install a service fix that includes APAR PK03507.

FIPS support in WebSphere Application Server

In WebSphere Application Server, Federal Information Processing Standard (FIPS) compliant algorithms for key encryption, data encryption, signature and digest are supported. To enable this mode, select **Use the Federal Information Processing Standard (FIPS)** on the Global security panel of the WebSphere administrative console.

After this option has been selected, and the WebSphere Application Server has been restarted, the lists of available algorithms that are displayed in the Web services security binding configuration panels of the administrative console are then FIPS compliant algorithms.

If a previously deployed application was configured to use a noncompliant algorithm, that application no longer starts after the FIPS mode has been enabled in WebSphere Application Server. The error message *Unauthorized data encryption method* appears in the case of a noncompliant data encryption algorithm. Similar errors are displayed for unauthorized key encryption, digest and signature methods.

FIPS support in WebSphere Application Server

In WebSphere Application Server, Federal Information Processing Standard (FIPS) compliant algorithms for key encryption, data encryption, signature and digest are supported. To enable this mode, select **Use the United States Federal Information Processing Standard (FIPS) algorithms** on the SSL certificate and key management panel of the WebSphere administrative console.

After this option has been selected, and the WebSphere Application Server has been restarted, the lists of available algorithms that are displayed in the Web services security binding configuration panels of the administrative console are then FIPS compliant algorithms.

If a previously deployed application was configured to use a noncompliant algorithm, that application no longer starts after the FIPS mode has been enabled in WebSphere Application Server. The error message *Unauthorized data encryption method* appears in the case of a noncompliant data encryption algorithm. Similar errors are displayed for unauthorized key encryption, digest and signature methods.

What is not supported

Web service security is still fairly new and some of the standards are still being defined or standardized. The following functionality is not supported in WebSphere Application Server Versions 6.0.x and later:

- Application programming interfaces (API) do not exist for Web services security in WebSphere Application Server Versions 6.0.x and later. The following standards exist for the Java application programming interface for XML security and Web services security:
 - JSR-105 (Java API for XML-Signature XPath Filter Version 2.0
W3C Recommendation, November 2002)
 - JSR-106 (Java API for XML Encryption Syntax and Processing)
W3C Recommendation, December 2002)
 - JSR-183 (Java API for Web Services Security: SOAP Message Security 1.0 specification)
- SAML token profile is not supported out of the box.
- WS-SecuredConversation is not supported out of the box.
- WS-Trust is not supported out of the box.
- WS-SecurityKerberos token profile is not supported out of the box.
- REL token profile is not supported.
- Web services security SOAP messages with an attachments profile (SwA) is not supported.
- WS-I Basic Security Profile Version 1.0 is not supported.
- Non-Web services container managed client is not supported out of the box.

For information on what is supported for Web services security in WebSphere Application Server Version 6.0.x and later, see “Supported functionality from OASIS specifications” on page 973.

Web services security specification for Version 6 and later- a chronology

This article describes the development of the Web services security specification. The article provides information on the Organization for the Advancement of Structured Information Standards (OASIS) Web services security Version 1.0 specification, which is the specification that serves as a basis for securing Web services in WebSphere Application Server Version 6 and later.

Non-OASIS activities

Web services is gaining rapid acceptance as a viable technology for interoperability and integration. However, securing Web services is one of the paramount quality of services that makes the adoption of Web services a viable industry and commercial solution for businesses. IBM and Microsoft jointly

published a security white paper on Web services entitled Security in a Web Services World: A Proposed Architecture and Roadmap. The white paper discusses the following initial and subsequent specifications in the proposed Web services security roadmap:

Web service security

This specification defines how to attach a digital signature, use encryption, and use security tokens in SOAP messages.

WS-Policy

This specification defines the language that is used to describe security constraints and the policy of intermediaries or endpoints.

WS-Trust

This specification defines a framework for trust models to establish trust between Web services.

WS-Privacy

This specification defines a model of how to express a privacy policy for a Web service and a requester.

WS-SecureConversation

This specification defines how to exchange and establish a secured context, which derives session keys between Web services.

WS-Federation

This specification defines a model for trust relationships in a heterogeneous, federated environment, including federated identities management.

WS-Authorization

This specification defines the authorization policy for a Web service. However, the WS-Authorization specification has not been published. The existing implementation of Web services security is based upon the Web Services for Java 2 Platform, Enterprise Edition (J2EE) or Java Specification Requirements (JSR) 109 specification. The implementation of Web services security leverages the J2EE role-based authorization checks. For conceptual information on role-based authorization, see “Role-based authorization” on page 334. If you develop a Web service that requires method-level authorization checks, then you must use stateless session beans to implement your Web service. For more information on using stateless session beans to implement a Web service, see Developing a Web service from an enterprise bean and “Securing enterprise bean applications” on page 943. If you develop a Web service that is implemented as a servlet, you can use coarse-grained or URL-based authorization in the Web container. However, in this situation, you cannot use the identity from Web services security for authorization checks. Instead, you can use the identity from the transport. If you use SOAP over HTTP, then the identity is in the HTTP transport.

This following figure shows the relationship between these specifications:

In April 2002, IBM, Microsoft, and VeriSign proposed the Web Services Security (WS-Security) specification on their Web sites as depicted by the green box in the previous figure. This specification included the basic ideas of a security token, XML digital signature, and XML encryption. The specification also defined the format for user name tokens and encoded binary security tokens. After some discussion and an interoperability test based on the specification, the following issues were noted:

- The specification requires that the Web services security processors understand the schema correctly so that the processor distinguishes between the ID attribute for XML digital signature and XML encryption.
- The freshness of the message, which indicates whether the message complies with predefined time constraints, cannot be determined.
- Digested password strings do not strengthen security.

In August 2002, IBM, Microsoft, and VeriSign published the *Web Services Security Addendum*, which attempted to address the previously listed issues. The following solutions were addressed in the addendum:

- Require a global ID attribute for XML signature and XML encryption.
- Use time stamp header elements that indicate the time of the creation, receipt, or expiration of the message.
- Use password strings that are digested with a time stamp and nonce, which is a randomly generated token.

The specifications for the blue boxes in the previous figure have been proposed by various industry vendors and various interoperability events have been organized by the vendors to verify and refine the proposed specifications.

OASIS activities

In June 2002, OASIS received a proposed Web services security specification from IBM, Microsoft, and Verisign. The Web Services Security Technical Committee (WSS TC) was organized at OASIS soon after the submission. The technical committee included many companies including IBM, Microsoft, VeriSign, Sun Microsystems, and BEA Systems.

In September 2002, WSS TC published its first specification, Web Services Security Core Specification, Working Draft 01. This specification included the contents of both the original Web services security specification and its addendum.

The coverage of the technical committee became larger as the discussion proceeded. Because the Web Services Security Core Specification allows arbitrary types of security tokens, proposals were published as profiles. The profiles described the method for embedding tokens, including Security Assertion Markup Language (SAML) tokens and Kerberos tokens embedded into the Web services security messages. Subsequently, the definitions of the usage for user name tokens and X.509 binary security tokens, which were defined in the original Web Services Security Specification, were divided into the profiles.

WebSphere Application Server Versions 5.0.2, 5.1, and 5.1.1 support the following specifications:

- Web Services Security: SOAP Message Security Draft 13 (formerly Web Services Security Core Specification)
- Web Services Security: Username Token Profile Draft 2

In April 2004, the Web service security specification (officially called Web Services Security: SOAP Message Security Version 1.0) became the Version 1.0 OASIS standard. Also, the Username token and X.509 token profiles are Version 1.0 specifications.

WebSphere Application Server 6 and later support the following Web services security specifications from OASIS:

- Web Services Security: SOAP Message Security 1.0 specification
- Web Services Security: Username Token 1.0 Profile
- Web Services Security: X.509 Token 1.0 Profile

The following figure shows the various Web services security-related specifications.

WebSphere Application Server Version 6 and later also extend and provide plug-in capability to enable security providers to extend the run-time capability and implement some of the higher level specifications in the Web service security stack. The plug-in points are exposed as Service Provider Programming Interfaces (SPI). For more information on these SPIs, see “Default implementations of the Web services security service provider programming interfaces” on page 1004.

Web services security specification development

The OASIS Web services security Version 1.0 specification defines the enhancements that are used to provide message integrity and confidentiality. It also provides a general framework for associating the security tokens with a SOAP message. The specification is designed to be extensible to support multiple security token formats. The particular security token usage is addressed with the security token profile. The OASIS Web services security specification is based upon the following World Wide Web Consortium (W3C) specifications. Most of the W3C specifications are in the standard body recommended status.

- XML-Signature Syntax and Processing
W3C recommendation, February 2002 (Also, IETF RFC 3275, March 2002)
- Canonical XML Version 1.0
W3C recommendation, March 2001
- Exclusive XML Canonicalization Version 1.0
W3C recommendation, July 2002
- XML-Signature XPath Filter Version 2.0
W3C Recommendation, November 2002
- XML Encryption Syntax and Processing
W3C Recommendation, December 2002

- Decryption Transform for XML Signature
W3C Recommendation, December 2002

These specifications are supported in WebSphere Application Server Version 6 and later in the context of Web services security. For example, you can sign a SOAP message by specifying the integrity option in the deployment descriptors. However, there is no application programming interface (API) that an application can use for XML signature on an XML element in a SOAP message.

The OASIS Web services security Version 1.0 specification defines the enhancements that are used to provide message integrity and confidentiality. It also provides a general framework for associating the security tokens with a SOAP message. The specification is designed to be extensible to support multiple security token formats. The particular security token usage is addressed with the security token profile.

Specification and profile support in WebSphere Application Server Version 6 and later

OASIS is working on various profiles. For more information, see Organization for the Advancement of Structured Information Standards Committees. WebSphere Application Server Versions 6 and later do not support these profiles. The following list is some of the published draft profiles and OASIS Web services security technical committee work in progress:

- Web Services Security: SAML token profile
- Web Services Security: REL token profile
- Web Services Security: Kerberos token profile
- Web Services Security: SOAP Messages with Attachments (SwA) profile

Because WebSphere Application Server Version 6 and later support the following specifications, support for Web services security draft 13 and Username token profile draft 2 in WebSphere Application 5.0.2, 5.1.0 and 5.1.1 is deprecated:

- OASIS Web Services Security Version 1.0 specification
- Web Services Security Username token profile
- X.509 token profile

The wire format of the SOAP message with Web services security in Web services security Version 1.0 has changed and is not compatible with previous drafts of the OASIS Web services security specification. Interoperability between OASIS Web services security Version 1.0 and previous Web services security drafts is not supported. However, it is possible to run an application that is based on Web services security draft 13 on WebSphere Application Server Version 6 and later. The application can interoperate with an application that is based on Web services security draft 13 on WebSphere Application Server Version 5.0.2, 5.1 or 5.1.1.

WebSphere Application Server Version 6 and later support both the OASIS Web services security draft 13 and the OASIS Web services security 1.0 specification. But in WebSphere Application Server Version 6 and later, the support of OASIS Web services security draft 13 is deprecated. However, applications that were developed using OASIS Web services security draft 13 on WebSphere Application Server 5.0.2, 5.1.0 and 5.1.1 can run on WebSphere Application Server Version 6 and later. OASIS Web services security Version 1.0 support is available only for Java 2 Platform, Enterprise Edition (J2EE) Version 1.4 applications. The configuration format for the deployment descriptor and the binding is different from previous versions of WebSphere Application Server. You must migrate the existing applications to J2EE 1.4 and migrate the Web services security configuration to the WebSphere Application Server Version 6 format. For migration information, see “Migrating Version 5.x applications with Web services security to Version 6.1 applications” on page 991.

Web Services Interoperability Organization (WS-I) activities

Web Services Interoperability Organization (WS-I) is an open industry effort to promote Web services interoperability across vendors, platforms, programming languages and applications. The organization is a consortium of companies across many industries including IBM, Microsoft, Oracle, Sun, Novell, VeriSign, and Daimler Chrysler. WS-I began working on the basic security profile (BSP) in the spring of 2003. BSP consists of a set of non-proprietary Web services specifications that clarifies and amplifies those specifications to promote Web services security interoperability across different vendor implementations. As of June 2004, BSP is a public draft. For more information, see the Web Services Interoperability Organization.

Specifically, see Basic Security Profile Version 1.0 for details about the BSP. WebSphere Application Server supports compliance with the BSP. See “Basic Security Profile compliance” on page 1013 for the details to configure your application in compliance with the BSP.

XML token

XML tokens are offered in two well-known formats called Security Assertion Markup Language (SAML) and eXtensible rights Markup Language (XrML).

In WebSphere Application Server Versions 6 and later, you can plug in your own implementation. By using extensibility of the `<wsse:Security>` header in XML-based security tokens, you can directly insert these security tokens into the header. SAML assertions are attached to Web services security messages using Web services by placing assertion elements inside the `<wsse:Security>` header. The following example illustrates a Web services security message with a SAML assertion token.

```
<S:Envelope xmlns:S="...">
<S:Header>
  <wsse:Security xmlns:wsse="...">
    <saml:Assertion
      MajorVersion="1"
      MinorVersion="0"
      AssertionID="SecurityToken-ef375268"
      Issuer="elliottw1"
      IssueInstant="2002-07-23T11:32:05.6228146-07:00"
      xmlns:saml="urn:oasis:names:tc:SAML:1.0:assertion">
      ...
    </saml:Assertion>
  </wsse:Security>
</S:Header>
<S:Body>
  ...
</S:Body>
</S:Envelope>
```

For more information on SAML and XrML, see Web services: Resources for learning.

Supported functionality from OASIS specifications

WebSphere Application Server Version 6 and later support the following Web services security specifications and profiles.

- OASIS: Web Services Security: SOAP Message Security 1.0 (WS-Security 2004)
- OASIS: Web Services Security: UsernameToken Profile 1.0
- OASIS: Web Services Security X.509 Certificate Token Profile 1.0
- Basic Security Profile Version 1.0

OASIS: Web Services Security: SOAP Message Security 1.0 (WS-Security 2004)

The following list shows the aspects of the OASIS: Web Services Security: SOAP Message Security 1.0 (WS-Security 2004) specification that is supported in WebSphere Application Server Versions 6 and later.

Supported topic	Specific aspect that is supported
Security header	<ul style="list-style-type: none"> • @S11 :actor (for an intermediary) • @S11:mustUnderstand
Security tokens	<ul style="list-style-type: none"> • Username token (user name and password) • Binary security token (X.509 and Lightweight Third Party Authentication (LTPA)) • Custom token <ul style="list-style-type: none"> – Other binary security token – XML token <p>Note: WebSphere Application Server does not provide an implementation, but you can use an XML token with plug-in point.</p>
Token references	<ul style="list-style-type: none"> • Direct reference • Key identifier • Key name • Embedded reference

Supported topic	Specific aspect that is supported
Signature algorithms	<ul style="list-style-type: none"> • Digest <ul style="list-style-type: none"> SHA1 http://www.w3.org/2000/09/xmlsig#sha1 SHA256 http://www.w3.org/2001/04/xmlenc#sha256 SHA512 http://www.w3.org/2001/04/xmlenc#sha512 • MAC <ul style="list-style-type: none"> HMAC-SHA1 http://www.w3.org/2000/09/xmlsig#hmac-sha1 • Signature <ul style="list-style-type: none"> DSA with SHA1 http://www.w3.org/2000/09/xmlsig#dsa-sha1 Do not use this algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP) RSA with SHA1 http://www.w3.org/2000/09/xmlsig#rsa-sha1 • Canonicalization <ul style="list-style-type: none"> Canonical XML (with comments) http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments Canonical XML (without comments) http://www.w3.org/TR/2001/REC-xml-c14n-20010315 Exclusive XML canonicalization (with comments) http://www.w3.org/2001/10/xml-exc-c14n#WithComments Exclusive XML canonicalization (without comments) http://www.w3.org/2001/10/xml-exc-c14n# • Transform <ul style="list-style-type: none"> STR transform http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soapmessage-security-1.0#STR-Transform XPath http://www.w3.org/TR/1999/REC-xpath-19991116 Do not use the original XPATH transform if you want your configured application to be in compliance with the Basic Security Profile (BSP). Note: When referring to an element in a SECURE_ENVELOPE that does not carry an attribute of type ID from a ds:Reference in a SIGNATURE, you must use the XPATH Filter 2.0 Transform, http://www.w3.org/2002/06/xmlsig-filter2 Enveloped signature http://www.w3.org/2000/09/xmlsig#enveloped-signature XPath Filter2 http://www.w3.org/2002/06/xmlsig-filter2 Note: When referring to an element in a SECURE_ENVELOPE that does not carry an ID attribute type from a ds:Reference in a SIGNATURE, you must use the XPATH Filter 2.0 Transform, http://www.w3.org/2002/06/xmlsig-filter2 Decryption transform http://www.w3.org/2002/07/decrypt#XML

Supported topic	Specific aspect that is supported
Signature signed parts	<ul style="list-style-type: none"> • WebSphere Application Server key words: <ul style="list-style-type: none"> – body, which signs the SOAP message body – timestamp, which signs all of the time stamps – securitytoken, which signs all of the security tokens – dsigkey, which signs the signing key – enckey, which signs the encryption key – messageid, which signs the wsa :MessageID element in WS-Addressing. – to, which signs the wsa:To element in WS-Addressing – action, which signs the wsa:Action element in WS-Addressing – relatesto, which signs the wsa:RelatesTo element in WS-Addressing wsa is the namespace prefix of http://schemas.xmlsoap.org/ws/2004/08/addressing – wscontext, which specifies the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services. • XPath expression to select the XML element in the SOAP message <ul style="list-style-type: none"> – XML elements – XML element contents
Time stamp	<ul style="list-style-type: none"> • Within Web services security header • WebSphere Application Server is extended to allow you to insert time stamps into other elements so that the age of those elements can be determined.
Error handling	SOAP faults

OASIS: Web Services Security: UsernameToken Profile 1.0

The following list shows the aspects of the OASIS: Web Services Security: UsernameToken Profile 1.0 specification that is supported in WebSphere Application Server Versions 6 and later.

Supported topic	Specific aspect that is supported
Password types	Text
Token references	Direct reference

OASIS: Web Services Security X.509 Certificate Token Profile

The following list shows the aspects of the OASIS: Web Services Security X.509 Certificate Token Profile specification that is supported in WebSphere Application Server Versions 6 and later.

Supported topic	Specific aspect that is supported
Token types	<ul style="list-style-type: none"> • X.509 Version 3: Single certificate http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3 • X.509 Version 3: X509PKIPathv1 without certificate revocation lists (CRL) http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1 • X.509 Version 3: PKCS7 with or without CRLs. The IBM software development kit (SDK) supports both. The Sun Java Development Kit (JDK) supports PKCS7 without CRL only.
Token references	<ul style="list-style-type: none"> • Key identifier – subject key identifier • Direct reference • Custom reference – issuer name and serial number

Functionality that is not supported

The following list shows the functionality that is supported in the Organization for the Advancement of Structured Information (OASIS) specifications, OASIS drafts, and other recommendations, but is not supported by WebSphere Application Server Versions 6 and later:

- Non-managed client with Web services security. For example, a Java 2 Platform, Standard Edition (J2SE) client or a Dynamic Invocation Interface (DII) client
- The Web services security binding is not collected during the application installation process. It can be configured after the application is deployed.
- Web services security for SOAP attachment
- Security Assertion Markup Language (SAML) token profile, WS-SecurityKerberos token profile, and XrML token profile
- XML enveloping digital signature
- XML enveloping digital encryption
- Security header
 - @S12:role
S12 is the namespace prefix of <http://www.w3.org/2003/05/soap-envelope>
- The following transport algorithms for digital signatures are not supported:
 - XSLT: <http://www.w3.org/TR/1999/REC-xslt-19991116>
 - SOAP Message Normalization
For more information, see [SOAP Version 1.2 Message Normalization](#).
- The following key agreement algorithm for encryption is not supported:
 - Diffie-Hellman: <http://www.w3.org/TR/2002/REC-xmlenc-core-20021210/Overview.html#sec-DHKeyValue>
- The following canonicalization algorithm for encryption, which is optional in the XML encryption specification, is not supported:
 - Canonical XML with or without comments
 - Exclusive XML canonicalization with or without comments
- In the Username Token Version 1.0 Profile specification, the digest password type is not supported.

Web services security enhancements

WebSphere Application Server Version 6 include a number of enhancements for securing Web services. These enhancements are explained in detail within this article.

Building your applications

To assemble your applications and to specify the security constraints for Web services security in the deployment descriptor and bindings, it is recommended that you use Rational Web Developer and the Application Server Toolkit. For more information on these tools, see [Assembly tools](#). You can also use the WebSphere Application Server administrative console to edit the application binding file.

Using identity assertion

In a secured environment such as an intranet, a secure sockets layer (SSL) connection or through a Virtual Private Network (VPN), it is useful to send the requester identity only without credentials, such as password, with other trusted credentials, such as the server identity. WebSphere Application Server Version 6 and later support the following types of identity assertions:

- A username token without a password
- An X.509 Token for a X.509 certificate

For the X.509 certificate, WebSphere Application Server uses the distinguished name in the certificate as a requester identity. There are two trust modes for validating the trust of the upstream server:

Basic authentication (username token)

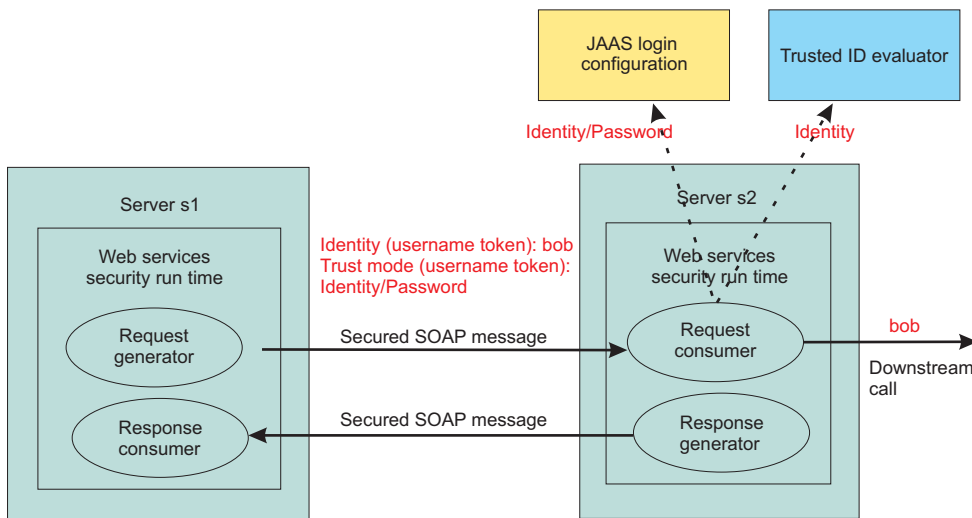

The upstream server sends a username token with a user name and password to a downstream server. The consumer or receiver of the message authenticates the username token and validates

the trust based upon the TrustedIDEvaluator implementation. The TrustedIDEvaluator implementation must implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` Java interface.

Signature

The upstream server signs the message, which can be any message part such as the SOAP body. The upstream server sends the X.509 token to a downstream server. The consumer or receiver of the message verifies the signature and validates the X.509 token. The identity or the distinguished name from the X.509 token that is used in the digital signature is validated based on the TrustedIDEvaluator implementation. The TrustedIDEvaluator implementation must implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` Java interface.

The following figure demonstrates the identity assertion trust process.

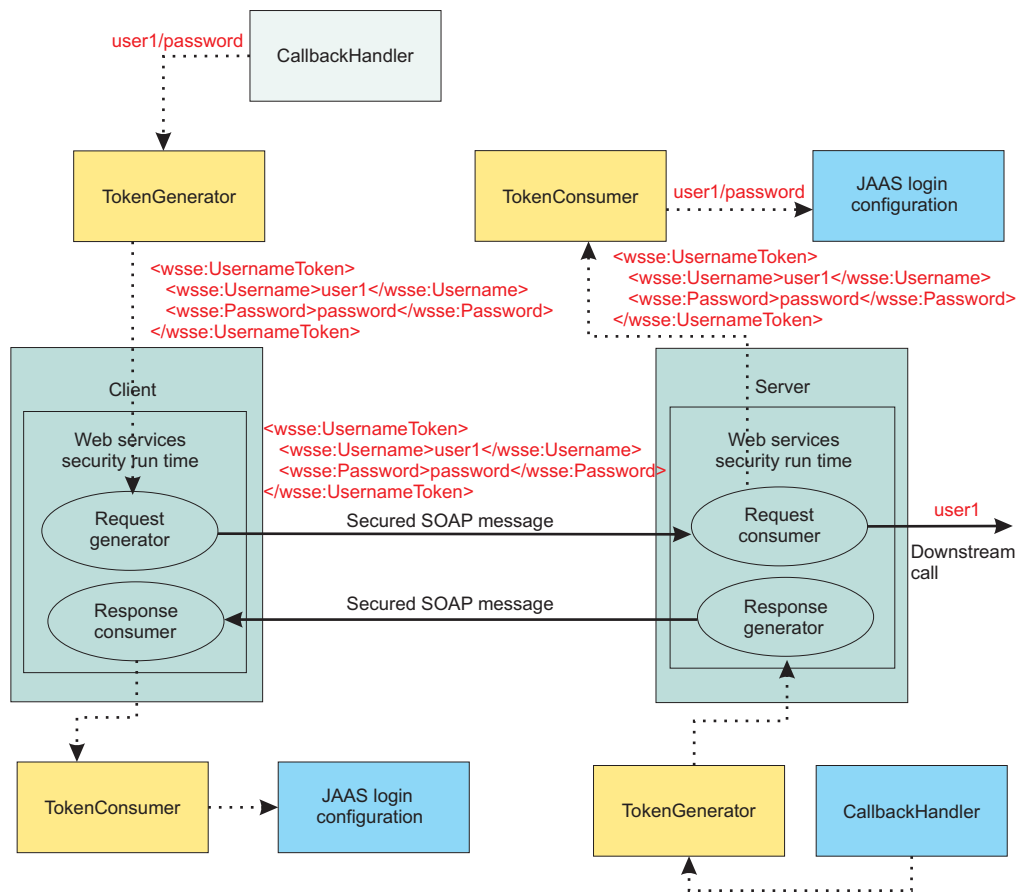

In this figure, server s1 is the upstream server and identity assertion is set up between server s1 and server s2. The s1 server authenticates the identity called *bob*. Server s1 wants to send *bob* to the s2 server with a password. The trust mode is an s1 credential that contains the identity and a password. Server s2 receives the request, authenticates the user using a Java Authentication and Authorization Service (JAAS) login module, and uses the trusted ID evaluator to determine whether to trust the identity. If the identity is trusted, *bob* is used as the caller that invokes the service. If authorization is required, *bob* is the identity that is used for authorization verification.

In WebSphere Application Server Version 6 and later, the identity can be asserted as the RunAs (invocation) identity of the current security context. For example, the Web services gateway authenticates a requester using a secure method such as password authentication and then sends the requester identity only to a back-end server. You might also use identity assertion for interoperability with another Web services security implementation.

Using the pluggable token framework

The Organization for the Advancement of Structured Information Standards (OASIS) Web Services Security Version 1.0 specification defines a generic mechanism to associate security tokens with a SOAP message. In WebSphere Application Server Versions 6 and later, the pluggable token framework is enhanced to handle this flexible mechanism. The following figure shows this pluggable framework.

The following terms are used in the previous figure:

TokenGenerator

The token generator, or the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` Java interface, is responsible for the following actions:

- Marshalling the token into the correct XML representation for the SOAP message. In this case, marshalling is the process of converting a token to a standardized format before transmitting it over the network.
- Setting the token to the local JAAS Subject.
- Generating the correct token identifier based on the key information type.

The token generator invokes the `CallbackHandler` or the `javax.security.auth.callback.CallbackHandler` Java interface for token acquisition. The `javax.security.auth.callback.Callback` Java interface is used to pass information from the callback handler to the token generator.

CallbackHandler

The callback handler, or the `javax.security.auth.callback.CallbackHandler` Java interface, is responsible for acquiring the token using a method such as GUI prompt, a standard-in prompt, talking to external token service, and so on.

TokenConsumer

The token consumer, or the `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` Java interface, is responsible for the following actions:

- Unmarshalling the token from the XML format within the SOAP message. In this case, *unmarshalling* is the process of converting the token from the standard network format to the local or native format.
- Calling the JAAS login configuration to validate the token

- Setting the correct WSSToken, or `com.ibm.wsspi.wssecurity.auth.token.WSSToken` Java abstract class, to the local JAAS Subject.

At the final stage of Web services security processing, the local JAAS Subject content is used to create the WebSphere credentials and principals. The Caller Subject is created based on the content of the local JAAS Subject.

JAAS login configuration

The JAAS login configuration is responsible for validating the token. The validation process might involve making a call to the WebSphere Application Server authentication module or calling a third-party token service.

Signing or encrypting data with a custom token

The key locator, or the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` Java interface, is enhanced to support the flexibility of the specification. The key locator is responsible for locating the key. The local JAAS Subject is passed into the `KeyLocator.getKey()` method in the context. The key locator implementation can derive the key from the token, which is created by the token generator or the token consumer, to sign a message, to verify the signature within a message, to encrypt a message, or to decrypt a message.

Important: The `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` Java interface is different from the version in WebSphere Application Server Version 5.x. The `com.ibm.wsspi.wssecurity.config.KeyLocator` interface from Version 5.x is deprecated. There is no automatic migration for the key locator from Version 5.x to Version 6 or later. You must migrate the source code for the Version 5.x key locator implementation to the key locator programming model for Version 6 and later.

Signing or encrypting any XML element

The deployment descriptor supports the XPath expression for selecting which XML element to sign or encrypt. However, an envelope signature is used when you sign the SOAP envelope, SOAP header, or Web services security header.

Supporting LTPA

Lightweight Third Party Authentication (LTPA) is supported as a binary security token in Web services security. The token type is `http://www.ibm.com/websphere/appserver/tokentype/5.0.2/LTPA`.

Extending the support for time stamps

You can insert a time stamp in other elements during the signing process besides the Web services security header. This time stamp provides a mechanism for adding a time limit to an element. However, this support is an extension for WebSphere Application Server Versions 6 and later. Other vendor implementations might not have the ability to consume a message that is generated with an additional time stamp that is inserted in the message.

Extending the support for nonce

You can insert a nonce, which is a randomly generated value, in other elements beside the username token. The nonce is used to reduce the chance of a replay attack. However, this support is an extension for WebSphere Application Server Versions 6 and later. Other vendor implementations might not have the ability to consume messages with a nonce that is inserted into elements other than a username token.

Supporting distributed nonce caching

Distributed nonce caching is a new feature for Web services in WebSphere Application Server Versions 6 and later that enables you to replicate nonce data between servers in a cluster. For example, you might

have application server A and application server B in cluster C. If application server A accepts a nonce with a value of X, then application server B creates a SoapSecurityException if it receives the nonce with the same value within a specified period of time. For more information, see the information that explains nonce cache timeout, nonce maximum age and nonce clock skew in “Web services: Default bindings for the Web services security collection” on page 1271. However, if application server B receives another nonce with a value of Y, then it does not throw an exception, but caches the nonce and copies it into the other application servers within the same cluster.

Important: The distributed nonce caching feature uses the WebSphere Application Server Distributed Replication Service (DRS). The data in the local cache is pushed to the cache in other servers in the same replication domain. The replication is an out-of-process call and, in some cases, is a remote call. Therefore, there is a possible delay in replication while the content of the cache in each application server within the cluster is updated. The delay might be due to network traffic, network workload, machine workload, and so on.

Caching the X.509 certificate

WebSphere Application Server Version 6 and later cache the X.509 certificates it receives, by default, to avoid certificate path validation and improve its performance. However, this change might lead to security exposure. You can disable X.509 certificate caching using the following steps:

On the cell level:

- Click **Security > Web services**.
- Under Additional properties, click **Properties > New**.
- In the Property name field, type `com.ibm.ws.wssecurity.config.token.certificate.useCache`.
- In the Property value field, type `false`.

On the server level:

- Click **Servers > Application servers > server_name**.
- Under Security, click **Web services: Default bindings for Web services security**.
- Under Additional properties, click **Properties > New**.
- In the Property name field, type `com.ibm.ws.wssecurity.config.token.certificate.useCache`.
- In the Property value field, type `false`.

Providing support for a certificate revocation list

The certificate revocation list (CRL) in WebSphere Application Server Version 6 and later is used to enhance certificate path validation. You can specify a CRL in the collection certificate store for validation. You can also encode a CRL in an X.509 token using PKCS#7 encoding. However, WebSphere Application Server Version 6 and later do not support X509PKIPathv1 CRL encoding in a X.509 token.

Important: The PKCS#7 encoding was tested with the IBM certificate path (IBM CertPath) provider only. The encoding is not supported for other certificate path providers.

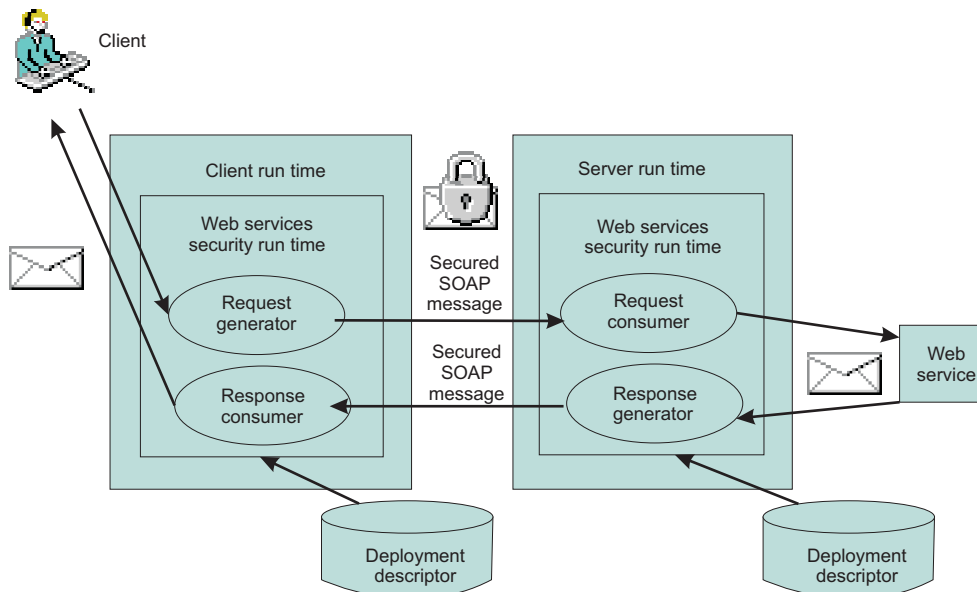

High-level architecture for Web services security

The Web services security constraints are specified in the IBM extension of the Web services deployments descriptors and bindings. The Web services security run time enforces the security constraints specified in the deployment descriptors.

WebSphere Application Server Version 6 and later use the Java 2 Platform, Enterprise Edition (J2EE) Version 1.4 Web services deployment model to implement Web services security. One of the advantages of deployment model is that you can define the Web services security requirements outside of the

application business logic. With the separation of roles, the application developer can focus on the business logic and the security expert can specify the security requirement.

The following figure shows the high-level architecture model that is used to secure Web services in WebSphere Application Server Version 6.

The deployment descriptor and binding for Web services security is based on Web service ports. Each Web service port can have its own unique Web services security constraints defined. For example, you might configure Web service port A to sign the SOAP body and the Username token. You might configure Web service port B to encrypt the SOAP body content and so on.

As shown in the previous figure, there are 2 sets of configurations on both the client side and the server side:

Request generator

This client-side configuration defines the Web services security requirements for the outgoing SOAP message request. These requirements might involve generating a SOAP message request that uses a digital signature, incorporates encryption, and attaches security tokens. In WebSphere Application Server Versions 5.0.2, 5.1, and 5.1.1, the request generator was known as the *request sender*.

Request consumer

This server-side configuration defines the Web services security requirements for the incoming SOAP message request. These requirements might involve verifying that the required integrity parts are digitally signed; verifying the digital signature; verifying that the required confidential parts were encrypted by the request generator; decrypting the required confidential parts; validating the security tokens, and verifying that the security context is set up with the appropriate identity. In WebSphere Application Server Versions 5.0.2, 5.1, and 5.1.1, the request consumer was known as the *request receiver*.

Response generator

This server-side configuration defines the Web services security requirements for the outgoing SOAP message response. These requirements might involve generating the SOAP message response with Web services security; including digital signature; and encrypting and attaching the security tokens, if necessary. In WebSphere Application Server Versions 5.0.2, 5.1, and 5.1.1, the response generator was known as the *response sender*.

Response consumer

This client-side configuration defines the Web services security requirements for the incoming SOAP response. The requirements might involve verifying that the integrity parts are signed and the signature is verified; verifying that the required confidential parts are encrypted and that the parts are decrypted; and validating the security tokens. In WebSphere Application Server Versions 5.0.2, 5.1, and 5.1.1, the response consumer was known as the *response receiver*.

WebSphere Application Server Versions 6 and later do not include security policy negotiation or exchange between the client and server. This security policy negotiation is defined by the WS-Policy, WS-PolicyAssertion, and WS-SecurityPolicy specifications and are not supported in WebSphere Application Server Version 6 and later.

Note: The Web services security requirements that are defined in the request generator must match the request consumer. The requirements that are defined in the response generator must match the response consumer. Otherwise, the request or response is rejected because the Web services security constraints can not be met by the request consumer and response consumer.

The format of the Web services security deployment descriptors and bindings are IBM proprietary. However, the following tools are available to edit the deployment descriptors and bindings:

Rational Application Developer Version 6.0.x

Use this tool to edit the Web services security deployment descriptor and binding. You can use this tool to assemble both Web and Enterprise JavaBeans (EJB) modules.

Rational Web Developer Version 6.0.x

Use this tool to edit the Web services security deployment descriptor and binding. You can use this tool to assemble Web modules only.

Application Server Toolkit

Use this tool to edit the Web services security deployment descriptor and binding.

WebSphere Application Server Administrative Console Version 6 and later

Use this tool to edit the Web services security binding of a deployed application.

Overview of platform configuration and default bindings

The Web services security constraints are defined in an IBM extension of the Web services deployment descriptor for Java 2 Platform, Enterprise Edition (J2EE). The IBM extension deployment descriptor and binding for Web services security are IBM proprietary. Due to the complexity of these files, it is not recommended that you edit the deployment descriptor and binding files manually with a text editor because they might cause errors. It is recommended, however, that you use the tools provided by IBM to configure the Web services security constraints for an application. These tools are the Rational Application Developer, Rational Web Developer, the Application Server Toolkit, and the WebSphere Application Server administrative console.

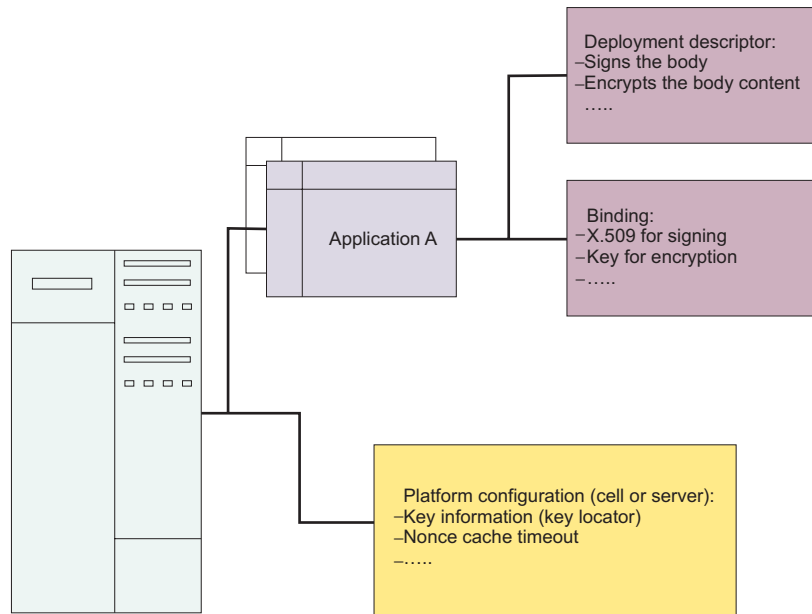

The following table provides the names of the deployment descriptor and binding files for the client and the server.

File type	Client side	Server side
Deployment descriptor	ibm-webservicesclient-ext.xmi	ibm-webservices-ext.xmi
Binding file	ibm-webservicesclient-bnd.xmi	ibm-webservices-bnd.xmi

The “what” is specified in the deployment descriptor such as what message part to sign and which token to encrypt. The “how” is specified in the binding file such as how the message is signed, how to generate and consume the security token.

In addition to the application deployment descriptor and binding files, WebSphere Application Server Versions 6 and later have a cell level and a server level configuration. These configurations are global for all applications. Because WebSphere Application Server Version 6 and later support 5.x applications, some of the configurations are valid for Version 5.x applications only and some are valid for Version 6 and later applications only.

The following figure represents the relationship of the application deployment descriptor and binding files to the cell or server level configuration.

WebSphere Application Server

Platform configuration

The following options are available in the administrative console:

Nonce cache timeout

This option, which is found on the cell level (Network Deployment only) and server level, specifies the cache timeout value for a nonce in seconds.

Nonce maximum age

This option, which is found on the cell level (Network Deployment only) and server level, specifies the default life span for the nonce in seconds.

Nonce clock skew

This option, which is found on the cell level (Network Deployment only) and server level, specifies the default clock skew to account for network delay, processing delay, and so on. It is used to calculate when the nonce expires. Its unit of measurement is seconds.

Distribute nonce caching

This feature enables you to distribute the cache for the nonce to different servers in a cluster. It is a new feature for WebSphere Application Server Version 6.0.x.

The following features can be referenced in the application binding:

Key locator

This feature specifies how the keys are retrieved for signing, encryption, and decryption. The implementation classes for the key locator are different in WebSphere Application Server Versions 6 and later and Version 5.x.

Collection certificate store

This feature specifies the certificate store for certificate path validation. It is typically used for validating X.509 tokens during signature verification or constructing the X.509 token with a certificate revocation list that is encoded in the PKCS#7 format. The certificate revocation list is supported for WebSphere Application Server Version 6 and later applications only.

Trust anchors

This feature specifies the trust level for the signer certificate and is typically used in the X.509 token validation during signature verification.

Trusted ID evaluators

This feature specifies how to verify the trust level for the identity. The feature is used with identity assertion.

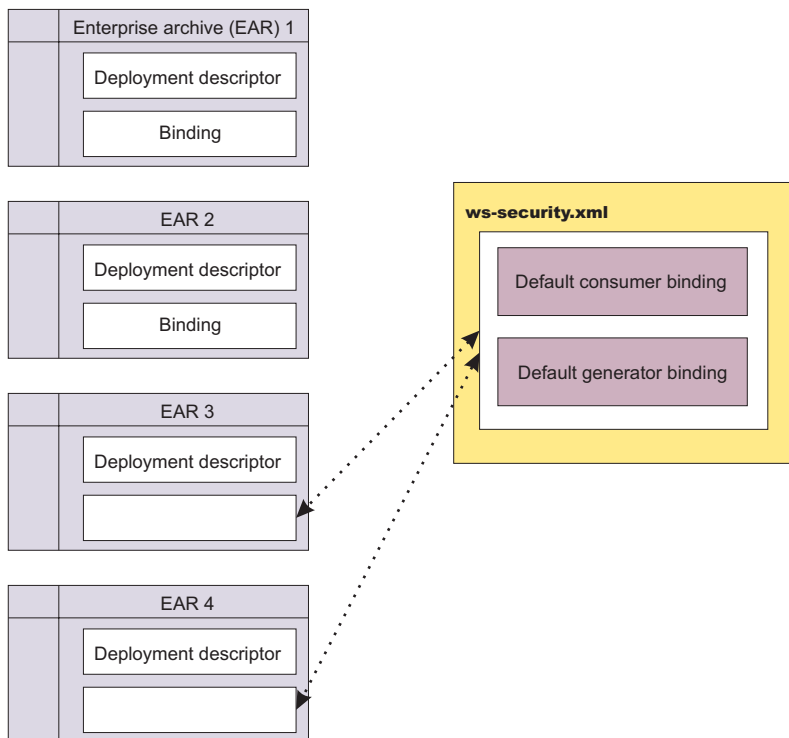

Login mappings

This feature specifies the login configuration binding to the authentication methods. This feature is used by WebSphere Application Server Version 5.x applications only and it is deprecated.

Default bindings

There is only one set of default bindings and they can be shared by multiple applications. This feature is available for WebSphere Application Server Version 6 and later applications only.

The following figure shows the relationship between the application enterprise archive (EAR) file and the `ws-security.xml` file.

Application EAR 1 and EAR 2 have specific bindings in the application binding file. However, application EAR 3 and EAR 4 do not have a binding in the application binding file, it must be referenced to use the default bindings defined in the `ws-security.xml` file. The configuration is resolved by nearest configuration in the hierarchy. For example, there might be three key locators named `mykeylocator` defined in the application binding file, the server level, and the cell level. If `mykeylocator` is referenced in the application binding, then the key locator defined in the application binding is used. The visibility scope of the data depends upon where the data is defined. If the data is defined in the application binding, then its visibility

is scoped to that particular application. If the data is defined on the server level, then the visibility scope is all of the applications deployed on that server. If the data is defined on the cell level, then the visibility scope is all of the applications deployed on servers in the cell. In general, if data is not meant to be shared by other applications, define the configuration in the application binding level.

The following figure shows the relationship of the bindings on the application, server, and cell levels.

Security model mixture

There can be multiple protocols and channels in the WebSphere Application Server Version 6 and later programming environments. Each of these applications serve different business needs.

For example, you might access:

- A Web-based application through the HTTP transport such as a servlet, JavaServer Pages (JSP) file, HTML and so on.
- An enterprise application through the Remote Method Invocation (RMI) over the Internet Inter-ORB (RMI/IIOP) protocol.
- A Web service application through the SOAP over HTTP, SOAP over the Java Message Service (JMS), or SOAP over the RMI/IIOP protocol.

More importantly, Web services are often implemented as servlets with a Enterprise JavaBeans (EJB) file. Therefore, you can mix and match the Web services security model with the Java 2 Platform, Enterprise Edition (J2EE) security model for Web and EJB components. It is intended that Web service security compliment the J2EE role-based security and the security run time for WebSphere Application Server Version 6 and later.

Web services security also can take advantage of the security features in J2EE and the security run time for WebSphere Application Server Version 6 and later. For example, Web services security can use the following security features to provide an end-to-end security deployment:

- Use the local OS, Lightweight Directory Access Protocol (LDAP), and custom user registries for authenticating the username token
- Propagate the Lightweight Third Party Authentication (LTPA) security token in the SOAP message
- Use identity assertion
- Use a trust association interceptor (TAI)
- Enable security attribute propagation

- Use J2EE role-based authorization
- Use a Java Authorization Contract for Containers (JACC) authorization provider, such as Tivoli Access Manager

The following figure shows that different security protocols are used to send authentication information to the application server. For a Web service, you might use either HTTP basic authentication with Secure Sockets Layer (SSL) or a Web services security username token with encryption. In the following figure, when identity *bob* from Web services security is authenticated and set as the caller identity of the SOAP message request, the J2EE Enterprise JavaBeans container performs authorization using *bob* before the call is dispatched to the service implementation, which, in this case, is the enterprise bean.

You can secure a Web service using the transport layer security. For example, when you are using SOAP over HTTP, HTTPS can be used to secure the Web service. However, transport layer security provides point-to-point security only. This layer of security might be adequate for certain scenarios. However, when the SOAP message must travel through intermediary servers (multi-hop) before it is consumed by the target endpoint, you might use SOAP over the Java Message Service (JMS). The usage scenarios and security requirements dictate how to secure Web services. The requirements depend upon the operating environment and the business needs. However, one key advantage of using Web services security is that it is transport layer independent; the same Web services security constraints can be used for SOAP over HTTP, SOAP over JMS, or SOAP over RMI/IIOP.

Security considerations for Web services

When you configure Web services security, you must make every effort to verify that the result is not vulnerable to a wide range of attack mechanisms. This article provides some information about the possible security concerns that arise when you are securing Web services.

In WebSphere Application Server Version 6 and later, when you enable integrity, confidentiality, and the associated tokens within a SOAP message, security is not guaranteed. This list of security concerns is not complete. You must conduct your own security analysis for your environment.

- Ensuring the message freshness

Message freshness involves protecting resources from a replay attack in which a message is captured and resent. Digital signatures, by themselves, cannot prevent a replay attack because a signed message can be captured and resent. It is recommended that you allow message recipients to detect message replay attacks when messages are exchanged through an open network. You can use the following elements, which are described in the Web services security specifications, for this purpose:

Timestamp

You can use the timestamp element to keep track of messages and to detect replays of previous messages. The WS-Security 2004 specification recommends that you cache time stamps for a given period of time. As a guideline, you can use five minutes as a minimum period of time to detect replays. Messages that contain an expired timestamp are rejected.

Nonce

A nonce is a child element of UsernameToken in the UsernameToken profile. Because each Nonce element has a unique value, recipients can detect replay attacks with relative ease.

Important: Both the time stamp and nonce element must be signed. Otherwise, these elements can be altered easily and therefore cannot prevent replay attacks.

- Using XML digital signature and XML encryption properly to avoid a potential security hole

The WS-Security 2004 specification defines how to use XML digital signature and XML encryption in SOAP headers. Therefore, users must understand XML digital signature and XML encryption in the context of other security mechanisms and their possible threats to an entity. For XML digital signature, you must be aware of all of the security implications resulting from the use of digital signatures in general and XML digital signature in particular. When you build trust into an application based on a digital signature, you must incorporate other technologies such as certification trust validation based upon the Public Key Infrastructure (PKI). For XML encryption, the combination of digital signing and encryption over a common data item might introduce some cryptographic vulnerabilities. For example, when you encrypt digitally signed data, you might leave the digital signature in plain text and leave your message vulnerable to plain text guessing attacks. As a general practice, when data is encrypted, encrypt any digest or signature over the data. For more information, see <http://www.w3.org/TR/xmlenc-core/#sec-Sign-with-Encrypt>.

- Protecting the integrity of security tokens

The possibility of a token substitution attack exists. In this scenario, a digital signature is verified with a key that is often derived from a security token and is included in a message. If the token is substituted, a recipient might accept the message based on the substituted key, which might not be what you expect. One possible solution to this problem is to sign the security token (or the unique identifying data from which the signing key is derived) together with the signed data. In some situations, the token that is issued by a trusted authority is signed. In this case, there might not be an integrity issue. However, because application semantics and the environment might change over time, the best practice is to prevent this attack. You must assess the risk assessment based upon the deployed environment.

- Verifying the certificate to leverage the certificate path verification and the certificate revocation list

It is recommended that you verify that the authenticity or validity of the token identity that is used for digital signature is properly trusted. Especially for an X.509 token, this issue involves verifying the certificate path and using a certificate revocation list (CRL). In the Web services security implementation in WebSphere Application Server Version 6 and later, the certificate is verified by the TokenConsumer element. WebSphere Application Server provides a default implementation for the X.509 certificate that uses the Java CertPath library to verify and validate the certificate. In the implementation, there is no explicit concept of a CRL. Rather, proper root certificates and intermediate certificates are prepared in files only. For a sophisticated solution, you might develop your own TokenConsumer implementation that performs certificate and CRL verification using the online CRL database or the Online Certificate Status Protocol (OCSP).

- Protecting the username token with a password

It is recommended that you do not send a password in a UsernameToken to a downstream server without protection. You can use transport-level security such as SSL (for example, HTTPS) or use XML

encryption within Web services security to protect the password. The preferred method of protection depends upon your environment. However, you might be able to send a password to a downstream server as plain text in some special environments where you are positive that you are not vulnerable to an attack.

Securing Web services involves more work than just enabling XML digital signature and XML encryption. To properly secure a Web service, you must have knowledge about the Public Key Infrastructure (PKI). The amount of security that you need depends upon the deployed environment and the usage patterns. However, there are some basic rules and best practices for securing Web services. It is recommended that you read some books on PKI and read information on the Web Services Interoperability Organization (WS-I) Basic Security Profile (BSP). See Basic Security Profile Version 1.0 for more information.

Migrating Version 5.x applications with Web services security to Version 6.1 applications

Migration of a Java 2 Platform, Enterprise Edition (J2EE) Version 1.3 application that uses Web services security to a Java 2 Platform, Enterprise Edition Version 1.4 application is possible.

You can install Java 2 Platform, Enterprise Edition Version 1.3 applications that use Web services security on a WebSphere Application Server Version 6.1 server. However, if you want J2EE Version 1.3 applications to use the Web services security (WSS) Version 1.0 specification and the other new features added in Version 6.1, you must migrate the J2EE Version 1.3 applications to J2EE Version 1.4.

Complete the following steps to migrate a Version 5.x application, along with the Web services security configuration information, to a Version 6.1 application:

1. Save the original J2EE Version 1.3 application. You need the Web services security configuration files of the J2EE Version 1.3 application to recreate the configuration in the new format for the J2EE Version 1.4 application.
2. Use the Java 2 Platform, Enterprise Edition (J2EE) Migration Wizard in an assembly tool to migrate the J2EE Version 1.3 application to J2EE Version 1.4.

Important: After you migrate to J2EE Version 1.4 using the J2EE Migration Wizard, you cannot view the J2EE Version 1.3 extension and binding information within an assembly tool. You can view the J2EE Version 1.3 Web services security extension and binding information using a text editor. However, do not edit the extension and binding information using a text editor. The J2EE Migration Wizard does not migrate the Web services security configuration files to the new format in the J2EE Version 1.4 application. Rather the wizard is used to migrate your files from J2EE Version 1.3 to Version 1.4.

To access the J2EE Migration Wizard, complete the following steps:

- a. Right-click the name of your application.
 - b. Click **Migrate > J2EE Migration Wizard**.
3. Manually delete all of the Web services security configuration information from the binding and extension files of the application that is migrated to J2EE Version 1.4.
 - a. Delete the `<securityRequestReceiverServiceConfig>` and `<securityResponseSenderServiceConfig>` sections from the server-side `ibm-webservices-ext.xmi` extension file.
 - b. Delete the `<securityRequestReceiverBindingConfig>` and `<securityResponseSenderBindingConfig>` sections from the server-side `ibm-webservices-bnd.xmi` binding file.
 - c. Delete the `<securityRequestSenderServiceConfig>` and `<securityResponseReceiverServiceConfig>` sections from the client-side `ibm-webservicesclient-ext.xmi` extension file.

- d. Delete the <securityRequestSenderBindingConfig> and <securityResponseReceiverBindingConfig> sections from client-side `ibm-webservicesclient-bnd.xmi` binding file.
4. Recreate the Web services security configuration information in the new J2EE Version 1.4 format. At this stage, because the application is already migrated to the J2EE Version 1.4, you can use the Application Server Toolkit to configure the original Web services security information in the new Version 6.1 format.

This task provides general information about how to migrate J2EE Version 1.3 applications to J2EE Version 1.4.

The following articles contain some general scenarios that map some of the basic Web services security information specified in a J2EE Version 1.3 application to a J2EE Version 1.4 application and specify this information using the Application Server Toolkit. The Web services security configuration information is contained in four configuration files: two server-side configuration files and two client-side configuration files. The migration of all of the configuration information is divided into four sections; one for each configuration file. When you recreate the Web services security information in the new J2EE Version 1.4 format, it is recommended that you configure the extensions and binding files in the following order:

1. Configure the `ibm-webservices-ext.xmi` server-side extensions file. For more information, see “Migrating the server-side extensions configuration.”
2. Configure the `ibm-webservicesclient-ext.xmi` client-side extensions file. For more information, see “Migrating the client-side extensions configuration” on page 994.
3. Configure the `ibm-webservices-bnd.xmi` server-side bindings file. For more information, see “Migrating the server-side bindings file” on page 995.
4. Configure the `ibm-webservicesclient-bnd.xmi` client-side bindings file. For more information, see “Migrating the client-side bindings file” on page 997.

Migrating the server-side extensions configuration

This article provides general information about migrating the Web services security server-side extensions configuration for a Java 2 Platform, Enterprise Edition (J2EE) Version 1.3 application to a J2EE Version 1.4 application. The steps are based on typical scenarios, but the steps are not all-inclusive.

The following table lists the mappings for the top-level sections under the server-side **Security Extensions** tab within an assembly tool from a J2EE Version 1.3 application to a J2EE Version 1.4 application.

Table 39. The mapping of the configuration sections

J2EE Version 1.3 extensions configuration	J2EE Version 1.4 extensions configuration
Request Receiver Service Configuration Details	Request Consumer Service Configuration Details
Response Sender Service Configuration Details	Response Generator Service Configuration Details

For information about the assembly tools that are available for WebSphere Application Server Version 6.0.x, see Assembly tools.

Consider the following steps to migrate the server-side extensions from a J2EE Version 1.3 application to a J2EE Version 1.4 application. These steps are dependent upon your specific configuration.

- Import the J2EE Version 1.3 application into an assembly tool and identify all the message parts that are required to be signed and encrypted. The message parts are listed in the Required Integrity and Required Confidentiality sections under the Request Receiver Service Configuration Details section. In a J2EE Version 1.4 application, these message parts map to the Message parts field of the **Required integrity** and **Required confidentiality** dialogs windows within the assembly tool. To specify these message parts within an assembly tool, complete the following steps in the Web Services editor:

1. Click the **Extensions** tab.
2. Navigate to the Required integrity subsection within the Request Consumer Service Configuration Details section.
3. Specify each message part to be signed in the Message Parts field.

For example, if the message part in the J2EE Version 1.3 application is body, you need to specify **body** in the Message parts keyword field. Similarly, on the **Extensions** tab, configure the message parts to be encrypted using the Required Confidentiality dialog. Also, for all the message parts that are migrated from a J2EE Version 1.3 application, you must select <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> in the Message parts dialect field and **Required** in the Usage type field.

- **Optional:** Configure the Required Security Token and Caller Part sections on the **Extensions** tab if the authentication method of BasicAuth is configured under the Login Config section of the J2EE Version 1.3 application. When you configure the Required Security Token section, select **Username** in the name field and **Required** in the Usage type field within the Required Security Token Dialog window. The following table shows how the authentication method values for a J2EE Version 1.3 application map to the token type values within the J2EE Version 1.4 application.

Table 40. Authentication method to token type mappings

Login Config Authentication method values in the J2EE Version 1.3 extensions configuration	Token type values in the J2EE Version 1.4 extensions configuration
BasicAuth	UsernameToken
Signature	X509 certificate
LTPA	LTPAToken

If the authentication method value is IDAssertion within the Login Config section, the token type that you must specify in the J2EE Version 1.4 application depends upon the IDType value within the IDAssertion section. The following table shows how the IDType values for J2EE Version 1.3 application map to the token type values in the J2EE Version 1.4 application.

Table 41. IDType values to token type mappings

IDType values in the J2EE Version 1.3 application extensions configuration	Token type values in the J2EE Version 1.4 application extensions configuration
X509Certificate	X509 certificate
Username	Username

- Select the appropriate token type in the Name field of the Call Part Dialog window based on the previous two tables. Select the **Username** token type when you are configuring the caller part for the basic authentication method. Configuring the other token types in the Caller part dialog is similar to configuring token types in the Required Security Token dialog. If you need to map the IDAssertion authentication method from a J2EE Version 1.3 application to a J2EE Version 1.4 application, select the **Use IDAssertion** option and configure the ID assertion section of the Caller Part Dialog window. The Trust Mode field under the IDAssertion section maps to the Trust method name field of the Trust method property section in the Caller Part Dialog window. If Signature is selected for the Trust method, specify the Required Integrity part that specifies the signature of the trusted intermediary certificate.
- Configure a nonce in the Version 6.1 Binding Configurations section if nonce is specified in the Add Authentication Method dialog under Login Config within the J2EE Version 1.3 application extensions configuration.

Important: Nonce is configured in the bindings for a J2EE Version 1.4 application and not in the extensions.

To configure a nonce on the Binding Configurations tab, set the `com.ibm.wsspi.wssecurity.token.Username.verifyNonce` property in the Token Consumer configuration for the Username token.

- Configure the Add Timestamp section to migrate the time stamp information if the `<addReceivedTimestamp>` element is configured in the J2EE Version 1.3 extensions. To migrate the Response Sender Service Configuration Details section in the J2EE Version 1.3 extensions, identify all of the message parts listed within the Integrity and Confidentiality sections. Configure these message parts using the Integrity and Confidentiality dialogs under the Response Generator Service Configuration details section. This configuration is similar to the configuration for Required Integrity and Required Confidentiality, with the exception of the Order field in the Integrity Dialog. The value of this Order field specifies the order in which the message parts specified in the Message Parts field are digitally signed or encrypted in the Simple Object Access Protocol (SOAP) message. For example, the extensions contain the following information:
 - One integrity entry called `int_part1` with a value of 1 in the Order field
 - One confidentiality entry called `conf_part1` with a value of 2 in the Order field

In this example, the message parts that are specified by the `int_part1` integrity entry are signed before the message parts specified by the `conf_part1` confidentiality entry are encrypted. The same rule for the order attribute applies for multiple integrity or confidentiality elements.

This set of steps describe the types of information that you need to migrate the Web services security server-side extensions for a J2EE Version 1.3 application to a J2EE Version 1.4 application.

Migrate the client-side extensions for a J2EE Version 1.3 application to a J2EE Version 1.4 application. For more information, see “Migrating the client-side extensions configuration.”

Migrating the client-side extensions configuration

This article provides general information about migrating the Web services security client-side extensions configuration for a Java 2 Platform, Enterprise Edition (J2EE) Version 1.3 application to a J2EE Version 1.4 application. The steps are based on typical scenarios, but the steps are not all-inclusive.

The following table lists the mappings of the top-level sections under the client-side **Security Extensions** tab for Web services security from a J2EE Version 1.3 application to a J2EE Version 1.4 application.

Table 42. The mapping of the configuration sections

J2EE Version 1.3 security extensions for Web services security	J2EE Version 1.4 extensions for Web services security
Request Sender Configuration	Request Generator Configuration
Response Receiver Configuration	Response Consumer Configuration

Consider the following steps to migrate the client-side extensions configuration from a J2EE Version 1.3 application to a J2EE Version 1.4 application. These steps are dependent upon your specific configuration.

- Migrate the message parts that you need to sign or encrypt from the Integrity and Confidentiality sections in the J2EE Version 1.3 application to the Integrity and Confidentiality sections on the **WS Extensions** tab in an assembly tool for a J2EE Version 1.4 application.
- Configure the Security Token section under the Request Generator Configuration on the **WS Extensions** tab if Login Config section is configured in the J2EE Version 1.3 extensions configuration. When you configure the security token, select the token type in the Token type field that matches the authentication method value of the Login Config in the J2EE Version 1.3 application. For example, if the authentication method in the J2EE Version 1.3 extensions configuration is BasicAuth, then select **Username** in the Token type field within the assembly tool. For more information on how the authentication methods for Web services security map from a J2EE Version 1.3 application to a J2EE Version 1.4 application, see Table 40 on page 993. If the authentication method is IDAssertion, there is no action required because in a J2EE Version 1.4 application the identity assertion configuration is not

required in the client-side extensions configuration. In a J2EE Version 1.4 application, the identity assertion configuration is specified in the server-side extensions configuration and in the client-side bindings configuration.

- Migrate the Required Integrity and Required Confidentiality sections by configuring the Required Integrity and Required Confidentiality sections in an assembly tool. Migrating the Response Receiver Configuration section is similar to migrating the Request Receiver Service Configuration Details section of the server-side extensions configuration. For more information, see “Migrating the server-side extensions configuration” on page 992.
- Migrate the nonce configuration in the Login Config section in a J2EE Version 1.3 extensions configuration for Web services security to a J2EE Version 1.4 application.

Important: Nonce is not configured in a J2EE Version 1.4 extension file for Web services security. Rather, it is configured in the binding file for Web services security.

To configure a nonce in the binding file, define the `com.ibm.wsspi.wssecurity.token.username.addNonce` property in the token generator of the username token.

- Configure the Add Timestamp section under the Request Generator Configuration in the assembly tool if the **Add Created Time Stamp** option is configured in the J2EE Version 1.3 extensions.

This set of steps describe the types of information that you need to migrate the client-side extensions configuration for Web services security for a J2EE Version 1.3 application to a J2EE Version 1.4 application.

Migrate the server-side bindings configuration for a J2EE Version 1.3 application to a J2EE Version 1.4 application. For more information, see “Migrating the server-side bindings file.”

Migrating the server-side bindings file

This article provides general information about migrating the server-side bindings configuration for a Java 2 Platform, Enterprise Edition (J2EE) Version 1.3 application to a J2EE Version 1.4 application. The steps are based on typical scenarios, but the steps are not all-inclusive.

The following table lists the mappings of the top-level sections under the server-side **Binding Configurations** tab from a J2EE Version 1.3 application to a J2EE Version 1.4 application.

Table 43. The mapping of the configuration sections

J2EE Version 1.3 Binding Configurations	J2EE Version 1.4 Binding Configurations
Request Receiver Binding Configuration Details	Request Consumer Service Binding Configuration Details
Response Sender Binding Configuration Details	Response Generator Binding Configuration Details

Consider the following steps to migrate the server-side bindings from J2EE Version 1.3 to J2EE Version 1.4. These steps are dependent upon your specific configuration.

- Migrate the configuration information under the Request Receiver Binding Configuration Details section of a J2EE Version 1.3 application.
 1. Migrate any trust anchor information that is specified in the J2EE Version 1.3 application to J2EE Version 1.4 using the Trust Anchor dialog.
 2. Migrate the information under the certificate store list that is specified in the J2EE Version 1.3 application to J2EE Version 1.4 by configuring the Certificate Store List section in the J2EE Version 1.4 application.
 3. Configure the key locator and token consumer information that is referenced from the Key Information dialog window. The configuration of the key locator and the token consumer depends upon the key information type. For example, if an X.509 certificate that is embedded in the `<wsse:Security>` security header is used for digital signature, complete the following steps:

- a. For configuring the key locator, specify the `com.ibm.wsspi.wssecurity.keyinfo.X509TokenKeyLocator` class as the key locator class and do not specify a key store.
 - b. For configuring the token consumer, select the `com.ibm.wsspi.wssecurity.token.509TokenConsumer` class, specify X509 certificate token for the value type Uniform Resource Identifier (URI), and specify `system.wssecurity.X509BST` in the `jaas.config.name` field. Also, you must specify the certificate path settings (the trust anchor reference and the certificate store reference) as part of the token consumer configuration.
4. Explicitly specify the key information type in the Key Information Dialog window. In a J2EE Version 1.3 application, the key information type, such as the security token reference and the key identifier, is not explicitly specified. The key information type is implied by the configuration. In a J2EE Version 1.4 application, you must specify the key information type explicitly using the Key Information Dialog when you have digital signature or encryption information in the binding file. Before you configure the key information, make sure that you have configured the key locator and token consumer information that is referenced from the Key Information dialog.

When you configure the key information for either digital signature or encryption, you need to specify the correct key information type. The value of the key information type depends upon the type of mechanism that is used to reference the security token that is used for digitally signing or encrypting. The following information describes the Security token reference (or Direct reference) and the Key identifier, which are the most common, recommended key information types that are used for digitally signing and encrypting:

Security token reference (or Direct reference)

The security token is directly referenced using the Uniform Resource Identifiers (URIs). The following `<KeyInfo>` element is generated in the Simple Object Access Protocol (SOAP) message for this key information type:

```
<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <wsse:Reference URI="#mytoken" />
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

Key identifier

The security token is referenced using an opaque value that uniquely identifies the token. The algorithm that is used for generating the `KeyIdentifier` value depends upon the token type. For example, a hash of the important elements of the security token is used for generating the `KeyIdentifier` value. The following `<KeyInfo>` element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
  <wsse:SecurityTokenReference>
    <wsse:KeyIdentifier ValueType="wsse:X509v3">/62wX0...</wsse:KeyIdentifier>
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

In the Key Information Dialog window, specify the names of the key locator and the token consumer that you configured previously. The Key name field is optional for the consumer side.

5. Migrate the information in the Signing Information section by configuring the Signing Information, Part References, and Transforms sections.
 - Specify the Signature method and Canonicalization method algorithms in the Signing Information Dialog window.
 - Specify the Digest method algorithm in the Part Reference Dialog window.
6. Migrate the information under the Encryption Information section. In the Encryption Information Dialog window, select the name of the Key Information element that is configured for encryption, and specify the `RequiredConfidentiality` part. Verify that the value for the selected `RequiredConfidentiality` part is the same name as the `Required Confidentiality` part that is configured in the extension file.

The Login Mapping section in the J2EE Version 1.3 application maps to the Token Consumer configuration for the type of token that is specified by the authentication method. For example, to migrate a Login Mappings configuration that uses the BasicAuth authentication method, configure a token consumer for the username token. To configure a token consumer for a username token, complete the following steps:

- a. Select the `com.ibm.wsspi.wssecurity.UsernameTokenConsumer` token consumer class.
 - b. Specify the name of the Required Security Token configuration from the Extensions within in the Security Token field.
 - c. Select **Username Token** for value type.
 - d. Specify the `system.wssecurity.UsernameToken` value in the `jaas.config.name` field.
- Migrate the configuration information in the Response Sender Binding Configuration Details section of the J2EE Version 1.3 bindings file to the Response Generator Binding Configuration Details section of the J2EE Version 1.4 application. Configuring the Response Generator section is very similar to configuring the Request Consumer section.
 1. Migrate the information from the Key Locators section by using the Key Locator Dialog window in an assembly tool.
 2. Configure a token generator, which is referenced in the Key Information Dialog window. You must configure a token generator for every security token that is generated in the SOAP message. If the token generator is for an X.509 certificate that is used for digital signature or encryption, complete the following steps:
 - a. For configuring the key locator, specify the `com.ibm.wsspi.wssecurity.keyinfo.X509TokenKeyLocator` class as the key locator class and do not specify a key store.
 - b. For configuring the token generator, select the `com.ibm.wsspi.wssecurity.X509TokenGenerator` class and specify `X509 certificate` token for the value type Uniform Resource Identifier (URI). The key store information that is specified for the token generator is the same information that is used for configuring the key locator. Therefore, the keystore information from the Key Locators configuration in a J2EE Version 1.3 application is used to configure the key locator and the token generator in a J2EE Version 1.4 application.
 - c. In the Token Generator Dialog window, specify the key store information that is required by the callback handler to obtain the key information that is required for generating the token.
 - d. For the callback handler, select the `com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler` class.
 3. Specify the names of the key locator and the token generator in the Key Information Dialog window that you configured previously. The Key name is required for the generator side. The key that is specified in the Key Information Dialog window must exist in the list of keys that is specified in the key locator configuration. Also, migrating the Signing Information and the Encryption Information configurations is similar to migrating the Signing Information and the Encryption Information configurations for the Request Receiver Binding Configuration section. Configuring the key information for the response generator section is similar to configuring the key information for the request consumer section.

This set of steps describe the types of information that you need to migrate the server-side bindings configuration for a J2EE Version 1.3 application to a J2EE Version 1.4 application.

Migrate the client-side binding configuration for a J2EE Version 1.3 application to a J2EE Version 1.4 application. For more information, see “Migrating the client-side bindings file.”

Migrating the client-side bindings file

This article provides general information about migrating the Web services security client-side binding configuration for a Java 2 Platform, Enterprise Edition Version 1.3 application to a J2EE Version 1.4 application. The steps are based on typical scenarios, but the steps are not all-inclusive.

The following table lists the mapping of the top-level sections under the client-side **Port Bindings** tab within a J2EE Version 1.3 application to a J2EE Version 1.4 application.

Table 44. The mapping of the configuration sections

J2EE Version 1.3 binding configuration for Web services security	J2EE Version 1.4 binding configuration for Web services security
Security Request Sender Binding Configuration	Security Request Generator Binding Configuration
Security Response Receiver Binding Configuration	Security Response Consumer Binding Configuration

Consider the following steps to migrate the client-side binding configuration from a J2EE Version 1.3 application to a J2EE Version 1.4 application. These steps are dependent upon your specific configuration.

- Migrate the information in the Security Request Sender Binding Configuration section in a J2EE Version 1.3 application to a J2EE Version 1.4 application. The migrations process for the Security Request Sender Binding Configuration section is similar to the process for the Response Sender Binding Configuration Details section in the server-side binding configuration. For more information, see “Migrating the server-side bindings file” on page 995.
- Migrate the information in the Key Locators, Signing Information, and the Encryption Information sections of the J2EE Version 1.3 application to a J2EE Version 1.4 application. The migration process for these elements on the client side is similar to migration process on the server side. For more information, see “Migrating the server-side bindings file” on page 995.
- Migrate the information in the Login Bindings section in a J2EE Version 1.3 application to a J2EE Version 1.4 application. The migration of the Login Bindings section depends upon the value of the authentication method. If the authentication method is `BasicAuth` or `IDAssertion`, configure a token generator for the username token. If the authentication method is `LTPA`, select the `com.ibm.wsspi.wssecurity.token.LTPATokenGenerator` class as the token generator class. If the client-side bindings for the Web service uses `IDAssertion`, complete the following steps:
 1. Configure a token generator for the authentication token of the original client.
 2. Define the `com.ibm.wsspi.wssecurity.token.IDAssertion.isUsed` property and set its value to `true` in the Token Generator Dialog window within an assembly tool. If the original client is using a username token for authentication and if the target Web service is using `BasicAuth` for authentication, configure the following token generators in the client-side binding file:
 - The username token of the original client. You must set the `com.ibm.wsspi.wssecurity.token.IDAssertion.isUsed` property in the token generator of the original client.
 - The username token of the intermediary Web service.
- Migrate the Security Response Receiver Binding Configuration section from a J2EE Version 1.3 application to a J2EE Version 1.4 application. Migrating the Security Response Receiver Binding Configuration section is similar to migrating the Request Receiver Binding Configuration Details section of the server-side bindings configuration. Migrate this information under the Security Response Consumer Binding Configuration section. For more information, see “Migrating the server-side bindings file” on page 995.

To configure a nonce in the binding file, define the `com.ibm.wsspi.wssecurity.token.username.addNonce` property in the token generator of the username token.

This set of steps describe the types of information that you need to migrate the Web services security client-side bindings configuration for a J2EE Version 1.3 application to a J2EE Version 1.4 application.

Verify that you have migrated both the server-side and the client-side extension and binding configurations for a J2EE Version 1.3 application to a J2EE Version 1.3 application. For more information, see “Migrating Version 5.x applications with Web services security to Version 6.1 applications” on page 991.

View Web services client deployment descriptor

Use this page to view your client deployment descriptor.

Before you begin this task, the Web services application must be installed.

By completing this task, you can gather information that enables your to maintain or configure binding information. After the Web services application is installed, you can view the Web services deployment descriptors.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Related Items, click **EJB modules** or **Web modules > *URI_file_name***.
3. Under Additional properties, click **View Web services client deployment descriptor extension**.

Application-level, server-level, and cell-level are the three levels of bindings that WebSphere Application Server Network Deployment offers. The information in the following implementation descriptions indicates how to configure your application-level bindings. If the Web server is acting as a client, the default bindings are used. To configure the server-level bindings, which are the defaults, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web Services: Default bindings for Web services security**.
3. To configure the cell-level bindings, click **Security > Web services**.

If you are using any of the following configurations, verify that the deployment descriptor is configured properly:

- Request signing
- Request encryption
- BasicAuth authentication
- Identity (ID) assertion authentication
- Identity (ID) assertion authentication with the signature TrustMode
- Response digital signature verification
- Response decryption

Request signing

If the integrity constraints (digital signature) are specified, verify that you configured the signing information in the binding files.

To configure the signing parameters, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Related Items, click **Web modules > *URI_file_name***
3. Under Additional properties, click **Web Services: Client security bindings**.
4. In the Response receiver binding column, click **Edit > Signing information > New**.

To configure the key locators, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Additional properties, click **Web Services: Default bindings for Web services security > Key locators**.

Request encryption

If the confidentiality constraints (encryption) are specified, verify that you configured the encryption information in the binding files.

To configure the encryption parameters, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Related Items, click **EJB modules** or **Web modules > *URI_file_name* > Web services: Client security bindings** .
3. In the Response receiver binding column, click **Edit > Encryption Information > New**.

To configure the key locators, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Additional properties, click **Web Services: Default bindings for Web services security > Key locators**.

BasicAuth authentication

If BasicAuth authentication is configured as the required security token, specify the callback handler in the binding file to collect the basic authentication data. The following list contains the Callback support implementations:

com.ibm.wsspi.wssecurity.auth.callback.GuiPromptCallbackHandler

This implementation prompts for basic authentication information, the user name and password, in an interface.

com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

This implementation reads the basic authentication information from the binding file.

com.ibm.wsspi.wssecurity.auth.callback.StdPromptCallbackHandler

This implementation prompts for a user name and password using the standard in (stdin) prompt.

To configure the login binding information, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Related items, click **EJB modules** or **Web modules > *URI_file_name* > Web services: Client security bindings**.
3. Under Request sender bindings, click **Edit > Login binding**.

Identity (ID) Assertion authentication with BasicAuth TrustMode

Configure a login binding in the bindings file with a `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler` implementation. Specify a BasicAuth user name and password that a trusted ID evaluator on a downstream server trusts.

To configure the login binding information, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Related items, click **EJB modules** or **Web modules > *URI_file_name* > Web services: Client security bindings**.
3. Under Request sender bindings, click **Edit > Login binding**.

Identity (ID) Assertion authentication with the Signature TrustMode

Configure the signing information in the bindings file with a signing key pointing to a key locator. The key locator contains the X.509 certificate that is trusted by the downstream server.

To configure ID assertion, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Additional properties, click **Web services: Default bindings for Web services security > Login mappings > IDAssertion**.

To configure the login binding information, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Related items, click **EJB modules** or **Web modules > *URI_file_name* > Web services: Client security bindings**.
3. Under Request sender bindings, click **Edit > Login binding**.

Response digital signature verification

If the integrity constraints, which require a signature, are defined, verify that you configured the signing information in the binding files.

To configure the signing parameters, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Related Items, click **EJB modules** or **Web modules > *URI_file_name* > Web services: Client security bindings**.
3. In the Response receiver binding column, click **Edit > Signing information > New**.

To configure the trust anchors, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Additional properties, click **Web Services: Default bindings for Web services security > Trust anchors > New**.

To configure the collection certificate store, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Additional properties, click **Web Services: Default bindings for Web services security > Collection certificate store > New**.

Response decryption

If the confidentiality constraints (encryption) are specified, verify that you defined the encryption information.

To configure the encryption information, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_file_name* > Web services: Client security bindings**.
3. In the Response receiver binding column, click **Edit > Encryption information > New**.

To configure the key locators, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Additional properties, click **Web Services: Default bindings for Web services security > Key locators**.

View Web services server deployment descriptor

Use this page to view your server deployment descriptor settings.

Before you begin this task, the Web services application must be installed.

By completing this task, you can gather information that enables you to maintain or configure binding information. After the Web services application is installed, you can view the Web services deployment descriptors.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.

2. Under Related items, click **EJB modules** or **Web modules** > *URI_file_name* > **View Web services server deployment descriptor**.

WebSphere Application Server Network Deployment has three levels of bindings: application-level, server-level, and cell-level. The information in the following implementation descriptions indicate how to configure your application-level bindings. To configure the server-level bindings, which are the defaults, complete the following steps:

1. Click **Servers** > **Application servers** > *server_name*.
2. Under Security, click **Web services: Default bindings for Web services security**.

To configure the cell-level bindings, click **Security** > **Web services**.

- Request digital signature verification
- Request decryption
- Basic authentication
- Identity (ID) assertion authentication
- Identity (ID) assertion authentication with the signature TrustMode
- Response signing
- Response encryption

Request digital signature verification

If the integrity constraints, which require a signature, are defined, verify that you configured the signing information in the binding files.

To configure the signing parameters, complete the following steps:

1. Click **Applications** > **Enterprise applications** > *application_name*.
2. Under Related items, click **EJB modules** or **Web modules** > *URI_file_name* > **Web services: Server security bindings**.
3. Under Request consumer (receiver) binding, click **Edit custom** > **Signing information**.

To configure the trust anchor, complete the following steps:

1. Click **Servers** > **Application servers** > *server_name*.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Trust anchors**.

To configure the collection certificate store, complete the following steps:

1. Click **Servers** > **Application servers** > *server_name*.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Collection certificate store**.

To configure the key locators, complete the following steps:

1. Click **Servers** > **Application servers** > *server_name*.
2. Under Security, click **Web Services: Default bindings for Web services security**.
3. Under Additional properties, click **Key locators**.

Request decryption

If the confidentiality constraints (encryption) are specified, verify that the encryption information is defined.

To configure the encryption information parameters, complete the following steps:

1. Click **Enterprise applications** > *application_name*.
2. Under Related items, click **EJB modules** or **Web modules** > *URI_name*.

3. Under Additional properties, click **Web services: Server security bindings**.
4. Under Request consumer (receiver) binding, click **Edit custom > Encryption information**.

To configure the key locators, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web Services: Default bindings for Web services security**.
3. Under Additional properties, click **Key locators**.

Basic authentication

If BasicAuth authentication is configured as the required security token, specify the callback handler in the binding file to collect the basic authentication data. The following list contains callback support implementations:

com.ibm.wsspi.wssecurity.auth.callback.GuiPromptCallbackHandler

The implementation prompts for BasicAuth information (user name and password) in an interface panel.

com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

This implementation reads the BasicAuth information from the binding file.

com.ibm.wsspi.wssecurity.auth.callback.StdPromptCallbackHandler

This implementation prompts for a user name and password using the standard in (stdin) prompt.

To configure the login mapping information, complete the following steps:

1. Click **Server > Application Servers > *server_name***.
2. Under Security, click **Web Services: Default bindings for Web services security**.
3. Under Additional properties, click **Login mappings**.

Identity (ID) assertion authentication with the BasicAuth TrustMode

Configure a login binding in the bindings file with a `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler` implementation. Specify a user name and password for basic authentication that a TrustedIDEvaluator on a downstream server trusts.

To configure the login mapping information, complete the following steps:

1. Click **Server > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Login mappings**.

Identity (ID) assertion authentication with the signature TrustMode

Configure the signing information in the bindings file with a signing key that points to a key locator. The key locator contains the X.509 certificate that is trusted by the downstream server.

To configure the login mapping information, complete the following steps:

1. Click **Server > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Login mappings**.

The Java Authentication and Authorization Service (JAAS) uses `WSLogin` as the name of the login configuration. To configure JAAS, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Authentication, click **Java Authentication and Authorization Service > Application logins**.

The value of the <TrustedIDEvaluatorRef> tag in the binding must match the value of the <TrustedIDEvaluator> name.

To configure the trusted ID evaluators, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Trusted ID evaluators**.

Response signing

If the integrity constraints (digital signature) are defined, verify that you have the signing information configured in the binding files.

To specify the signing information, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Related items, click **EJB modules** or **Web modules > *URI_file_name* > Web services: Server security bindings**.
3. In the Request receiver binding column, click **Edit > Signing information**.

To configure the key locators, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Key locators**.

Response encryption

If the confidentiality constraints (encryption) are specified, verify that the encryption information is defined.

To specify the encryption information, complete the following steps:

1. Click **Enterprise applications > *application_name***.
2. Under Related items, click **EJB modules** or **Web modules**.
3. Under Additional properties, click **Web services: Server security bindings**.
4. Under Request consumer (receiver) binding, click **Edit custom > Encryption information**.

To configure the key locators, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Key locators**.

Default implementations of the Web services security service provider programming interfaces

This information describes the default implementations of the service provider interfaces (SPI) for Web services security within WebSphere Application Server Version 6 and later.

The default implementations of the service provider interfaces for WebSphere Application Server Version 5.x are not described in this document. Instead, see “Securing Web services for Version 5.x applications based on WS-Security” on page 1260 for the Version 5.x implementations that are deprecated in Version 6.0.x and later.

com.ibm.wsspi.wssecurity.token.X509TokenGenerator

This class implements the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface. It is responsible for creating the X.509 token object from the X.509 certificate, which is returned by

the `com.ibm.wsspi.wssecurity.auth.callback.{X509,PKCS7,PkiPath}CallbackHandler` interface. Encode the token using the base 64 format and insert its XML representation into the Simple Object Access Protocol (SOAP) message, if necessary.

`com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler`

This class implements the `javax.security.auth.callback.CallbackHandler` interface and it retrieves the X.509 certificate from the keystore file.

`com.ibm.wsspi.wssecurity.token.UsernameTokenGenerator`

This class implements the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface. It is responsible for creating the username token object from user name and password that is returned by a `javax.security.auth.callback.CallbackHandler` implementation such as the following callback handlers:

`com.ibm.wsspi.wssecurity.auth.callback.{GUIPrompt,NonPrompt,StdinPrompt}CallbackHandler`

It also inserts the XML representation of the token into the SOAP message, if necessary.

`com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator`

This class implements the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` interface and it retrieves the keys from the keystore files for digital signature and encryption.

`com.ibm.wsspi.wssecurity.token.X509TokenConsumer`

This class implements the `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` interface and processes the X.509 token from the binary security token. This class decodes the Base64 encryption within the X.509 token and then invokes the `system.wssecurity.X509BST` Java Authentication and Authorization Service (JAAS) Login Configuration with the `com.ibm.wsspi.wssecurity.auth.module.X509LoginModule` login module to validate the X.509 token. An object of the `com.ibm.wsspi.wssecurity.auth.token.X509Token` is created for the validated X.509 token and stored in JAAS Subject.

`com.ibm.wsspi.wssecurity.token.IDAssertionUsernameTokenConsumer`

This class implements `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` interface and processes the username token for identity assertion (IDAssertion), which does not have a password element. This interface invokes the `system.wssecurity.IDAssertionUsernameToken` JAAS login configuration with the `com.ibm.wsspi.wssecurity.auth.module.IDAssertionUsernameLoginModule` login module to validate the IDAssertion user name token. An object of the `com.ibm.wsspi.wssecurity.auth.token.UsernameToken` class is created for the validated username token and stored in the JAAS Subject.

`com.ibm.wsspi.wssecurity.auth.module.IDAssertionUsernameLoginModule`

This class implements the `javax.security.auth.spi.LoginModule` interface and checks whether the username value is not empty. The login module assumes that the UsernameToken is valid if the username value is not empty.

`com.ibm.wsspi.wssecurity.token.LTPATokenGenerator`

This class implements the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface and is responsible for Base 64 encoding the LTPA token object obtained from the `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler` callback handler. The object is inserted into the Web services security header within the SOAP message, if necessary.

`com.ibm.wsspi.wssecurity.token.LTPATokenConsumer`

This class implements the `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` interface, processes the LTPA token from the binary security token, and decodes the Base64 encoding within the LTPA token. An object of the `com.ibm.wsspi.wssecurity.auth.token.LTPAToken` class is created for the validated LTPA token and stored in the JAAS Subject.

`com.ibm.wsspi.wssecurity.auth.module.X509LoginModule`

This class implements the `javax.security.auth.spi.LoginModule` interface and validates the X.509 Certificate based on the trust anchor and the collection certification store configuration.

com.ibm.wsspi.wssecurity.token.UsernameTokenConsumer

This class implements the `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` interface, processes the username token, extracts the user name and password, and then invokes the `system.wssecurity.UsernameToken` JAAS login configuration using the `com.ibm.wsspi.wssecurity.auth.module.UsernameLoginModule` login module to validate the user name and password. An object of the `com.ibm.wsspi.wssecurity.auth.token.UsernameToken` class is created for the validated username token and stored in the JAAS Subject.

com.ibm.wsspi.wssecurity.keyinfo.X509TokenKeyLocator

This class implements the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` interface and it is used to retrieve a public key from a X.509 certificate. The X.509 certificate is stored in the X.509 token (`com.ibm.wsspi.wssecurity.auth.token.X509Token`) in the JAAS Subject. The X.509 token is created by the X.509 Token Consumer (`com.ibm.wsspi.wssecurity.token.X509TokenConsumer`).

com.ibm.wsspi.wssecurity.keyinfo.SignerCertKeyLocator

This class implements the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` interface, which is used to retrieve a public key from the X.509 certificate of the request signer and encrypt the response. You can use this key locator in the response generator binding configuration only.

Important: This implementation assumes that only one signer certificate is used in the request.

com.ibm.wsspi.wssecurity.auth.token.UsernameToken

This implementation extends the `com.ibm.wsspi.wssecurity.auth.token.WSSToken` abstract class to represent the username token.

com.ibm.wsspi.wssecurity.auth.token.X509Token

This implementation extends the `com.ibm.wsspi.wssecurity.auth.token.WSSToken` abstract class to represent the X.509 binary security token (X.509 certificate).

com.ibm.wsspi.wssecurity.auth.token.LTPAToken

This implementation extends the `com.ibm.wsspi.wssecurity.auth.token.WSSToken` abstract class as a wrapper to the LTPA token that is extracted from the binary security token.

com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler

This class implements the `javax.security.auth.callback.CallbackHandler` interface and is responsible for creating a certificate and binary data with or without a certificate revocation list (CRL) using the PKCS#7 encoding. The certificate and the binary data is passed back to the `com.ibm.wsspi.wssecurity.token.X509TokenGenerator` implementation through the `com.ibm.wsspi.wssecurity.auth.callback.X509BSCallback` callback handler.

com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler

This class implements the `javax.security.auth.callback.CallbackHandler` interface and it is responsible for creating a certificate and binary data without a CRL using the PkiPath encoding. The certificate and binary data is passed back to the `com.ibm.wsspi.wssecurity.token.X509TokenGenerator` implementation through the `com.ibm.wsspi.wssecurity.auth.callback.X509BSCallback` callback handler.

com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler

This class implements the `javax.security.auth.callback.CallbackHandler` interface and it is responsible for creating a certificate from the keystore file. The X.509 token certificate is passed back to the `com.ibm.wsspi.wssecurity.token.X509TokenGenerator` implementation through the `com.ibm.wsspi.wssecurity.auth.callback.X509BSCallback` callback handler.

com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler

This implementation generates a Lightweight Third Party Authentication (LTPA) token in the Web services security header as a binary security token. If basic authentication data is defined in the application binding file, it is used to perform a login, to extract the LTPA token from the WebSphere Application Server credentials, and to insert the token in the Web services security header. Otherwise, it extracts the LTPA security token from the invocation credentials (run as identity) and inserts the token in the Web services security header.

com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

This implementation reads the basic authentication data from the application binding file. You might use this implementation on the server side to generate a username token.

com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler

This implementation presents you with a login prompt to gather the basic authentication data. Use this implementation on the client side only.

com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler

This implementation collects the basic authentication data using a standard in (stdin) prompt. Use this implementation on the client side only.

com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator

This interface is used to evaluate the level of trust for identity assertion. The default implementation is `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`, which enables you to define a list of trusted identities.

com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl

This default implementation enables you to define a list of trusted identities for identity assertion.

com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorException

This exception class is used by an implementation of the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` to communicate the exception and errors to the Web services security run time.

Default configuration

WebSphere Application Server Version 6 and later provide a variety of sample configurations that you can configure through the administrative console. The configurations that you specify are reflected on the cell or server level.

Do not use these configurations in a production environment as they are for sample and testing purposes only. To make modifications to these sample configurations, it is recommended that you use the administrative console provided by WebSphere Application Server.

For a Web services security-enabled application, you must correctly configure a deployment descriptor and a binding. In WebSphere Application Server Version 6 and later, one set of default bindings is shared by the applications to make application deployment easier. The default binding information for the cell level and the server level can be overridden by the binding information on the application level. The Application Server searches for binding information for an application on the application level before searching the server level, and then the cell level.

This article contains information on the sample default bindings, keystores, key locators, collection certificate store, trust anchors, and trusted ID evaluators.

Default generator binding

WebSphere Application Server Version 6 and later provide a sample set of default generator binding. The default generator binding contain both signing information and encryption information.

The sample signing information configuration is called `gen_signinfo` and contains the following configurations:

- Uses the following algorithms for the `gen_signinfo` configuration:
 - Signature method: `http://www.w3.org/2000/09/xmlsig#rsa-sha1`
 - Canonicalization method: `http://www.w3.org/2001/10/xml-exc-c14n#`
- References the `gen_signkeyinfo` signing key information. The following information pertains to the `gen_signkeyinfo` configuration:

- Contains a part reference configuration that is called `gen_signpart`. The part reference is not used in default binding. The signing information applies to all of the Integrity or Required Integrity elements within the deployment descriptors and the information is used for naming purposes only. The following information pertains to the `gen_signpart` configuration:
 - Uses the transform configuration called `transform1`. The following transforms are configured for the default signing information:
 - Uses the `http://www.w3.org/2001/10/xml-exc-c14n#` algorithm
 - Uses the `http://www.w3.org/2000/09/xmlsig#sha1` digest method
 - Uses the security token reference, which is the configured default key information.
 - Uses the `SampleGeneratorSignatureKeyStoreKeyLocator` key locator. For more information on this key locator, see “Sample key locators” on page 1010.
 - Uses the `gen_sigtgen` token generator, which contains the following configuration:
 - Contains the X.509 token generator, which generates the X.509 token of the signer.
 - Contains the `gen_sigtgen_vtype` value type URI.
 - Contains the `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509` value type local name value.
 - Uses X.509 Callback Handler. The callback handler calls the `${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-sender.ks` keystore.
 - The keystore password is `client`.
 - The alias name of the trusted certificate is `soapca`.
 - The alias name of the personal certificate is `soaprequester`.
 - The key password `client` issued by intermediary certificate authority `Int CA2`, which is in turn issued by `soapca`.

The sample encryption information configuration is called `gen_encinfo` and contains the following configurations:

- Uses the following algorithms for the `gen_encinfo` configuration:
 - Data encryption method: `http://www.w3.org/2001/04/xmlenc#tripledes-cbc`
 - Key encryption method: `http://www.w3.org/2001/04/xmlenc#rsa-1_5`
- References the `gen_enckeyinfo` encryption key information. The following information pertains to the `gen_enckeyinfo` configuration:
 - Uses the key identifier as the default key information.
 - Contains a reference to the `SampleGeneratorEncryptionKeyStoreKeyLocator` key locator. For more information on this key locator, see “Sample key locators” on page 1010.
 - Uses the `gen_sigtgen` token generator, which has the following configuration:
 - Contains the X.509 token generator, which generates the X.509 token of the signer.
 - Contains the `gen_enctgen_vtype` value type URI.
 - Contains the `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509` value type local name value.
 - Uses X.509 Callback Handler. The callback handler calls the `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-sender.jceks` keystore.
 - The keystore password is `storepass`.
 - The secret key `CN=Group1` has an alias name of `Group1` and a key password of `keypass`.
 - The public key `CN=Bob, O=IBM, C=US` has an alias name of `bob` and a key password of `keypass`.
 - The private key `CN=Alice, O=IBM, C=US` has an alias name of `alice` and a key password of `keypass`.

Default consumer binding

WebSphere Application Server Version 6 and later provide a sample set of default consumer binding. The default consumer binding contain both signing information and encryption information.

The sample signing information configuration is called `con_signinfo` and contains the following configurations:

- Uses the following algorithms for the `con_signinfo` configuration:
 - Signature method: `http://www.w3.org/2000/09/xmlsig#rsa-sha1`
 - Canonicalization method: `http://www.w3.org/2001/10/xml-exc-c14n#`
- Uses the `con_signkeyinfo` signing key information reference. The following information pertains to the `con_signkeyinfo` configuration:
 - Contains a part reference configuration that is called `con_signpart`. The part reference is not used in default binding. The signing information applies to all of the Integrity or RequiredIntegrity elements within the deployment descriptors and the information is used for naming purposes only. The following information pertains to the `con_signpart` configuration:
 - Uses the transform configuration called `reqint_body_transform1`. The following transforms are configured for the default signing information:
 - Uses the `http://www.w3.org/2001/10/xml-exc-c14n#` algorithm.
 - Uses the `http://www.w3.org/2000/09/xmlsig#sha1` digest method.
 - Uses the security token reference, which is the configured default key information.
 - Uses the `SampleX509TokenKeyLocator` key locator. For more information on this key locator, see “Sample key locators” on page 1010.
 - References the `con_sigtcon` token consumer configuration. The following information pertains to the `con_sigtcon` configuration:
 - Uses the X.509 Token Consumer, which is configured as the consumer for the default signing information.
 - Contains the `sigtconsumer_vtype` value type URI.
 - Contains the `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509` value type local name value.
 - Contains a JAAS configuration called `system.wssecurity.X509BST` that references the following information:
 - Trust anchor: `SampleClientTrustAnchor`
 - Collection certificate store: `SampleCollectionCertStore`

The encryption information configuration is called `con_encinfo` and contains the following configurations:

- Uses the following algorithms for the `con_encinfo` configuration:
 - Data encryption method: `http://www.w3.org/2001/04/xmlenc#tripleDES-cbc`
 - Key encryption method: `http://www.w3.org/2001/04/xmlenc#rsa-1_5`
- References the `con_enckeyinfo` encryption key information. This key actually decrypts the message. The following information pertains to the `con_enckeyinfo` configuration:
 - Uses the key identifier, which is configured as the key information for the default encryption information.
 - Contains a reference to the `SampleConsumerEncryptionKeyStoreKeyLocator` key locator. For more information on this key locator, see “Sample key locators” on page 1010.
 - References the `con_enctcon` token consumer configuration. The following information pertains to the `con_enctcon` configuration:
 - Uses the X.509 token consumer, which is configured for the default encryption information.
 - Contains the `enctconsumer_vtype` value type URI.

- Contains the `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509` value type local name value.
- Contains a JAAS configuration called `system.wssecurity.X509BST`.

Sample keystore configurations

The following sample keystores are for testing purposes only; do not use these keystores in a production environment:

- `${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-sender.ks`
 - The keystore format is JKS.
 - The keystore password is `client`.
 - The trusted certificate has a `soapca` alias name.
 - The personal certificate has a `soaprequester` alias name and a `client` key password that is issued by the Int CA2 intermediary certificate authority, which is, in turn, issued by `soapca`.
- `${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-receiver.ks`
 - The keystore format is JKS.
 - The keystore password is `server`.
 - The trusted certificate has a `soapca` alias name.
 - The personal certificate has a `soapprovider` alias name and a `server` key password that is issued by the Int CA2 intermediary certificate authority, which is, in turn, issued by `soapca`.
- `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-sender.jceks`
 - The keystore format is JCEKS.
 - The keystore password is `storepass`.
 - The `CN=Group1` DES secret key has a `Group1` alias name and a `keypass` key password.
 - The `CN=Bob, O=IBM, C=US` public key has a `bob` alias name and a `keypass` key password.
 - The `CN=Alice, O=IBM, C=US` private key has a `alice` alias name and a `keypass` key password.
- `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-receiver.jceks`
 - The keystore format is JCEKS.
 - The keystore password is `storepass`.
 - The `CN=Group1` DES secret key has a `Group1` alias name and a `keypass` key password.
 - The `CN=Bob, O=IBM, C=US` private key has a `bob` alias name and a `keypass` key password.
 - The `CN=Alice, O=IBM, C=US` public key has a `alice` alias name and a `keypass` key password.
- `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`
 - The intermediary certificate is signed by `soapca` and it signs both the `soaprequester` and the `soapprovider`.

Sample key locators

Key locators are used to locate the key for digital signature, encryption, and decryption. For information on how to modify these sample key locator configurations, see the following articles:

- “Configuring the key locator for the generator binding on the application level” on page 1142
- “Configuring the key locator for the consumer binding on the application level” on page 1203
- “Configuring the key locator on the server or cell level” on page 1234

Version 5.x application

SampleClientSignerKey

This key locator is used by the request sender for a Version 5.x application to sign the Simple Object Access Protocol (SOAP) message. The signing key name is `clientsignerkey`, which is referenced in the signing information as the signing key name.

Version 5.x application

SampleServerSignerKey

This key locator is used by the response sender for a Version 5.x application to sign the SOAP message. The signing key name is `serversignerkey`, which can be referenced in the signing information as the signing key name.

Version 5.x application

SampleSenderEncryptionKeyLocator

This key locator is used by the sender for a Version 5.x application to encrypt the SOAP message. It is configured to use the `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-sender.jceks` keystore and the `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator` keystore key locator. The implementation is configured for the DES secret key. To use asymmetric encryption (RSA), you must add the appropriate RSA keys.

Version 5.x application

SampleReceiverEncryptionKeyLocator

This key locator is used by the receiver for a Version 5.x application to decrypt the encrypted SOAP message. The implementation is configured to use the `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-receiver.jceks` keystore and the `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator` keystore key locator. The implementation is configured for symmetric encryption (DES or TRIPLEDES). To use RSA, you must add the private key `CN=Bob, O=IBM, C=US`, alias name `bob`, and key password `keypass`.

Version 5.x application

SampleResponseSenderEncryptionKeyLocator

This key locator is used by the response sender for a Version 5.x application to encrypt the SOAP response message. It is configured to use the `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-receiver.jceks` keystore and the `com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator` keystore key locator. This key locator maps an authenticated identity (of the current thread) to a public key for encryption. By default, WebSphere Application Server is configured to map to public key `alice`, and you must change WebSphere Application Server to the appropriate user. The `SampleResponseSenderEncryptionKeyLocator` key locator also can set a default key for encryption. By default, this key locator is configured to use public key `alice`.

Version 6 and later applications

SampleGeneratorSignatureKeyStoreKeyLocator

This key locator is used by generator to sign the SOAP message. The signing key name is `SOAPRequester`, which is referenced in the signing information as the signing key name. It is configured to use the `${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-sender.ks` keystore and the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` keystore key locator.

Version 6 and later applications

SampleConsumerSignatureKeyStoreKeyLocator

This key locator is used by the consumer to verify the digital signature in the SOAP message. The signing key is `SOAPProvider`, which is referenced in the signing information. It is configured to use the `${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-receiver.ks` keystore and the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` keystore key locator.

Version 6 and later applications

SampleGeneratorEncryptionKeyStoreKeyLocator

This key locator is used by the generator to encrypt the SOAP message. It is configured to use the `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-sender.jceks` keystore and the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` keystore key locator.

Version 6 and later applications

SampleConsumerEncryptionKeyStoreKeyLocator

This key locator is used by the consumer to decrypt an encrypted SOAP message. It is configured to use the `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-receiver.jceks` keystore and the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` keystore key locator.

Version 6 and later applications

SampleX509TokenKeyLocator

This key locator is used by the consumer to verify a digital certificate in an X.509 certificate. It is configured to use the `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-receiver.jceks` keystore and the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` keystore key locator.

Sample collection certificate store

Collection certificate stores are used to validate the certificate path. For information on how to modify this sample collection certificate store, see the following articles:

- “Configuring the collection certificate store for the generator binding on the application level” on page 1113
- “Configuring the collection certificate store for the consumer binding on the application level” on page 1189
- “Configuring the collection certificate store for the server or cell-level bindings” on page 1218

SampleCollectionCertStore

This collection certificate store is used by the response consumer and the request generator to validate the signer certificate path.

Sample trust anchors

Trust anchors are used to validate the trust of the signer certificate. For information on how to modify the sample trust anchor configurations, see the following articles:

- “Configuring trust anchors for the generator binding on the application level” on page 1108
- “Configuring trust anchors for the consumer binding on the application level” on page 1188
- “Configuring trust anchors on the server or cell level” on page 1217

Version 5.x application

SampleClientTrustAnchor

This trust anchor is used by the response consumer to validate the signer certificate. This trust anchor is configured to access the `${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-sender.ks` keystore.

Version 5.x application

SampleServerTrustAnchor

This trust anchor is used by the request consumer to validate the signer certificate. This trust anchor is configured to access the `${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-sender.ks` keystore.

Sample trusted ID evaluators

Trusted ID evaluators are used to establish trust before asserting the identity in identity assertion. For information on how to modify the sample trusted ID evaluator configuration, see “Configuring trusted ID evaluators on the server or cell level” on page 1242.

SampleTrustedIDEvaluator

This trusted ID evaluator uses the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl` implementation. The default implementation of `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` contains a list of trusted identities. This list, which is used for identity assertion, defines the key

name and value pair for the trusted identity. The key name is in the form `trustedId_*` and the value is the trusted identity. For more information, see the example in “Configuring trusted ID evaluators on the server or cell level” on page 1242.

Complete the following steps to define this information for the cell level in the administrative console:

1. Click **Security > Web services**.
2. Under Additional properties, click **Trusted ID evaluators > SampleTrustedIDEvaluator**.

Complete the following steps to define this information for the server level in the administrative console:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Trusted ID evaluators > SampleTrustedIDEvaluator**.

Basic Security Profile compliance

The Web Services Interoperability Organization (WS-I) Basic Security Profile (BSP) 1.0 promotes interoperability by providing clarifications and amplifications to a set of non-proprietary Web services specifications. WebSphere Application Server Web Services Security provides configuration options to ensure that the BSP recommendations and security considerations can be enabled to ensure interoperability. The degree to which you follow these recommendations is then a measure of how well the application you are configuring complies with the Basic Security Profile (BSP).

Support for applications to comply to the Basic Security Profile (BSP) is new in WebSphere Application Server Version 6.1. For more information on the Basic Security Profile, see Web Services Interoperability Organization (WS-I) Basic Security Profile (BSP), Basic Security Profile Version 1.0.

You can use either a predefined list of keywords or XPath expressions to comply to the BSP. Both the keywords and the XPath expressions are specified in the deployment descriptor configuration file and are configured using an assembly tool.

Basic Security Profile recommendations

Follow these recommendations to ensure that your configured applications are Basic Security Profile (BSP) compliant.

- Do not use the original XPath transform, <http://www.w3.org/TR/1999/REC-xpath-19991116>
When you refer to an element in a `SECURE_ENVELOPE` that does not carry an ID attribute type from a `ds:Reference` in a `SIGNATURE` element, you must use the XPath Filter 2.0 transform, <http://www.w3.org/2002/06/xmldsig-filter2> to refer to that element.
Any `ds:Transform/@Algorithm` attribute in a `SIGNATURE` element must have one of these values:
 - <http://www.w3.org/2001/10/xml-exc-c14n#>
 - <http://www.w3.org/2002/06/xmldsig-filter2>
 - <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform>
 - <http://www.w3.org/2000/09/xmldsig#enveloped-signature>
 - <http://docs.oasis-open.org/wss/2004/XX/oasis-2004XX-wss-swa-profile-1.0#Attachment-Content-Only-Transform>
 - <http://docs.oasis-open.org/wss/2004/XX/oasis-2004XX-wss-swa-profile-1.0#Attachment-Complete-Transform>
- Do not use the <http://www.w3.org/2000/09/xmldsig#dsa-sha1> signature algorithm.
Any `ds:SignatureMethod/@Algorithm` element in a `SIGNATURE` that is based on a symmetric key must have one of the following values:

- <http://www.w3.org/2000/09/xmldsig#rsa-sha1>
- <http://www.w3.org/2000/09/xmldsig#hmac-sha1>
- Do not specify the digestvalue keyword for the message part to encrypt. Instead, use the signature keyword.
If the value of a ds:DigestValue element in a SIGNATURE element requires encryption, the entire parent ds:Signature element must be encrypted. A SIGNATURE must not have any xenc:EncryptedData elements among its descendants.
- Do not use the KEYNAME key information type
KEYNAME references can be ambiguous and compliance with the BSP disallows the use of KEYNAME. A SECURITY_TOKEN_REFERENCE must not use a key name to reference a SECURITY_TOKEN. The child element of a ds:KeyInfo element in an ENCRYPTED_KEY must be either a SECURITY_TOKEN_REFERENCE or a ds:MgmtData element. Using a KEYNAME key information type for an encryption key results in a KeyName child element of a ds:KeyInfo element and is disallowed for BSP compliance.
- Do not use the <http://www.w3.org/2001/04/xmlenc#aes192-cbc> bit data encryption algorithm.
Any xenc:EncryptionMethod/@Algorithm attribute in an ENCRYPTED_DATA element must have one of these values:
 - <http://www.w3.org/2001/04/xmlenc#tripleDES-cbc>
 - <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
 - <http://www.w3.org/2001/04/xmlenc#aes256-cbc>
- Do not use the advanced encryption standard (AES) key wrap (aes192): <http://www.w3.org/2001/04/xmlenc#kw-aes192> key encryption algorithm.
When used for key wrap, any xenc:EncryptionMethod/@Algorithm attribute in an ENCRYPTED_KEY element must have one of these values:
 - <http://www.w3.org/2001/04/xmlenc#kw-tripleDES>
 - <http://www.w3.org/2001/04/xmlenc#kw-aes128>
 - <http://www.w3.org/2001/04/xmlenc#kw-aes256>

Configuration Options for BSP Compliance

You achieve BSP compliance when certain configuration choices are made. The assembly tool assists you in using appropriate choices when configuring the application by issuing warning messages. The following configuration descriptions comprise these warnings:

- When configuring the ds:Transforms element in a signature, the list of transforms must include as its last child element <http://www.w3.org/2001/10/xml-exc-c14n#> or <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform>
- Add a wsse:Nonce or wsse:Created element to a Username token to prevent replay. After the element is added, sign the Username token to prevent undetected alteration of these fields; otherwise, replay can occur.

Configuring an application for Web services security with an assembly tool

There are eight parts of Web services security that you must configure to secure your SOAP messages using either digital signature or encryption. Four of these parts involve the deployment descriptor extensions and four parts involve the bindings that correspond to the deployment descriptors.

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see Importing an enterprise application EAR file.

Decide whether or not you are to configure your application to comply with the Basic Security Profile. For more information on how to ensure compliance, see “Basic Security Profile compliance” on page 1013

The following table illustrates these eight parts that involve both the client and the server or a server acting as a client. It is recommended that you configure each of these parts in order from left to right in the table. For example, configure the request generator extensions and then the request consumer extensions because the configurations must match. After you configure the request generator and request consumer extensions, configure the request generator and the request consumer bindings, and so on.

Table 45. Client and server extensions and bindings relationship

Client	Server
1. Request generator extensions	2. Request consumer extensions
3. Request generator bindings	4. Request consumer bindings
5. Response consumer extensions	6. Request generator extensions
7. Response consumer bindings	8. Response generator bindings

In Web services security for WebSphere Application Server Versions 6 and later, *integrity* refers to digital signature and *confidentiality* refers to encryption. Integrity decreases the risk of data modification when data is transmitted across a network. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality, however, the message is encrypted before it is sent and decrypted when it is received by its target server. The article provides the steps needed to secure your Web services using either integrity or confidentiality.

In the generator bindings, you can specify which message parts to sign (integrity) or encrypt (confidentiality) and what method is used. In the consumer bindings, you specify when the message parts are signed or encrypted. After you verify the digital signature or encryption in the consumer, the consumer verifies that the specified message parts are actually signed or encrypted. If the digital signature or encryption is required and the message is not signed or encrypted, the message is rejected by the consumer.

There are two different methods to specify what needs to be signed (integrity) or encrypted (confidentiality). You can use either keywords or an XPath expression to configure message parts, a nonce, or a time stamp. When you use keywords, you can specify only certain elements within a message. With an XPath expression, you can specify any part of the message.

In addition to securing Web services for integrity and confidentiality, the assembly tools enable you to complete the following tasks:

- Configure a standalone time stamp for the generator and the consumer extensions. For more information, see “Adding a stand-alone time stamp to generator security constraints” on page 1099 and “Adding a stand-alone time stamp in consumer security constraints” on page 1100.
- Configure the security token in the generator and consumer constraints. For more information, see “Configuring the security token in generator security constraints” on page 1102 and “Configuring the security token requirement in consumer security constraints” on page 1103.
- Configure a caller part for the consumer security constraints. For more information, see “Configuring the caller in consumer security constraints” on page 1104.
- Configure identity assertion. For more information, see “Configuring identity assertion” on page 1106.
- Configure the client and the server for integrity. To properly configure Web services security for integrity, complete the following steps for the request generator and the request consumer and then repeat the steps for the response generator and the response consumer.
 1. Specify which message elements to sign in the generator security constraints using either keywords or an XPath expression. For more information, see either “Signing message elements in generator security constraints with keywords” on page 1018 or “Signing message elements in

generator security constraints with an XPath expression” on page 1027. When you sign the message elements, you can also add a nonce or a time stamp configuration. For more information on these configurations, see:

- “Adding time stamps for integrity to generator security constraints with keywords” on page 1021
 - “Adding time stamps for integrity to generator security constraints with an XPath expression” on page 1028
 - “Adding a nonce for integrity in generator security constraints with keywords” on page 1024
 - “Adding a nonce for integrity to generator security constraints with an XPath expression” on page 1030
2. Configure a collection certificate store for the generator security constraints. For more information, see “Configuring the collection certificate store for the generator binding with an assembly tool” on page 1033.
 3. Configure the token generator. For more information, see “Configuring token generators with an assembly tool” on page 1034.
 4. Configure the key locators in the generator binding. For more information, see “Configuring key locators for the generator binding with an assembly tool” on page 1040.
 5. Configure the key information in the generator binding. For more information, see “Configuring key information for the generator binding with an assembly tool” on page 1042.
 6. Configure the signing information in the generator binding. For more information, see “Configuring signing information for the generator binding with an assembly tool” on page 1044.
 7. Specify which message elements to sign in the consumer security constraints using either keywords or an XPath expression. For more information, see either “Signing message elements in consumer security constraints with keywords” on page 1048 or “Signing message elements in consumer security constraints with an XPath expression” on page 1054. When you sign the message elements, you can also add a nonce or a time stamp configuration. For more information on these configurations, see:
 - “Adding time stamps for integrity in consumer security constraints with keywords” on page 1050
 - “Adding a nonce for integrity in consumer security constraints with keywords” on page 1052
 - “Adding time stamps for integrity in consumer security constraints with an XPath expression” on page 1055
 - “Adding a nonce for integrity in consumer security constraints with an XPath expression” on page 1057
 8. Configure a collection certificate store for the consumer security constraints. For more information, see “Configuring the collection certificate store for the consumer binding with an assembly tool” on page 1058.
 9. Configure a token consumer. For more information, see “Configuring token consumers with an assembly tool” on page 1060.
 10. Configure the key locators in the consumer binding. For more information, see “Configuring the key locator for the consumer binding with an assembly tool” on page 1063.
 11. Configure the key information in the consumer bindings. For more information, see “Configuring key information for the consumer binding with an assembly tool” on page 1064.
 12. Configure the signing information in the consumer binding. For more information, see “Configuring signing information for the consumer binding with an assembly tool” on page 1067.
- Configure the client and the server for confidentiality. To properly configure Web services security for confidentiality, complete the following steps for the request generator and the request consumer, and then repeat the steps for the response generator and the response consumer.
 1. Specify which message elements to encrypt in the generator security constraints using either keywords or an XPath expression. For more information, see either “Encrypting the message elements in generator security constraints with keywords” on page 1070 or “Encrypting the message elements in generator security constraints with an XPath expression” on page 1077.

When you encrypt the message elements, you can also add a nonce or a time stamp configuration. For more information on these configurations, see:

- “Adding time stamps for confidentiality to generator security constraints with keywords” on page 1072
 - “Adding the nonce for confidentiality to generator security constraints with keywords” on page 1074
 - “Adding time stamps for confidentiality to generator security constraints with an XPath expression” on page 1078
 - “Adding the nonce for confidentiality to generator security constraints with an XPath expression” on page 1080
2. Configure the token generator. For more information, see “Configuring token generators with an assembly tool” on page 1034.
 3. Configure the key locators in the generator binding. For more information, see “Configuring key locators for the generator binding with an assembly tool” on page 1040.
 4. Configure the key information in the generator binding. For more information, see “Configuring key information for the generator binding with an assembly tool” on page 1042.
 5. Configure the encryption information in the generator binding. For more information, see “Configuring encryption information for the consumer binding with an assembly tool” on page 1085.
 6. Specify which message elements to encrypt in the consumer security constraints using either keywords or an XPath expression. For more information, see either “Encrypting message elements in consumer security constraints with keywords” on page 1087 or “Encrypting message elements in consumer security constraints with an XPath expression” on page 1092. When you encrypt the message elements, you can also add a nonce or a time stamp configuration. For more information on these configurations, see:
 - “Adding time stamps for confidentiality in consumer security constraints with keywords” on page 1088
 - “Adding a nonce for confidentiality in consumer security constraints with keywords” on page 1090
 - “Adding time stamps for confidentiality in consumer security constraints with an XPath expression” on page 1093
 - “Adding the nonce for confidentiality in consumer security constraints with an XPath expression” on page 1095
 7. Configure a token consumer. For more information, see “Configuring token consumers with an assembly tool” on page 1060.

Also, the token consumer article provides the steps that are needed to optionally configure a trust anchor.
 8. Configure the key locators in the consumer binding. For more information, see “Configuring the key locator for the consumer binding with an assembly tool” on page 1063.
 9. Configure the key information in the consumer bindings. For more information, see “Configuring key information for the consumer binding with an assembly tool” on page 1064.
 10. Configure the encryption information in the consumer binding. For more information, see “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

By completing the previous steps, you have configured your application for either digital signature (integrity) or encryption (confidentiality).

XML digital signature

XML-Signature Syntax and Processing (XML digital signature) is a specification that defines XML syntax and processing rules to sign and verify digital signatures for digital content. The specification was developed jointly by the World Wide Web Consortium (W3C) and the Internet Engineering Task Force (IETF).

XML digital signature does not introduce new cryptographic algorithms. WebSphere Application Server uses XML digital signature with existing algorithms such as RSA, HMAC, and SHA1. XML signature defines many methods for describing key information and enables the definition of a new method.

XML canonicalization (c14n) is often needed when you use XML signature. Information can be represented in various ways within serialized XML documents. For example, although their octet representations are different, the following examples are identical:

- `<person first="John" last="Smith"/>`
- `<person last="Smith" first="John"></person>`

C14n is a process that is used to canonicalize XML information. Select an appropriate c14n algorithm because the information that is canonicalized is dependent upon this algorithm. One of the major c14n algorithms, Exclusive XML Canonicalization, canonicalizes the character encoding scheme, attribute order, namespace declarations, and so on. The algorithm does not canonicalize white space outside tags, namespace prefixes, or data type representation.

XML signature in the Web Services Security-Core specification

The Web Services Security-Core (WSS-Core) specification defines a standard way for Simple Object Access Protocol (SOAP) messages to incorporate an XML signature. You can use almost all of the XML signature features in WSS-Core except enveloped signature and enveloping signature. However, WSS-Core has some recommendations such as exclusive canonicalization for the c14n algorithm and some additional features such as SecurityTokenReference and KeyIdentifier. The KeyIdentifier is the value of the SubjectKeyIdentifier field within the X.509 certificate. For more information on the KeyIdentifier, see "Reference to a Subject Key Identifier" within the OASIS Web Services Security X.509 Certificate Token Profile documentation.

By including XML signature in SOAP messages, the following issues are realized:

Message integrity

A message receiver can confirm that attackers or accidents have not altered parts of the message after these parts are signed by a key.

Authentication

You can assume that a valid signature is *proof of possession*. A message with a digital certificate that is issued by a certificate authority and a signature in the message that is validated successfully by a public key in the certificate, is proof that the signer has the corresponding private key. The receiver can authenticate the signer by checking the trustworthiness of the certificate.

Signing message elements in generator security constraints with keywords

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.

Complete the following steps to specify which message parts to digitally sign when you configure the generator security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure.

- a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure.
- a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the Integrity section. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing Simple Object Access Protocol (SOAP) messages, see “XML digital signature” on page 1017.
6. Click **Add** to indicate which parts of the message to sign. The Integrity Dialog window is displayed.
- a. Specify a name for the integrity element in the Integrity Name field. For example, you might specify `int_webskey`.
 - b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the digital signature is processed. An order value of 1 specifies that the signing is done first.
7. Click **Add** under the Message Parts section and select the Message parts dialect. The <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> dialect specifies the message part that is signed using keywords. If you select this dialect, you can select one of the following keywords under the Message parts keyword heading:

action Specifies that the `<wsa:Action>` element is signed.

body Specifies the user data portion of the message. If you select this keyword, the body is signed.

dsigkey

Specifies that the key information element, which is used for digital signature, is signed.

enckey

Specifies that the key information element, which is used for encryption, is signed.

messageid

Specifies that the `<wsa:MessageID>` element within the message is signed.

relatesto

Specifies that the `<wsa:RelatesTo>` element within the message is signed.

securitytoken

Specifies that the UsernameToken in the SOAP message is signed.

timestamp

Specifies that the stand-alone timestamp element within the message is signed. The timestamp element determines whether the message is valid based upon the time that the message is sent and then received. If the timestamp option is selected, make sure that there is a stand-alone timestamp element in the message. If the element does not exist, see “Adding a stand-alone time stamp to generator security constraints” on page 1099.

to

Specifies that the `<wsa:To>` element within the message is signed.

wsaall Specifies all of the WS-Addressing elements in the SOAP header.

wsafaultto

Specifies the `<wsa:FaultTo>` WS-Addressing FaultTo element in the SOAP header.

wsafrom

Specifies the `<wsa:From>` WS-Addressing From element in the SOAP header.

wsareplyto

Specifies the `<wsa:ReplyTo>` WS-Addressing ReplyTo element in the SOAP header.

wsccontext

Specifies the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services.

8. Click **OK** to save the configuration changes.

Note: These configurations for the generator and the consumer must match.

In addition to the message parts, you also can specify that WebSphere Application Server sign the nonce and timestamp elements. For more information, see the following articles:

- “Adding time stamps for integrity to generator security constraints with keywords” on page 1021
- “Adding time stamps for integrity to generator security constraints with an XPath expression” on page 1028
- “Adding a nonce for integrity in generator security constraints with keywords” on page 1024
- “Adding a nonce for integrity to generator security constraints with an XPath expression” on page 1030

The following example is a SOAP message whose body is signed using the body keyword and the `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was dialect`:

```
<soapenv:Envelope xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <soapenv:Header soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">

  </soapenv:Body>
</soapenv:Envelope>

```

After you specify which message parts to digitally sign, you must specify which method is used to digitally sign the message. For more information, see “Configuring signing information for the generator binding with an assembly tool” on page 1044.

Adding time stamps for integrity to generator security constraints with keywords:

You can specify that a time stamp be embedded in a particular element and that the element be signed.

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see the article about importing an enterprise application EAR file in the Application Server Toolkit documentation.

Complete the following steps to specify the time stamp for integrity using keywords when you configure the generator security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the Integrity section. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing SOAP messages, see “XML digital signature” on page 1017.
6. Click **Add** to specify a time stamp for integrity. The Integrity Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the integrity element in the Integrity Name field.
 - b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the digital signature is processed. An order value of 1 specifies that the signing is done first.
7. In the Timestamp section, click **Add** and select the Timestamp dialect. The `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was` dialect specifies the message element to which the time stamp is added prior to signing the element using the keywords. If you select this dialect, you can select one of the following keywords under the Timestamp keyword heading:

body Specifies the user data portion of the message. If you select the body option, a time stamp is embedded in SOAP body and the body is signed.

timestamp

Specifies that the time stamp is embedded in the standalone timestamp element within the message and that it is signed. If you select the timestamp option, make sure that there is a standalone timestamp element in the message. If the element does not exist, see “Adding a stand-alone time stamp to generator security constraints” on page 1099.

securitytoken

Specifies that the security token authenticates the client. If you select this option, the timestamp element is embedded in the securitytoken element and the security token is signed.

dsigkey

Specifies that the time stamp is inserted into the key information element, which is used for digital signature, and the key information element is signed.

enckey Specifies that the time stamp is inserted into the key information element, which is used for encryption, and the key information element is signed.

messageid

Specifies that the time stamp is inserted into the <wsa:MessageID> element and the <wsa:MessageID> element is signed.

to Specifies that the time stamp is inserted into the <wsa:To> element within the message and that the <wsa:To> element is signed.

action Specifies that the <wsa:Action> element is signed.

relatesto

Specifies that the time stamp is inserted into the <wsa:RelatesTo> element within the message and the <wsa:RelatesTo> element is signed.

wscontext

Specifies the WS-Context header for the SOAP header.

For more information, see Propagating work area context over Web services.

wsafrom

Specifies the <wsa:From> WS-Addressing From element in the SOAP header.

wsareplyto

Specifies the <wsa:ReplyTo> WS-Addressing ReplyTo element in the SOAP header

wsafaultto

Specifies the <wsa:FaultTo> WS-Addressing FaultTo element in the SOAP header.

wsaa11 Specifies all of the WS-Addressing elements in the SOAP header.

- Specify an expiration time for the time stamp in the Timestamp expires field. The time stamp helps defend against replay attacks. The lexical representation for the duration is the [ISO 8601] extended format PnYnMnDTnHnMnS, where:

P Precedes the date and time values.

nY Represents the number of years in which the time stamp is in effect. Select a value from 0 to 99 years.

nM Represents the number of months in which the time stamp is in effect. Select a value from 0 to 11 months.

nD Represents the number of days in which the time stamp is in effect. Select a value from 0 to 30 days.

T Separates the date and time values.

- nH** Represents the number of hours in which the time stamp is in effect. Select a value from 0 to 23 hours.
- nM** Represents the number of minutes in which the time stamp is in effect. Select a value from 0 to 59 minutes.
- nS** Represents the number of seconds in which the time stamp is in effect. The number of seconds can include decimal digits to arbitrary precision. You can select a value from 0 to 59 for the seconds and from 0 to 9 for tenths of a second.

For example, to indicate 1 year, 2 months, 3 days, 10 hours, and 30 minutes, the format is P1Y2M3DT10H30M. Typically, you might configure a message time stamp for between 10 and 30 minutes. For example, 10 minutes is represented as P0Y0M0DT0H10M0S or PT10M.

9. In the Message Parts section, click **Add** and select `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was` in the Message parts dialect field.
10. In the Message Parts section, select the message parts keyword.

Important: You must define at least one message part in the Message Parts section in order to specify a time stamp for integrity.

11. Click **OK** to save the configuration changes.

Note: These configurations for the generator and the consumer must match.

In addition to the time stamp, you can specify that the nonce is signed. For more information, see the following articles:

- “Adding a nonce for integrity in generator security constraints with keywords” on page 1024
- “Adding a nonce for integrity to generator security constraints with an XPath expression” on page 1030

The following example shows a time stamp that is inserted in the SOAP message body and signed:

```
<soapenv:Envelope xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <soapenv:Header soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">

```

After you specify which message parts to digitally sign, you must specify which method is used to digitally sign the message. For more information, see “Configuring signing information for the generator binding with an assembly tool” on page 1044.

Adding a nonce for integrity in generator security constraints with keywords:

Prior to completing this task, you must import your application into an assembly tool.

See the information about Importing an enterprise application EAR file in the Application Server Toolkit documentation.

Nonce for integrity is used to specify that the nonce is embedded in a particular element and the element is signed. Nonce is a randomly generated, cryptographic token. When nonce is added to the specific parts of a message, it might prevent theft and replay attacks because a generated nonce is unique. For example, without nonce, when a user name token is passed from one machine to another machine using a non-secure transport, such as HTTP, the token might be intercepted and used in a replay attack. The user name token can be stolen even if you use XML digital signature and XML encryption. However, it might be prevented by adding a nonce.

Complete the following steps to specify a nonce for integrity using keywords when you configure the generator security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool and click **Window > Open Perspective > J2EE**.
2. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure.
 - a. Expand the **Web Services > Client** section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
3. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure.
 - a. Expand the **Web Services > Services** section and double-click the name of the Web service.

- b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
4. Expand the **Integrity** section. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing SOAP messages, see “XML digital signature” on page 1017.
5. Click **Add** to specify a nonce for integrity. The Integrity Dialog window is displayed.
 - a. Specify a name for the integrity element in the Required Integrity Name field. For example, you might specify `int_nonce`.
 - b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the digital signature is processed. An order value of 1 specifies that the signing is done first.
6. Under Nonce, click **Add** and select the nonce dialect. The `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was` dialect specifies the message part to which a nonce is added and signed. If you select this dialect, you can select one of the following keywords under Nonce keyword:

body Specifies the user data portion of the message. If this option is selected, a nonce is embedded in the SOAP body element and the body element is signed.

timestamp

Specifies that the nonce is embedded in the standalone `timestamp` element within the message and the element is signed. If `timestamp` is selected, make sure that there is a standalone `timestamp` element in the message. If not, see “Adding a stand-alone time stamp to generator security constraints” on page 1099.

securitytoken

Specifies that the `securitytoken` element is signed. The security token authenticates the client. If this option is selected, the nonce element is embedded in the `securitytoken` element.

dsigkey

Specifies that the nonce is inserted into the key information element, which is used for digital signature, and the key information element is signed.

enckey Specifies that the nonce is inserted into the key information element, which is used for encryption, and the key information element is signed.

messageid

Specifies that the nonce is inserted into the `<wsa:MessageID>` element and that the `<wsa:MessageID>` element is signed.

to Specifies that the nonce is inserted into the `<wsa:To>` element within the message and that the `<wsa:To>` element is signed.

action Specifies that the `<wsa:Action>` element is signed.

relatesto

Specifies that the nonce is inserted into the `<wsa:RelatesTo>` element within the message and that the `<wsa:RelatesTo>` element is signed.

wscontext

Specifies the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services.

wsafrom

Specifies the `<wsa:From>` WS-Addressing From element in the SOAP header.

wsareplyto

Specifies the `<wsa:ReplyTo>` WS-Addressing ReplyTo element in the SOAP header.

wsafaultto

Specifies the `<wsa:FaultTo>` WS-Addressing FaultTo element in the SOAP header.

wsaa11 Specifies all of the WS-Addressing elements in the SOAP header.

7. In the Message Parts section, click **Add** and select `http://www.ibm.com/websphere/webservices/wssecurity/ dialect-was` in the Message parts dialect field.
8. In the Message Parts section, select the message parts keyword.

Important: You must define at least one message part in the Message Parts section in order to specify a nonce for integrity. This message part is signed as well as the parent element of the nonce.

9. Click **OK** to save the configuration changes.

Note: These configurations on the consumer side and the generator side must match.

In addition to the nonce, you can specify that the timestamp element is signed. For more information, see the following articles:

- “Adding time stamps for integrity in consumer security constraints with keywords” on page 1050
- “Adding time stamps for integrity in consumer security constraints with an XPath expression” on page 1055

The following example is a SOAP message that has a nonce that is inserted in the SOAP message body and signed:

```
<soapenv:Envelope xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <soapenv:Header soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
    <wsse:Security soapenv:mustUnderstand="1" xmlns:wsse="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd">

```

After you specify which message parts to digitally sign, you must specify which method is used to digitally sign the message. For more information, see “Configuring signing information for the consumer binding with an assembly tool” on page 1067.

Signing message elements in generator security constraints with an XPath expression

You can specify which message parts to digitally sign when you configure the generator security constraints for either the request generator or the response generator.

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

Complete the following steps to specify which message parts to digitally sign when you configure the generator security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server.

In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure.
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you must configure.
 - a. Expand the **Web Services > Services** section and double-click the name of the Web service.

- b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the Integrity section. Integrity refers to digital signature and confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing SOAP messages, see “XML digital signature” on page 1017.
6. Click **Add** to indicate which parts of the message to sign. The Integrity Dialog window is displayed.
 - a. Specify a name for the integrity element in the Integrity Name field. For example, you might specify `int_xpath`.
 - b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the digital signature is processed. An order value of 1 specifies that the signing is done first.
7. Click **Add** under the Message Parts section of the Integrity Dialog window.
 - a. Select the Message parts dialect from the Message Parts section of the Integrity Dialog window. If you select the `http://www.w3.org/TR/1999/REC-xpath-19991116` dialect, the message part that will be signed is specified by an XPath expression.
Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use `http://www.w3.org/2002/06/xmldsig-filter2` to ensure compliance.
 - b. Specify the message part to be signed using an XPath expression in the Message parts keyword field. For example, to specify that the body is signed, you might add the following expression in the Message parts keyword field as one continuous line:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/
soap/envelope/' and local-name()='Body']
```
8. Click **OK** to save the configuration changes.

Note: These configurations for the generator and the consumer must match.

In addition to the message parts, you also can specify that WebSphere Application Server sign the nonce and timestamp elements. For more information, see the following articles:

- “Adding time stamps for integrity to generator security constraints with keywords” on page 1021
- “Adding time stamps for integrity to generator security constraints with an XPath expression”
- “Adding a nonce for integrity in generator security constraints with keywords” on page 1024
- “Adding a nonce for integrity to generator security constraints with an XPath expression” on page 1030

After you specify which message parts to digitally sign, you must specify which method is used to digitally sign the message. For more information, see “Configuring signing information for the generator binding with an assembly tool” on page 1044.

Adding time stamps for integrity to generator security constraints with an XPath expression:

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

This task is used to specify that a time stamp is embedded in a particular element and that the element is signed. Complete the following steps to specify the time stamp for integrity using keywords when you configure the generator security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side extensions.
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the server-side extensions.
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the Integrity section. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing Simple Object Access Protocol (SOAP) messages, see “XML digital signature” on page 1017.
6. Click **Add** to specify a time stamp for integrity. The Integrity Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the integrity element in the Integrity Name field. For example, you might specify `int_tmstamp`.
 - b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the digital signature is processed. An order value of 1 specifies that the signing is done first.
7. Click **Add** in the Timestamp section of the Integrity Dialog window. Complete the following steps to specify a time stamp configuration:
 - a. Select the Timestamp dialect from the Timestamp section. The `http://www.w3.org/TR/1999/REC-xpath-19991116` dialect specifies the message part to which the time stamp is added and signed using the XPath expression.
 - b. Select the message part in the Timestamp keyword field to which the time stamp is added and signed using an XPath expression. For example, to specify that the time stamp is added to the body and is signed, you might specify the following expression for the Timestamp keyword:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Body']
```
 - c. Specify an expiration time for the time stamp in the Timestamp expires field. The time stamp helps defend against replay attacks. The lexical representation for the duration is the [ISO 8601] extended format `PnYnMnDTnHnMnS`, where:
 - P** Precedes the date and time values.
 - nY** Represents the number of years in which the time stamp is in effect. Select a value from 0 to 99 years.

- nM** Represents the number of months in which the time stamp is in effect. Select a value from 0 to 11 months.
- nD** Represents the number of days in which the time stamp is in effect. Select a value from 0 to 30 days.
- T** Separates the date and time values.
- nH** Represents the number of hours in which the time stamp is in effect. Select a value from 0 to 23 hours.
- nM** Represents the number of minutes in which the time stamp is in effect. Select a value from 0 to 59 minutes.
- nS** Represents the number of seconds in which the time stamp is in effect. The number of seconds can include decimal digits to arbitrary precision. You can select a value from 0 to 59 for the seconds and from 0 to 9 for tenths of a second.

For example, to indicate 1 year, 2 months, 3 days, 10 hours, and 30 minutes, the format is P1Y2M3DT10H30M. Typically, you might configure a message time stamp for between 10 and 30 minutes. For example, 10 minutes is represented as P0Y0M0DT0H10M0S or PT10M.

8. In the Message Parts section, click **Add** and select <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> in the Message parts dialect field.
9. In the Message Parts section, select the message parts keyword.

Important: You must define at least one message part in the Message Parts section in order to specify a time stamp for integrity. This message part is signed as well as the parent element of the time stamp.

10. Click **OK** to save the configuration changes.

Note: These configurations for the generator and the consumer must match.

In addition to the time stamp, you can specify that the nonce is signed. For more information, see the following articles:

- “Adding a nonce for integrity in generator security constraints with keywords” on page 1024
- “Adding a nonce for integrity to generator security constraints with an XPath expression”

After you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message. For more information, see “Configuring signing information for the generator binding with an assembly tool” on page 1044.

Adding a nonce for integrity to generator security constraints with an XPath expression:

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

Nonce for integrity is used to specify that the nonce is embedded in a particular element and the element is signed. Nonce is a randomly generated, cryptographic token. When nonce is added to the specific parts of a message, it might prevent theft and replay attacks because a generated nonce is unique. For example, without nonce, when a user name token is passed from one machine to another machine using a non-secure transport, such as HTTP, the token might be intercepted and used in a replay attack. The user name token can be stolen even if you use XML digital signature and XML encryption. However, it might be prevented by adding a nonce.

Complete the following steps to specify a nonce for integrity using an XPath expression when you configure the generator security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool and click **Window > Open Perspective > J2EE**.
2. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
3. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
4. Expand the Integrity section. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing Simple Object Access Protocol (SOAP) messages, see “XML digital signature” on page 1017.
5. Click **Add** to specify a nonce for integrity. The Integrity Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the integrity element in the Integrity Name field.
 - b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the digital signature is processed. An order value of 1 specifies that the signing is done first.
6. Click **Add** in the Nonce section of the Integrity Dialog window. Complete the following steps to specify a nonce dialect and message part:
 - a. Select the Nonce dialect from the Nonce section. The `http://www.w3.org/TR/1999/REC-xpath-19991116` dialect specifies the message part to which a nonce is added and signed using an XPath expression.
 - b. Select the message part in the Nonce keyword field to which a nonce is added and signed using an XPath expression. For example, to specify that a nonce is added to the body and that it is signed, you might specify the following expression for the Nonce keyword:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'  
and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/  
soap/envelope/' and local-name()='Body']
```
7. In the Message Parts section, click **Add** and select `http://www.w3.org/TR/1999/REC-xpath-19991116` in the Message parts dialect field.
8. In the Message Parts section, select the message parts keyword.

Important: You must define at least one message part in the Message Parts section in order to specify a nonce for integrity. This message part is signed as well as the parent element of the nonce.

9. Click **OK** to save the configuration changes.

Note: These configurations for the consumer and the generator must match.

In addition to the nonce, you can specify that the timestamp element is signed. For more information, see the following articles:

- “Adding time stamps for integrity to generator security constraints with keywords” on page 1021
- “Adding time stamps for integrity to generator security constraints with an XPath expression” on page 1028

After you specify that a nonce is added to the message parts and signed, you must specify which method is used to digitally sign the message. For more information, see “Configuring signing information for the generator binding with an assembly tool” on page 1044.

Collection certificate store

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check the signature of a digitally signed SOAP message.

A collection certificate store is used when WebSphere Application Server is processing a received SOAP message. This collection is configured in the Request Consumer Service Configuration Details section of the binding file for servers and in the Response Consumer Configuration section of the binding file for clients. You can configure these two sections using one of the assembly tools provided by WebSphere Application Server. For more information on the assembly tools, see *Assembly tools*.

A collection certificate store is one kind of certificate store. A certificate store is defined as `javax.security.cert.CertStore` in the Java CertPath application programming interface (API). The Java CertPath API defines the following types of certificate stores:

Collection certificate store

A collection certificate store accepts the certificates and CRLs as Java collection objects.

Lightweight Directory Access Protocol certificate store

The Lightweight Directory Access Protocol (LDAP) certificate store accepts certificates and CRLs as LDAP entries.

The CertPath API uses the certificate store and the trust anchor to validate the incoming X.509 certificate that is embedded in the SOAP message. The Web services security implementation in the WebSphere Application Server supports the collection certificate store. Each certificate and CRL is passed as an encoded file.

Certificate revocation list:

A *certificate revocation list* is a time-stamped list of certificates that have been revoked by a certificate authority (CA).

A certificate that is found in a certificate revocation list (CRL) might not be expired, but is no longer trusted by the certificate authority that issued the certificate. The certificate authority creates the CRL that contains the serial number and issuing CA distinguished name of the certificate that has been revoked. The CA might add the certificate to the certificate revocation list if it believes that the client certificate is compromised. The certificate revocation list is maintained and issued by the certificate authority.

Configuring the collection certificate store for the generator binding with an assembly tool

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.

This task describes the steps to specify the collection certificate store for the generator bindings at the application level using an assembly tool. A collection certificate store is a collection of non-root certificate authority (CA) certificates and certificate revocation lists (CRLs) that is used for validating an X.509 certificate embedded within the received SOAP message. The request generator is configured for the client and the response generator is configured for the server. On the generator side, a configuration for the collection certificate store is required only when you configure CRLs that are embedded in the PKCS#7 format. Complete the following steps to configure a collection certificate store for the generator. Specifying either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the bindings that you need to configure.
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Binding** tab and expand the Security Request Generator Binding Configuration section.
4. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you need to configure.
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Response Generator Binding Configuration Details section.
5. Expand the Certificate Store List > Collection Certificate Store section and click **Add**.
6. Specify a unique certificate store name in the Name field. For example, specify cert1. The name of the collection certificate store must be unique on the level in which it is defined. For example, the name must be unique at the application level. The name specified in the certificate store name field is used by other configurations to refer to a predefined collection certificate store. WebSphere Application Server looks up the collection certificate store based on proximity. For example, if an application binding refers to certificate store cert1, WebSphere Application Server looks first for cert1 at the application level. If it is not found, it looks at the server level, and finally at the cell level.
7. Specify a certificate store provider in the Provider field. The IBM CertPath certificate path provider is supported. To use another certificate path provider, you must define the provider implementation in the provider list within the `java.security` file in the Software Development Kit (SDK).
8. Click **Add** under X509 Certificate to specify a fully qualified path to an X.509 certificate, click the name of an existing certificate path entry to edit it, or click **Remove** to delete it. This collection certificate store is used to validate the certificate path of the incoming X.509-formatted security tokens.

You can use the `USER_INSTALL_ROOT` variable as part of the path name. For example, you might specify `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. However, do not use this X.509 certificate path for production use. Obtain your own X.509 certificate from a certificate authority before putting your WebSphere Application Server environment into production.

In the WebSphere Application Server administrative console, you can click **Environment > WebSphere Variables** to configure the `USER_INSTALL_ROOT` variable.

9. Click **Add** under CRL to specify the fully qualified path to a certificate revocation list (CRL), click an existing CRL entry to edit it or click **Remove** to delete it.

For portability reasons, it is recommended that you use the WebSphere Application Server variables to specify a relative path to the certificate revocation list. For example, you might use the `USER_INSTALL_ROOT` variable to define a path such as `${USER_INSTALL_ROOT}/mycertstore/mycrl`. For a list of the supported variables in the WebSphere Application Server administrative console, click **Environment > WebSphere Variables**.

The following list provides recommendations for using CRLs:

- If CRLs are added to the collection certificate store, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.
- When the CRL file is updated, the new CRL does not take effect until you restart the Web service application.
- Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.

10. Click **OK** to save your configuration.

Trust anchor

A *trust anchor* specifies the keystores that contain trusted root certificates. These certificates are used to validate the X.509 certificate that is embedded in the SOAP message.

These keystores are used by the following message points to validate the X.509 certificate that is used for digital signature or XML encryption:

- Request consumer, as defined in the `ibm-webservices-bnd.xmi` file
- Response consumer, as defined in the `ibm-webservicesclient-bnd.xmi` file when a Web service is acting as a client to another Web service

The keystores are critical to the integrity of the digital signature validation. If the keystores are tampered with, the result of the digital signature verification is doubtful and compromised. Therefore, it is recommended that you secure these keystores. The binding configuration specified for the request consumer in the `ibm-webservices-bnd.xmi` file must match the binding configuration for the request generator in the `ibm-webservicesclient-bnd.xmi` file.

The trust anchor is defined as `java.security.cert.TrustAnchor` in the Java CertPath application programming interface (API). The Java CertPath API uses the trust anchor and the certificate store to validate the incoming X.509 certificate that is embedded in the SOAP message. The Web services security implementation in WebSphere Application Server supports this trust anchor. In WebSphere Application Server, the trust anchor is represented as a Java keystore object. The type, path, and password of the keystore are passed to the implementation through the administrative console or by scripting.

Configuring token generators with an assembly tool

Prior to completing this task, you must complete the following steps:

- Import your application into an assembly tool.
For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.
- Configure the security token in the extensions file. For example, if you are configuring a token generator for a Lightweight Third Party Authentication (LTPA) token, you must first configure the LTPA token under the Security Token section on the **Extensions** tab. For more information, see "Configuring the security token in generator security constraints" on page 1102.
- Configure a collection certificate store if the token generator uses the PKCS#7 token type and you want to package the certificate revocation lists (CRL) in the security token. For more information, see "Configuring the collection certificate store for the generator binding with an assembly tool" on page 1033.

A security token represents a set of claims that are made by a client. This set of claims might include a name, password, identity, key, certificate, group, privilege, and so on. A security token is embedded in the SOAP message within the SOAP header. The security token within the SOAP header is propagated from the message sender to the intended message receiver.

Complete the following steps to configure either the client-side bindings for the token generator in step 2 or the server-side bindings for the token generator in step 3:

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the bindings that you need to configure.
 - a. Expand the Web Services > Clients section and double-click the name of the Web service.
 - b. Click the **WS Binding** tab and expand the Security Request Generator Binding Configuration section.
4. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you need to configure.
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Response Generator Binding Configuration Details section.
5. **Optional:** Configure a trust anchor if you are configuring this token consumer for an X.509 security token.
 - a. Expand the Trust anchor section and click **Add** to add a new entry or click **Edit** to edit a selected entry. The Trust anchor dialog window is displayed.
 - b. Specify a name for the trust anchor configuration in the Trust anchor name field.
 - c. Specify a keystore password in the Key store storepass field. The keystore storepass is the password that is required to access the keystore file.
 - d. Specify the path to the keystore file in the Key store path field. The key store path is the directory where the keystore resides. Make sure that wherever you deploy your application that can locate your keystore file.
 - e. Select a key store type from the Key store type field. The key store type that you select must match the keystore file that is specified in the Key store path field.
6. Expand the Token generator section and click **Add** to add a new entry or click **Edit** to edit a selected entry. The Token Generator Dialog window is displayed.
7. Specify a unique name in the Token generator name field. For example, you might specify `gen_sigtgen`. If this token generator is for an X.509 certificate and is used for signature generation or encryption, the token generator name is referenced in the Token field of the Key Information dialog window.
8. Select a token generator class in the Token generator class field. Select the token generator class that matches the type of token that you are configuring. This class must implement the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface. The following default token generator implementations are supported:
 - `com.ibm.wsspi.wssecurity.token.LTPATokenGenerator`
 - `com.ibm.wsspi.wssecurity.token.UsernameTokenGenerator`
 - `com.ibm.wsspi.wssecurity.token.X509TokenGenerator`
9. Select a security token reference in the Security token field. The value in this field references the security token that is configured in the extensions file.
10. Select the **Use value type** option and select the value type in the Value type field. Select the value type of the security token that matches the type of token generator that you are configuring. When you select the value type, the assembly tool automatically enters the correct values in the Local name

and URI fields depending upon the type of security token that is specified by the value type. If you select **Custom Token**, you must specify the local name and the namespace URI of the value type for the generated token. The following value types are supported:

- Username Token
- X509 certificate token
- X509 certificates in a PKIPath
- A list of X509 certificates and CRLs in a PKCS#7
- LTPA Token
- Custom Token

11. Specify the Callback handler class name in the Call back handler field. This name is the callback handler implementation class that is used to plug-in a security token framework. The specified callback handler class must implement the `javax.security.auth.callback.CallbackHandler` interface. The implementation of the Java Authentication and Authorization Service (JAAS) `javax.security.auth.callback.CallbackHandler` interface must provide a constructor using the following syntax:

```
MyCallbackHandler(String username, char[] password, java.util.Map properties)
```

Where:

- *username* specifies the user name that is passed into the configuration.
- *password* specifies the password that is passed into the configuration.
- *properties* specifies the other configuration properties that are passed into the configuration.

The following default callback handler implementations are supported:

com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler

This callback handler uses a login prompt to gather the user name and password information. However, if you specify the user name and password on this panel, a prompt is not displayed and WebSphere Application Server returns the user name and password to the token generator if it is specified on this panel. Use this implementation for a J2EE application client only.

com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

This callback handler does not issue a prompt and returns the user name and password if it is specified on this panel. You can use this callback handler when the Web service is acting as a client.

com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler

This callback handler uses a standard-in prompt to gather the user name and password. However, if the user name and password is specified on this panel, WebSphere Application Server does not issue a prompt, but returns the user name and password to the token generator. Use this implementation for a J2EE application client only.

com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler

This callback handler is used to obtain the Lightweight Third Party Authentication (LTPA) security token from the Run As invocation Subject. This token is inserted in the Web services security header within the SOAP message as a binary security token. However, if the user name and password are specified on this panel, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token rather than obtaining it from the Run As Subject. Use this callback handler only when the Web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a J2EE application client.

com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler

This callback handler is used to create the X.509 certificate that is inserted in the Web services security header within the SOAP message as a binary security token. A keystore and a key definition is required for this callback handler.

com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler

This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web services security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You must specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format.

com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler

This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web services security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used.

The callback handler implementation obtains the required security token and passes it to the token generator. The token generator inserts the security token in the Web services security header within the SOAP message. Also, the token generator is a plug-in point for the pluggable security token framework. Service providers can provide their own implementation, but the implementation must use the `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` interface.

12. Specify the basic authentication User ID in the User ID field. This user name is passed to the constructors of the callback handler implementation. The basic authentication user name and password are used if you select one of the following default callback handler implementations, as described in the previous step:
 - `com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler`
 - `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`
 - `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`
 - `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`
13. Specify the basic authentication password in the Password field. This password is passed to the constructors of the callback handler implementation.
14. **Optional:** Select the **Use key store** option and complete the following substeps if you previously selected one of the following callback handlers:
`com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler`,
`com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler`, or
`com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler`.
 - a. Specify the password for the keystore in the Key store storepass field. This password is used to access the keystore file.
 - b. Specify the location of the keystore in the Key store path field.
 - c. Specify the type of keystore in the Key store type field. The following keystore types are supported:

JKS Use this option if the keystore uses the Java Keystore (JKS) format.

JCEKS

Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in WebSphere Application Server. This option provides stronger protection for stored private keys by using Triple DES encryption.

JCERACFKS

Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

PKCS11

Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12

Use this option if your keystore uses the PKCS#12 file format.

- d. In the Keys section, click **Add** to add a key. You can also click **Remove** to remove an existing key.
 - e. In the Key section, specify an alias for the key in the Alias field. For example, you might specify bob. The key alias is used by the key locator to locate the key within the keystore file.
 - f. In the Keys section, specify a password for the key in the Key pass field. This password is needed to access the key object within the keystore file.
 - g. In the Keys section, specify a name in the Key name field. The key name must be a fully qualified, distinguished name. For example, you might specify CN=Bob,O=IBM,C=US.
15. **Optional:** Select the **Use certificate path settings** option if the token generator uses the PKCS#7 token type and you want to package the certificate revocation lists (CRL) in the security token.
- a. Select the **Certificate path reference** option and a certificate store reference. This selection references a certificate store that is configured in the Certificate Store List section. For more information, see “Configuring the collection certificate store for the generator binding with an assembly tool” on page 1033.
16. **Optional:** Click **Add** and specify additional properties in the Property section.

If the token generator includes a nonce in the user name token, add the following name and value pair:

Name com.ibm.wsspi.wssecurity.token.username.addNonce
Value true

Nonce is a unique cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. A property is valid only when the generated token type is a user name token. This option is available for the request generator binding only.

If this token generator might include a time stamp in the user name token, add the following name and value pair:

Name com.ibm.wsspi.wssecurity.token.username.addTimestamp
Value true

This option is valid only when the generated token type is a user name token and it is available for the request generator binding only.

If you have defined identity assertion in the IBM extended deployment descriptor, add the following name and value pair:

Name com.ibm.wsspi.wssecurity.token.IDAssertion.isUsed
Value true

This option indicates that only the identity of the initial sender is required and inserted into the Web services security header within the SOAP message. For example, WebSphere Application Server only sends the user name of the original caller for a Username token generator. For an X.509 token generator, the application server sends the original signer certification only.

If you have defined identity assertion in the IBM extended deployment descriptor and you want to use the Run As identity instead of the initial caller identity for identity assertion for a downstream call, add the following name and value pair:

Name com.ibm.wsspi.wssecurity.token.IDAssertion.useRunAsIdentity
Value true

This option is valid only when the generated token type is a user name token.

17. Click **OK** to save your configuration.

Configure the key information if this token generator configuration is for an X.509 security token. For more information, see “Configuring key information for the generator binding with an assembly tool” on page 1042.

Key locator

A key locator or the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` class, is an abstraction of the mechanism that retrieves the key for digital signature and encryption.

You can use any of the following infrastructure from which to retrieve the keys depending upon the implementation:

- Java keystore file
- Database
- Lightweight Third Party Authentication (LTPA) server

Key locators search for the key using some type of a clue. The following types of clues are supported:

- A string label of the key, which is explicitly passed through the application programming interface (API). The relationship between each key and its name (string label) is maintained inside the key locator.
- The implementation context of the key locator; explicit information is not passed to the key locator. A key locator determines the appropriate key according to the implementation context.

WebSphere Application Server Versions 6 and later support a secret key-based signature called HMAC-SHA1. If you use HMAC-SHA1, the SOAP message does not contain a binary security token. In this case, it is assumed that the key information within the message contains the key name that is used to specify the secret key within the keystore.

Because the key locators support the public key-based signature, the key for verification is embedded in the X.509 certificate as a `<BinarySecurityToken>` element in the incoming message. For example, key locators can obtain the identity of the caller from the context and can retrieve the public key of the caller for response encryption.

This section describes the usage scenarios for key locators.

Signing

The name of the signing key is specified in the Web services security configuration. This value is passed to the key locator and the actual key is returned. The corresponding X.509 certificate also can be returned.

Verification

By default, WebSphere Application Server Versions 6 and later supports the following types of key locators:

KeyStoreKeyLocator

Uses the keystore to retrieve the key that is used for digital signature and verification or encryption and decryption.

X509CertKeyLocator

Uses an X.509 certificate within a message to retrieve the key for verification or decryption.

SignerCertKeyLocator

Uses the X.509 certificate within the request message to retrieve the key that is used for encryption in the response message.

Encryption

The name of the encryption key is specified in the Web services security configuration. This value is passed to the key locator and the actual key is returned. On the server side, you can use the `SignerCertKeyLocator` to retrieve the key for encryption in the response message from the X.509 certificate in the request message.

Decryption

The Web services security specification recommends using the key identifier instead of the key name. However, while the algorithm for computing the identifier for the public keys is defined in Internet Engineering Task Force (IETF) Request for Comment (RFC) 3280, there is no agreed-upon algorithm for the secret keys. Therefore, the current implementation of Web services security uses the identifier only when public key-based encryption is performed. Otherwise, the ordinal key name is used.

When you use public key-based encryption, the value of the key identifier is embedded in the incoming encrypted message. Then, the Web services security implementation searches for all of the keys managed by the key locator and decrypts the message using the key whose identifier value matches the one in the message.

When you use secret key-based encryption, the value of the key name is embedded in the incoming encrypted message. The Web services security implementation asks the key locator for the key with the name that matches the name in the message and decrypts the message using the key.

Keys:

Keys are used for XML digital signature and encryption.

There are two predominant kinds of keys used in the current Web services security implementation:

- Public key - such as Rivest Shamir Adleman (RSA) encryption and Digital Signature Algorithm (DSA) encryption
- Secret key - such as triple-strength DES (3DES) encryption

In public key-based signature, a message is signed using the sender private key and is verified using the sender public key. In public key-based encryption, a message is encrypted using the receiver public key and is decrypted using the receiver private key. In secret key-based signature and encryption, the same key is used by both parties.

While the current implementation of Web services security can support both kinds of keys, the format of the message differs slightly between public key-based encryption and secret key-based encryption.

Configuring key locators for the generator binding with an assembly tool

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.

Before configuring a key locator, you should know which key information configuration will reference this key locator. For example, if you configure this key locator for the STRREF key information type, select the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` key locator class.

WebSphere Application Server Version 6 and later provide default key locator implementations that you can choose or you can write your own implementation. Custom key locators must implement the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` interface. Using this implementation, you can locate keys within any data source.

Complete the following steps to configure a key locator for the generator using an assembly tool. The purpose of the key locators is to retrieve keys from the keystore for digital signature and encryption. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool and click **Window > Open Perspective > J2EE**.
2. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the bindings that you need to configure.
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Binding** tab and expand the Security Request Generator Binding Configuration section.
3. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you need to configure.
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Response Generator Binding Configuration Details section.
4. Expand the Key locators section and click **Add** to add a new entry or click **Edit** to edit a selected entry.
5. Specify a name for this configuration in the Key locator name field. This configuration name is referenced in the Key locator field of the Key Information dialog.
6. Select a key locator implementation in the Key locator class field. Select the key locator class that matches the Key Information configuration that references this key locator. The following default key locator class implementations are supported for Version 6 and later applications:

com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator

This implementation locates and obtains the key from the specified keystore file.

com.ibm.wsspi.wssecurity.keyinfo.SignerCertKeyLocator

This implementation uses the public key from the certificate of the signer. This class implementation is used by the response generator.

com.ibm.wsspi.wssecurity.keyinfo.X509TokenKeyLocator

This implementation uses the X.509 security token from the sender message for digital signature validation and encryption. This class implementation is used by the request consumer and the response consumer.

7. Select the **Use key store** option if you need to configure a key store for this key locator. Whether you need to configure the key store information for a key locator depends upon the key locator class and your application configuration. For example, if you select the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` key locator class in the previous step, configure the key store information for this key locator.
 - a. Specify a keystore password in the Key store storepass field. The keystore storepass is the password that is required to access the keystore file.
 - b. Specify the path to the keystore file in the Key store path field. The key store path is the directory where the keystore resides. Make sure that wherever you deploy your application that can locate your keystore file. Thus it is recommended that you use `${USER_INSTALL_ROOT}` in the path name as this variable expands to the WebSphere Application Server path on your machine.
 - c. Select a key store type from the Key store type field. The key store type that you select must match the keystore file that is specified in the Key store path field. The following keystore types are supported:

JKS Use this option if you are not using Java Cryptography Extensions (JCE) policy file and if your keystore file uses the Java Keystore (JKS) format.

JCEKS

Use this option if you are using Java Cryptography Extensions policy file.

JCERACFKS

Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

PKCS11

Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12

Use this option if your keystore uses the PKCS#12 file format.

8. Click **Add** under the Key field to add a key entry from the keystore file that you specified in the previous step. This key is used for signature generation or encryption. The key that you specify must match the key that is used for validation or decryption for the consumer.
 - a. Specify an alias name for the key in the Alias field. The key alias is used by the key locator to find the key within the keystore file.
 - b. Specify the password that is associated with the key in the Key pass field. This password is needed to access the key object within the keystore file.
 - c. Specify the key name in the Key name field. For digital signatures, the key name is used in the signing information for the request generator or response generator to determine which key is used to digitally sign the message. For encryption, the key name is used to determine which key is used for encryption. You must specify a fully qualified, distinguished name for the key name. For example, you might specify CN=Bob,O=IBM,C=US.
9. Click **OK** to save the configuration.

After you configure the key locator and any token generator that you need to configure, you can configure the key information that references this key locator. For more information, see “Configuring key information for the generator binding with an assembly tool.”

Configuring key information for the generator binding with an assembly tool

Prior to completing this task, you must complete the following steps:

1. Import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.
2. Configure the key locator that is referenced by the key information configuration. For more information, see “Configuring key locators for the generator binding with an assembly tool” on page 1040.
3. Configure the token generator that is referenced by the key information configuration. For more information, see “Configuring token generators with an assembly tool” on page 1034

Complete the following steps to configure the key information for the server-side and client-side bindings using an assembly tool. This key information is used to specify the configuration that is needed to generate the key for digital signature and encryption. The signing information and encryption information configurations can share the key information. The key information on the consumer side is used for specifying the information about the key that is used for validating the digital signature in the received message or for decrypting the encrypted parts of the message. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the bindings that you need to configure.
 - a. Expand the Web Services > Client section and double-click the name of the Web service.

- b. Click the **WS Binding** tab and expand the Security Request Generator Binding Configuration section.
4. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you need to configure.
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Response Generator Binding Configuration Details section.
5. Expand the Key Information section and click **Add** to add a new entry or click **Edit** to edit a selected entry.
6. Specify a unique name for this configuration in the Key information name field. For example, you might specify `gen_signkeyinfo`. This configuration name is referenced by the Key information element within the Signing Information and Encryption Information dialog windows. For more information, see “Configuring signing information for the generator binding with an assembly tool” on page 1044 and “Configuring encryption information for the generator binding with an assembly tool” on page 1097.
7. Select a key information type from the Key information type field. The key information types specify different mechanisms for referencing security tokens. The assembly tools support the following key information types:

STRREF

This type is the security token reference. The security token is directly referenced using Universal Resource Identifiers (URIs). The following `<KeyInfo>` element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <wsse:Reference URI="#mytoken" />
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

EMB This type is the embedded token. The security token is directly embedded within the `<SecurityTokenReference>` element. The following `<KeyInfo>` element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <wsse:Embedded wsu:Id="tok1" />
    ...
  </wsse:Embedded>
</wsse:SecurityTokenReference>
</ds:KeyInfo>
```

KEYID

This type is a key identifier. The security token is referenced using an opaque value that uniquely identifies the token. The algorithm that is used for generating the key identifier value depends upon the token type. The following `<KeyInfo>` element is generated in the Simple Object Access Protocol (SOAP) message for this key information type:

```
<ds:KeyInfo xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
  <wsse:SecurityTokenReference>
    <wsse:KeyIdentifier ValueType="wsse:X509v3"/>62wX0...</wsse:KeyIdentifier>
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

KEYNAME

This type is the key name. The security token is referenced using a name that matches an asserted identity within the token. The following `<KeyInfo>` element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <ds:KeyName>CN=Group1</ds:KeyName>
</ds:KeyInfo>
```

Note: To be compliant with the Basic Security Profile (BSP), do not use the KEYNAME information type. A SECURITY_TOKEN_REFERENCE must not use a KEYNAME to reference a SECURITY_TOKEN.

X509ISSUER

This type is the X.509 certificate issuer name and serial number. The security token is referenced by an issuer name and issuer serial number of an X.509 certificate. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <ds:X509Data>
      <ds:X509IssuerSerial>
        <ds:X509IssuerName>CN=Jones, O=IBM, C=US</ds:X509IssuerName>
        <ds:X509SerialNumber>1040152879</ds:X509SerialNumber>
      </ds:X509IssuerSerial>
    </ds:X509Data>
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

8. Select the **Use key locator** option.
 - a. Select the name of a key locator configuration from the Key locator field. The value of this field is a reference to a key locator that specifies how to find keys or certificates. For more information, see “Configuring key locators for the generator binding with an assembly tool” on page 1040.
 - b. Specify a key name in the Key name field. The value is the name of a key that is used for generating the digital signature and for encryption. The list of key names come from the key locator that you specified previously.
9. **Optional:** Select the **Use token** option and a token generator configuration in the Token field if a token generator is required for the key information configuration. The token that you select specifies a reference to a token generator that is used for processing the security token within the message. Before you specify a token reference, you must configure a token generator. For more information on token generator configurations, see “Configuring token generators with an assembly tool” on page 1034.

After completing this task, configure the signing information or encryption information that references the key information that is specified by this task. For more information, see “Configuring signing information for the generator binding with an assembly tool” or “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

Configuring signing information for the generator binding with an assembly tool

You can configure the signing information for the server-side and client-side generator bindings by using an assembly tool.

Prior to completing this task, you must complete the following steps:

1. Import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.
2. Specify which message parts to digitally sign. For more information, see “Signing message elements in generator security constraints with keywords” on page 1018 or “Signing message elements in generator security constraints with an XPath expression” on page 1027.
3. Configure the key information that is referenced by the Key information element within the Signing information dialog window. For more information, see “Configuring key information for the generator binding with an assembly tool” on page 1042.

Complete the following steps to configure the signing information for the server-side and client-side bindings by using an assembly tool. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the bindings that you must configure.
 - a. Expand the **Web Services > Client** section and double-click the name of the Web service.
 - b. Click the **WS Binding** tab and expand the Security Request Generator Binding Configuration section.
4. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you must configure.
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Response Generator Binding Configuration Details section.
5. Expand the Signing Information section and click **Add** to add a new entry or select an existing entry and click **Edit**. The Signing Information dialog window is displayed.
 - a. Specify a name for the signing information configuration in the Signing information name field. For example, you might specify `gen_signinfo`.
 - b. Select a canonicalization method from the **Canonicalization method algorithm** field. The canonicalization method algorithm is used to canonicalize the signing information before it is digested as part of the signature operation. The following pre-configured algorithms are supported:
 - <http://www.w3.org/2001/10/xml-exc-c14n#>
 - <http://www.w3.org/2001/10/xml-exc-c14n#WithComments>
 - <http://www.w3.org/TR/2001/REC-xml-c14n-20010315>
 - <http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments>

You must specify the same canonicalization algorithm for both the generator and the consumer. For more information on configuring the signing information for the consumer, see “Configuring signing information for the consumer binding with an assembly tool” on page 1067.
 - c. **Optional:** Select **Show only FIPS Compliant Algorithms** if you want only the FIPS compliant algorithms to show in the encryption method algorithm drop-down lists. Use this option if you expect this application to run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.
 - d. Select a signature method algorithm from the Signature method algorithm field. The following pre-configured algorithms are supported:
 - <http://www.w3.org/2000/09/xmldsig#rsa-sha1>
 - <http://www.w3.org/2000/09/xmldsig#hmac-sha1>
 - <http://www.w3.org/2000/09/xmldsig#dsa-sha1>

Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP). Any `ds:SignatureMethod/@Algorithm` element in a SIGNATURE based on a symmetric key must have a value of <http://www.w3.org/2000/09/xmldsig#rsa-sha1> or <http://www.w3.org/2000/09/xmldsig#hmac-sha1>.

You must specify the same canonicalization algorithm for both the generator and the consumer. For more information on configuring the signing information for the consumer, see “Configuring signing information for the consumer binding with an assembly tool” on page 1067.
6. Click **Add** in the Signing Key Information section to add a new key information entry or click **Remove** to delete a selected entry. Complete the following substeps if you are adding a new key information entry.
 - a. Specify a name in the Key information name field. For example, you might specify `gen_keyinfo`.

- b. Select a key information reference from the list under the Key information element field. The value in this field references the key information configuration that you specified previously. If you have a key information configuration called `gen_signkeyinfo` that you want to use with this signing information configuration, specify `gen_signkeyinfo` in the Key information element field. For more information, see “Configuring key information for the generator binding with an assembly tool” on page 1042.
 - c. **Optional:** Select the **Use key information signature** option if you want to sign the key information within the SOAP message.
 - d. **Optional:** Select a key information signature type from the Type field if you select the **Use key information signature** option. Select the **keyinfo** value to specify that the entire KeyInfo element must be signed within the SOAP message. Select the **keyinfochildelements** value to specify that the child elements within the KeyInfo element must be signed, but the KeyInfo element itself does not need to be signed.
7. **Optional:** Determine whether to disable the Inclusive namespace prefix list. The Exclusive XML Canonicalization Version 1.0 specification recommends that you include all of the namespace declarations that correspond to the namespace prefix in the canonicalization form. For security reasons, WebSphere Application Server, by default, includes the prefix in the digital signature for Web services security. However, some implementations of Web services security cannot handle this prefix list. WebSphere Application Server can handle digitally signed messages that either contain or do not contain the prefix list. If you experience a signature validation failure when a signed SOAP message is sent and you are using another vendor in your environment, it is highly recommended that you check with their Web site for a possible fix to their implementation before you disable this property. To disable this property, complete the following steps:
 - a. Under Properties, click **Add**.
 - b. In the Name field, enter the `com.ibm.wsspi.wssecurity.dsig.inclusiveNamespaces` property.
 - c. In the Value field, enter the `false` value.
 - d. Click **OK**.
 8. Click **OK** to save your signing information configuration.
 9. Expand the Part References subsection and select the signing information configuration from the Signing Information section.
 10. Click **Add** in the Part References subsection to add a new entry or select an existing entry and click **Edit**. The Part References dialog window is displayed.
 - a. Specify a name for the part reference configuration in the Part reference name field.
 - b. Select a integrity part configuration in the Integrity part field. For more information on how to configure the integrity part, see “Signing message elements in generator security constraints with keywords” on page 1018 or “Signing message elements in generator security constraints with an XPath expression” on page 1027.
 - c. **Optional:** Select **Show only FIPS Compliant Algorithms** if you want only the FIPS compliant algorithms to show in the encryption method algorithm drop-down lists. Use this option if you expect this application to run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.
 - d. Select a digest method algorithm in the Digest method algorithm field.
WebSphere Application Server supports the following digest method algorithms:
 - <http://www.w3.org/2000/09/xmldsig#sha1>
 - <http://www.w3.org/2001/04/xmlenc#sha256>
 - <http://www.w3.org/2001/04/xmlenc#sha512>
 This digest method algorithm is used to create the digest for each message part that is specified by this part reference.

- e. Expand the Transforms subsection and the part reference configuration from the Part reference subsection.
- f. Click **Add** in the Transforms subsection to add a new entry or select an existing entry and click **Edit**. The Transform dialog window is displayed.
- g. Specify a transform name in the Name field. For example, you might specify `reqint_body_transform1`.
- h. Select a transform algorithm from the Algorithm field. The following transform algorithms are supported:

<http://www.w3.org/2001/10/xml-exc-c14n#>

This algorithm specifies the World Wide Web Consortium (W3C) Exclusive Canonicalization recommendation.

<http://www.w3.org/TR/1999/REC-xpath-19991116>

This algorithm specifies the W3C XML path language recommendation. If you specify this algorithm, you must specify the property name and value by clicking **Properties**, which is displayed under Additional properties. For example, you might specify the following information:

Property

`com.ibm.wsspi.wssecurity.dsig.XPathExpression`

Value

`not(ancestor-or-self::*[namespace-uri()='http://www.w3.org/2000/09/xmlsig#' and local-name()='Signature'])`

Note: Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use <http://www.w3.org/2002/06/xmlsig-filter2> to ensure compliance.

<http://www.w3.org/2002/06/xmlsig-filter2>

This algorithm specifies the XML-Signature XPath Filter Version 2.0 proposed recommendation.

When you use this algorithm, you must specify a set of properties in the Transform property fields. You can use multiple property sets for the XPath Filter Version 2. Thus, it is recommended that your property names end with the number of the property set, which is denoted by an asterisk in the following examples:

- To specify an XPath expression for the XPath filter2, you might use:

name `com.ibm.wsspi.wssecurity.dsig.XPath2Expression_*`

- To specify a filter type for each XPath, you might use:

name `com.ibm.wsspi.wssecurity.dsig.XPath2Filter_*`

Following this expression, you can have a value, `[intersect]`, `[subtract]`, or `[union]`.

- To specify the processing order for each XPath, you might use:

name `com.ibm.wsspi.wssecurity.dsig.XPath2Order_*`

Following this expression, indicate the processing order of the XPath.

The following is a list of complete examples:

```
com.ibm.wsspi.wssecurity.dsign.XPath2Filter_1 = [intersect]
com.ibm.wsspi.wssecurity.dsign.XPath2Order_1 = [1]
com.ibm.wsspi.wssecurity.dsign.XPath2Expression_2 = [XPath expression#2]
com.ibm.wsspi.wssecurity.dsign.XPath2Filter_2 = [subtract]
com.ibm.wsspi.wssecurity.dsign.XPath2Filter_2 = [1]
```

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform>

<http://www.w3.org/2002/07/decrypt#XML>

This algorithm specifies the W3C decryption transform for XML Signature recommendation.

<http://www.w3.org/2000/09/xmlsig#enveloped-signature>

This algorithm specifies the W3C recommendation for XML digital signatures.

The transform algorithm that you select for the generator must match the transform algorithm for the consumer.

11. Click **OK**.

After you complete this task for the generator binding, you must configure the signing information for consumer binding.

Signing message elements in consumer security constraints with keywords

You can specify which message parts or elements must be signed when you configure the consumer security constraints for either the response consumer or the request consumer.

Prior to completing this task, you must import your application into an assembly tool.

See information about importing an enterprise application EAR file in the Application Server Toolkit documentation.

Complete the following steps to specify which message parts or elements must be signed when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. If the required parts are not signed, the request or response is rejected and a SOAP fault is returned to the caller. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure.
 - a. Expand the **Web Services > Client** section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure.
 - a. Expand the **Web Services > Services** section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Required Integrity section. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing SOAP messages, see “XML digital signature” on page 1017.
6. Click **Add** to indicate which message parts or elements the consumer expects to be signed. The Required Integrity Dialog window is displayed.
 - a. Specify a name for the integrity element under Required Integrity Name field.
 - b. Specify a usage type in the Usage type field. This field specifies the requirement for the integrity element. The following options are available:

Required

If you select **Required** and the required message parts or elements are not signed, then the message is rejected with SOAP fault.

Optional

If you select **Optional**, then the digital signature of the selected message parts or elements is verified if they are signed. However, the consumer does not reject the message if the selected message parts or elements are not signed.

7. Click **Add** under the Message Parts section and select the Message parts dialect. The <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> dialect specifies which message parts or elements are expected to be signed using keywords. If you select this dialect, you can select one of the following keywords under the Message parts keyword heading:

body Specifies the user data portion of the message. If you select this keyword, the body is checked to see if it is signed.

timestamp

Specifies that the standalone `timestamp` element within the message is checked for a digital signature. The timestamp element determines whether the message is valid based upon the time that the message is sent and then received. If the timestamp option is selected, make sure that there is a standalone `timestamp` element in the message. If the element does not exist, see “Adding a stand-alone time stamp in consumer security constraints” on page 1100.

securitytoken

Specifies that the security token authenticates the client. If this keyword is selected, the security token or tokens in the SOAP message are checked to determine if they are signed. For example, if you are sending a UsernameToken element within the message, you can specify that it is signed using this keyword.

dsigkey

Specifies that the key information element, which is used for digital signature, is checked to determine if it is signed.

enckey Specifies that the key information element, which is used for encryption, is checked to determine if it is signed.

messageid

Specifies that the `<wsa:MessageID>` element within the message is checked to determine if it is signed.

to Specifies that the `<wsa:To>` element within the message is checked to determine if it is signed.

action Specifies that the `<wsa:Action>` element is checked to determine if it is signed.

relatesto

Specifies that the `<wsa:RelatesTo>` element within the message is checked to determine if it is signed.

wscontext

Specifies the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services.

wsafrom

Specifies the `<wsa:From>` WS-Addressing From element in the SOAP header.

wsareplyto

Specifies the `<wsa:ReplyTo>` WS-Addressing ReplyTo element in the SOAP header.

wsafaultto

Specifies the `<wsa:FaultTo>` WS-Addressing FaultTo element in the SOAP header.

wsaa11 Specifies all of the WS-Addressing elements in the SOAP header.

8. Click **OK** to save the configuration changes.

Note: These configurations for the consumer and the generator must match.

In addition to specifying the message parts or elements that are expected to be signed, you also can specify that nonce and timestamp elements are expected to be included in the signed elements. For more information, see the following articles:

- “Adding time stamps for integrity in consumer security constraints with keywords”
- “Adding time stamps for integrity in consumer security constraints with an XPath expression” on page 1055
- “Adding a nonce for integrity in consumer security constraints with keywords” on page 1052
- “Adding a nonce for integrity in consumer security constraints with an XPath expression” on page 1057

After you specify which message parts to check for a digital signature, you must specify which signature algorithm is used to validate the signature. For more information, see “Configuring signing information for the consumer binding with an assembly tool” on page 1067.

Adding time stamps for integrity in consumer security constraints with keywords:

You can specify that when a time stamp is embedded in a particular element, the parent of the time stamp is expected to be signed with the message parts.

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

Complete the following steps to specify that the parent element of the time stamp is expected in the element. Also, the time stamp is included in the signature for the message parts. Configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Required Integrity section. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing SOAP messages, see “XML digital signature” on page 1017.
6. Click **Add** to specify a time stamp that is expected in the parent element of the keyword. The parent element of the time stamp is also expected to be included in the signature for the message part. The Required Integrity Dialog window is displayed. Before you configure the time stamp in the Required Integrity, you must configure at least one message part or element that is expected to be signed. Complete the following steps to specify a configuration:
 - a. Specify a name for the integrity element in the Required Integrity Name field.

- b. Specify a usage type in the Usage type field. This field specifies the requirement for the integrity element. The value of this attribute is either Required or Optional. The following options are available:

Required

If you select **Required** and the required message parts or elements are not signed, then the message is rejected with SOAP fault.

Optional

If you select **Optional**, then the digital signature of the selected message parts or elements is verified if they are signed. However, the consumer does not reject the message if the selected message parts or elements are not signed.

7. In the Timestamp section, click **Add** and select the Timestamp dialect. The <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> dialect specifies the parent element of the expected time stamp. If you select this dialect, you can select one of the following keywords under the Timestamp keyword heading:

body Specifies the user data portion of the message. If you select the body option, a time stamp is embedded in SOAP body. Also, the parent of the time stamp (SOAP body) is expected to be signed with the message parts in the Required Integrity.

securitytoken

Specifies that a time stamp is expected to be embedded in the security token element. Also, the parent of the time stamp (security token) is expected to be signed with the message parts in the Required Integrity.

dsigkey

Specifies that the time stamp is inserted into the key information element, which is used for digital signature, and the key information element is signed.

enckey Specifies that the time stamp is inserted into the key information element, which is used for encryption, and the key information element is signed.

messageid

Specifies that the time stamp is inserted into the <wsa:MessageID> element and the <wsa:MessageID> element is signed.

to Specifies that the time stamp is inserted into the <wsa:To> element within the message and that the <wsa:To> element is signed.

action Specifies that the <wsa:Action> element is signed.

relatesto

Specifies that the time stamp is inserted into the <wsa:RelatesTo> element within the message and the <wsa:RelatesTo> element is signed.

wscontext

Specifies the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services.

wsafrom

Specifies the <wsa:From> WS-Addressing From element in the SOAP header.

wsareplyto

Specifies the <wsa:ReplyTo> WS-Addressing ReplyTo element in the SOAP header.

wsafaultto

Specifies the <wsa:FaultTo> WS-Addressing FaultTo element in the SOAP header.

wsaa11 Specifies all of the WS-Addressing elements in the SOAP header.

8. If you have not defined a message part for Required Integrity, you must define at least one message part to add a time stamp for Required Integrity. Complete the following steps to define a message part:

- a. In the Message Parts section, click **Add** and select `http://www.ibm.com/websphere/webservices/wssecurity/ dialect-was` in the Message parts dialect field.
- b. In the Message Parts section, select the message parts keyword.
- c. Click **OK** to save the configuration changes.

Note: These configurations for the consumer and the generator must match.

In addition to the time stamp, you can specify that the nonce is signed. For more information, see the following articles:

- “Adding a nonce for integrity in consumer security constraints with keywords”
- “Adding a nonce for integrity in consumer security constraints with an XPath expression” on page 1057

After you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message. For more information, see “Configuring signing information for the consumer binding with an assembly tool” on page 1067.

Adding a nonce for integrity in consumer security constraints with keywords:

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

Nonce for integrity is used to specify that a nonce is embedded in a particular element. The parent element of the nonce is signed with the message parts in the required integrity. Complete the following steps to specify a nonce for integrity using keywords when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool and click **Window > Open Perspective > J2EE**.
2. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side bindings:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
3. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you need to configure. Complete the following steps to locate the server-side bindings:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
4. Expand the Required Integrity section. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing Simple Object Access Protocol (SOAP) messages, see “XML digital signature” on page 1017.
5. Click **Add** to specify a nonce for integrity. The Required Integrity Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the integrity element in the Required Integrity Name field.
 - b. Specify a usage type in the Usage type field. This field specifies the requirement for the integrity element. The value of this attribute is either Required or Optional.

Required

If you select **Required** and the required message parts or elements are not signed, then the consumer rejects the message and issues a SOAP fault.

Optional

If you select **Optional** and the message parts or elements are signed, then the digital signature is verified. However, the consumer does not reject the message if the selected message parts or elements are not signed.

6. Under Nonce, click **Add** and select the nonce dialect. The <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> dialect specifies the message part to which a nonce is added as a child element and signed with the message parts in the required integrity. If you select this dialect, you can select one of the following keywords under Nonce keyword:

body Specifies the user data portion of the message. If this option is selected, a nonce is embedded in the Simple Object Access Protocol (SOAP) body element. Also, the parent of the nonce (SOAP body) is expected to be signed with the message parts in the required integrity.

timestamp

Specifies that the nonce is embedded in the stand-alone timestamp element within the message. Also, the parent of the nonce (timestamp) is expected to be signed with the message parts in the required integrity. If timestamp keyword is selected, make sure that there is a standalone timestamp element in the message. If not, refer to the “Adding a stand-alone time stamp in consumer security constraints” on page 1100 article.

securitytoken

Specifies that the nonce element is expected to exist within the security token element. Also, the parent of the nonce (securitytoken) is expected to be signed with the message parts in the required integrity.

dsigkey

Specifies that the nonce is inserted into the key information element, which is used for digital signature, and the key information element is signed.

enckey

Specifies that the nonce is inserted into the key information element, which is used for encryption, and the key information element is signed.

messageid

Specifies that the nonce is inserted into the <wsa:MessageID> element and that the <wsa:MessageID> element is signed.

to Specifies that the nonce is inserted into the <wsa:To> element within the message and that the <wsa:To> element is signed.

action Specifies that the <wsa:Action> element is signed.

relatesto

Specifies that the nonce is inserted into the <wsa:RelatesTo> element within the message and that the <wsa:RelatesTo> element is signed.

wscontext

Specifies the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services.

wsafrom

Specifies the <wsa:From> WS-Addressing From element in the SOAP header.

wsareplyto

Specifies the <wsa:ReplyTo> WS-Addressing ReplyTo element in the SOAP header.

wsafaultto

Specifies the <wsa:FaultTo> WS-Addressing FaultTo element in the SOAP header.

wsaall Specifies all of the WS-Addressing elements in the SOAP header.

7. If you have not previously specified message part in required integrity, click **Add** in the Message Parts section to add the message parts. You must define at least one message part in required integrity to specify a nonce in required integrity.
8. In the Message Parts section, select the message parts keyword.
9. Click **OK** to save the configuration changes.

Note: These configurations on the consumer side and the generator side must match.

In addition to the nonce, you can specify that the timestamp element is signed. For more information, see the following articles:

- “Adding time stamps for integrity in consumer security constraints with keywords” on page 1050
- “Adding time stamps for integrity in consumer security constraints with an XPath expression” on page 1055

After you specify which message parts to digitally sign, you must specify which method is used to digitally sign the message. For more information, see “Configuring signing information for the consumer binding with an assembly tool” on page 1067.

Signing message elements in consumer security constraints with an XPath expression

You can specify which message parts are expected to be signed using an XPath expression.

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

Complete the following steps to specify which message parts are expected to be signed using an XPath expression. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the **Web Services > Services** section and double-click the name of the Web service.

- b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Required Integrity section. Integrity refers to digital signature and confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing SOAP messages, see “XML digital signature” on page 1017.
6. Click **Add** to indicate which message parts to validate for digital signature. The Required Integrity Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the integrity element under Required Integrity Name field.
 - b. Specify a usage type in the Usage type field. This field specifies the requirement for the integrity element. The value of this attribute is either Required or Optional.

Required

If you select **Required** and the required message parts or elements are not signed, the message is rejected with SOAP fault.

Optional

If you select **Optional**, then the digital signature of the selected message parts or elements is verified if they are signed. However, the consumer does not reject the message if the selected message parts or elements are not signed.

7. Click **Add** under the Message Parts section of the Required Integrity Dialog window. Complete the following steps to specify the message parts dialect and its message part:
 - a. Select the Message parts dialect from the Message Parts section of the Required Integrity Dialog window. If you select the `http://www.w3.org/TR/1999/REC-xpath-19991116` dialect, the message part that is validated for digital signature is specified by the XPath expression.
Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use `http://www.w3.org/2002/06/xmldsig-filter2` to ensure compliance.
 - b. Specify the message part to be validated for digital signature using an XPath expression in the Message parts keyword field. For example, to specify that the message body is checked to determine if it is signed, you might add the following expression in the Message parts keyword field as one continuous line:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/
soap/envelope/' and local-name()='Body']
```

Important: Verify that your XPath syntax is correct.

8. Click **OK** to save the configuration changes.

Note: These configurations for the consumer and the generator must match.

In addition to the message parts, you also can specify that WebSphere Application Server check the nonce and timestamp elements for a digital signature. For more information, see the following articles:

- “Adding time stamps for integrity in consumer security constraints with keywords” on page 1050
- “Adding time stamps for integrity in consumer security constraints with an XPath expression”
- “Adding a nonce for integrity in consumer security constraints with keywords” on page 1052
- “Adding a nonce for integrity in consumer security constraints with an XPath expression” on page 1057

After you specify which message parts to check for a digital signature, you must specify which method is used to validate the signature. For more information, see “Configuring signing information for the consumer binding with an assembly tool” on page 1067.

Adding time stamps for integrity in consumer security constraints with an XPath expression:

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

This task is to specify that a time stamp is expected to be added in an element of the SOAP message that is specified by the XPath language syntax. The element is expected to be signed with the message part that is specified in the Required Integrity Dialog window. Complete the following steps to specify the time stamp for integrity using an XPath expression when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure.
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure.
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Required Integrity section. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing Simple Object Access Protocol (SOAP) messages, see "XML digital signature" on page 1017.
6. Click **Add** to specify a time stamp for integrity. The Required Integrity Dialog window is displayed.
 - a. Specify a name for the integrity element in the Required Integrity Name field.
 - b. Specify a usage type in the Usage type field. This field specifies the requirement for the integrity element. The value of this attribute is either Required or Optional.
7. Click **Add** in the Timestamp section of the Required Integrity Dialog window.
 - a. Select the Timestamp dialect from the Timestamp section. The <http://www.w3.org/TR/1999/REC-xpath-19991116> dialect specifies the message part to which the time stamp is added and signed using the XPath expression.
 - b. Select the message part in the Timestamp keyword field to which the time stamp is added and signed using an XPath expression. For example, to specify that the time stamp is added to the body and is signed, you might specify the following expression for the Timestamp keyword:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'  
and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/  
soap/envelope/' and local-name()='Body']
```

Important: Verify that your XPath expression syntax is correct.

8. If you have not previously defined a message part in the Required Integrity Dialog window, click **Add** under the Message Parts section and define a message part.
9. In the Message Parts section, select the message parts keyword.
10. Click **OK** to save the configuration changes.

Note: These configurations for the consumer and the generator must match.

In addition to the time stamp, you can specify that the nonce is signed. For more information, see the following articles:

- “Adding a nonce for integrity in consumer security constraints with keywords” on page 1052
- “Adding a nonce for integrity in consumer security constraints with an XPath expression”

Important: You must define one message part in the required integrity if you want to use the time stamp feature for required integrity.

After you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message. For more information, see “Configuring signing information for the consumer binding with an assembly tool” on page 1067.

Adding a nonce for integrity in consumer security constraints with an XPath expression:

You can specify a nonce for integrity using an XPath expression when you configure the consumer security constraints for either the response consumer or the request consumer.

Prior to completing this task, you must import your application into an assembly tool.

See information about Importing an enterprise application EAR file in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

Nonce for integrity is used to specify that a nonce is embedded in a particular element within the message and that the element is signed.

Complete the following steps to specify a nonce for integrity using an XPath expression when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool and click **Window > Open Perspective > J2EE**.
2. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side bindings:
 - a. Expand the **Web Services > Client** section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.

3. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you need to configure. Complete the following steps to locate the server-side bindings:
 - a. Expand the **Web Services > Services** section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
4. Expand the Required Integrity section. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification when you transmit data across a network. For more information on digitally signing SOAP messages, see “XML digital signature” on page 1017.
5. Click **Add** to specify a nonce for integrity. The Required Integrity Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the integrity element in the Required Integrity Name field.
 - b. Specify a usage type in the Usage type field. This field specifies the requirement for the integrity element. The value of this attribute is either Required or Optional.
6. Click **Add** in the Nonce section of the Required Integrity Dialog window. Complete the following steps to configure the nonce dialect and message part:
 - a. Select the Nonce dialect from the Nonce section. The `http://www.w3.org/TR/1999/REC-xpath-19991116` dialect specifies the message part to which a nonce is added and signed using an XPath expression.
 - b. Select the message part in the Nonce keyword field to which a nonce is added and signed using an XPath expression. For example, to specify that a nonce is added to the body and that it is signed, you might specify the following expression for the Nonce keyword:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/
soap/envelope/' and local-name()='Body']
```
7. In the Message Parts section, click **Add** and select `http://www.w3.org/TR/1999/REC-xpath-19991116` in the Message parts dialect field.
8. In the Message Parts section, select the message parts keyword.

Important: You must select the same keyword in the Message parts keyword field as the keyword that you selected in the Nonce keyword field.

9. Click **OK** to save the configuration changes.

Note: These configurations on the consumer side and the generator side must match.

In addition to the nonce, you can specify that the timestamp element is signed. For more information, see the following articles:

- “Adding time stamps for integrity in consumer security constraints with keywords” on page 1050
- “Adding time stamps for integrity in consumer security constraints with an XPath expression” on page 1055

After you specify which message parts to digitally sign, you must specify which method is used to digitally sign the message. For more information, see “Configuring signing information for the consumer binding with an assembly tool” on page 1067.

Configuring the collection certificate store for the consumer binding with an assembly tool

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

This task describes the steps to specify the collection certificate store for the consumer bindings at the application level using an assembly tool. A collection certificate store is a collection of non-root certificate authority (CA) certificates and certificate revocation lists (CRLs) that is used for validating an X.509 certificate embedded within the received SOAP message. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the bindings that you need to configure. Complete the following steps to locate the client-side bindings:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Binding** tab and expand the Security Response Consumer Binding Configuration section.
4. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you need to configure. Complete the following steps to locate the server-side bindings:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Request Consumer Binding Configuration Details section.
5. Expand the Certificate Store List > Collection Certificate Store section and click **Add**.
6. Specify a unique certificate store name in the Name field. For example, specify cert1. The name of the collection certificate store must be unique on the level in which it is defined. For example, the name must be unique at the application level. The name specified in the certificate store name field is used by other configurations to refer to a predefined collection certificate store. WebSphere Application Server looks up the collection certificate store based on proximity. For example, if an application binding refers to certificate store cert1, WebSphere Application Server will look first for cert1 at the application level. If it is not found, it will look at the server level, and finally at the cell level.
7. Specify a certificate store provider in the Provider field. The IBM CertPath certificate path provider is supported. To use another certificate path provider, you must define the provider implementation in the provider list within the `java.security` file in the Software Development Kit (SDK).
8. Click **Add** under X509 Certificate to specify a fully qualified path to an X.509 certificate, click the name of an existing certificate path entry to edit it, or click **Remove** to delete it. This collection certificate store is used to validate the certificate path of the incoming X.509-formatted security tokens.

You can use the `USER_INSTALL_ROOT` variable as part of the path name. For example you might specify `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. However, do not use this X.509 certificate path for production use. Obtain your own X.509 certificate from a certificate authority before putting your WebSphere Application Server environment into production.

In the WebSphere Application Server administrative console, you can click **Environment > WebSphere Variables** to configure the `USER_INSTALL_ROOT` variable.

9. Click **Add** under CRL to specify the fully qualified path to a certificate revocation list (CRL), click an existing CRL entry to edit it or click **Remove** to delete it.

For portability reasons, it is recommended that you use the WebSphere Application Server variables to specify a relative path to the certificate revocation list. For example, you might use the `USER_INSTALL_ROOT` variable to define a path such as `${USER_INSTALL_ROOT}/mycertstore/mycr1`. For a list of the supported variables in the WebSphere Application Server administrative console, click **Environment > WebSphere Variables**.

The following list provides recommendations for using CRLs:

- If CRLs are added to the collection certificate store, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.
- When the CRL file is updated, the new CRL does not take effect until you restart the Web service application.
- Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.

10. Click **OK** to save your configuration.

Trusted ID evaluator

A *trusted ID evaluator* (`com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`) is an abstraction of the mechanism that evaluates whether the given ID name is trusted.

Depending upon the implementation, you can use various types of infrastructure to store a list of the trusted IDs, such as:

- Plain text file
- Database
- Lightweight Directory Access Protocol (LDAP) server

The trusted ID evaluator is typically used by the eventual receiver in a multi-hop environment. The Web services security implementation invokes the trusted ID evaluator and passes the identity name of the intermediary as a parameter. If the identity is evaluated and deemed trustworthy, the procedure continues. Otherwise, an exception is created and the procedure is stopped.

Configuring token consumers with an assembly tool

Prior to completing this task, you must complete the following steps:

- Import your application into an assembly tool.
For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.
- Configure the security token in the extension file. For example, if you are configuring a token consumer for a Lightweight Third Party Authentication (LTPA) token, you must first configure the LTPA token under the Required Security Token section on the **Extensions** tab. For more information, see "Configuring the security token requirement in consumer security constraints" on page 1103
- Configure a collection certificate store if the token consumer uses the PKCS#7 token type and you want to package the certificate revocation lists (CRL) in the security token. For more information, see "Configuring the collection certificate store for the consumer binding with an assembly tool" on page 1058.

A security token represents a set of claims that are made by a client. This set of claims might include a name, password, identity, key, certificate, group, privilege, and so on. A security token is embedded in the SOAP message within the SOAP header. The security token within the SOAP header is propagated from the message sender to the intended message receiver. On the receiving side, the security handler for WebSphere Application Server authenticates the security token and sets up the caller identity on the running thread.

Complete the following steps to configure a token consumer for either the client-side bindings in step 2 or the server-side bindings in step 3:

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.

3. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the bindings that you need to configure. Complete the following steps to locate the client-side bindings:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Binding** tab and expand the Security Response Consumer Configuration section.
4. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you need to configure. Complete the following steps to locate the server-side bindings:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Request Consumer Binding Configuration Details section.
5. **Optional:** Configure a trust anchor if you are configuring this token consumer for an X.509 security token. Complete the following steps to configure the trust anchors:
 - a. Expand the Trust anchor section and click **Add** to add a new entry or click **Edit** to edit a selected entry. The Trust anchor dialog window is displayed.
 - b. Specify a name for the trust anchor configuration in the Trust anchor name field.
 - c. Specify a keystore password in the Key store storepass field. The keystore storepass is the password that is required to access the keystore file.
 - d. Specify the path to the keystore file in the Key store path field. The key store path is the directory where the keystore resides. Make sure that wherever you deploy your application that the server can locate your keystore file.
 - e. Select a key store type from the Key store type field. The key store type that you select must match the keystore file that is specified in the Key store path field.
 - f. Click **OK** to save the trust anchor configuration.
6. Expand the Token Consumer section and click **Add** to add a new entry or click **Edit** to edit a selected entry. The Token Consumer Dialog window is displayed.
7. Specify a name in the Token consumer name field. If this token consumer is for an X.509 certificate and is used for signature validation or decryption, the token consumer name is referenced in the Token field of the Key Information dialog window.
8. Select a token consumer class in the Token consumer class field. Select the token consumer class that matches the type of token that you are configuring. For example, if you are configuring a token consumer that processes an X.509 security token in the received message, select the `com.ibm.wsspi.wssecurity.token.X509TokenConsumer` token consumer class.
9. Select a security token reference in the Security token field. The value in this field references the security token that is configured in the extensions file. If you are configuring this token consumer for an X.509 security token, where the token consumer class is `com.ibm.wsspi.wssecurity.token.X509tokenConsumer`, leave this field blank.
10. Select the **Use value type** option and select the value type in the Value type field. Select the value type of the security token that matches the type of token consumer that you are configuring. When you select the value type, the assembly tool automatically enters the correct values in the Local name and URI fields depending upon the type of security token that is specified by the value type.
11. **Optional:** Select the **Use jaas.config** option and specify a Java Authentication and Authorization Service (JAAS) configuration name in the `jaas.config.name` field if a JAAS configuration is required for the security token. The JAAS configuration name that you specify must be for the security token that is specified for this token consumer. The following table lists the JAAS configuration names for the different security tokens specified by the value type.

Table 46. JAAS configuration names and the corresponding value type

<code>jaas.config</code> name	Value type
<code>system.wssecurity.UsernameToken</code>	Username Token

Table 46. JAAS configuration names and the corresponding value type (continued)

jaas.config name	Value type
system.wssecurity.IDAssertionUsernameToken	Username Token (for IDAssertion)
system.wssecurity.X509BST	X509 certificate token
system.wssecurity.PkiPath	X509 certificates in a PKIPath
system.wssecurity.PKCS7	X509 certificates and CRLs in a PKCS#7

12. **Optional:** If a trusted ID evaluator is required for this token consumer, select either the **Use trusted ID evaluator** option to define a new trusted ID evaluator or select the **Use trusted ID evaluator reference** option to select an existing trusted ID evaluator that is defined in a default binding file. A trusted ID evaluator is typically used by the target Web service in a multi-hop environment to determine whether to trust the identity of the intermediary Web service. Complete the following steps if you select the **Use trusted ID evaluator** option:
- Specify a trusted ID evaluator implementation in the Trusted ID evaluator class field. The trusted ID evaluators are implemented by specifying a class that implements the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface. WebSphere Application Server Version 6.0.x provides the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl` default implementation of a trusted ID evaluator.
The implementation is initialized with a list of trusted identity names. The trusted identities are specified as `trustedIDEvaluator` properties in the binding file. When a name is evaluated, it is checked against a list of trusted identity names. If the name is in the list, it is trusted and if the name is not in the list, it is not trusted.
 - Click **Add** under the Trusted ID evaluator property section to add a new entry or click **Remove** to delete a selected entry. Each property entry represents a trusted identity.
 - Specify `trustedId_trustmode` in the Name field and the identity of the intermediary in the Value field.

If you select the **Use trusted ID evaluator reference** option, specify the name of an existing Trusted ID evaluator in the Trusted ID evaluator reference field.

13. **Optional:** Click **Add** under Property to add a new property for this token consumer or click **Remove** to delete a selected property. If this token consumer needs to process a nonce and a time stamp that is contained in a username token, define the properties in the following table.

Table 47. Nonce and time stamp properties

Name	Value
<code>com.ibm.wsspi.wssecurity.token.username.verifyNonce</code>	true
<code>com.ibm.wsspi.wssecurity.token.username.verifyTimestamp</code>	true

14. **Optional:** Select the **Use certificate path settings** option if you are configuring this token consumer for an X.509 security token.
15. Select either the **Certificate path reference** option or the **Trust any certificate** option if you are configuring this token consumer for an X.509 security token.

Important: When you configure a token consumer for an X.509 certificate token, use caution when you select the **Trust any certificate** option. This option might compromise the security of your Web service application by allowing the SOAP message to be signed or encrypted using any certificate. It is recommended that you use the trust anchor and certificate store list to validate the X.509 certificate embedded in the received SOAP message.

If you select the **Certificate path reference** option, complete the following steps:

- Select a trust anchor reference from the list in the Trust anchor reference field. This reference is the name of the trust anchor that specifies the key store, which contains the trusted root certificate authority (CA) certificates.

- b. Select a certificate store from the Certificate store reference field. A certificate store list contains both non-root CA certificates (or intermediary certificates) and certificate revocation lists (CRLs).
16. Click **OK** to save your configuration.

Configure the key information if this token consumer configuration is for an X.509 security token. For more information, see “Configuring key information for the consumer binding with an assembly tool” on page 1064.

Configuring the key locator for the consumer binding with an assembly tool

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

Before configuring a key locator, you should know which key information configuration references this key locator. For example, if you configure this key locator for the STRREF key information type, select the `com.ibm.wsspi.wssecurity.keyinfo.X509TokeyKeyLocator` key locator class.

WebSphere Application Server, Version 6.0.x and later provides default key locator implementations that you can choose or you can write your own implementation. Custom key locators must implement the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` interface. Using this implementation, you can locate keys within any data source.

Complete the following steps to configure a key locator for the consumer using an assembly tool. The purpose of the key locators is to find keys or certificates. The key locator information on the consumer side is used to find the key for validating the digital signature in the received SOAP message or for decrypting the encrypted parts of the message. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the bindings that you need to configure. Complete the following steps to locate the client-side bindings:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Binding** tab and expand the Security Response Consumer Binding Configuration section.
4. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you need to configure. Complete the following steps to locate the server-side bindings:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Request Consumer Binding Configuration Details section.
5. Expand the Key locators section and click **Add** to add a new entry or click **Edit** to edit a selected entry.
6. Specify a name for this configuration in the Key locator name field. This configuration name is referenced in the Key locator field of the Key Information dialog.
7. Select a key locator implementation in the Key locator class field. Select the key locator class that matches the Key Information configuration that references this key locator. For example, select the `com.ibm.wsspi.wssecurity.keyinfo.X509TokenKeyLocator` key locator class if the received Simple Object Access Protocol (SOAP) message contains an X.509 certificate that is needed for signature

validation. Select the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` key locator class if the key that is required for signature validation or decryption needs to be specified using a keystore file. The `com.ibm.wsspi.wssecurity.keyinfo.SignerCertKeyLocator` key locator class is not used on the consumer side. It is typically used in the response generator configuration for encrypting the response message using the signer key from the request message.

8. Select the **Use key store** option if you need to configure a key store for this key locator. Whether you need to configure the key store information for a key locator depends upon the key locator class and your application configuration. For example, if you select the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` key locator class in the previous step, configure the key store information for this key locator.
 - a. Specify a keystore password in the Key store storepass field. The keystore storepass is the password that is required to access the keystore file.
 - b. Specify the path to the keystore file in the Key store path field. The key store path is the directory where the keystore resides. Make sure that wherever you deploy your application that the server can locate your keystore file.
 - c. Select a key store type from the Key store type field. The key store type that you select must match the keystore file that is specified in the Key store path field. The following keystore types are supported:
 - JKS** Use this option if you are not using Java Cryptography Extensions (JCE) policy file and if your keystore file uses the Java Keystore (JKS) format.
 - JCEKS** Use this option if you are using Java Cryptography Extensions policy file.
 - JCERACFKS** Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).
 - PKCS11** Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.
 - PKCS12** Use this option if your keystore uses the PKCS#12 file format.
9. Click **Add** under the Key field to add a key entry from the keystore file that you specified in the previous step. This key is used for signature validation or decryption. The key that you specify must match the key that is used for digital signing or encryption for the generator. Complete the following steps to add a key entry:
 - a. Specify an alias name for the key in the Alias field.
 - b. Specify the password that is associated with the key in the Key pass field. This password protects the private key of the key pair that is specified by this key.
 - c. Specify the key name in the Key name field. The key name specifies the Distinguished Name (DN) for the owner of the key.
10. Click **OK** to save the key locator configuration

After you configure the key locator and any token consumer that you need to configure, you can configure the key information that references this key locator. For more information, see “Configuring key information for the consumer binding with an assembly tool.”

Configuring key information for the consumer binding with an assembly tool

Prior to completing this task, you must complete the following steps:

1. Import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

2. Configure the key locator that is referenced by the key information configuration. For more information, see “Configuring the key locator for the consumer binding with an assembly tool” on page 1063.
3. Configure the token consumer that is referenced by the key information configuration. For more information, see “Configuring token consumers with an assembly tool” on page 1060

Complete the following steps using an assembly tool to configure the key information for the server-side and client-side bindings. The key information on the consumer side is used for specifying the information about the key that is used for validating the digital signature in the received message or for decrypting the encrypted parts of the message. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool and click **Window > Open Perspective > J2EE**.
2. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side bindings:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Binding** tab and expand the Security Response Consumer Binding Configuration section.
3. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you must configure. Complete the following steps to locate the server-side bindings:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Request Consumer Binding Configuration Details section.
4. Expand the Key Information section and click **Add** to add a new entry or click **Edit** to edit a selected entry.
5. Specify a name for this configuration in the Key information name field. This configuration name is referenced by the Key information element within the Signing Information and Encryption Information Dialog windows. For more information, see “Configuring signing information for the consumer binding with an assembly tool” on page 1067 and “Configuring encryption information for the consumer binding with an assembly tool” on page 1085.
6. Select a key information type from the Key information type field. The key information types specify different mechanisms for referencing security tokens. The assembly tools support the following key information types:

STRREF

This type is the security token reference. The security token is directly referenced using Universal Resource Identifiers (URIs). The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <wsse:Reference URI="#mytoken" />
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

EMB

This type is the embedded token. The security token is directly embedded within the <SecurityTokenReference> element. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <wsse:Embedded wsu:Id="tok1" />
    ...
  </wsse:Embedded>
</wsse:SecurityTokenReference>
</ds:KeyInfo>
```

KEYID

This type is a key identifier. The security token is referenced using an opaque value that uniquely identifies the token. The algorithm that is used for generating the key identifier value depends upon the token type. For example, a hash of the important elements of the security token is used for generating the KeyIdentifier value. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
  <wsse:SecurityTokenReference>
    <wsse:KeyIdentifier ValueType="wsse:X509v3"/>/wsse:KeyIdentifier>
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

KEYNAME

This type is the key name. The security token is referenced using a name that matches an asserted identity within the token.

Note: Do not use this key type as it might result in multiple security tokens that match the specified name.

The KEYNAME type does not require a token consumer reference. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <ds:KeyName>CN=Group1</ds:KeyName>
</ds:KeyInfo>
```

Note: To be compliant with the Basic Security Profile (BSP), do not use the KEYNAME information type. A SECURITY_TOKEN_REFERENCE must not use a KEYNAME to reference a SECURITY_TOKEN.

X509ISSUER

This type is the X.509 certificate issuer name and serial number. The security token is referenced by an issuer name and issuer serial number of an X.509 certificate. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <ds:X509Data>
      <ds:X509IssuerSerial>
        <ds:X509IssuerName>CN=Jones, O=IBM, C=US</ds:X509IssuerName>
        <ds:X509SerialNumber>1040152879</ds:X509SerialNumber>
      </ds:X509IssuerSerial>
    </ds:X509Data>
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

7. Select the **Use key locator** option. Complete the following steps:
 - a. Select the name of a key locator configuration from the Key locator field. The value of this field is a reference to a key locator that specifies how to find keys or certificates. For more information, see “Configuring the key locator for the consumer binding with an assembly tool” on page 1063.
 - b. **Optional:** Specify a key name in the Key name field. You do not need to specify the key name when you configure the key information for the consumer.
8. **Optional:** Select the **Use token** option and a token consumer configuration in the Token field if a token consumer is required for the key information configuration. The token that you select specifies a reference to a token consumer that is used for processing the security token within the message. A token consumer is required for all key information types except the KEYNAME type. Before you specify a token reference, you must configure a token consumer. For more information on token consumer configurations, see “Configuring token consumers with an assembly tool” on page 1060.

After completing this task, configure the signing information or encryption information that references the key information that is specified by this task. For more information, see “Configuring signing information for the consumer binding with an assembly tool” or “Configuring encryption information for the consumer binding with an assembly tool” on page 1085.

Configuring signing information for the consumer binding with an assembly tool

Prior to completing this task, you must complete the following steps:

1. Import your application into an assembly tool.
For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.
2. Specify which message parts to digitally sign. For more information, see “Signing message elements in consumer security constraints with keywords” on page 1048 or “Signing message elements in consumer security constraints with an XPath expression” on page 1054.
3. Configure the key information that is referenced by the Key information element within the Signing information dialog window. For more information, see “Configuring key information for the consumer binding with an assembly tool” on page 1064.

Complete the following steps to configure the signing information for the server-side and client-side bindings using an assembly tool. The signing information on the consumer side is used to verify the integrity of the received Simple Object Access Protocol (SOAP) message by validating the message parts that are signed. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the bindings that you must configure. Complete the following steps to locate the client-side bindings:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Binding** tab and expand the Security Response Consumer Binding Configuration section.
4. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you must configure. Complete the following steps to locate the server-side bindings:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Request Consumer Binding Configuration Details section.
5. Expand the Signing Information section and click **Add** to add a new entry or select an existing entry and click **Edit**. The Signing Information Dialog window is displayed. Complete the following steps to specify the signing information:
 - a. Specify a name for the signing information configuration in the Signing information name field.
 - b. Select a canonicalization method from the Canonicalization method algorithm field. The canonicalization method algorithm is used to canonicalize the signing information before it is integrated as part of the signature operation. The following preconfigured algorithms are supported:
 - <http://www.w3.org/2001/10/xml-exc-c14n#>
 - <http://www.w3.org/2001/10/xml-exc-c14n#WithComments>
 - <http://www.w3.org/TR/2001/REC-xml-c14n-20010315>
 - <http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments>

You must specify the same canonicalization algorithm for both the generator and the consumer. For more information on configuring the signing information for the generator, see “Configuring signing information for the generator binding with an assembly tool” on page 1044.

- c. **Optional:** Select **Show only FIPS Compliant Algorithms** if you want only the FIPS compliant algorithms to show in the **Digest method algorithm** drop-down list. Use this option if you expect this application to run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

- d. Select a signature method algorithm from the Signature method algorithm field. The following preconfigured algorithms are supported:

- <http://www.w3.org/2000/09/xmldsig#rsa-sha1>
- <http://www.w3.org/2000/09/xmldsig#hmac-sha1>
- <http://www.w3.org/2000/09/xmldsig#dsa-sha1>

Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP). Any ds:SignatureMethod/@Algorithm element in a SIGNATURE based on a symmetric key must have a value of <http://www.w3.org/2000/09/xmldsig#rsa-sha1> or <http://www.w3.org/2000/09/xmldsig#hmac-sha1>.

You must specify the same signature algorithm for both the generator and the consumer. For more information on configuring the signing information for the generator, see “Configuring signing information for the generator binding with an assembly tool” on page 1044.

6. Click **Add** in the Signing Key Information section to add a new key information entry or click **Remove** to delete a selected entry. Complete the following substeps if you are adding a new key information entry.
 - a. Specify a name in the Key information name field.
 - b. Select a key information reference from the list under the Key information element field. The value in this field references the key information configuration that you specified previously. If you have a key information configuration called `con_signkeyinfo` that you want to use with this signing information configuration, specify `con_signkeyinfo` in the Key information element field. For more information, see “Configuring key information for the consumer binding with an assembly tool” on page 1064.
7. **Optional:** Select the **Use key information signature** option if you want to sign the key information within the SOAP message.
8. **Optional:** Select a key information signature type from the Type field if you select the **Use key information signature** option. Select the **keyinfo** value to specify that the entire KeyInfo element must be signed within the SOAP message. Select the **keyinfochildelements** value to specify that the child elements within the KeyInfo element must be signed. However, the KeyInfo element itself does not need to be signed.
9. Click **OK** to save your signing information configuration.
10. Expand the Part References subsection and select the signing information configuration from the Signing Information section.
11. Click **Add** in the Part References subsection to add a new entry or select an existing entry and click **Edit**. The Part References Dialog window is displayed. Complete the following steps to configure a part reference:
 - a. Specify a name for the part reference configuration in the Part reference name field.
 - b. Select a required integrity part configuration in the RequiredIntegrity part field. The required integrity part configuration specifies the message parts that are required to be signed. For more information on how to configure the required integrity, see “Signing message elements in consumer security constraints with keywords” on page 1048 or “Signing message elements in consumer security constraints with an XPath expression” on page 1054.
 - c. **Optional:** Select **Show only FIPS Compliant Algorithms** if you want only the FIPS compliant algorithms to show in the **Digest method algorithm** drop-down list. Use this option if you expect

this application to run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

- d. Select a digest method algorithm in the Digest method algorithm field.

WebSphere Application Server supports the following digest method algorithms:

- <http://www.w3.org/2000/09/xmlsig#sha1>
- <http://www.w3.org/2001/04/xmlenc#sha256>
- <http://www.w3.org/2001/04/xmlenc#sha512>

This digest method algorithm is used to create the digest for each message part that is specified by this part reference.

- e. Click **OK** to save your part reference configuration.

12. Expand the Transforms subsection and the part reference configuration from the Part reference subsection.

13. Click **Add** in the Transforms subsection to add a new entry or select an existing entry and click **Edit**. The Transform dialog window is displayed.

- a. Specify a transform name in the Name field.

- b. Select a transform algorithm from the Algorithm field. The following transform algorithms are supported:

<http://www.w3.org/2001/10/xml-exc-c14n#>

This algorithm specifies the World Wide Web Consortium (W3C) Exclusive Canonicalization recommendation.

<http://www.w3.org/TR/1999/REC-xpath-19991116>

This algorithm specifies the W3C XML path language recommendation. If you specify this algorithm, you must click **Add** to specify the property name and value, which is displayed under Transform properties. For example, you might specify the following information:

Name com.ibm.wsspi.wssecurity.dsig.XPathExpression

Value not(ancestor-or-self::*[namespace-uri()='http://www.w3.org/2000/09/xmlsig#' and local-name()='Signature'])

Note: Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use <http://www.w3.org/2002/06/xmlsig-filter2> to ensure compliance.

<http://www.w3.org/2002/06/xmlsig-filter2>

This algorithm specifies the XML-Signature XPath Filter Version 2.0 proposed recommendation.

When you use this algorithm, you must specify a set of properties in the Transform property fields. You can use multiple property sets for the XPath Filter Version 2.

Note: End your property names with the number of the property set, which is denoted by an asterisk in the following examples:

- To specify an XPath expression for the XPath filter2, you might use:

name com.ibm.wsspi.wssecurity.dsig.XPath2Expression_*

- To specify a filter type for each XPath, you might use:

name com.ibm.wsspi.wssecurity.dsig.XPath2Filter_*

Following this expression, you can have a value, [intersect], [subtract], or [union].

- To specify the processing order for each XPath, you might use:

```
name com.ibm.wsspi.wssecurity.dsign.XPath2Order_*
```

Following this expression, indicate the processing order of the XPath.

The following is a list of complete examples:

```
com.ibm.wsspi.wssecurity.dsign.XPath2Filter_1 = [intersect]
com.ibm.wsspi.wssecurity.dsign.XPath2Order_1 = [1]
com.ibm.wsspi.wssecurity.dsign.XPath2Expression_2 = [XPath expression#2]
com.ibm.wsspi.wssecurity.dsign.XPath2Filter_2 = [subtract]
com.ibm.wsspi.wssecurity.dsign.XPath2Filter_2 = [1]
```

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform>

<http://www.w3.org/2002/07/decrypt#XML>

This algorithm specifies the W3C decryption transform for XML Signature recommendation.

<http://www.w3.org/2000/09/xmlsig#enveloped-signature>

This algorithm specifies the W3C recommendation for XML digital signatures.

- c. Click **OK** to save your transforms configuration.

After you complete this task for the consumer binding, you must configure the signing information for generator binding if this task was not previously completed.

Encrypting the message elements in generator security constraints with keywords

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.

Complete the following steps to specify which message parts to encrypt when you configure the consumer security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the Required Confidentiality section. Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves

across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see “XML encryption” on page 1082.

6. Click **Add** to specify which parts of the message to encrypt. The Confidentiality Dialog window is displayed. Complete the following steps to specify the message parts:
 - a. Specify a name for the confidentiality element in the Confidentiality Name field. For example, you might specify `conf_webskey`.
 - b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the encryption is processed. An order value of 1 specifies that the encryption is done first.
7. Click **Add** under Message parts and select the Message parts dialect. The `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was dialect` specifies which message part is encrypted using keywords. If you select this dialect, you can select one of the following keywords under Message parts keyword:

bodycontent

Specifies the user data portion of the message. If you select this keyword, the body is encrypted.

usnametoken

Specifies a username token that contains the basic authentication information such as a user name and a password. Usually, the username token is encrypted so that the user information is secure. If you select this keyword, the username token element is encrypted.

digestvalue

Specifies a unique digest value. When a part of the SOAP message is signed, a unique digest value is created and is used by the receiving party to check the integrity of the message. You can encrypt the `digestvalue` element to secure the digest value.

signature

Specifies an entire signature. You can encrypt the signature element, `ds:Signature`, by selecting this message part.

Note: If the value of a `ds:DigestValue` element in a signature needs to be encrypted, the entire parent `ds:Signature` element must be encrypted to ensure that the application complies to the Basic Security Profile (BSP). You can use the signature keyword to perform the encryption.

wscontextcontent

Encrypts the content in the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services.

Note: You must have a matching configuration for the consumer side.

In addition to the message parts, you also can specify that WebSphere Application Server encrypt the nonce and timestamp elements. For more information, see the following articles:

- “Adding time stamps for confidentiality to generator security constraints with keywords” on page 1072
- “Adding time stamps for confidentiality to generator security constraints with an XPath expression” on page 1078
- “Adding the nonce for confidentiality to generator security constraints with keywords” on page 1074
- “Adding the nonce for confidentiality to generator security constraints with an XPath expression” on page 1080

8. Click **OK** to save your configuration.

The following sample is a part of a Simple Object Access Protocol (SOAP) message; the message content is encrypted using the `bodycontent` keyword and the `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was dialect`:

```

<soapenv:Body soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
  <EncryptedData Id="wssecurity_encryption_id_8770799378696212005"
    Type="http://www.w3.org/2001/04/xmlenc#Content" xmlns="http://www.w3.org/2001/
    04/xmlenc#">
    <EncryptionMethod Algorithm="http://www.w3.org/2001/04/xmlenc#tripleDES-cbc"/>
    <CipherData>
      <CipherValue>n1lF+Uthee0H96HbtRro1J/tBm0azyryNYRwr/reF4nqtbHqGtNuew==
      </CipherValue>
    </CipherData>
  </EncryptedData>
</soapenv:Body>

```

After you specify which message parts to encrypt, you must specify which method is used to encrypt the message parts. For more information, see “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

Adding time stamps for confidentiality to generator security constraints with keywords:

You can specify that a time stamp is embedded in a particular element and that the element is encrypted.

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

Complete the following steps to specify the time stamp for confidentiality by using keywords when you configure the generator security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server.

In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the Confidentiality section. Confidentiality refers to encryption and integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see “XML encryption” on page 1082.
6. Click **Add** to specify a time stamp for confidentiality. The Confidentiality Dialog window is displayed. Complete the following steps to specify a confidentiality configuration:
 - a. Specify a name for the confidentiality element in the Confidentiality Name field. For example, you might specify `conf_tmstamp`.

- b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the encryption is processed. An order value of 1 specifies that the encryption is done first.
7. In the Timestamp section, click **Add** and select the Timestamp dialect. The <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> dialect specifies the message part that is encrypted using the keywords. If you select this dialect, you can select one of the following keywords under the Timestamp keyword heading:

bodycontent

Specifies the user data portion of the message. If this keyword is selected, the time stamp is embedded in the SOAP message body and the body is encrypted.

username token

Specifies a user name token that contains the basic authentication information such as a user name and a password. Usually, the username token is encrypted so that the user information is secure. If you select this keyword, the timestamp element is embedded in the username token element and it is encrypted.

digestvalue

Specifies a unique digest value. When a part of the SOAP message is signed, a unique digest value is created and is used by the receiving party to check the integrity of the message. You can encrypt the `digestvalue` element to secure the digest value. If you select this keyword, the time stamp is embedded in the `digestvalue` element and the element is encrypted.

signature

Specifies an entire signature. You can encrypt the signature element, `ds:Signature`, by selecting this message part.

Note: If the value of a `ds:DigestValue` element in a signature needs to be encrypted, the entire parent `ds:Signature` element must be encrypted to ensure that the application complies to the Basic Security Profile (BSP). You can use the signature keyword to perform the encryption.

wscontextcontent

Encrypts the content in the WS-Context header for the SOAP header. For more information, see *Propagating work area context over Web services*.

8. Specify an expiration time for the time stamp in the Timestamp expires field. The time stamp helps defend against replay attacks. The lexical representation for the duration is the [ISO 8601] extended format `PnYnMnDTnHnMnS`, where:

P Precedes the date and time values.

nY Represents the number of years in which the time stamp is in effect. Select a value from 0 to 99 years.

nM Represents the number of months in which the time stamp is in effect. Select a value from 0 to 11 months.

nD Represents the number of days in which the time stamp is in effect. Select a value from 0 to 30 days.

T Separates the date and time values.

nH Represents the number of hours in which the time stamp is in effect. Select a value from 0 to 23 hours.

nM Represents the number of minutes in which the time stamp is in effect. Select a value from 0 to 59 minutes.

nS Represents the number of seconds in which the time stamp is in effect. The number of

seconds can include arbitrary decimal digits. You can select a value from 0 to 59 for the seconds and from 0 to 9 for tenths of a second.

For example, 1 year, 2 months, 3 days, 10 hours, and 30 minutes is represented as P1Y2M3DT10H30M. Typically, you might configure a message time stamp for between 10 and 30 minutes. For example, 10 minutes is represented as P0Y0M0DT0H10M0S.

9. In the Message Parts section, click **Add** and select `http://www.ibm.com/websphere/webservices/wssecurity/ dialect-was` in the Message parts dialect field.
10. In the Message Parts section, select the message parts keyword.

Important: You must define at least one message part in Message Parts section in order to specify a times tamp for confidentiality. When you select the message part, you are encrypting the message part in addition to the parent element of the time stamp.

11. Click **OK** to save the configuration changes.

Note: These configurations for the consumer and generator must match.

In addition to the time stamp, you can specify that the nonce is signed. For more information, see the following articles:

- “Adding the nonce for confidentiality to generator security constraints with keywords”
- “Adding the nonce for confidentiality to generator security constraints with an XPath expression” on page 1080

For example, the following example is a part of a SOAP message where a time stamp is inserted into the `bodycontent` element and is encrypted using `bodycontent` keyword and the `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was dialect`.

Important: You cannot see the time stamp in the message because it is encrypted.

```
<soapenv:Body soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
  <EncryptedData Id="wssecurity_encryption_id_4349704672508984224" Type=
    "http://www.w3.org/2001/04/xmlenc#Content" xmlns="http://www.w3.org/2001/
    04/xmlenc#">
    <EncryptionMethod Algorithm="http://www.w3.org/2001/04/xmlenc#tripleDES-cbc"/>
      <CipherData>
        <CipherValue>IxSuTmF1vAygF/SBLCd8bgu8opPiwHmroIBLzZbENGr9JpxhSFt/0fV0sF
        un0uxg/h/Y+1erE+NaysREuL+E9AQm01xALNEdBX9zpeVf+ZffUCSzfXXe9iosQ1Pe9jG
        7yTp+rhZGdp/KOp26c3DZXCNDr0Wgz31wn3KNm6bG06RmBzahEOSW8d0wR999DeqSp0Y12
        d8iWJa3HZ8gnGnineCiZ3wrHy9r0C58iijcsNv1fP31ExuA5WkHra6rndhbi8P7jDMhkzf
        40dj2yy1M3XURWa1OLNYhNJ9YaWACsaYCY2ukcKtzw==</CipherValue>
      </CipherData>
    </EncryptedData>
</soapenv:Body>
```

After you specify which message parts to encrypt, you must specify which method is used to encrypt the message. For more information, see “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

Adding the nonce for confidentiality to generator security constraints with keywords:

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

Nonce for confidentiality is used to specify that the nonce is embedded in a particular element within the message and that the element is encrypted. Nonce is a randomly generated, cryptographic token. When you add a nonce to a specific part of a message, it can prevent theft and replay attacks because a generated nonce is unique. For example, without a nonce, the token might be intercepted and used in a

replay attack when a user name token is passed from one machine to another machine using a non-secure transport, such as HTTP. The user name token can be stolen even if you use XML digital signature and XML encryption. This situation might be prevented by adding a nonce.

Complete the following steps to specify a nonce for confidentiality using keywords when you configure the generator security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the Confidentiality section. Confidentiality refers to encryption and integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see “XML encryption” on page 1082.
6. Click **Add** to specify a nonce for integrity. The Confidentiality Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the confidentiality element in the Confidentiality Name field. For example, you might specify `conf_nonce`.
 - b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the encryption is processed. An order value of 1 specifies that the encryption is done first.
7. Under Nonce, click **Add** and select the Nonce dialect. The `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was` dialect specifies the message part to which a nonce is added and encrypted. If you select this dialect, you can select one of the following keywords under Nonce keyword:

bodycontent

Specifies the user data portion of the message. If this keyword is selected, the nonce is embedded in the Simple Object Access Protocol (SOAP) message body and the body is encrypted.

username token

Specifies a username token that contains the basic authentication information such as a user name and a password. Usually, the username token is encrypted so that the user information is secure. If you select this keyword, the nonce element is embedded in the username token element and it is encrypted.

digestvalue

Specifies a unique digest value. When a part of the SOAP message is signed, a unique digest value is created and is used by the receiving party to check the integrity of the

message. You can encrypt the digestvalue element to secure the digest value. If you select this keyword, the nonce is embedded in the digestvalue element and the element is encrypted.

signature

Specifies an entire signature. You can encrypt the signature element, ds:Signature, by selecting this message part.

Note: If the value of a ds:DigestValue element in a signature needs to be encrypted, the entire parent ds:Signature element must be encrypted to ensure that the application complies to the Basic Security Profile (BSP). You can use the signature keyword to perform the encryption.

wscontextcontent

Encrypts the content in the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services.

8. In the Message Parts section, click **Add** and select <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> in the Message parts dialect field.
9. In the Message Parts section, select the message parts keyword.

Important: You must define at least one message part in Message Parts section in order to specify a nonce for confidentiality. When you select the message part, you are encrypting the message part in addition to the parent element of the nonce.

10. Click **OK** to save the configuration changes.

Note: These configurations for the generator and the consumer must match.

In addition to the nonce, you can specify that the timestamp element is encrypted. For more information, see the following articles:

- “Adding time stamps for confidentiality to generator security constraints with keywords” on page 1072
- “Adding time stamps for confidentiality to generator security constraints with an XPath expression” on page 1078

The following example is a part of a SOAP message where a nonce is inserted into the bodycontent element and it is encrypted using the bodycontent keyword and the <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> dialect.

Important: You cannot see the nonce in the message because it is encrypted.

```
<soapenv:Body soapenv:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
  <EncryptedData Id="wssecurity_encryption_id_1669600751905274321"
    Type="http://www.w3.org/2001/04/xmlenc#Content" xmlns="http://www.w3.org/2001/
    04/xmlenc#">

    </CipherData>
  </EncryptedData>
</soapenv:Body>
```

After you specify which message parts to encrypt, you must specify which method is used to encrypt the message. For more information, see “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

Encrypting the message elements in generator security constraints with an XPath expression

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

Complete the following steps to specify which message parts to encrypt using an XPath expression when you configure the consumer security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to configure the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to configure the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the Confidentiality section. Confidentiality refers to encryption and integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see "XML encryption" on page 1082.
6. Click **Add** to specify which parts of the message to encrypt. The Confidentiality Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the confidentiality element in the Confidentiality Name field. For example, you might specify `conf_xpath`.
 - b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the encryption is processed. An order value of 1 specifies that the encryption is done first.
7. Click **Add** under the Message parts section of the Confidentiality Dialog window. Complete the following steps to specify the message parts:

- a. Select the message parts dialect from the Message parts section. The <http://www.w3.org/TR/1999/REC-xpath-19991116> dialect specifies which message part is encrypted using an XPath expression.

Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use <http://www.w3.org/2002/06/xmlsig-filter2> to ensure compliance.

- b. Specify the message part to be encrypted using an XPath expression in the Message parts keyword field. For example, to specify that the body is encrypted, you might add the following expression in the Message parts keyword field as one continuous line:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'  
and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/  
soap/envelope/' and local-name()='Body']
```

Note: These configurations for the generator and the consumer must match.

In addition to the message parts, you also can specify that WebSphere Application Server encrypt the nonce and timestamp elements. For more information, see the following articles:

- “Adding time stamps for confidentiality to generator security constraints with keywords” on page 1072
- “Adding time stamps for confidentiality to generator security constraints with an XPath expression”
- “Adding the nonce for confidentiality to generator security constraints with keywords” on page 1074
- “Adding the nonce for confidentiality to generator security constraints with an XPath expression” on page 1080

8. Click **OK** to save your configuration.

After you specify which message parts to encrypt, you must specify which method is used to encrypt the message parts. For more information, see “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

Adding time stamps for confidentiality to generator security constraints with an XPath expression:

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

This task is used to specify that a time stamp is embedded in a particular element and that the element is encrypted. Complete the following steps to specify the time stamp for confidentiality using an XPath expression when you configure the generator security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.

2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the Confidentiality section. Confidentiality refers to encryption and integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see “XML encryption” on page 1082.
6. Click **Add** to specify a time stamp for confidentiality. The Confidentiality Dialog window is displayed. Complete the following information to specify a configuration:
 - a. Specify a name for the confidentiality element in the Confidentiality Name field.
 - b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the encryption is processed. An order value of 1 specifies that the encryption is done first.
7. Click **Add** under the Timestamp section of the Confidentiality Dialog window. Complete the following steps to configure the time stamp information:
 - a. Select the timestamp dialect from the Timestamp section. The `http://www.w3.org/TR/1999/REC-xml-19991116` dialect specifies which message part is encrypted using an XPath expression. Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use `http://www.w3.org/2002/06/xmldsig-filter2` to ensure compliance.
 - b. Specify the message part to which a time stamp is added and encrypted using an XPath expression in the Timestamp keyword field. For example, to specify that a time stamp is added to the `bodycontent` element and it is encrypted, you might add the following expression in the Timestamp keyword field as one continuous line:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Bodycontent']
```
 - c. Specify an expiration time for the time stamp in the Timestamp expires field. The time stamp helps defend against replay attacks. The lexical representation for the duration is the [ISO 8601] extended format `PnYnMnDTnHnMnS`, where:

P	Precedes the date and time values.
nY	Represents the number of years in which the time stamp is in effect. Select a value from 0 to 99 years.
nM	Represents the number of months in which the time stamp is in effect. Select a value from 0 to 11 months.
nD	Represents the number of days in which the time stamp is in effect. Select a value from 0 to 30 days.
T	Separates the date and time values.

- nH** Represents the number of hours in which the time stamp is in effect. Select a value from 0 to 23 hours.
- nM** Represents the number of minutes in which the time stamp is in effect. Select a value from 0 to 59 minutes.
- nS** Represents the number of seconds in which the time stamp is in effect. The number of seconds can include decimal digits to arbitrary precision. You can select a value from 0 to 59 for the seconds and from 0 to 9 for tenths of a second.

For example, to indicate 1 year, 2 months, 3 days, 10 hours, and 30 minutes, the format is P1Y2M3DT10H30M. Typically, you might configure a message time stamp for between 10 and 30 minutes. For example, 10 minutes is represented as P0Y0M0DT0H10M0S.

8. In the Message Parts section, click **Add** and select <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> in the Message parts dialect field.
9. In the Message Parts section, select the message parts keyword.

Important: You must define at least one message part in Message Parts section in order to specify Timestamp for Confidentiality. The selection of message part here is for encrypting a message part in addition to the parent element of the timestamp

10. Click **OK** to save the configuration changes.

Note: These configurations for the consumer and the generator must match.

In addition to the time stamp, you can specify that the nonce is signed. For more information, see the following articles:

- “Adding the nonce for confidentiality to generator security constraints with keywords” on page 1074
- “Adding the nonce for confidentiality to generator security constraints with an XPath expression”

After you specify which message parts to encrypt, you must specify which method is used to encrypt sign the message. For more information, see “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

Adding the nonce for confidentiality to generator security constraints with an XPath expression:

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

Nonce for confidentiality is used to specify that the nonce is embedded in a particular element within the message and that the element is encrypted. Nonce is a randomly generated, cryptographic token. When you add a nonce to a specific part of a message, it can prevent theft and replay attacks because a generated nonce is unique. For example, without a nonce, the token might be intercepted and used in a replay attack when a user name token is passed from one machine to another machine using a non-secure transport, such as HTTP. The user name token can be stolen even if you use XML digital signature and XML encryption. This situation might be prevented by adding a nonce.

Complete the following steps to specify a nonce for confidentiality using an XPath expression when you configure the generator security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the Confidentiality section. Confidentiality refers to encryption and integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see “XML encryption” on page 1082.
6. Click **Add** to specify a nonce for integrity. The Confidentiality Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the confidentiality element in the Confidentiality Name field. For example, you might specify `conf_nonce`.
 - b. Specify an order in the Order field. The value, which must be a positive integer value, specifies the order in which the encryption is processed. An order value of 1 specifies that the encryption is done first.
7. Click **Add** under the Nonce section of the Confidentiality Dialog window. Complete the following steps to specify the none dialect and the message part:
 - a. Select the nonce dialect from the Nonce section. The `http://www.w3.org/TR/1999/REC-xpath-19991116` dialect specifies the message part to which a nonce is added and encrypted using an XPath expression.

Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use `http://www.w3.org/2002/06/xmlsig-filter2` to ensure compliance.
 - b. Specify the message part to which a nonce is added and encrypted using an XPath expression in the Nonce keyword field. For example, to specify that a nonce is added to the `bodycontent` element and it is encrypted, you might add the following expression in the Nonce keyword field as one continuous line:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'  
and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/  
soap/envelope/' and local-name()='Bodycontent']
```
8. In the Message Parts section, click **Add** and select `http://www.w3.org/TR/1999/REC-xpath-19991116` in the Message parts dialect field. Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use `http://www.w3.org/2002/06/xmlsig-filter2` to ensure compliance.
9. In the Message Parts section, select the message parts keyword.

Important: You must define at least one message part in the Message Parts section to specify nonce for Confidentiality. The selection of message part here is for encrypting a message part in addition to the parent element of the nonce.

10. Click **OK** to save the configuration changes.

Note: These configurations for the consumer and the generator must match.

In addition to the nonce, you can specify that the timestamp element is signed. For more information, see the following articles:

- “Adding time stamps for confidentiality to generator security constraints with keywords” on page 1072
- “Adding time stamps for confidentiality to generator security constraints with an XPath expression” on page 1078

After you specify which message parts to encrypt, you must specify which method is used to encrypt sign the message. For more information, see “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

XML encryption

XML encryption is a specification developed by World Wide Web (WWW) Consortium (W3C) in 2002 that contains the steps to encrypt data, the steps to decrypt encrypted data, the XML syntax to represent encrypted data, the information used to decrypt the data, and a list of encryption algorithms such as triple DES, AES, and RSA.

You can apply XML encryption to an XML element, XML element content, and arbitrary data, including an XML document. For example, suppose that you need to encrypt the CreditCard element shown in the example 1.

Example 1: Sample XML document

```
<PaymentInfo xmlns='http://example.org/paymentv2'>
  <Name>John Smith</Name>
  <CreditCard Limit='5,000' Currency='USD'>
    <Number>4019 2445 0277 5567</Number>
    <Issuer>Example Bank</Issuer>
    <Expiration>04/02</Expiration>
  </CreditCard>
</PaymentInfo>
```

Example 2: XML document with a common secret key

Example 2 shows the XML document after encryption. The EncryptedData element represents the encrypted CreditCard element. The EncryptionMethod element describes the applied encryption algorithm, which is triple DES in this example. The KeyInfo element contains the information to retrieve a decryption key, which is a KeyName element in this example. The CipherValue element contains the ciphertext obtained by serializing and encrypting the CreditCard element.

```
<PaymentInfo xmlns='http://example.org/paymentv2'>
  <Name>John Smith</Name>
  <EncryptedData Type='http://www.w3.org/2001/04/xmlenc#Element'
    xmlns='http://www.w3.org/2001/04/xmlenc#'>
    <EncryptionMethod
      Algorithm='http://www.w3.org/2001/04/xmlenc#tripleDES-cbc' />
    <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
      <KeyName>John Smith</KeyName>
    </KeyInfo>
    <CipherData>
      <CipherValue>ydUNqHkMrD...</CipherValue>
    </CipherData>
  </EncryptedData>
</PaymentInfo>
```

Example 3: XML document encrypted with the public key of the recipient

In example 2, it is assumed that both the sender and recipient have a common secret key. If the recipient has a public and private key pair, which is most likely the case, the CreditCard element can be encrypted as shown in example 3. The EncryptedData element is the same as the EncryptedData element found in Example 2. However, the KeyInfo element contains an EncryptedKey.

```
<PaymentInfo xmlns='http://example.org/paymentv2'>
  <Name>John Smith</Name>
  <EncryptedData Type='http://www.w3.org/2001/04/xmlenc#Element'
    xmlns='http://www.w3.org/2001/04/xmlenc#'>
    <EncryptionMethod
      Algorithm='http://www.w3.org/2001/04/xmlenc#tripledes-cbc' />
    <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
      <EncryptedKey xmlns='http://www.w3.org/2001/04/xmlenc#'>
        <EncryptionMethod
          Algorithm='http://www.w3.org/2001/04/xmlenc#rsa-1_5' />
        <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
          <KeyName>Sally Doe</KeyName>
        </KeyInfo>
        <CipherData>
          <CipherValue>yMTEy0TA1M...</CipherValue>
        </CipherData>
      </EncryptedKey>
    </KeyInfo>
    <CipherData>
      <CipherValue>ydUNqHkMrD...</CipherValue>
    </CipherData>
  </EncryptedData>
</PaymentInfo>
```

XML Encryption in the WSS-Core

WSS-Core specification is under development by Organization for the Advancement of Structured Information Standards (OASIS). The specification describes enhancements to Simple Object Access Protocol (SOAP) messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. The message confidentiality is realized by encryption based on XML Encryption.

The WSS-Core specification supports encryption of any combination of body blocks, header blocks, their substructures, and attachments of a SOAP message. The specification also requires that when you encrypt parts of a SOAP message, you prepend a reference from the security header block to the encrypted parts of the message. The reference can be a clue for a recipient to identify which encrypted parts of the message to decrypt.

The XML syntax of the reference varies according to what information is encrypted and how it is encrypted. For example, suppose that the CreditCard element in example 4 is encrypted with either a common secret key or the public key of the recipient.

Example 4: Sample SOAP message

```
<SOAP-ENV:Envelope
  SOAP-ENV:encodingStyle='http://schemas.xmlsoap.org/soap/encoding/'
  xmlns:SOAP-ENV='http://schemas.xmlsoap.org/soap/envelope/'>
  <SOAP-ENV:Body>
    <PaymentInfo xmlns='http://example.org/paymentv2'>
      <Name>John Smith</Name>
      <CreditCard Limit='5,000' Currency='USD'>
        <Number>4019 2445 0277 5567</Number>
        <Issuer>Example Bank</Issuer>
        <Expiration>04/02</Expiration>
      </CreditCard>
    </PaymentInfo>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

```

    </CreditCard>
  </PaymentInfo>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

The resulting SOAP messages are shown in Examples 5 and 6. In these example, the ReferenceList and EncryptedKey elements are used as references, respectively.

Example 5: SOAP message encrypted with a common secret key

```

<SOAP-ENV:Envelope
  SOAP-ENV:encodingStyle='http://schemas.xmlsoap.org/soap/encoding/'
  xmlns:SOAP-ENV='http://schemas.xmlsoap.org/soap/envelope/'>
  <SOAP-ENV:Header>
    <Security SOAP-ENV:mustUnderstand='1'
      xmlns='http://schemas.xmlsoap.org/ws/2003/06/secext'>
      <ReferenceList xmlns='http://www.w3.org/2001/04/xmlenc#'>
        <DataReference URI='#ed1' />
      </ReferenceList>
    </Security>
  </SOAP-ENV:Header>
  <SOAP-ENV:Body>
    <PaymentInfo xmlns='http://example.org/paymentv2'>
      <Name>John Smith</Name>
      <EncryptedData Id='ed1'
        Type='http://www.w3.org/2001/04/xmlenc#Element'
        xmlns='http://www.w3.org/2001/04/xmlenc#'>
        <EncryptionMethod
          Algorithm='http://www.w3.org/2001/04/xmlenc#tripleDES-cbc' />
        <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
          <KeyName>John Smith</KeyName>
        </KeyInfo>
        <CipherData>
          <CipherValue>yDUNqHkMRD...</CipherValue>
        </CipherData>
      </EncryptedData>
    </PaymentInfo>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

Example 6: SOAP message encrypted with the public key of the recipient

```

<SOAP-ENV:Envelope
  SOAP-ENV:encodingStyle='http://schemas.xmlsoap.org/soap/encoding/'
  xmlns:SOAP-ENV='http://schemas.xmlsoap.org/soap/envelope/'>
  <SOAP-ENV:Header>
    <Security SOAP-ENV:mustUnderstand='1'
      xmlns='http://schemas.xmlsoap.org/ws/2003/06/secext'>
      <EncryptedKey xmlns='http://www.w3.org/2001/04/xmlenc#'>
        <EncryptionMethod
          Algorithm='http://www.w3.org/2001/04/xmlenc#rsa-1_5' />
        <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
          <KeyName>Sally Doe</KeyName>
        </KeyInfo>
        <CipherData>
          <CipherValue>yMTEy0TA1M...</CipherValue>
        </CipherData>
        <ReferenceList>
          <DataReference URI='#ed1' />
        </ReferenceList>
      </EncryptedKey>
    </Security>
  </SOAP-ENV:Header>
  <SOAP-ENV:Body>
    <PaymentInfo xmlns='http://example.org/paymentv2'>
      <Name>John Smith</Name>
      <EncryptedData Id='ed1'

```

```

Type='http://www.w3.org/2001/04/xmlenc#Element'
xmlns='http://www.w3.org/2001/04/xmlenc#'>
  <EncryptionMethod
    Algorithm='http://www.w3.org/2001/04/xmlenc#tripledes-cbc' />
  <CipherData>
    <CipherValue>ydUNqHkMrD...</CipherValue>
  </CipherData>
</EncryptedData>
</PaymentInfo>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

Relationship to digital signature

The WSS-Core specification also provides message integrity, which is realized by a digital signature based on the XML-Signature specification.

A combination of encryption and digital signature over common data introduces cryptographic vulnerabilities.

Configuring encryption information for the consumer binding with an assembly tool

Prior to completing this task, you must complete the following steps:

1. Import your application into an assembly tool.
For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.
2. Specify which message parts to encrypt. For more information, see "Encrypting message elements in consumer security constraints with keywords" on page 1087 or "Encrypting message elements in consumer security constraints with an XPath expression" on page 1092.
3. Configure the key information that is referenced by the Key information element within the Encryption information dialog window. For more information, see "Configuring key information for the consumer binding with an assembly tool" on page 1064.

Complete the following steps to configure the encryption information for the server-side and client-side bindings using an assembly tool. The encryption information on the consumer side is used for decrypting the encrypted message parts in the incoming SOAP message. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side bindings:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Binding** tab and expand the Security Response Consumer Binding Configuration section.
4. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you must configure. Complete the following steps to locate the server-side bindings:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Request Consumer Binding Configuration Details section.

5. Expand the Encryption Information section and click **Add** to add a new entry or select an existing entry and click **Edit**. The Encryption Information dialog window is displayed. Complete the following steps to specify an encryption information configuration:

- a. Specify a name for the encryption information configuration in the Encryption name field.
- b. **Optional:** Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the encryption method algorithm drop-down lists. Use this option if you expect this application to run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.
- c. Select a data encryption algorithm from the Data encryption method algorithm field. The data encryption algorithm is used for encrypting or decrypting parts of a SOAP message, such as the SOAP body or the username token. The following pre-configured algorithms are supported:

- <http://www.w3.org/2001/04/xmlenc#tripledes-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes256-cbc>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

- <http://www.w3.org/2001/04/xmlenc#aes192-cbc>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

This algorithm must match the data encryption algorithm that is configured for the generator. For more information on configuring the encryption information for the generator, see “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

- d. Select a key encryption algorithm from the Key encryption method algorithm field. The key encryption algorithm is used to encrypt the key that is used for encrypting the message parts within the SOAP message. The following pre-configured algorithms are supported:

- <http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p>.

When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms will not include this one. This algorithm will appear in the list of supported key transport algorithms when running with SDK Version 1.5.

Restriction: This algorithm is not supported when the WebSphere Application Server is running in Federal Information Processing Standard (FIPS) mode.

- http://www.w3.org/2001/04/xmlenc#rsa-1_5
- <http://www.w3.org/2001/04/xmlenc#kw-tripledes>
- <http://www.w3.org/2001/04/xmlenc#kw-aes128>
- <http://www.w3.org/2001/04/xmlenc#kw-aes256>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

- <http://www.w3.org/2001/04/xmlenc#kw-aes192>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

Select the blank entry if the data encryption key, which is the key used for encrypting the message parts, is not encrypted. This key encryption algorithm for the consumer must match the key encryption algorithm for the generator. For more information on configuring the encryption information for the generator, see “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

6. Click **Add** in the Encryption Key Information section to add a new key information entry or click **Remove** to delete a selected entry. Complete the following substeps if you are adding a new key information entry.
 - a. Specify a name in the Key information name field.
 - b. Select a key information reference from the list under the Encryption key information field. The value in this field references the key information configuration that you specified previously. If you have a key information configuration called `con_enckeyinfo` that you want to use with this encryption information configuration, specify `con_enckeyinfo` in the Key information element field. For more information, see “Configuring key information for the consumer binding with an assembly tool” on page 1064.
7. Select a required confidentiality part from the list in the RequiredConfidentiality part field. The value in this field specifies a reference to the message parts for encryption.
8. Click **OK** to save your encryption information configuration.

After you complete this task for the consumer binding, you must configure the encryption information for generator binding if this task was not previously completed. For more information, see “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

Encrypting message elements in consumer security constraints with keywords

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

Complete the following steps to specify which message parts to check for encryption when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool and click **Window > Open Perspective > J2EE**.
2. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side bindings:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
3. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you must configure. Complete the following steps to locate the server-side bindings:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
4. Expand the Required Confidentiality section. Confidentiality refers to encryption and integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see “XML encryption” on page 1082.

5. Click **Add** to specify which parts of the message to check for encryption. The Required Confidentiality Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the confidentiality element in the Required Confidentiality Name field.
 - b. Specify a usage type in the Usage type field. This field specifies the requirement for the confidentiality element. The value of this attribute is either Required or Optional.
6. Click **Add** under Message parts and select the message parts dialect. The <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> dialect specifies which message part to be checked for encryption using keywords. If you select this dialect, you can select one of the following keywords under Message parts keyword:

bodycontent

Specifies the user data portion of the message. If you select this keyword, the body is checked for encryption.

username token

Specifies a username token that contains the basic authentication information such as a user name and a password. Usually, the username token is encrypted so that the user information is secure. If you select this keyword, the username token element is checked for encryption.

digestvalue

Specifies a unique digest value. When a part of the Simple Object Access Protocol (SOAP) message is signed, a unique digest value is created and is used by the receiving party to check the integrity of the message. You can encrypt the digestvalue element to secure the digest value. If you select this keyword, the digestvalue is checked for encryption.

signature

Specifies an entire signature. You can encrypt the signature element, ds:Signature, by selecting this message part.

Note: If the value of a ds:DigestValue element in a signature needs to be encrypted, the entire parent ds:Signature element must be encrypted to ensure that the application complies to the Basic Security Profile (BSP). You can use the signature keyword to perform the encryption.

wscontextcontent

Encrypts the content in the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services.

Note: You must have a matching configuration for the generator.

In addition to the message parts, you also can specify that WebSphere Application Server check the encryption of the nonce and timestamp elements. For more information, see the following articles:

- “Adding time stamps for confidentiality in consumer security constraints with keywords”
- “Adding time stamps for confidentiality in consumer security constraints with an XPath expression” on page 1093
- “Adding a nonce for confidentiality in consumer security constraints with keywords” on page 1090
- “Adding the nonce for confidentiality in consumer security constraints with an XPath expression” on page 1095

7. Click **OK** to save your configuration.

After you specify which message parts to check for encryption, you must specify which method is used to verify the encryption of the message parts. For more information, see “Configuring encryption information for the consumer binding with an assembly tool” on page 1085.

Adding time stamps for confidentiality in consumer security constraints with keywords:

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.

This task is used to specify that a time stamp embedded in a particular element and encrypted is checked for encryption along with the message parts in the Required Integrity . Complete the following steps to specify the time stamp for confidentiality using keywords when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Required Confidentiality section. Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see "XML encryption" on page 1082.
6. Click **Add** to specify that the element within which a timestamp is added and encrypted, is checked for confidentiality. The Required Confidentiality Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the confidentiality element in the Required Confidentiality Name field.
 - b. Specify a usage type in the Usage type field. This field specifies the requirement for the confidentiality element. The value of this attribute is either Required or Optional.
7. In the Timestamp section, click **Add** and select the Timestamp dialect. The <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> dialect specifies the message part that is verified for encryption using the keywords. If you select this dialect, you can select one of the following keywords under the Timestamp keyword heading:

bodycontent

Specifies the user data portion of the message. If this keyword is selected, the body along with the embedded timestamp is checked for confidentiality.

username token

Specifies a username token that contains the basic authentication information such as a user name and a password. Usually, the username token is encrypted so that the user information is secure. If you select this keyword, the username token along with the embedded timestamp is checked for confidentiality.

digestvalue

Specifies a unique digest value. When a part of the Simple Object Access Protocol (SOAP) message is signed, a unique digest value is created and is used by the receiving party to

check the integrity of the message. You can encrypt the digestvalue element to secure the digest value. If you select this keyword, the digestvalue along with the embedded timestamp is checked for confidentiality.

signature

Specifies an entire signature. You can encrypt the signature element, ds:Signature, by selecting this message part.

Note: If the value of a ds:DigestValue element in a signature needs to be encrypted, the entire parent ds:Signature element must be encrypted to ensure that the application complies to the Basic Security Profile (BSP). You can use the signature keyword to perform the encryption.

wscontextcontent

Encrypts the content in the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services.

8. If you have not specified message part(s) in Required Confidentiality, in the Message Parts section click **Add** to add message parts. You must define at least one message part in Required Confidentiality for specifying Timestamp in Required Confidentiality."
9. In the Message Parts section, select the message parts keyword.
10. Click **OK** to save the configuration changes.

Note: These configurations for the consumer and the generator must match.

In addition to the time stamp, you can specify that the nonce is checked for confidentiality. For more information, see the following articles:

- "Adding a nonce for integrity in consumer security constraints with keywords" on page 1052
- "Adding a nonce for integrity in consumer security constraints with an XPath expression" on page 1057

After you specify which message parts to check for encryption, you must specify which method is used to check the encryption. For more information, see "Configuring encryption information for the consumer binding with an assembly tool" on page 1085.

Adding a nonce for confidentiality in consumer security constraints with keywords:

You can check the confidentiality of an element that has nonce embedded in it and is encrypted using keywords when you configure the consumer security constraints for either the response consumer or the request consumer.

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.

Nonce for confidentiality is used to specify that the nonce is embedded in a particular element within the message and that the element is encrypted. Complete the following steps to check the confidentiality of an element that has nonce embedded in it and is encrypted using keywords when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.

3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the **Web Services > Client** section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the **Web Services > Services** section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Required Confidentiality section. Confidentiality refers to encryption and integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see “XML encryption” on page 1082.
6. Click **Add** to specify that the element within which a nonce is added and encrypted, is checked for confidentiality. The Required Confidentiality Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the confidentiality element in the **Required Confidentiality Name** field.
 - b. Specify a usage type in the **Usage type** field. This field specifies the requirement for the confidentiality element. The value of this attribute is either Required or Optional.
7. Under Nonce, click **Add** and select the Nonce dialect. The <http://www.ibm.com/websphere/webservices/wssecurity/dialect-was> dialect specifies the message part that has an embedded nonce is verified for encryption. If you select this dialect, you can select one of the following keywords under Nonce keyword:

bodycontent

Specifies the user data portion of the message. If this keyword is selected, the nonce is embedded in the SOAP message body and the body along with the embedded nonce is checked for confidentiality.

username token

Specifies a username token that contains the basic authentication information such as a user name and a password. Usually, the username token is encrypted so that the user information is secure. If you select this keyword, the user name token element along with the embedded nonce is checked for confidentiality.

digestvalue

Specifies a unique digest value. When a part of the SOAP message is signed, a unique digest value is created and is used by the receiving party to check the integrity of the message. You can encrypt the `digestvalue` element to secure the digest value. If you select this keyword, the `digestvalue` element along with the embedded nonce is checked for confidentiality.

signature

Specifies an entire signature. You can encrypt the signature element, `ds:Signature`, by selecting this message part.

Note: If the value of a `ds:DigestValue` element in a signature needs to be encrypted, the entire parent `ds:Signature` element must be encrypted to ensure that the application complies to the Basic Security Profile (BSP). You can use the signature keyword to perform the encryption.

wscontextcontent

Encrypts the content in the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services.

8. If you have not specified message parts in Required Confidentiality, in the Message Parts section, click **Add** to add message parts. You must define at least one message part in Required Confidentiality for specifying Nonce in Required Confidentiality.
9. In the Message Parts section, select the message parts keyword.
10. Click **OK** to save the configuration changes.

Note: These configurations for the consumer and the generator must match.

In addition to the nonce, you can specify that the `timestamp` element is checked for confidentiality. For more information, see the following articles:

- “Adding time stamps for confidentiality in consumer security constraints with keywords” on page 1088
- “Adding time stamps for confidentiality in consumer security constraints with an XPath expression” on page 1093

After you specify which message parts to check for confidentiality, you must specify which method is used to verify the encryption. For more information, see “Configuring encryption information for the consumer binding with an assembly tool” on page 1085.

Encrypting message elements in consumer security constraints with an XPath expression

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

Complete the following steps to specify which message parts to check for encryption when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.

4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Required Confidentiality section. Confidentiality refers to encryption and integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see “XML encryption” on page 1082.
6. Click **Add** to specify which parts of the message to check for encryption. The Required Confidentiality Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the confidentiality element in the Required Confidentiality Name field.
 - b. Specify a usage type in the Usage type field. This field specifies the requirement for the confidentiality element. The value of this attribute is either Required or Optional.
7. Click **Add** under the Message parts section of the Required Confidentiality Dialog window. Complete the following steps to specify the message part and its associated message parts dialect:
 - a. Select the message parts dialect from the Message parts section. The `http://www.w3.org/TR/1999/REC-xpath-19991116` dialect specifies which message part is checked for encryption using an XPath expression.
Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use `http://www.w3.org/2002/06/xmlsig-filter2` to ensure compliance.
 - b. Specify the message part to be checked for encryption using an XPath expression in the Message parts keyword field. For example, to specify that the body is checked for encryption, you might add the following expression in the Message parts keyword field as one continuous line:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/
soap/envelope/' and local-name()='Body']
```

Note: These configurations for the consumer and the generator must match.

In addition to the message parts, you also can specify that WebSphere Application Server check the nonce and timestamp elements for encryption. For more information, see the following articles:

- “Adding time stamps for confidentiality in consumer security constraints with keywords” on page 1088
- “Adding time stamps for confidentiality in consumer security constraints with an XPath expression”
- “Adding a nonce for confidentiality in consumer security constraints with keywords” on page 1090
- “Adding the nonce for confidentiality in consumer security constraints with an XPath expression” on page 1095

8. Click **OK** to save your configuration.

After you specify which message parts to check for encryption, you must specify which method is used to verify the encryption of the message parts. For more information, see “Configuring encryption information for the consumer binding with an assembly tool” on page 1085.

Adding time stamps for confidentiality in consumer security constraints with an XPath expression:

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

This task is used to specify that a time stamp embedded in a particular element and encrypted on the generator side is checked for encryption on the consumer side. Complete the following steps to specify the time stamp for confidentiality using an XPath expression when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Required Confidentiality section. Confidentiality refers to encryption and integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see "XML encryption" on page 1082.
6. Click **Add** to specify that the element within which a timestamp is added and encrypted, is checked for confidentiality. The Required Confidentiality Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the confidentiality element in the Required Confidentiality Name field.
 - b. Specify a usage type in the Usage type field. This field specifies the requirement for the confidentiality element. The value of this attribute is either Required or Optional.
7. Click **Add** under the Timestamp section of the Required Confidentiality Dialog window. Complete the following steps to specify the timestamp dialect and the message part:
 - a. Select the timestamp dialect from the Timestamp section. The <http://www.w3.org/TR/1999/REC-xpath-19991116> dialect specifies which message part is verified for encryption using an XPath expression.

Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use <http://www.w3.org/2002/06/xmldsig-filter2> to ensure compliance.

- b. Specify the message part that has an embedded time stamp and is checked for encryption using an XPath expression in the Timestamp keyword field. For example, to specify that the bodycontent element along with the embedded timestamp is checked for encryption, you might add the following expression in the Timestamp keyword field as one continuous line:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'  
and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/  
soap/envelope/' and local-name()='Bodycontent']
```

If you have not specified message parts in Required Confidentiality, you can click **Add** in the Message Parts section to add the message parts. You must define at least one message part in Required Confidentiality to specify a time stamp in Required Confidentiality.

8. Click **OK** to save the configuration changes.

Note: These configurations for the consumer and the generator must match.

In addition to the time stamp, you can specify that the nonce is checked for encryption. For more information, see the following articles:

- “Adding a nonce for integrity in consumer security constraints with keywords” on page 1052
- “Adding a nonce for integrity in consumer security constraints with an XPath expression” on page 1057

After you specify which message parts to check for encryption, you must specify which method is used to verify the encryption. For more information, see “Configuring encryption information for the consumer binding with an assembly tool” on page 1085.

Adding the nonce for confidentiality in consumer security constraints with an XPath expression:

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

The following information explains the difference between using an XPath expression and using keywords to specify which part of the message to sign:

XPath expression

Specify any part of the message using an XPath expression. XPath is a language that is used to address parts of an XML document. You can find information on XPath syntax at the following Web site: <http://www.w3.org/TR/1999/REC-xpath-19991116>.

Keywords

Specify only elements within the message using predefined keywords.

Nonce for confidentiality is used to specify that the nonce is embedded in a particular element within the message and that the element is encrypted. Complete the following steps to check the confidentiality of an element that has nonce embedded in it and is encrypted using an XPath expression when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you must configure. Complete the following steps to locate the client-side bindings:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.

- b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
4. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you must configure. Complete the following steps to locate the server-side bindings:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Required Confidentiality section. Confidentiality refers to encryption and integrity refers to digital signing. Confidentiality reduces the risk of someone intercepting the message as it moves across a network. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the intended target. For more information on encryption, see “XML encryption” on page 1082.
6. Click **Add** to specify that the element within which a nonce is added and encrypted is checked for confidentiality. The Required Confidentiality Dialog window is displayed. Complete the following steps to specify a configuration:
 - a. Specify a name for the confidentiality element in the Required Confidentiality Name field.
 - b. Specify a usage type in the Usage type field. This field specifies the requirement for the confidentiality element. The value of this attribute is either Required or Optional.
7. Click **Add** under the Nonce section of the Required Confidentiality Dialog window. Complete the following steps to specify a nonce dialect and its associated message part:
 - a. Select the nonce dialect from the Nonce section. The `http://www.w3.org/TR/1999/REC-xpath-19991116` dialect specifies the message part which has an embedded nonce is verified for encryption using an XPath expression.
Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use `http://www.w3.org/2002/06/xmldsig-filter2` to ensure compliance.
 - b. Specify the message part that has an embedded nonce is unencryption using an XPath expression in the Nonce keyword field. For example, to specify that the bodycontent element along with the embedded nonce is checked for confidentiality, you might add the following expression in the Nonce keyword field as one continuous line:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Bodycontent']
```
8. If you have not specified message parts in Required Confidentiality, click **Add** in the Message Parts section to add message parts. You must define at least one message part in Required Confidentiality for specifying Nonce in Required Confidentiality.
9. In the Message Parts section, select the message parts keyword.
10. Click **OK** to save the configuration changes.

Note: These configurations on the consumer side and the generator side must match.

In addition to the nonce, you can specify that the timestamp element is checked for encryption. For more information, see the following articles:

- “Adding time stamps for confidentiality in consumer security constraints with keywords” on page 1088
- “Adding time stamps for confidentiality in consumer security constraints with an XPath expression” on page 1093

After you specify which message parts to check for encryption, you must specify which method is used to verify the encryption. For more information, see “Configuring encryption information for the consumer binding with an assembly tool” on page 1085.

Configuring encryption information for the generator binding with an assembly tool

The encryption information on the generator side is used for encrypting an outgoing SOAP message. You can configure the encryption information for the generator binding by using an assembly tool.

Prior to completing this task, you must complete the following steps:

1. Import your application into an assembly tool.
For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.
2. Specify which message parts to encrypt. For more information, see "Encrypting the message elements in generator security constraints with keywords" on page 1070 or "Encrypting the message elements in generator security constraints with an XPath expression" on page 1077.
3. Configure the key information that is referenced by the Key information element within the Encryption information dialog window. For more information, see "Configuring key information for the generator binding with an assembly tool" on page 1042.

Complete the following steps to configure the encryption information for the server-side and client-side bindings using an assembly tool. The request generator is configured for the client and the response generator is configured for the server.

In the following steps, you must configure either the client-side bindings in step 2 or the server-side bindings in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side bindings using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the bindings that you must configure. Complete the following steps to locate the client-side bindings:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Binding** tab and expand the Security Request Generator Binding Configuration section.
4. **Optional:** Locate the server-side bindings using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the bindings that you must configure. Complete the following steps to locate the server-side bindings:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Binding Configurations** tab and expand the Response Generator Binding Configuration Details section.
5. Expand the Encryption Information section and click **Add** to add a new entry or select an existing entry and click **Edit**. The Encryption Information Dialog window is displayed. Complete the following steps to specify an encryption information configuration:
 - a. Specify a name for the encryption information configuration in the Encryption name field. For example, you might specify `gen_encinfo`.
 - b. **Optional:** Select **Show only FIPS Compliant Algorithms** if you want only the FIPS compliant algorithms to be shown in the encryption method algorithm drop-down lists. Use this option if you expect this application to run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.
 - c. Select a data encryption algorithm from the Data encryption method algorithm field. This specifies the algorithm used to encrypt parts of the message. The following pre-configured algorithms are supported:
 - <http://www.w3.org/2001/04/xmlenc#tripleDES-cbc>

- <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes256-cbc>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

- <http://www.w3.org/2001/04/xmlenc#aes192-cbc>

To use this algorithm, you must download the unrestricted JCE policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

This algorithm must match the data encryption algorithm that is configured for the consumer. For more information on configuring the encryption information for the consumer, see “Configuring encryption information for the consumer binding with an assembly tool” on page 1085.

- d. Select a key encryption algorithm from the Key encryption method algorithm field. This algorithm is used to encrypt the keys. The following pre-configured algorithms are supported:

- <http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p>.

When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms will not include this one. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5.

Restriction: This algorithm is not supported when the WebSphere Application Server is running in Federal Information Processing Standard (FIPS) mode.

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoep.DigestMethod`. The property value is one of the following URIs of the digest method:

- <http://www.w3.org/2001/04/xmlenc#sha256>
- <http://www.w3.org/2001/04/xmlenc#sha512>

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

- http://www.w3.org/2001/04/xmlenc#rsa-1_5
- <http://www.w3.org/2001/04/xmlenc#kw-tripledes>
- <http://www.w3.org/2001/04/xmlenc#kw-aes128>
- <http://www.w3.org/2001/04/xmlenc#kw-aes256>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

- <http://www.w3.org/2001/04/xmlenc#kw-aes192>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

Select the blank entry if the data encryption key, which is the key that is used for encrypting the message parts, is not encrypted. The key encryption algorithm for the generator and the consumer must match. For more information on configuring the encryption information for the generator, see “Configuring encryption information for the generator binding with an assembly tool” on page 1097.

- e. Specify a name in the Key information name field. For example, you might specify `gen_ekeyinfo`.
 - f. Select a key information element in the Key information element field. The value in this field references the key information configuration that you specified previously. If you have a key information configuration called `gen_enckeyinfo` that you want to use with this encryption information configuration, specify `get_enckeyinfo` in the Key information element field. For more information, see “Configuring key information for the generator binding with an assembly tool” on page 1042.
 - g. Select a confidentiality part in the Confidentiality part field. The value in this field specifies the name of the confidentiality element that is encrypted.
6. Click **OK** to save your encryption information configuration.

After you complete this task for the consumer binding, you must configure the encryption information for consumer binding. For more information, see “Configuring encryption information for the consumer binding with an assembly tool” on page 1085.

Adding a stand-alone time stamp to generator security constraints

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

The timestamp determines if the message is valid based upon the time that the message is sent by one machine and then received by another machine.

Complete the following steps to specify a standalone time stamp when you configure the generator security constraints for either the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the Add Timestamp section and select the **Use Add Timestamp** option. When you select this option, a time stamp is added to the message that is sent.

6. Specify an expiration time for the time stamp, which helps defend against replay attacks. Complete the following steps to configure the time stamp:
 - a. Expand the Expires subsection within the Add Timestamp section.
 - b. Select the **Use Expires** option.
 - c. Specify an expiration time for the time stamp. The lexical representation for the duration is the [ISO 8601] extended format PnYnMnDnHnMnS, where:

P	Precedes the date and time values.
nY	Represents the number of years in which the time stamp is in effect. Select a value from 0 to 99 years.
nM	Represents the number of months in which the time stamp is in effect. Select a value from 0 to 11 months.
nD	Represents the number of days in which the time stamp is in effect. Select a value from 0 to 30 days.
T	Separates the date and time values.
nH	Represents the number of hours in which the time stamp is in effect. Select a value from 0 to 23 hours.
nM	Represents the number of minutes in which the time stamp is in effect. Select a value from 0 to 59 minutes.
nS	Represents the number of seconds in which the time stamp is in effect. The number of seconds can include decimal digits to arbitrary precision. You can select a value from 0 to 59 for the seconds and from 0 to 9 for tenths of a second.

For example, 1 year, 2 months, 3 days, 10 hours, and 30 minutes is represented as P1Y2M3DT10H30M. Typically, you might configure a message time stamp for between 10 and 30 minutes. For example, 10 minutes is represented as P0Y0M0DT0H10M0S.

Adding a stand-alone time stamp in consumer security constraints

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see "Importing an enterprise application EAR file" in the Application Server Toolkit documentation.

The timestamp determines if the message is valid based upon the time that the message is sent by one machine and then received by another machine.

Complete the following steps to specify a standalone time stamp when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the server-side extensions:

- a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Add Timestamp section and select **Use Add Timestamp** option. When you select this option, a time stamp is added to the message that is sent.
 6. Specify an expiration time for the time stamp, which helps defend against replay attacks. Complete the following steps to configure the time stamp:
 - a. Expand the Expires subsection within the Add Timestamp section.
 - b. Select the **Use Expires** option.
 - c. Specify an expiration time for the time stamp. The lexical representation for the duration is the [ISO 8601] extended format PnYnMnDnHnMnS, where:

P	Precedes the date and time values.
nY	Represents the number of years in which the time stamp is in effect. Select a value from 0 to 99 years.
nM	Represents the number of months in which the time stamp is in effect. Select a value from 0 to 11 months.
nD	Represents the number of days in which the time stamp is in effect. Select a value from 0 to 30 days.
T	Separates the date and time values.
nH	Represents the number of hours in which the time stamp is in effect. Select a value from 0 to 23 hours.
nM	Represents the number of minutes in which the time stamp is in effect. Select a value from 0 to 59 minutes.
nS	Represents the number of seconds in which the time stamp is in effect. The number of seconds can include decimal digits to arbitrary precision. You can select a value from 0 to 59 for the seconds and from 0 to 9 for tenths of a second.

For example, 1 year, 2 months, 3 days, 10 hours, and 30 minutes is represented as P1Y2M3DT10H30M. Typically, you might configure a message time stamp for between 10 and 30 minutes. For example, 10 minutes is represented as P0Y0M0DT0H10M0S.

Security token

Web services security provides a general-purpose mechanism to associate security tokens with messages for single message authentication. A security token represents a set of claims made by a client that might include a name, password, identity, key, certificate, group, privilege, and so on.

A specific type of security token is not required by Web services security. Web services security is designed to be extensible and support multiple security token formats to accommodate a variety of authentication mechanisms. For example, a client might provide proof of identity and proof of a particular business certification. However, the security token usage for Web services security is defined in separate profiles such as the Username token profile, the X.509 token profile, the Security Assertion Markup Language (SAML) token profile, the eXtensible rights Markup Language (XrML) token profile, the Kerberos token profile and so on.

A security token is embedded in the SOAP message within the SOAP header. The security token within the SOAP header is propagated from the message sender to the intended message receiver. On the receiving side, the WebSphere Application Server security handler authenticates the security token and sets up the caller identity on the running thread.

WebSphere Application Server Version 6.0.x contains an enhanced security token that has the following features:

- The client can send multiple tokens to downstream servers.
- The receiver can determine which security token to use for authorization based upon the type or signed part for X.509 tokens.
- You can use the custom token for digital signing or encryption.

Configuring the security token in generator security constraints

You can specify the security token when you configure the request generator or the response generator.

Prior to completing this task, you must import your application into an assembly tool.

See the information about Importing an enterprise application EAR file in the Application Server Toolkit documentation.

A security token represents a set of claims that are made by a client and might include a name, password, identity, key, certificate, group, privilege, and so on. It is embedded in the SOAP message within the SOAP header. WebSphere Application Server propagates the security token within the SOAP header from the message sender to the intended message receiver. On the receiving side, the security handler for WebSphere Application Server authenticates the security token and sets up the caller identity on the thread.

Complete the following steps to specify the security token when you configure the request generator or the response generator. The request generator is configured for the client and the response generator is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the **Web Services > Client** section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the **Web Services > Services** section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Response Generator Service Configuration Details section.
5. Expand the **Security Token** section. The Security Token Dialog window is displayed.
6. Click **Add** to configure the security token. Complete the following steps to configure the security token:
 - a. Specify a name for the security token in the Name field. For example, you might specify `un_token`.
 - b. Select a token type from the Token type field. For example, if you wish to send a username token, select Username for the token type. If you select a token type other than custom token, you do not need to specify values in the Uniform Resource Identifier (URI) and Local name fields. These fields are automatically specified when you select a token type other than custom token.
For a username token or an X.509 token, you do not need to specify a value in the URI field.
 - c. **Optional:** Specify a value for the URI and Local name fields if you are configuring a custom token. For example, you might specify `http://www.ibm.com/custom` in the URI field and `CustomToken` in the Local name field.
7. Click **OK** to save the configuration changes.

When you configure the token generator, select the security token that you created using these steps. For more information, see “Configuring token generators with an assembly tool” on page 1034.

Configuring the security token requirement in consumer security constraints

You can specify the security token when you configure the response consumer or the request consumer.

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

A security token represents a set of claims that are made by a client and might include a name, password, identity, key, certificate, group, privilege, and so on. It is embedded in the SOAP message within the SOAP header. WebSphere Application Server propagates the security token within the SOAP header from the message sender to the intended message receiver. On the receiving side, the security handler for WebSphere Application Server authenticates the security token and sets up the caller identity on the thread.

Complete the following steps to specify the security token when you configure the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the **Web Services > Client** section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Required Security Token section. The Required Security Token Dialog window is displayed.
6. Click **Add** to configure the security token. Complete the following steps to configure the security token:
 - a. Specify a name for the security token in the Name field. For example, you might specify `un_token`.
 - b. Select a token type from the Token type field. For example, if you want to send a username token, select Username for the token type. If you select a token type other than custom token, you do not need to specify values in the Uniform Resource Identifier (URI) and Local name fields. These fields are automatically specified when you select a token type other than custom token.

For a username token or an X.509 token, you do not need to specify a value in the URI field.
 - c. **Optional:** Specify a value for the URI and Local name fields if you are configuring a custom token. For example, you might specify `http://www.ibm.com/custom` in the URI field and `CustomToken` in the Local name field.
 - d. Specify a usage type in the Usage type field. This field specifies the requirement for the confidentiality element. The value of this attribute is either Required or Optional.
7. Click **OK** to save the configuration changes.

When you configure the token consumer, select the security token that you created using these steps. For more information, see “Configuring token consumers with an assembly tool” on page 1060.

Configuring the caller in consumer security constraints

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

The caller is used to identify the token. The run time for Web services security uses this token identity to create the security credential and principal for WebSphere Application Server. The token identity must be in the configured user registry so that the Application Server can use the token identity in Java 2 Platform, Enterprise Edition (J2EE) authorization checks.

Complete the following steps to specify the caller part when you configure the consumer security constraints for either the response consumer or the request consumer. The response consumer is configured for the client and the request consumer is configured for the server. In the following steps, you must configure either the client-side extensions in step 2 or the server-side extensions in step 3.

1. Start the assembly tool.
2. Switch to the J2EE perspective. Click **Window > Open Perspective > J2EE**.
3. **Optional:** Locate the client-side extensions using the Project Explorer window. The Client Deployment Descriptor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the client-side extensions:
 - a. Expand the Web Services > Client section and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Response Consumer Configuration section.
4. **Optional:** Locate the server-side extensions using the Project Explorer window. The Web Services Editor window is displayed. This Web service contains the extensions that you need to configure. Complete the following steps to locate the server-side extensions:
 - a. Expand the Web Services > Services section and double-click the name of the Web service.
 - b. Click the **Extensions** tab and expand the Request Consumer Service Configuration Details section.
5. Expand the Caller Part section.
6. Click **Add** to specify the caller part. The Caller Part Dialog window is displayed. Complete the following steps to configure the caller part:
 - a. Specify the name of the caller in the Name field.
 - b. **Optional:** Specify the name of an integrity or confidentiality part in the Required Integrity or Required Confidentiality part field if you want to select the token that used for either digital signature or encryption as the caller token. For more information on these configurations, see the following tasks:
 - “Signing message elements in consumer security constraints with keywords” on page 1048
 - “Signing message elements in consumer security constraints with an XPath expression” on page 1054
 - “Encrypting message elements in consumer security constraints with keywords” on page 1087
 - “Encrypting message elements in consumer security constraints with an XPath expression” on page 1092
 - c. **Important:** Either complete this step or specify a token type in the Token type field in the next step.
 - c. **Optional:** Specify a token type in the Token type field if you want to select a standalone security token as the caller token.

If a standalone security token is used for authentication, then the Uniform Resource Identifier (URI) and local name attributes must define the type of security token that is used for authentication. You can select standard or custom security tokens by URI and local name.

If you specify a token type in the Token type field, complete the following steps:

- 1) Specify the namespace URI of the security token that is used for authentication in the URI field.
- 2) Specify the local name of the security token that is used for authentication in the Local name field. The following table shows the URI and local name combinations that are supported:

Table 48. URI and Local name combinations

URI	Local name	Description
A namespace URI is not applicable.	Specify <code>http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3</code> as the local name value.	Specifies the name of an X.509 certificate token
A namespace URI is not applicable.	Specify <code>http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1</code> as the local name value.	Specifies the name of the X.509 certificates in a PKI path
A namespace URI is not applicable.	Specify <code>http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7</code> as the local name value.	Specifies a list of X509 certificates and certificate revocation lists (CRL) in a PKCS#7
Specify <code>http://www.ibm.com/websphere/appserver/tokentype/5.0.2</code> as the URI value.	Specify LTPA as the local name value.	Specifies a binary security token that contains an embedded Lightweight Third Party Authentication (LTPA) token.
Specify <code>http://www.ibm.com/websphere/appserver/tokentype</code> as the URI value.	Specify LTPA_PROPAGATION as the local name value.	Specifies a binary security token that contains an embedded propagation token.
Specify the namespace URI value as indicated by the provider.	Specify <code>http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken</code> as the local name value.	<p>Specifies the token type that is configured to perform token validation. This local name is used to remap an incoming security token to a different security token. You can use this local name value in a situation that is similar to the following scenario:</p> <p>A client sends a username token to the server. The custom token consumer on the server uses the security token service to authenticate the user name information. The username token is used to create a new token type such as a Security Assertion Markup Language (SAML) token. You can use the identity from the SAML token for authentication and authorization verification in WebSphere Application Server.</p>

The custom token requires that you specify both the URI and the Local name.

7. **Optional:** Configure identity assertion. For more information, see “Configuring identity assertion”
8. **Optional:** Click **Add** and specify a Trust method property in the Trust method property section, if necessary.
9. **Optional:** Click **Add** and specify an additional property in the Property section, if necessary.
10. Click **OK** to save the configuration changes.

Note: These configurations on the consumer side and the generator side must match.

Configuring identity assertion

Prior to completing this task, you must import your application into an assembly tool.

For information on how to import your application, see “Importing an enterprise application EAR file” in the Application Server Toolkit documentation.

Identity assertion is one of the WebSphere Application Server Version 6.0.x and later enhancements, but it must be used in a secured environment such as a Virtual Private Network (VPN) or HTTPs. In a secure environment, it is possible to send the requester identity without credentials with other trusted credentials such as the server identity. With identity assertion, WebSphere Application server supports the following types of trust modes:

None Specifies that a trusted credential is not attached to the Simple Object Access protocol (SOAP) message

BasicAuth

Specifies that a username token with a user name and a password is used as a trusted credential

Signature

Specifies that an X.509 certificate security token is used in the digital signature

The specific configuration for identity assertion is necessary on the consumer side in a service configuration only. On the generator side, you need to configure two token generators in a client configuration: one for a requester token and one for a token of a trusted party.

Complete the following steps to configure an application for identity assertion. You must configure both the consumer and the generator to complete the configuration.

1. Start the assembly tool.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Expand the Web Services > Services section in the Project Explorer and double-click the name of the Web service.
4. Click the **Extensions** tab and expand the Response Consumer Service Configuration Details > Caller Part section to configure the caller token.
5. Configure the caller token for the consumer. Complete the following steps to configure the caller token for the consumer:
 - a. Click **Add** to configure the caller part. The Caller Part Dialog window is displayed. In this window, configure both a token that is used as a caller (requester) credential and a token for the trusted party.
 - b. Specify a name for the caller token in the Name field.
 - c. Select the type of caller token in Token type field. For example, you can select **Username** if a username token is used as the caller token. When you select the token type, the Local name is automatically specified.

- d. **Optional:** If you select the **Custom token** in the Token type field, you must specify the Local name and the Uniform Resource Identifier (URI) of the custom token. The URI field is used only for a custom token.
 - e. **Optional:** If the caller token is also used as a certificate of a required integrity or confidentiality part, select the name of the part in Integrity or Confidentiality part field. The list contains the names of the integrity and confidentiality parts that are defined in the Required Integrity and Required Confidentiality sections for the consumer. For example, when an X.509 certificate token is used for both a caller token and a signature certificate of the body element, you can select **X.509 certificate token** in the Token type field and select **reqint_body1** in Integrity or Confidentiality part field. This example assumes that **reqint_body1** is a required integrity configuration.
6. Configure a trusted party token for the consumer. Complete the following steps to configure the trusted party token:
- a. Select the **Use IDAssertion** option to associate a trust method with this caller and to verify an asserted identity from the intermediary (caller).
 - b. Select the name of the trust method in the Trust method name field. The following selections are supported:
 - None** Select this option to specify that a trusted credential is not attached to the SOAP message.
 - BasicAuth**
Select this option to specify that a username token with a user name and password is used as a trusted credential.
 - Signature**
Select this option to specify that an X.509 certificate security token is used in the digital signature.

When you select either BasicAuth or Signature, the URI and the Local name fields are automatically specified.
 - c. **Optional:** Select a name of an integrity or confidentiality part in the Integrity or Confidentiality part field if you require digital signature or encryption by the trusted party token. For example, if you select **Signature** in the Trust method name field and you require that the trusted party token signs the body element, select **reqint_body2** in Integrity and Confidentiality part field. This example assumed that **reqint_body2** is a required integrity configuration.
7. **Optional:** If you select **BasicAuth** or **Signature** in the Trust method name field, specify a trusted ID evaluator in Token Consumer Dialog window of the binding configuration. Complete the following steps to specify a trusted ID evaluator:
- a. Click **Binding Configurations** in the Web services editor.
 - b. Expand the Token Consumer section and click **Add**.
 - c. Click the **Use trusted ID evaluator** option.
 - d. Specify a class name in the Trusted ID evaluator class field. The class implements the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface and validates a trusted party token. WebSphere Application Server provides the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl` class, which is a sample implementation of the `TrustedIDEvaluator` interface. If you use this class, specify `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl` in Trusted ID evaluator class field and click **Add** to add the following trusted ID evaluator property:
 - In the name field, specify `trustedid`
 - In the value field, specify `CN=Alice,O=IBM,C=US`

The value of the property is the distinguished name (DN) of the username or X.509 certificate token of the trusted party token.
 - e. Click **OK** to save the configuration.

8. Expand the Web Services > Client section in the Project Explorer and double-click the name of the Web service.
9. Click the **WS Extension** tab and expand the Request Generator Configuration > Security Token section.
10. Specify the caller token for the generator. Do not specify a token in the required token if the token is used for signing or encryption. However, you must specify a token in the required token for a stand-alone token. A stand-alone token is a token that is not used for signing or encryption. When the caller token type is a username token or an X.509 certificate token and it is not used for signing or encryption, specify a security token for this caller token.
 - a. Click **Add** to configure a security token.
 - b. Specify a name for the caller token in the Name field.
 - c. Select either the **Username** or **X.509 certificate token** option in the Token type field. After you select one of these two options, a value for the Local name field is automatically defined.
 - d. Click **OK** to save the configuration.
 - e. Click the **WS Binding** tab and expand the Security Request Generator Binding Configuration > Token Generator section.
 - f. Click **Add** and add the token generator configuration for the caller token.
 - g. Click **OK** to save the configuration.
11. Configure the trusted party token. When the trust mode, which was specified previously, is None only the caller token is attached and you do not need to specify the security token of the trusted party. When the trust mode is BasicAuth or Signature you need to specify a username token or an X.509 certificate token of the trusted party token. However, if the X.509 certificate token of trusted party is used for digital signing or encryption as well, you do not need to specify the security token of the trusted party. Complete the following steps to configure the trusted party token:
 - a. Expand the Web Services > Client section in the Project Explorer and double-click the name of the Web service.
 - b. Click the **WS Extension** tab and expand the Request Generator Configuration > Security Token section.
 - c. Click **Add** to configure a security token.
 - d. Specify a name for the trusted party token in the Name field.
 - e. Select either the **Username** or **X.509 certificate token** option in the Token type field. After you select one of these two options, a value for the Local name field is automatically defined.
 - f. Click **OK** to save the configuration.
 - g. Click the **WS Binding** tab and expand the Security Request Generator Binding Configuration > Token Generator section.
 - h. Click **Add** and add the token generator configuration for the trusted party token.
 - i. Click **OK** to save the configuration.

Your environment is configured for identity assertion.

Configuring trust anchors for the generator binding on the application level

This document describes how to configure trust anchors for the generator binding at the application level. It does not describe how to configure trust anchors at the server or cell level. Trust anchors defined at the application level have a higher precedence over trust anchors defined at the server or cell level. For more information on creating and configuring trust anchors on the server or cell level, see “Configuring trust anchors on the server or cell level” on page 1217.

You can configure a trust anchor for the application-level trust anchor using an Application Server Toolkit or the administrative console. This document describes how to configure the application-level trust anchor using the administrative console.

A trust anchor specifies key stores that contain trusted root certificates, which validate the signer certificate. These key stores are used by the request generator and the response generator (when Web services is acting as client) to generate the signer certificate for the digital signature. The keystores are critical to the integrity of the digital signature validation. If they are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these keystores. The binding configuration specified for the request generator must match the binding configuration for the response generator.

The trust anchor configuration for the request generator on the client must match the configuration for the request consumer on the server. Also, the trust anchor configuration for the response generator on the server must match the configuration for the response consumer on the client.

Complete the following steps to configure trust anchors for the generator binding on the application level:

1. Locate the trust anchor panel in the administrative console.
 - a. Click **Applications > Enterprise applications > *application_name***.
 - b. Under Manage modules, click *URI_name*.
 - c. Under Web Services Security Properties you can access the trust anchor configuration for the following bindings:
 - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 - d. Under Additional properties, click **Trust anchors**.
 - e. Click **New** to create a trust anchor configuration, click **Delete** to delete an existing configuration, or click the name of an existing trust anchor configuration to edit its settings. If you are creating a new configuration, enter a unique name in the Trust anchor name field.
2. Specify the keystore password, the keystore location, and the keystore type. Key store files contain public and private keys, root certificate authority (CA) certificates, the intermediate CA certificate, and so on. Keys retrieved from the keystore are used to sign and validate or encrypt and decrypt messages or message parts. If you specified the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` implementation for the key locator class implementation, you must specify a key store password, location, and type.
 - a. Specify a password in the Key store password field. This password is used to access the keystore file.
 - b. Specify the location of the key store file in the Key store path field.
 - c. Select a keystore type from the Key store type field. The Java Cryptography Extension (JCE) used by IBM supports the following key store types:
 - JKS** Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.
 - JCEKS** Use this option if you are using Java Cryptography Extensions.
 - JCERACFKS** Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).
 - PKCS11KS (PKCS11)** Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)

Use this option if your keystore uses the PKCS#12 file format.

WebSphere Application Server provides some sample keystore files in the `${USER_INSTALL_ROOT}/etc/ws-security/samples` directory. For example, you might use the `enc-receiver.jceks` keystore file for encryption keys. The password for this file is `Storepass` and the type is `JCEKS`.

Attention: Do not use these keystore files in a production environment. These samples are provided for testing purposes only.

This task configures trust anchors for the generator binding at the application level.

You must specify a similar trust anchor configuration for the consumer.

Trust anchor collection

Use this page to view a list of keystore objects that contain trusted root certificates. These objects are used for certificate path validation of incoming X.509-formatted security tokens. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath API to validate the trust of a certificate chain.

To create the keystore file, use the key tool that is located in the `install_dir\java\jre\bin\keytool` directory.

To view this administrative console page for trust anchors on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Trust anchors**.

To view this administrative console page for trust anchors on the server level, complete the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Trust anchors**.

To view this administrative console page for trust anchors on the application level,

1. Click **Applications > Enterprise applications > application_name**.
2. Click **Manage modules > URI_name**.
3. **Version 6 and later applications** Under Web Services Security Properties, you can access trust anchors information for the following bindings:
 - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
 - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
4. **Version 5.x application** Under Additional properties, you can access the trust anchors information for the following bindings:
 - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**.
 - For the Request receiver binding, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**.
5. Under Additional properties, click **Trust anchors**.

If you click **Update runtime**, the Web services security run time is updated with the default binding information, which is contained in the `ws-security.xml` file that was previously saved. If you make changes on this panel, you must complete the following steps:

1. Save your changes by clicking **Save** at the top of the administrative console. When you click **Save**, you are returned to the administrative console home panel.
2. Return to the Trust anchors collection panel and click **Update runtime**. When you click **Update runtime**, the configuration changes made to the other Web services also are updated in the Web services security run time.

Trust anchor name:

Specifies the unique name that is used to identify the trust anchor.

Key store path:

Specifies the location of the keystore file that contains the trust anchors.

Key store type:

Specifies the type of keystore file.

The value for this field is **JKS**, **JCEKS**, **JCERACFKS** (z/OS only), **JCE4758RACFKS** (z/OS only), **PKCS11KS (PKCS11)**, or **PKCS12KS (PKCS12)**.

The value for this field is **JKS**, **JCEKS**, **JCERACFKS** (z/OS only), **PKCS11KS (PKCS11)**, or **PKCS12KS (PKCS12)**.

Trust anchor configuration settings

Use this information to configure a trust anchor. Trust anchors point to keystores that contain trusted root or self-signed certificates. This information enables you to specify a name for the trust anchor and the information that is needed to access a keystore. The application binding uses this name to reference a predefined trust anchor definition in the binding file (or the default).

To view this administrative console page for trust anchors on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Trust anchors**.
3. Click **New** to create a trust anchor or click the name of an existing configuration to modify its settings.

To view this administrative console page for trust anchors on the server level, complete the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Trust anchors**.
4. Click **New** to create a trust anchor or click the name of an existing configuration to modify its settings.

To view this administrative console page for trust anchors on the application level,

1. Click **Applications > Enterprise applications > application_name**.
2. Click **Manage modules > URI_name**.
3. Under Web Services Security Properties, you can access trust anchors information for the following bindings:
 - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.

- For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
4. **Version 5.x application** Under Additional properties, you can access the trust anchors information for the following bindings:
 - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**.
 - For the Request receiver binding, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**.
 5. Under Additional properties, click **Trust anchors**.
 6. Click **New** to create a trust anchor or click the name of an existing configuration to modify its settings.

Trust anchor name:

Specifies the unique name that is used by the application binding to reference a predefined trust anchor definition in the default binding.

Key store configuration name:

Specifies the name of the key store configuration defined in the keystore settings in secure communications.

Key store password:

Specifies the password that is needed to access the key store file.

Key store path:

Specifies the location of the keystore file.

Use `${USER_INSTALL_ROOT}` as this path expands to the WebSphere Application Server path on your machine.

Key store type:

Specifies the type of keystore file.

Choose from the following options:

Version 5.x or 6 application **JKS**

Use this option if you are not using Java Cryptography Extensions (JCE).

Version 5.x or 6 application **JCEKS**

Use this option if you are using Java Cryptography Extensions.

Version 6 and later applications **JCERACFKS**

Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

Version 6 and later applications **PKCS11KS (PKCS11)**

Use this format if your keystore uses the PKCS#11 file format. Keystores that use this format might contain Rivest Shamir Adleman (RSA) keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

Version 6 and later applications **PKCS12KS (PKCS12)**

Use this option if your keystore uses the PKCS#12 file format.

Default	JKS
Range	JKS, JCEKS, PKCS11KS (PKCS11), PKCS12KS (PKCS12)

Configuring the collection certificate store for the generator binding on the application level

You can configure a collection certificate for the generator bindings on the application level.

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check for a valid signature in a digitally signed SOAP message.

Complete the following steps to configure a collection certificate for the generator bindings on the application level:

1. Locate the collection certificate store configuration panel in the administrative console.
 - a. Click **Applications > Enterprise applications > *application_name***.
 - b. Under Manage modules, click *URL_name*.
 - c. Under Web Services Security Properties, you can access the key information for the request generator and response generator bindings.
 - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 - d. Under Additional properties, click **Collection certificate store**.
2. Specify the Certificate store name. Click **New** to create a collection certificate store configuration, select the box next to the configuration and click **Delete** to delete an existing configuration, or click the name of an existing collection certificate store configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field.

The name of the collection certificate store must be unique to the level of the application server. For example, if you create the collection certificate store for the application level, the store name must be unique to the application level. The name that is specified in the Certificate store name field is used by other configurations to refer to a predefined collection certificate store. WebSphere Application Server searches for the collection certificate store based on proximity.

For example, if an application binding refers to a collection certificate store named cert1, the Application Server searches for cert1 at the application level before searching the server level and then the cell level.
3. Specify a certificate store provider in the Certificate store provider field. WebSphere Application Server supports the IBM CertPath certificate store provider. To use another certificate store provider, you must define the provider implementation in the provider list within the *install_dir/java/jre/lib/security/java.security* file. However, make sure that your provider supports the same requirements of the certificate path algorithm as WebSphere Application Server.
4. Click **OK** and **Save** to save the configuration.
5. Click the name of your certificate store configuration. After you specify the certificate store provider, you must specify either the location of a certificate revocation list or the X.509 certificates. However, you can specify both a certificate revocation list and the X.509 certificates for your certificate store configuration.
6. Under Additional properties, click **Certificate revocation lists**.

7. Click **New** to specify a certificate revocation list path, click **Delete** to delete an existing list reference, or click the name of an existing reference to edit the path. You must specify the fully qualified path to the location where WebSphere Application Server can find your list of certificates that are not valid. For portability reasons, it is recommended that you use the WebSphere Application Server variables to specify a relative path to the certificate revocation lists (CRL). This recommendation is especially important when you are working in a WebSphere Application Server Network Deployment environment. For example, you might use the `USER_INSTALL_ROOT` variable to define a path such as `$USER_INSTALL_ROOT/mycertstore/mycrl1`. For a list of supported variables, click **Environment > WebSphere variables** in the administrative console. The following list provides recommendation for using certificate revocation lists:
 - If CRLs are added to the collection certificate store, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.
 - When the CRL file is updated, the new CRL does not take effect until you restart the Web service application.
 - Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.
8. Click **OK** and **Save** to save the configuration.
9. Return to the collection certificate store configuration panel. To access the panel, complete the following steps:
 - a. Click **Applications > Enterprise applications > application_name**.
 - b. Under Manage modules, click `URI_name`.
 - c. Under Web Services Security properties, you can access the key information for the request generator and response generator bindings.
 - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 - d. Under Additional properties, click **Collection certificate store > certificate_store_name**.
10. Under Additional properties, click **X.509 certificates**.
11. Click **New** to create a X.509 certificate configuration, click **Delete** to delete an existing configuration, or click the name of an existing X.509 certificate configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field.
12. Specify a path in the X.509 certificate path field. This entry is the absolute path to the location of the X.509 certificate. The collection certificate store is used to validate the certificate path of incoming X.509-formatted security tokens.

You can use the `USER_INSTALL_ROOT` variable as part of path name. For example, you might type: `USER_INSTALL_ROOT/etc/ws-security/samples/intca2.cer`. Do not use this certificate path for production use. You must obtain your own X.509 certificate from a certificate authority before putting your WebSphere Application Server environment into production.

Click **Environment > WebSphere variables** in the administrative console to configure the `USER_INSTALL_ROOT` variable.
13. Click **OK** and then **Save** to save your configuration.

You have configured the collection certificate store for the generator binding.

You must specify a similar collection certificate store configuration for the consumer.

Collection certificate store collection

Use this page to view a list of certificate stores that contains untrusted, intermediary certificate files awaiting validation. Validation might consist of checking to see if the certificate is on a certificate revocation list (CRL), checking that the certificate is not expired, and checking that the certificate is issued by a trusted signer.

The following list provides recommendations for using CRLs:

- If CRLs are added to the collection certificate store collection, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.
- When the CRL file is updated, the new CRL does not take effect until you restart the Web service application.
- Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.

To view the administrative console panel for the collection certificate store on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Collection certificate store**.

To view the administrative console panel for the collection certificate store on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Collection certificate store**.

To view this administrative console page for the collection certificate store on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:
 - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom > Collection certificate store**.
 - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom > Collection certificate store**.
4. **Version 5.x application** Under Additional properties, you can access collection certificate stores for the following bindings:
 - For the Request receiver binding, click **Web services: Server security bindings**. Under Response receiver binding, click **Edit > Collection certificate store**.
 - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit > Collection certificate store**.

Complete the following steps:

1. Click **New** to specify a new certificate store name and certificate store provider.
2. Click **OK** and messages display at the top of the administrative console panel.
3. Within the messages at the top of the administrative console panel, click **Save**.
4. Return to the collection certificate store collection panel and click **Update runtime** to update the Web services security run time with the default binding information, which is found in the `ws_security.xml` file. When you click **Update runtime**, the configuration changes made to the other Web services are also updated in the Web services security run time.

Certificate store name:

Specifies the name of the certificate store.

Certificate store provider:

Specifies the provider of the certificate store.

Collection certificate store configuration settings

Use this page to specify the name and the provider for a collection certificate store. A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check the signature of a digitally signed Simple Object Access Protocol (SOAP) message.

To view the administrative console panel for the collection certificate store on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Collection certificate store**.
3. Specify a new collection certificate store by clicking **New** or click the collection certificate store name to modify its settings.

To view the administrative console panel for the collection certificate store on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Collection certificate store**.
4. Specify a new collection certificate store by clicking **New** or by clicking the collection certificate store name to modify its settings.

To view this administrative console page for the collection certificate store on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:
 - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom > Collection certificate store**.
 - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom > Collection certificate store**.

4. **Version 5.x application** Under Additional properties, you can access collection certificate stores for the following bindings:
 - For the Request receiver binding click **Edit > Collection certificate store**.
 - For the Response receiver binding, click **Edit > Collection certificate store**.
5. Specify a new collection certificate store by clicking **New** or by clicking the collection certificate store name to modify its settings.

After configuring a collection certificate store, you can select the new configuration under Certificate store on the token generator and token consumer panels. To access these panels, complete the following steps:

1. Click **Security > Web services**.
2. Under Default generator bindings, click **Token generators** or under Default consumer bindings, click **Token consumers**.
3. Click **New** to create a new token generator or token consumer, or click the name of an existing configuration to make modifications.

After you configure your collection certificate store on this panel, you must click **Apply** before configuring either the certificate revocation list or an X.509 certificate. The certificate revocation list configuration is not available for version 5.x applications through the administrative console. After you configure your certificate revocation list or X.509 certificate, complete the following steps:

1. Click **Save**, at the top of the administrative console panel, which returns you to the list of the configured collection certificate stores.
2. Click **Update runtime** to update the Web services security run time with the default binding information, which is found in the `ws_security.xml` file.

Certificate store name:

Specifies the name for the certificate store.

The name of the collection certificate store must be unique in the scope. For example, the name must be unique at the server level. The name specified in **Certificate store name** field is used by other configurations to refer to a pre-defined collection certificate store. For example, the application binding refers to a collection certificate store that is defined on the server level. The application server looks up the collection certificate store based on proximity. For example, if *cert1* is defined as the name of the certificate store on the cell and server levels and *cert1* is referenced in the application binding, the application server uses the server-level collection certificate store.

Certificate Store Provider:

Specifies the provider for the certificate store implementation.

This product supports the IBM CertPath certificate path provider. If you need to use another certificate path provider, define the provider implementation in the provider list within the `java.security` file in the Software Development Kit (SDK).

Data type	String
Default	IBMCertPath

X.509 certificates collection

Use this page to view a list of untrusted, intermediate certificate files. This collection certificate store is used for certificate path validation of incoming X.509-formatted security tokens.

To view the administrative console panel for the collection certificate store on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Collection certificate store**.
3. Click the name of a configured collection certificate store or create a new collection certificate store first.
4. Under Additional properties, click **X.509 certificates**.

To view the administrative console panel for the collection certificate store on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
5. Under Additional properties, click **X.509 certificates**.

To view this administrative console page for an X.509 certificate on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:
 - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom > Collection certificate store**.
 - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom > Collection certificate store**.
4. **Version 5.x application** Under Additional properties, you can access the collection certificate stores for the following bindings:
 - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit > Collection certificate store**.
 - For the Request receiver binding, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit > Collection certificate store**.
5. Click the name of a configured collection certificate store or create a new collection certificate store first.
6. Under Additional properties, click **X.509 certificates**.

X.509 certificate path:

Specifies the location of the X.509 certificate.

X.509 certificate configuration settings

Use this page to specify a list of untrusted, intermediate certificate files. This collection certificate store is used for certificate path validation of incoming X.509-formatted security tokens.

To view the administrative console panel for the collection certificate store on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under additional properties, click **Collection certificate store**.
3. Click the name of a configured collection certificate store or create a new collection certificate store first.
4. Under Additional properties, click **X.509 certificates**.
5. Specify a new X.509 certificate path by clicking **New** or by clicking the X.509 certificate path to modify its settings.

To view the administrative console panel for the collection certificate store on the server level, complete the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
5. Under Additional properties, click **X.509 certificates**.
6. Specify a new X.509 certificate path by clicking **New** or by clicking the X.509 certificate path to modify its settings.

To view this administrative console page for an X.509 certificate on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > application_name**.
2. Click **Manage modules > URI_name**.
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:
 - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom > Collection certificate store**.
 - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom > Collection certificate store**.
4. **Version 5.x application** Under Additional properties, you can access the collection certificate stores for the following bindings.
 - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit > Collection certificate store**.
 - For the Request receiver binding, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit > Collection certificate store**.
5. Click the name of a configured collection certificate store or create a new collection certificate store first.
6. Under Additional properties, click **X.509 certificates**.
7. Specify a new X.509 certificate path by clicking **New** or click the X.509 certificate path to modify its settings.

X.509 Certificate Path:

Specifies the absolute path to the location of the X.509 certificate.

As shown in the following example, you can use the `USER_INSTALL_ROOT` variable as part of the path name: `{USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. This X.509 certificate path is not for production use. Obtain your own X.509 from a certificate authority before putting your application server environment into production.

You can configure the `USER_INSTALL_ROOT` variable in the administrative console by clicking **Environment > WebSphere Variables**.

Certificate revocation list collection

Use this page to determine the location of the certificate revocation lists (CRL) known to the application server. The Application Server checks the CRLs to determine the validity of the client certificate. A certificate that is found in a certificate revocation list might not be expired, but is no longer trusted by the certificate authority (CA) that issued the certificate. The CA might add the certificate to the certificate revocation list if it believes that the client authority is compromised.

To view the administrative console panel for the collection certificate store on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under additional properties, click **Collection certificate store**.
3. Click the name of a configured collection certificate store or create a new collection certificate store first.
4. Under Additional properties, click **Certificate revocation lists**.

To view the administrative console panel for the collection certificate store on the server level, complete the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
5. Under Additional properties, click **Certificate revocation lists**.

Version 6 and later applications

To view this administrative console page for the collection certificate store on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > application_name**.
2. Click **Manage modules > URI_name**.
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:
 - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom > Collection certificate store**.
 - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom > Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.

5. Under Additional properties, click **Certificate revocation lists**.
6. Under Additional properties, you can access collection certificate stores for the following bindings:
 - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**.
7. Under Additional properties, click **Collection certificate store** > *certificate_store_name*.
8. Under Additional properties, click **X.509 certificates**.
9. Click **New** and specify the path to the certificate revocation list.

Version 5.x application

To add a certificate revocation list for a version 5.x application, complete the following steps:

1. Click **Applications** > **Enterprise applications** > *application_name*.
2. Under Related items, click **Manage modules** > *URI_name*.

Certificate revocation list path:

Specifies the location where you can find the list of certificates that are not valid.

Certificate revocation list configuration settings

Use this page to specify a list of certificate revocations that check the validity of a certificate. The application server checks the certificate revocation lists (CRL) to determine the validity of the client certificate. A certificate that is found in a certificate revocation list might not be expired, but is no longer trusted by the certificate authority (CA) that issued the certificate. The CA might add the certificate to the certificate revocation list if it believes that the client authority is compromised.

To view the administrative console panel for the collection certificate store on the cell level, complete the following steps:

1. Click **Security** > **Web services**.
2. Under additional properties, click **Collection certificate store**.
3. Click the name of a configured collection certificate store or create a new collection certificate store first.
4. Under Additional properties, click **Certificate revocation lists** > **New** to specify the path to a new list or click the name of a certificate revocation list to modify its path.

To view the administrative console panel for the collection certificate store on the server level, complete the following steps:

1. Click **Servers** > **Application servers** > *server_name*.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
5. Under Additional properties, click **Certificate revocation lists** > **New** to specify the path to a new list or click the name of a certificate revocation list to modify its path.

To view this administrative console page for the collection certificate store on the application level, complete the following steps:

1. Click **Applications** > **Enterprise applications** > *application_name*.
2. Click **Manage modules** > *URI_name*.
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:

- For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom > Collection certificate store**.
 - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom > Collection certificate store**.
 - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom > Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
 5. Under Additional properties, click **Certificate revocation lists > New** to specify the path to a new list or click the name of a certificate revocation list to modify its path.

Certificate revocation list path:

Specifies a fully qualified path to the location where you can find the list of certificates that are not valid.

For portability reasons, it is recommended that you use application server variables to specify a relative path to the certificate revocation list. This recommendation is especially important when you are working in a WebSphere Application Server Network Deployment environment. For example, you might use the *USER_INSTALL_ROOT* variable to define a path such as *\$USER_INSTALL_ROOT/mycertstore/mycrl* where *mycertstore* represents the name of your certificate store and *mycrl* represents the certificate revocation list. For a list of the supported variables, click **Environment > WebSphere variables** in the administrative console.

The following list provides recommendations for using CRLs:

- If CRLs are added to the collection certificate store collection, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.
- When the CRL file is updated, the new CRL does not take effect until you restart the Web service application.
- Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.

Username token element

You can use the UsernameToken element to propagate a user name and, optionally, password information. Also, you can use this token type to carry basic authentication information. Both a user name and a password are used to authenticate the message. A UsernameToken containing the user name is used in identity assertion, which establishes the identity of the user based on the trust relationship.

The following example shows the syntax of the UsernameToken element:

```
<wsse:UsernameToken wsu:Id="Example-1">
  <wsse:Username>
    ...
  </wsse:Username>
  <wsse:Password Type="...">
    ...
  </wsse:Password>
  <wsse:Nonce EncodingType="...">
    ...
  </wsse:Nonce>
```

```

    <wsu:Created>
    ...
  </wsu:Created>
</wsse:UsernameToken>

```

The Web services security specification defines the following password types:

wsse:PasswordText (default)

This type is the actual password for the user name.

wsse:PasswordDigest

The type is the digest of the password for the user name. The value is a base64-encoded SHA1 hash value of the UTF8-encoded password.

WebSphere Application Server supports the default PasswordText type. However, it does not support password digest because most user registry security policies do not expose the password to the application software.

The following example illustrates the use of the <UsernameToken> element:

```

<S:Envelope
  xmlns:S="http://schemas.xmlsoap.org/soap/envelope/"
  xmlns:wsse="http://docs.oasis-open.org
/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd">
  <S:Header>
    ...
    <wsse:Security>
      <wsse:UsernameToken>
        <wsse:Username>Joe</wsse:Username>
        <wsse:Password>ILoveJava</wsse:Password>
      </wsse:UsernameToken>
    </wsse:Security>
  </S:Header>
</S:Envelope>

```

Nonce, a randomly generated token

Nonce is a randomly generated, cryptographic token that is used to prevent replay attacks. Although Nonce can be inserted anywhere in the SOAP message, it is typically inserted in the <UsernameToken> element.

Without nonce, when a user name token is passed from one machine to another machine using a nonsecure transport, such as HTTP, the token might be intercepted and used in a replay attack. The same password might be reused when the user name token is transmitted between the client and the server, which leaves it vulnerable to attack. The user name token can be stolen even if you use XML digital signature and XML encryption.

To help eliminate these replay attacks, the <wsse:Nonce> and <wsu:Created> elements are generated within the <wsse:UsernameToken> element and used to validate the message. The server checks the freshness of the message by verifying that the difference between the nonce creation time, which is specified by the <wsu:Created> element, and the current time falls within a specified time period. Also, the server checks a cache of used nonces to verify that the user name token in the received SOAP message has not been processed within the specified time period. These two features are used to lessen the chance that a user name token is used for a replay attack.

To add nonce for the user name token, you can specify it in the token generator for the user name token. When the token generator for the user name token is specified, you can select the **Add nonce** option if you want to include nonce in the user name token.

Custom security token propagation

Web services security has the ability to send security tokens in the security header of a SOAP message. These security tokens can be used to sign, verify, encrypt or decrypt message parts. They can also be sent as stand-alone security tokens and set as the caller on the request consumer. *Custom security token propagation* is a feature that is used to propagate these custom security tokens using Web services security.

Web services security supports the Username, X.509 and Lightweight Third-Party Authentication (LTPA) security token types. When you use security token propagation, the propagation token is sent in the `wsse:BinarySecurityToken` element in the security header of the SOAP message. Web services security uses the same propagation token format as used by the Security attribute propagation feature.

Configuring this option is similar to the configuration for sending and receiving LTPA tokens. The same token generator and token consumer implementations are used, for example:

- `com.ibm.wsspi.wssecurity.token.LTPATokenGenerator`
- `com.ibm.wsspi.wssecurity.token.LTPATokenConsumer`

But, the token type Uniform Resource Identifier (URI) and local name for the token generator and token consumer are different. For custom token properties, use the following values:

- **Token type URI:** `http://www.ibm.com/websphere/appserver/tokentype`
- **Token type local name:** `LTPA_PROPAGATION`

By default, the custom token propagation uses the following JAAS login configuration entries:

- **Inbound:** `WSS_INBOUND`
- **Outbound:** `WSS_OUTBOUND`

You can use the `com.ibm.ws.webservices.wssecurity.constants.jaasConfig` custom property to specify a different JAAS login configuration for the generator. You can do this configuration on the CallbackHandler configuration panel. To specify a different JAAS login configuration on the consumer side, use the JAAS configuration name field in the Token consumer panel.

rrdSecurity.props file

Remote request dispatcher (RRD) supports LTPA and security attribute propagation for Web services security (WS-Security). You can enable token propagation in the `was_install/profiles/profileName/properties/rrdSecurity.props` file.

The `rrdSecurity.props` file contains comments to describe the security attributes.

The following is the format of the `rrdSecurity.props` file. The default values are in bold face type.

- `LTPAPropagation= (True | False)`
- `SecurityAttributePropagation= (True | False)`
- `SSLRequired= (True | False)`

The WS-Security runtime inspects the run as (invocation) subject and propagates the security tokens in the subject. The default setting is to only propagate the LTPA tokens.

Custom security tokens can be passed as attributes of the LTPA tokens. The security attribute propagation support uses the same pluggable JAAS login module as the CS1v2 support. The security attribute is not signed or encrypted, therefore, you should not send the attribute in clear text form. You must require SSL to ensure integrity and confidentiality. If SSL is not required, RRD uses the same scheme, such as HTTP or HTTPS, to make the Web services call that the original request used. See Custom security token propagation for more information.

You must also configure the target Web service to validate the LTPA tokens and security attributes.

These links are provided for convenience. Often, the information is not specific to an IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Configuring the token generator on the application level

This task describes the steps that are needed to specify the token generators at the application level. The information is used on the generator side to generate the security token.

Complete the following steps to configure the token generator on the application level:

1. Locate the token generator panel in the administrative console.
 - a. Click **Applications > Enterprise applications > *application_name***.
 - b. Under Manage modules, click *URI_name*.
 - c. Under Web Services Security Properties you can access the token generators for the following bindings:
 - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 - d. Under Additional properties, click **Token generators**.
 - e. Click **New** to create a token generator configuration, select the box next to an existing configuration and click **Delete** to delete an existing configuration, or click the name of an existing token generator configuration to edit its settings. If you are creating a new configuration, enter a unique name in the Token generator name field. For example, you might specify *gen_sigtgen*.
2. Specify a class name in the Token generator class name field. The token generator class must implement the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface. The token generator class name for the request generator and the response generator must be similar to the token consumer class name for the request consumer and the response consumer. For example, if your application requires a username token consumer, you can specify the `com.ibm.wsspi.wssecurity.token.UsernameTokenConsumer` class name on the token consumer panel for the application level and the `com.ibm.wsspi.wssecurity.token.UsernameTokenGenerator` class name in this field.
3. **Optional:** Select a part reference in the Part reference field. The part reference indicates the name of the security token that is defined in the deployment descriptor.

Important: On the application level, if you do not specify a security token in your deployment descriptor, the Part reference field is not displayed. If you define a security token called `user_tgen` in your deployment descriptor, `user_tgen` is displayed as an option in the Part reference field. You can specify a security token in the deployment descriptor when you assemble your application using an assembly tool.

4. Select either **None** or **Dedicated signing information** for the certificate path. Select **None** when the token generator does not use the PKCS#7 token type. When the token generator uses the PKCS#7 token type and you want to package certificate revocation lists (CRLs) in the security token, select **Dedicated signing information** and select a certificate store. To configure a collection certificate store and certificate revocation lists for the generator bindings on the application level, complete the following steps:
 - a. Click **Applications > Enterprise applications > *application_name***.
 - b. Under Related Items, click **EJB Modules** or **Web Modules > *URI_name***.
 - c. Under Additional Properties you can access the collection certificate store configuration for the following bindings:

- For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
- For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.

d. Under Additional properties, click **Collection certificate store**.

For more information about configuring a collection certificate store, see “Configuring the collection certificate store for the generator binding on the application level” on page 1113.

5. **Optional:** Select the **Add nonce** option. This option indicates whether a nonce is included in the user name token for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The **Add nonce** option is valid only when the generated token type is a user name token and is available only for the request generator binding.

If you select the **Add nonce** option, you can specify the following properties under Additional properties. These properties are used by the request consumer.

Table 49. Additional nonce properties

Property name	Default value	Explanation
com.ibm.ws.wssecurity.config.token.BasicAuth.Nonce.cacheTimeout	600 seconds	Specifies the timeout value, in seconds, for the nonce value that is cached on the server.
com.ibm.ws.wssecurity.config.token.BasicAuth.Nonce.clockSkew	0 seconds	Specifies the time, in seconds, before the nonce time stamp expires.
com.ibm.ws.wssecurity.config.token.BasicAuth.Nonce.maxAge	300 seconds	Specifies the clock skew value, in seconds, to consider when WebSphere Application Server checks the timeliness of the message.

On the cell and server levels, you can specify these additional properties for a nonce on the Default bindings for Web services security panel within the administrative console.

- For the cell level, click **Security > Web services**.
 - For the server level, click **Servers > Application servers > server_name**. Under Security, click **Web services: Default bindings for Web services security**.
6. **Optional:** Select the **Add timestamp** option. This option indicates whether to insert a time stamp into the user name token. The **Add timestamp** option is valid only when the generated token type is a user name token and is available only for the request generator binding.
 7. Specify the value type local name in the Local name field. For a user name token and an X.509 certificate security token, WebSphere Application Server provides predefined local names for the value type. When you specify any of the following local names, you do not need to specify a value type URI:

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken>

This local name specifies a user name token.

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509>

This local name specifies an X.509 certificate token.

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1>

This local name specifies X.509 certificates in a public key infrastructure (PKI) path.

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7>

This local name specifies a list of X.509 certificates and certificate revocation lists in a PKCS#7 format.

For an LTPA token, you can use LTPA for the value type local name and <http://www.ibm.com/websphere/appserver/tokentype/5.0.2> for the value type Uniform Resource Identifier (URI). For

LTPA token propagation, you can use `LTPA_PROPAGATION` for the value type local name and `http://www.ibm.com/websphere/appserver/tokentype` for the value type URI.

8. **Optional:** Specify the value type URI in the URI field. This entry specifies the namespace URI of the value type for the generated token.
9. Click **OK** and **Save** to save the configuration.
10. Click the name of your token generator configuration.
11. Under Additional properties, click **Callback handler**.
12. Specify the settings for the callback handler.
 - a. Specify a class name in the Callback handler class name field. This class name is the name of the callback handler implementation class that is used to plug-in a security token framework. The specified callback handler class must implement the `javax.security.auth.callback.CallbackHandler` interface and must provide a constructor using the following syntax:

```
MyCallbackHandler(String username, char[] password, java.util.Map properties)
```

Where:

username

Specifies the user name that is passed into the configuration.

password

Specifies the password that is passed into the configuration.

properties

Specifies the other configuration properties that are passed into the configuration.

This constructor is required if the callback handler needs a user name and a password. However, if the callback handler does not need a user name and a password, such as `X509CallbackHandler`, use a constructor with the following syntax:

```
MyCallbackHandler(java.util.Map properties)
```

WebSphere Application Server provides the following default callback handler implementations:

com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler

This callback handler uses a login prompt to gather the user name and password information. However, if you specify the user name and password on this panel, a prompt is not displayed and WebSphere Application Server returns the user name and password to the token generator. Use this implementation for a Java 2 Platform, Enterprise Edition (J2EE) application client only. If you use this implementation, you must provide a basic authentication user ID and password on this panel.

com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

This callback handler does not issue a prompt and returns the user name and password if it is specified on this panel. You can use this callback handler when the Web service is acting as a client. If you use this implementation, you must provide a basic authentication user ID and password on this panel.

com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler

This callback handler uses a standard-in prompt to gather the user name and password. However, if the user name and password is specified on this panel, WebSphere Application Server does not issue a prompt, but returns the user name and password to the token generator. Use this implementation for a Java 2 Platform, Enterprise Edition (J2EE) application client only. If you use this implementation, you must provide a basic authentication user ID and password on this panel.

com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler

This callback handler is used to obtain the Lightweight Third Party Authentication (LTPA) security token from the Run As invocation Subject. This token is inserted in the Web services security header within the SOAP message as a binary security token. However, if the user name and password are specified on this panel, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token rather than

obtaining it from the Run As Subject. Use this callback handler only when the Web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a J2EE application client. If you use this implementation, you must provide a basic authentication user ID and password on this panel.

com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler

This callback handler is used to create the X.509 certificate that is inserted in the Web services security header within the SOAP message as a binary security token. A keystore and a key definition is required for this callback handler. If you use this implementation, you must provide a key store password, path, and type on this panel.

com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler

This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web services security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You can specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format. If you use this implementation, you must provide a key store password, path, and type on this panel.

com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler

This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web services security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used. If you use this implementation, you must provide a key store password, path, and type on this panel.

The callback handler implementation obtains the required security token and passes it to the token generator. The token generator inserts the security token in the Web services security header within the SOAP message. Also, the token generator is a plug-in point for the pluggable security token framework. Service providers can provide their own implementation, but the implementation must use the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface.

- b. **Optional:** Select the **Use identity assertion** option. Select this option if you have identity assertion defined in the IBM extended deployment descriptor. This option indicates that only the identity of the initial sender is required and inserted into the Web services security header within the SOAP message. For example, WebSphere Application Server sends only the user name of the original caller for a username token generator. For an X.509 token generator, the application server sends the original signer certification only.
- c. **Optional:** Select the **Use RunAs identity** option. Select this option if you have identity assertion defined in the IBM extended deployment descriptor and you want to use the Run As identity instead of the initial caller identity for identity assertion in a downstream call. This option is valid only if you have Username TokenGenerator configured as a token generator.
- d. **Optional:** Specify the basic authentication user ID in the Basic authentication user ID field. This entry specifies the user name that is passed to the constructors of the callback handler implementation. The basic authentication user name and password are used if you specified one of the following default callback handler implementations in the Callback handler class name field:
 - `com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler`
 - `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`
 - `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`
 - `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`
- e. **Optional:** Specify the basic authentication password in the Basic authentication password field. This entry specifies the password that is passed to the constructors of the callback handler implementation.

- f. **Optional:** Specify the key store password in the Key store password field. This entry specifies the password used to access the key store file. The key store and its configuration are used if you select one of the following default callback handler implementations that are provided by WebSphere Application Server:

com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler

The keystore is used to build the X.509 certificate with the certificate path.

com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler

The keystore is used to build the X.509 certificate with the certificate path.

com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler

The keystore is used to retrieve the X.509 certificate.

- g. **Optional:** Specify the key store path in the Path field. It is recommended that you use the `${USER_INSTALL_ROOT}` in the path name as this variable expands to the WebSphere Application Server path on your machine. To change the path used by this variable, click **Environment > WebSphere variables**, and click **USER_INSTALL_ROOT**. This field is required when you use the `com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler`, `com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler`, or `com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler` callback handler implementations.
- h. **Optional:** Select the key store type in the Type field. This selection indicates the format used by the keystore file. You can select one of the following values for this field:

JKS Use this option if the keystore uses the Java Keystore (JKS) format.

JCEKS

Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in WebSphere Application Server. This option provides stronger protection for stored private keys by using Triple DES encryption.

JCERACFKS

Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

PKCS11KS (PKCS11)

Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)

Use this option if your keystore uses the PKCS#12 file format.

13. Click **OK** and then click **Save** to save the configuration.
14. Click the name of your token generator configuration.
15. Under Additional properties, click **Callback handler > Keys**.
16. Specify the key name, key alias, and the key password.
 - a. Click **New** to create a key configuration, click **Delete** to delete an existing configuration, or click the name of an existing key configuration to edit its settings. If you are creating a new configuration, enter a unique name in the key name field. For digital signatures, the key name is used by the request generator or response generator signing information to determine which key is used to digitally sign the message. For encryption, the key name is used to determine the key used for encryption. The key name must be a fully qualified, distinguished name. For example, `CN=Bob,O=IBM,C=US`.
 - b. Specify the key alias in the Key alias field. The key alias is used by the key locator to find the key within the keystore file.
 - c. Specify the key password in the Key password field. This password is needed to access the key object within the keystore file.
17. Click **OK** and **Save** to save the configuration.

You have configured the token generator for the application level.

You must specify a similar token consumer configuration for the application level.

Request generator (sender) binding configuration settings

Use this page to specify the binding configuration for the request generator.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules**.
3. Click the Uniform Resource Identifier (URI).
4. Under Web Services Security Properties, click **Web services: Client security bindings**.
5. Under Request generator (sender) binding, click **Edit custom**.

The security constraints or bindings are defined using the application assembly process before the application is installed.

If the security constraints are defined in the application, you must either define the corresponding binding information or select the Use defaults option on this panel and use the default binding information for the cell or server level. The default binding provided by this product is a sample. Do not use this sample in a production environment without modifying the configuration. The security constraints define what is signed or encrypted in the Web services security message. The bindings define how to enforce the requirements.

Digital signature security constraint (integrity)

The following table shows the required and optional binding information when the digital signature security constraint (integrity) is defined in the deployment descriptor.

Information type	Required or optional
Signing information	Required
Key information	Required
Key locators	Optional
Collection certificate store	Optional
Token generator	Optional
Properties	Optional

You can use the key locators and the collection certificate store that are defined at either the server-level or the cell-level.

Encryption constraint (confidentiality)

The following table shows the required and optional binding information when the encryption constraint (confidentiality) is defined in the deployment descriptor.

Information type	Required or optional
Encryption information	Required
Key information	Required
Key locators	Optional
Collection certificate store	Optional
Token generator	Optional
Properties	Optional

You can use the key locators and the collection certificate store that are defined at either the server-level or the cell-level.

Security token constraint

The following table shows the required and optional binding information when the security token constraint is defined in the deployment descriptor.

Information type	Required or optional
Token generator	Required
Collection certificate store	Optional
Properties	Optional

You can use the collection certificate store that is defined at either the server-level or the cell-level.

Use defaults:

Select this option if you want to use the default binding information from the server or cell level.

If you select this option, the application server checks for binding information on the server level. If the binding information does not exist on the server level, the application server checks the cell level.

Component:

Specifies the enterprise bean in an assembled EJB module.

Port:

Specifies the port in the Web service that is defined during application assembly.

Web service:

Specifies the name of the Web service that is defined during application assembly.

Response generator (sender) binding configuration settings

Use this page to specify the binding configuration for the response generator or response sender.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules**.
3. Click the Uniform Resource Identifier (URI).
4. Under Web Services Security Properties, click **Web services: Server security bindings**.
5. Under Response generator (sender) binding, click **Edit custom**.

The security constraints or bindings are defined using the application assembly process before the application is installed.

If the security constraints are defined in the application, you must either define the corresponding binding information or select the Use defaults option on this panel and use the default binding information for the server or cell level. The default binding that is provided by this product is a sample. Do not use this sample in a production environment without modifying the configuration. The security constraints define what is signed or encrypted in the Web services security message. The bindings define how to enforce the requirements.

Digital signature security constraint (integrity)

The following table shows the required and optional binding information when the digital signature security constraint (integrity) is defined in the deployment descriptor.

Information type	Required or optional
Signing information	Required
Key information	Required
Key locators	Optional
Collection certificate store	Optional
Token generator	Optional
Properties	Optional

You can use the key locators and the collection certificate store that are defined at either the server-level or the cell-level.

Encryption constraint (confidentiality)

The following table shows the required and optional binding information when the encryption constraint (confidentiality) is defined in the deployment descriptor.

Information type	Required or optional
Encryption information	Required
Key information	Required
Key locators	Optional
Collection certificate store	Optional
Token generator	Optional
Properties	Optional

You can use the key locators and the collection certificate store that are defined at either the server-level or the cell-level.

Security token constraint

The following table shows the required and optional binding information when the security token constraint is defined in the deployment descriptor.

Information type	Required or optional
Token generator	Required
Collection certificate store	Optional
Properties	Optional

You can use the collection certificate store that is defined at either the server-level or the cell-level.

Use defaults:

Select this option if you want to use the default binding information from the server or cell level.

If you select this option, the application server checks for binding information on the server level. If the binding information does not exist on the server level, the application server checks the cell level.

Port:

Specifies the port number in the Web service that is defined during application assembly.

Web service:

Specifies the name of the Web service that is defined during application assembly.

Callback handler configuration settings

Use this page to specify how to acquire the security token that is inserted in the Web services security header within the Simple Object Access Protocol (SOAP) message. The token acquisition is a pluggable framework that leverages the Java Authentication and Authorization Service (JAAS) `javax.security.auth.callback.CallbackHandler` interface for acquiring the security token.

To view this administrative console page for the callback handler on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Default generator bindings, click **Token generators > *token_generator_name***.
3. Under Additional properties, click **Callback handler**.

To view this administrative console page for the callback handler on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings, click **Token generators > *token_generator_name***.
4. Under Additional properties, click **Callback handler**.

To view this administrative console page for the callback handler on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Additional properties, you can access the callback handler information for the following bindings:
 - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**. Under Additional properties, click **Token generator**. Click **New** to create a new token generator configuration or click the name of an existing configuration to modify its settings. Under Additional properties, click **Callback handler**.
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. Under Additional properties, click **Token generator**. Click **New** to create a new token generator configuration or click the name of an existing configuration to modify its settings. Under Additional properties, click **Callback handler**.

Callback handler class name:

Specifies the name of the callback handler implementation class that is used to plug in a security token framework.

The specified callback handler class must implement the `javax.security.auth.callback.CallbackHandler` class. The implementation of the JAAS `javax.security.auth.callback.CallbackHandler` interface must provide a constructor using the following syntax:

```
MyCallbackHandler(String username, char[] password, java.util.Map properties)
```

Where:

username

Specifies the user name that is passed into the configuration.

password

Specifies the password that is passed into the configuration.

properties

Specifies the other configuration properties that are passed into the configuration.

The application server provides the following default callback handler implementations:

Version 5.x or 6 application**com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler**

This callback handler uses a login prompt to gather user name and password information.

However, if you specify the user name and password on this panel, a prompt is not displayed and the application server returns the user name and password to the token generator if it is specified on this panel. Use this implementation for a Java 2 Platform, Enterprise Edition (J2EE) application client only.

Version 5.x or 6 application**com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler**

This callback handler does not issue a prompt and returns the user name and password if it is specified on this panel. You can use this callback handler when the Web service is acting as a client.

Version 5.x or 6 application**com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler**

This callback handler uses a standard-in prompt to gather the user name and password. However, if the user name and password is specified on this panel, the application server does not issue a prompt, but returns the user name and password to the token generator. Use this implementation for a Java 2 Platform, Enterprise Edition (J2EE) application client only.

Version 5.x or 6 application**com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler**

This callback handler is used to obtain the Lightweight Third Party Authentication (LTPA) security token from the Run As invocation Subject. This token is inserted in the Web services security header within the SOAP message as a binary security token. However, if the user name and password are specified on this panel, the application server authenticates the user name and password to obtain the LTPA security token rather than obtaining it from the Run As Subject. Use this callback handler only when the Web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a J2EE application client.

Version 6 and later applications**com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler**

This callback handler is used to create the X.509 certificate that is inserted in the Web services security header within the SOAP message as a binary security token. A keystore and a key definition is required for this callback handler.

Version 6 and later applications**com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler**

This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web services security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You must specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format.

Version 6 and later applications

com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler

This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web services security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used.

The callback handler implementation obtains the required security token and passes it to the token generator. The token generator inserts the security token in the Web services security header within the SOAP message. Also, the token generator is the plug-in point for the pluggable security token framework. Service providers can provide their own implementation, but the implementation must use the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface.

Use identity assertion:

Select this option if you have identity assertion defined in the IBM extended deployment descriptor.

This option indicates that only the identity of the initial sender is required and inserted into the Web services security header within the SOAP message. For example, the application server sends only the user name of the original caller for a Username TokenGenerator. For an X.509 token generator, the application server sends the original signer certification only.

Use RunAs identity:

Select this option if you have identity assertion defined in the IBM extended deployment descriptor and you want to use the Run As identity instead of the initial caller identity for identity assertion for a downstream call.

This option is valid only if you have Username TokenGenerator configured as a token generator.

Basic authentication user ID:

Specifies the user name that is passed to the constructors of the callback handler implementation.

The basic authentication user name and password are used if you select one of the following default callback handler implementations provided by this product:

- `com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler`
- `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`
- `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`
- `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`

These implementations are described in detail under the **Callback handler class name** field description in this article.

Basic authentication password:

Specifies the password that is passed to the constructor of the callback handler.

The keystore and its related configuration are used if you select one of the following default callback handler implementations provided by this product:

com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler

The keystore is used to build the X.509 certificate with the certificate path.

com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler

The keystore is used to build the X.509 certificate with the certificate path.

com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler

The keystore is used to retrieve the X.509 certificate.

Key store configuration name:

Specifies the name of the key store configuration defined in the keystore settings in secure communications.

Key store password:

Specifies the password that is used to access the keystore file.

Key store path:

Specifies the location of the keystore file.

Use `${USER_INSTALL_ROOT}` in the path name because this variable expands to the product path on your machine. To change the path used by this variable, click **Environment > WebSphere variables** and click **USER_INSTALL_ROOT**.

Key store type:

Specifies the type of keystore file format

Choose one of the following values for this field:

JKS Use this option if the keystore uses the Java Keystore (JKS) format.

JCEKS

Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in the application server. This option provides stronger protection for stored private keys by using Triple DES encryption.

JCERACFKS

Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

PKCS11KS (PKCS11)

Use this option if your keystore file uses the PKCS#11 file format. Keystore files that use this format might contain Rivest Shamir Adleman (RSA) keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)

Use this option if your keystore file uses the PKCS#12 file format.

Key collection

Use this page to view a list of logical names that is mapped to a key alias in the keystore file.

To view this administrative console panel for the key collection on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Default generator bindings, click **Token Generators > token_generator_name**.
3. Under Additional properties, click **Callback handler > Keys**.

Keys are also available by clicking **Key locators > key_locator_name**. Under Additional properties, click **Keys**.

To view this administrative console page for the key locator collection on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings, click **Token Generators > *token_generator_name***.
4. Under Additional properties, click **Callback handler > Keys**.

Keys are also available by clicking **Key locators > *key_locator_name***. Under Additional properties, click **Keys**.

To use this administrative console page for the key locator collection on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Services Security Properties, you can access key locators for the following bindings:
 - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom > Key locators**. Under Additional properties, click **Keys**.
 - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom > Key locators**. Under Additional properties, click **Keys**.
 - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom > Key locators**. Under Additional properties, click **Keys**.
 - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom > Key locators**. Under Additional properties, click **Keys**.

4. **Version 5.x application** Under Additional properties, you can access key locators for the following bindings:
 - For the Request sender, click **Web services: Client security bindings**. Under Request sender binding, click **Edit > Key locators**. Under Additional properties, click **Keys**.
 - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit > Key locators**. Under Additional properties, click **Keys**.
 - For the Response sender, click **Web services: Server security bindings**. Under Response sender binding, click **Edit > Key locators**. Under Additional properties, click **Keys**.
 - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit > Key locators**. Under Additional properties, click **Keys**.

Key name:

Specifies the name of the key object that is found in the keystore file.

Key alias:

Specifies an alias for the key object.

The alias is used when the key locator searches for the key objects in the keystore file.

Key configuration settings

Use this page to define the mapping of a logical name to a key alias in a keystore file.

To view this administrative console panel for the key collection on the cell level, complete the following steps:

1. Click **Security > Web services**
2. Under Default generator bindings, click **Token Generators > *token_generator_name***.
3. Under Additional properties, click **Callback handler > Keys**.
4. Specify a new key configuration by clicking **New** or by clicking the key configuration name to modify the settings.

Keys are also available by clicking **Key locators > *key_locator_name***. Under Additional properties, click **Keys > New**.

To view this administrative console page for the key locator collection on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings, click **Token Generators > *token_generator_name***.
4. Under Additional properties, click **Callback handler > Keys**.
5. Specify a new key configuration by clicking **New** or by clicking the key configuration name to modify the settings.

Keys are also available by clicking **Key locators > *key_locator_name***. Under Additional properties, click **Keys > New**.

To use this administrative console page for the key locator collection on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.

3. **Version 6 and later applications** Under Additional properties, you can access key locators for the following bindings:

- For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom > Key locators**. Under Additional properties, click **Keys**.
- For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom > Key locators**. Under Additional properties, click **Keys**.
- For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom > Key locators**. Under Additional properties, click **Keys**.
- For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom > Key locators**. Under Additional properties, click **Keys**.

4. Under Web Services Security Properties, you can access key locators for the following bindings:
 - For the Request sender, click **Web services: Client security bindings**. Under Request sender binding, click **Edit > Key locators**. Under Additional properties, click **Keys**.
 - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit > Key locators**. Under Additional properties, click **Keys**.
 - For the Response sender, click **Web services: Server security bindings**. Under Response sender binding, click **Edit > Key locators**. Under Additional properties, click **Keys**.
 - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit > Key locators**. Under Additional properties, click **Keys**.

5. Specify a new key configuration by clicking **New** or by clicking the key configuration name to modify the settings.

Key name:

Specifies the name of the key object. For digital signatures, the key name is used by the request sender or request generator signing information to determine which key is used to digitally sign the message. For encryption, the key name is used to determine the key used for encryption.

The key name must be a fully qualified, distinguished name. For example, CN:Bob,O=IBM,C=US.

Note: If you enter the distinguished name with spaces before or after commas and equal symbols, the application server normalizes the distinguished names automatically during run time by removing these extra spaces.

Key alias:

Specifies the alias for the key object, which is used by the key locator to find the key within the keystore file.

Key password:

Specifies the password that is needed to access the key object within the keystore file.

Web services: Client security bindings collection

Use this page to view a list of application-level, client-side binding configurations for Web services security. These bindings are used when a Web service is a client to another Web service.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > application_name**.
2. Click **Manage modules > URI_file_name**.
3. Under Web Services Security Properties, click **Web services: Client security bindings**.

Component:

Specifies the enterprise bean in an assembled Enterprise JavaBeans (EJB) module.

Port:

Specifies the port that is used to send messages to a server and receive messages from a server.

Web service:

Specifies the name of the Web service that is defined during application assembly.

Request generator (sender) binding:

Specifies the binding configuration that is used to send request messages to the request consumer.

Click **Edit custom** to configure the required and additional properties such as signing information, key information, token generators, key locators, and collection certificate stores.

The binding information for the request generator that is specified for the client must match the binding information for the request consumer that is specified for the server.

Response consumer (receiver) binding:

Specifies the binding configuration that is used to receive response messages from the response generator.

Click **Edit custom** to configure the required and additional properties such as signing information, key information, token consumers, key locators, collection certificate stores, and trust anchors.

The binding information for the response consumer that is specified for the client must match the binding information for the response generator that is specified for the server.

Request sender binding:

Specifies the binding configuration that is used to send request messages to the request receiver.

Click **Edit** to configure the additional properties for the request sender such as signing information, key information, encryption information, key locators, and the login binding.

The binding information for the request sender that is specified for the client must match the binding information for the request receiver that is specified for the server.

Response receiver binding:

Specifies the binding configuration that is used to receive response messages from the response sender.

Click **Edit** to configure the additional properties for the response receiver such as signing information, encryption information, trust anchors, collection certificate stores, and key locators.

The binding information for the response receiver that is specified for the client must match the binding information for the response sender that is specified for the server.

HTTP basic authentication:

Specifies the user name and password to use for this port with HTTP transport-level basic authentication. You can enable transport-level authentication security independently of message-level security.

Click **Edit** to configure the basic authentication ID and password for transport-level authentication.

HTTP SSL configuration:

Enables and configures transport-level Secure Sockets Layer (SSL) security for this port. You can enable transport-level SSL security independently of message-level security.

Click **Edit** to specify the settings for transport-level HTTP SSL configuration for this port.

Web services: Server security bindings collection

Use this page to view a list of server-side binding configurations for Web services security.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_file_name***.
3. Under Web Services Security Properties, click **Web services: Server security bindings**.

Port:

Specifies the port in which messages are received from the request generator or the request sender. The request generator is the term that is used for Version 6.x applications and the request sender is the term that is used for Version 5.x applications.

Web service:

Specifies the name of the Web service that is defined during application assembly.

Request consumer (receiver) binding:

Specifies the binding configuration that is used to receive request messages from the request generator (sender) binding.

Click **Edit custom** to configure the required and additional information such as signing information, key information, token consumers, key locators, intermediate certificates in the collection certificate store, and trust anchors.

The binding information for the request consumer that is specified for the server must match the binding information for the request generator that is specified for the client.

Response generator (sender) binding:

Specifies the binding configuration that is used to send request messages to the response consumer.

Click **Edit custom** to configure the required and additional information such as signing information, key information, token generators, key locators, and intermediate certificates in the collection certificate store.

The binding information for the response generator that is specified for the server must match the binding information for the response consumer that is specified for the client.

Request receiver binding:

Specifies the binding configuration that is used to receive request messages from the request sender binding.

Click **Edit** to configure additional properties for the request receiver such as signing information, encryption information, trust anchors, collection certificate stores, key locators, trusted ID evaluators, and login mappings.

The binding information for the request receiver that is specified for the server must match the binding information for the request sender that is specified for the client.

Response sender binding:

Specifies the binding configuration that is used to send request messages to the response receiver.

Click **Edit** to configure additional properties for the response sender such as signing information, encryption information, and key locators.

The binding information for the response sender that is specified for the server must match the binding information for the response receiver that is specified for the client.

Configuring the key locator for the generator binding on the application level

The key locator information for the default generator specifies which key locator implementation is used to locate the key to be used for signature and encryption information. The key locator information for the generator specifies which key locator implementation is used to locate the key to be used for signature validation or encryption.

WebSphere Application Server provides default values for the bindings. However, you must modify the defaults for a production environment.

Complete the following steps to configure the key locator for the generator binding on the application level:

1. Locate the encryption information configuration panel in the administrative console.
 - a. Click **Applications > Enterprise applications > application_name**.
 - b. Under Manage modules, click *URI_name*.
 - c. Under Web Services Security Properties you can access the key information for the request generator and response generator bindings.
 - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 - d. Under Additional properties, click **Key locators**.
 - e. Click **New** to create a key locator configuration, select the box next to the configuration and click **Delete** to delete an existing configuration, or click the name of an existing key locator configuration to edit its settings. If you are creating a new configuration, enter a unique name in the **Key locator name** field. For example, you might specify *gen_keyLoc*.
2. Specify a class name for the key locator class implementation in the **Key locator class name** field. Key locators associated with Version 6.0.x and later applications must implement the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` interface. Specify a class name according to the requirements of the application. For example, if the application requires that the key is read from a keystore file, specify the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` implementation. WebSphere Application Server supports the following default key locator class implementations for Version 6.0.x and later applications that are available to use with the request generator or response generator:
 - `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator`**
This implementation locates and obtains the key from the specified keystore file.
 - `com.ibm.wsspi.wssecurity.keyinfo.SignerCertKeyLocator`**
This implementation uses the public key from the signer certificate and is used by the response generator.
3. Specify the keystore password, the keystore location, and the keystore type. Keystore files contain public and private keys, root certificate authority (CA) certificates, the intermediate CA certificate, and so on. Keys retrieved from the keystore are used to sign and validate or encrypt and decrypt messages or message parts. If you specified the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` implementation for the key locator class implementation, you must specify a keystore password, location, and type.
 - a. Specify a password in the keystore **Password** field. This password is used to access the keystore file.
 - b. Specify the location of the keystore file in the keystore **Path** field.
 - c. Select a keystore type from the **Type** field. The Java Cryptography Extension (JCE) that is used by IBM supports the following keystore types:

JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

JCEKS

Use this option if you are using Java Cryptography Extensions.

JCERACFKS

Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

PKCS11KS (PKCS11)

Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)

Use this option if your keystore uses the PKCS#12 file format.

WebSphere Application Server provides some sample keystore files in the `${USER_INSTALL_ROOT}/etc/ws-security/samples` directory. For example, you might use the `enc-receiver.jceks` keystore file for encryption keys. The password for this file is `Storepass` and the type is `JCEKS`.

Important: Do not use the sample keystore files in a production environment. These samples are provided for testing purposes only.

4. Click **OK** and then click **Save** to save the configuration.
5. Under Additional properties, click **Keys**.
6. Click **New** to create a key configuration, select the box next to the configuration and click **Delete** to delete an existing configuration, or click the name of an existing key configuration to edit its settings. This entry specifies the name of the key object within the keystore file. If you are creating a new configuration, enter a unique name in the **Key name** field. For digital signatures, the key name is used by the request generator or the response generator signing information to determine which key is used to digitally sign the message.

You must use a fully qualified distinguished name for the key name. For example, you might use `CN=Bob,O=IBM,C=US`.

Important: Do not use the sample key files in a production environment. These samples are provided for testing purposes only.

7. Specify an alias in the **Key alias** field. The key alias is used by the key locator to search for key objects in the keystore.
8. Specify a password in the **Key password** field. The password is used to access the key object within the keystore file.
9. Click **OK** and **Save** to save the configuration.

You have configured the key locator for the generator binding at the application level.

You must specify a similar key information configuration for the consumer.

Key locator collection

Use this page to view a list of key locator configurations that retrieve keys from the keystore for digital signature and encryption. A key locator must implement the `com.ibm.wsspi.wssecurity.config.KeyLocator` interface.

To view the administrative console panel for the key locator collection on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Key locators**.

To view this administrative console page for the key locator collection on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Key locators**.

To use this administrative console page for the key locator collection on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Services Security Properties, you can access key locators for the following bindings:
 - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom > Key locators**.
 - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom > Key locators**.
 - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom > Key locators**.
 - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom > Key locators**.
4. **Version 5.x application** Under Additional properties, you can access key locators for the following bindings:
 - For the Request sender, click **Web services: Client security bindings**. Under Request sender binding, click **Edit > Key locators**.
 - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit > Key locators**.
 - For the Response sender, click **Web services: Server security bindings**. Under Response sender binding, click **Edit > Key locators**.
 - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit > Key locators**.

Tip: The bindings for a version 5.x application has a link that says **Edit** and the bindings for a Version 6.0.x. or later application has a link that says **Edit custom**. This is quick reference to determine which application version you are configuring.

Using this **Key locator collection** panel, complete the following steps:

1. Specify a key locator name and a key locator class name on the panel.
2. Save your changes by clicking **Save** in the messages section at the top of the administrative console. The administrative console home panel is displayed.
3. After saving your changes, update the Web services security run time with the default binding information by clicking **Update runtime**. When you click **Update runtime**, the configuration changes made to the other Web services also are updated in the Web services security run time.
4. After you define key locators, click the key locator name to specify additional properties and keys under **Additional Properties**.

Key locator name:

Specifies the unique name of the key locator.

Key locator class name:

Specifies the class name of the key locator, which retrieves the key that is used for digital signing and encryption.

Key locator configuration settings

Use this page to specify the settings for a key locator configuration. The key locators retrieve keys from the keystore file for digital signature and encryption. This product enables you to plug in a custom key locator configuration.

To view the administrative console panel for the key locator collection on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Key locators**.
3. Click **New** to create a new configuration or click the name of a configuration to modify its settings.

To view this administrative console page for the key locator collection on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Key locators**.
4. Click **New** to create a new configuration or click the name of a configuration to modify its settings.

To use this administrative console page for the key locator collection on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Services Security properties, you can access key locators for the following bindings:
 - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom > Key locators**.
 - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom > Key locators**.
 - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom > Key locators**.
 - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom > Key locators**.
4. **Version 5.x application** Under Additional properties, you can access key locators for the following bindings:
 - For the Request sender, click **Web services: Client security bindings**. Under Request sender binding, click **Edit > Key locators**.
 - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit > Key locators**.
 - For the Response sender, click **Web services: Server security bindings**. Under Response sender binding, click **Edit > Key locators**.
 - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit > Key locators**.
5. Click **New** to create a new configuration or click the name of a configuration to modify its settings.

Key locator name:

Specifies the name of the key locator.

Data type String

Key locator class name:

Specifies the name for the key locator class implementation.

Version 6 and later applications

Key locators that are associated with Version 6 and later applications must implement the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` interface. This product provides the following default key locator class implementations for Version 6 and later applications:

com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator

This implementation locates and obtains the key from the specified keystore file.

com.ibm.wsspi.wssecurity.keyinfo.SignerCertKeyLocator

This implementation uses the public key from the certificate of the signer. This class implementation is used by the response generator.

com.ibm.wsspi.wssecurity.keyinfo.X509TokenKeyLocator

This implementation uses the X.509 security token from the sender message for digital signature validation and encryption. This class implementation is used by the request consumer and the response consumer.

Version 5.x application

Key locators that are associated with Version 5.x applications must implement the `com.ibm.wsspi.wssecurity.config.KeyLocator` interface. This product provides the following default key locator class implementations for Version 5.x applications.

com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator

This implementation maps an authenticated identity to a key and is used by the response sender. If encryption is used, this class is used to locate a key to encrypt the response message. The `com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator` class can map an authenticated identity from the invocation credential of the current thread to a key that is used to encrypt the message. If an authenticated identity is present on the current thread, the class maps the ID to the mapped name. For example, `user1` is mapped to `mappedName_1`. Otherwise, `name="default"`. When a matching key is not found, the authenticated identity is mapped to the default key that is specified in the binding file. This implementation supports the following formats: JKS, JCEKS, and PKCS12.

com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator

This implementation maps a name to an alias and is used by the response receiver, request sender, and request receiver. The encryption process uses this class to obtain a key to encrypt a message, and the digital signature process uses this class to obtain a key to sign a message. The `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator` class maps a logical name to a key alias in the keystore file. For example, key `#105115176771` is mapped to `CN=Alice, O=IBM, c=US`.

com.ibm.wsspi.wssecurity.config.CertInRequestKeyLocator

This implementation uses the signer certificate to encrypt the response. This class implementation is used by the response sender and response receiver.

Data type String

Key store password:

Specifies the password that is used to access the keystore file.

Key store configuration name:

Specifies the name of the key store configuration defined in the keystore settings in secure communications.

Key store path:

Specifies the location of the keystore file.

Key store type:

Specifies the type of keystore file.

JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

JCEKS

Use this option if you are using Java Cryptography Extensions.

JCERACFKS

Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

PKCS11KS (PKCS11)

Use this format if your keystore file uses the PKCS#11 file format. Keystores files that use this format might contain Rivest Shamir Adleman (RSA) keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)

Use this option if your keystore file uses the PKCS#12 file format.

Default

JKS

Range

JKS, JCEKS, PKCS11KS (PKCS11), PKCS12KS (PKCS12)

Web services security property collection

Use this page to view a list of additional properties for the configuration.

You can view a Web services security property collection panel in several ways. Complete the following steps to view one of these administrative console pages:

1. Click **Security > Web services**.
2. Under Default generator bindings or Default consumer bindings, click **Properties**.
3. Click **New** to create a new property.
4. Click **Delete** to delete a property that you specified previously.

Property name:

Specifies the name of the property.

Property value:

Specifies the value for the property.

Web services security property configuration settings

Use this page to configure additional properties.

You can view a Web services security property configuration settings panel in several ways. Complete the following steps to view one of these administrative console pages:

1. Click **Security > Web services**.
2. Under Default generator bindings or Default consumer bindings, click **Properties > New**.

Property Name:

Specifies the name of the property.

Data type: String

Property Value:

Specifies the value for the property.

Data type: String

The following table lists the properties that you can configure using the Web services security property panels.

Configuration panel name	Property name	Property value	Description
JAAS configuration	com.ibm.wsspi.wssecurity.token.X509.issuerName	Specify the SubjectDN or the IssuerDN of the issuer for the X.509 certificate.	This property is used to specify the issuer of the certificate in the token consumer component.
JAAS configuration	com.ibm.wsspi.wssecurity.token.X509.issuerSerial	Specify the serial number of the X.509 certificate.	This property is used to specify the serial number of the certificate in the token consumer component.
Key information	com.ibm.wsspi.wssecurity.keyinfo.EncodingNS	Specify the namespace Uniform Resource Identifier (URI) for the qualified name (QName).	This property is used to specify the namespace URI part of the QName that represents the encoding method.
Request generator and Response generator	com.ibm.wsspi.wssecurity.timestamp.SOAPHeaderElement	Specify 1 or true.	This property is used with the Add nonce option to set the mustUnderstand flag in the deployment descriptor.
Request generator and Response generator	com.ibm.wsspi.wssecurity.timestamp.dialect		
Signing information	com.ibm.wsspi.wssecurity.dsig.dumpPath	Specify the path used to locate the output file.	This property is used to specify an output file for dumping the target UTF-8 binary data before signing and verifying messages.
Token generator	com.ibm.wsspi.wssecurity.token.username.timestampExpires	Specify 1 or true.	This property is used to specify an expiration date for the user name token.
Transform algorithms	com.ibm.wsspi.wssecurity.dsig.XPathExpression	not(ancestor-or-self::*[namespace-uri()='http://www.w3.org/2000/09/xml#sig#' and local-name()='Signature'])	This property is used with this algorithm: http://www.w3.org/TR/1999/REC-xpath-19991116

Configuring the key information for the generator binding on the application level

Before you begin this task, configure the key locators and the token consumers that are referenced by the Key locator reference and Token reference fields within the key information panel.

This task provides the steps needed for configuring the key information for the request generator (client side) and the response generator (server side) bindings at the application level. The key information is

used to specify the configuration needed to generate the key for digital signature and encryption. The signing information and the encryption information configurations can share the key information, which is why they are both defined at the same level.

Complete the following information to configure the key information for the generator binding on the application level:

1. Locate the key information configuration panel in the administrative console.
 - a. Click **Applications > Enterprise applications > application_name**.
 - b. Under Manage modules, click *URI_name*.
 - c. Under Web Services Security Properties you can access the key information for the request generator and response generator bindings.
 - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 - d. Under Required properties, click **Key information**.
 - e. Click **New** to create a key information configuration, select the box next to an existing configuration and click **Delete** to delete the configuration, or click the name of an existing signing information configuration to edit its settings. If you are creating a new configuration, enter a name in the Key information name field. For example, you might specify *gen_signkeyinfo*.
2. Select a key information type from the Key information type field. The key information type specifies how to reference the security tokens. WebSphere Application Server supports the following key information types:

Key identifier

The security token is referenced using an opaque value that uniquely identifies the token. The algorithm that is used for generating the <KeyIdentifier> element value depends upon the token type. For example, a hash of the important elements of the security token is used for generating the <KeyIdentifier> element value. The following <KeyInfo> element is generated in the Simple Object Access Protocol (SOAP) message for this key information type:

```
<ds:KeyInfo xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
  <wsse:SecurityTokenReference>
    <wsse:KeyIdentifier ValueType="wsse:X509v3">/62wX0...</wsse:KeyIdentifier>
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

Key name

The security token is referenced using a name that matches an identity assertion within the token. It is recommended that you do not use this key type as it might result in multiple security tokens that match the specified name. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <ds:KeyName>CN=Group1</ds:KeyName>
</ds:KeyInfo>
```

Security token reference

The security token is directly referenced using Universal Resource Identifiers (URIs). The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <wsse:Reference URI="#mytoken" />
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

Embedded token

The security token is directly embedded within the <SecurityTokenReference> element. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```

<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <wsse:Embedded wsu:Id="tok1" />
    ...
  </wsse:SecurityTokenReference>
</ds:KeyInfo>

```

X509 issuer name and issuer serial

The security token is referenced by an issuer name and an issuer serial number of an X.509 certificate. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```

<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <ds:X509Data>
      <ds:X509IssuerSerial>
        <ds:X509IssuerName>CN=Jones, O=IBM, C=US</ds:X509IssuerName>
        <ds:X509SerialNumber>1040152879</ds:X509SerialNumber>
      </ds:X509IssuerSerial>
    </ds:X509Data>
  </wsse:SecurityTokenReference>
</ds:KeyInfo>

```

Each type of key information is described in the Web Services Security: SOAP Message Security 1.0 (WS-Security 2004) OASIS standard, which is located at: <http://www.oasis-open.org/home/index.php> under Web services security.

3. Select a key locator reference from the Key locator reference field. This reference specifies a key locator that WebSphere Application Server uses to locate the keys that are used for digital signature and encryption. Before you can select a key locator, you must have configured a key locator. For more information on configuring a key locator, see the following articles:
 - “Configuring the key locator for the generator binding on the application level” on page 1142
 - “Configuring the key locator for the consumer binding on the application level” on page 1203
4. Click **Get keys** to view a list of key name references. After you click **Get keys**, the key names that are defined in the sig_klocator element are shown in the key name reference menu. If you change the key locator reference, you must click **Get keys** again to display the list of key names associated with the new key locator.
5. Select a key name reference from the Key name reference field. This reference specifies the name of a key that is used for generating a digital signature and for encryption. The list of key names provided comes from the key locator specified with the key locator reference.
6. Select a token reference from the Token reference field. This token reference specifies the name of token generator that is used for processing the security token. However, WebSphere Application Server requires this field only when you select Security token reference or Embedded token in the Key information type field. Before specifying a token reference, you must configure a token generator. For more information on configuring a token generator, see “Configuring the token generator on the application level” on page 1125.
7. **Optional:** If you select Key identifier as the key information type on this panel, you must specify an encoding method, calculation method, value type namespace URI, and a value type local name.
 - a. Select an encoding method from the Encoding method field. The encoding method specifies the encoding format for the key identifier. WebSphere Application Server supports the following encoding methods:
 - <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#Base64Binary>
 - <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#HexBinary>
 - b. Select a calculation method from the Calculation method field. WebSphere Application Server supports the following calculation methods:
 - <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#ITSHA1>

- <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#IT60SHA1>
- c. Specify a value type namespace Uniform Resource Identifier (URI) in the Namespace URI field. In this field, specify the namespace URI of the value type for a security token that is referenced by the key identifier. When you specify the X.509 certificate token, you do not need to specify this option. If you want to specify another token, you must specify the URI of the qualified name (QName) for value type.
 - d. Specify a value type local name. This name is the local name of the value type for a security token that is referenced by the key identifier. When this local name is used in conjunction with the corresponding namespace URI, the information is called the value type qualified name or QName. When you specify the X.509 certificate token, it is recommended that you use the predefined local names. When you specify the predefined local names, you do not need to specify the namespace URI of the value type. However, if you do not use one of the predefined local names, you must specify both the uniform resource identifier (URI) and the local name. WebSphere Application Server provides the following predefined local names:

X.509 certificate token

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3>

X.509 certificates in a PKIPath

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1>

A list of X509 certificates and CRLs in a PKCS#7

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7>

LTPA Lightweight Third-Party Authentication token. When you specify a value type local name of LTPA, you must also specify a namespace URI of <http://www.ibm.com/websphere/appserver/tokentype/5.0.2>.

LTPA_PROPAGATION

Lightweight Third-Party Authentication propagation token. When you specify a value type local name of LTPA_PROPAGATION, you must also specify a namespace URI of <http://www.ibm.com/websphere/appserver/tokentype>.

8. Click **OK** and then click **Save** to save the configuration.

You have configured the key information for the generator binding at the application level

You must specify a similar key information configuration for the consumer.

Key information collection

Use this page to view the configurations that are currently available for generating or consuming the key for XML digital signatures and XML encryption.

To view this administrative console page on the cell level for the key information references, complete the following steps:

1. Click **Security > Web services**.
2. Under Default generator bindings or the Default consumer bindings, click **Key information**.

To view this administrative console page on the server level for the key information references, complete the following steps:

1. Click **Servers > Application Servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings or the Default consumer bindings, click **Key information**.

To view this administrative console page on the application level for the key information references, complete the following steps.

Note: This option is available on the application level for Version 6 and later applications.

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Services Security Properties, you can access the signing information for the following bindings:
 - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
4. Under Required properties, click **Key information**.

Key information name:

Specifies the name that is given for the key configuration.

Key information class name:

Specifies the class name that is used for the key information type.

Key information type:

Specifies the type of mechanism used to reference the security token. The type corresponds to the class name that is specified in the Key information class name field.

Key information configuration settings

Use this page to specify the related configuration need to specify the key for XML digital signature or XML encryption.

To view this administrative console page on the cell level for the key information references, complete the following steps:

1. Click **Security > Web services**.
2. Under Default generator bindings or the Default consumer bindings, click **Key information**.

To view this administrative console page on the server level for the key information references, complete the following steps:

1. Click **Servers > Application Servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings or the Default consumer bindings, click **Key information**.
4. Click **New** to create a new configuration or click the configuration name to modify its contents.

To view this administrative console page on the application level for the key information references, complete the following steps.

Note: This option is available on the application level for Version 6.0.x applications.

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Related items, click **Manage modules > *URI_name***.
3. Under Additional properties, you can access the signing information for the following bindings:

- For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
4. Under Required properties, click **Key information**.
 5. Click **New** to create a new configuration or click the configuration name to modify its contents.

Before clicking **Properties** under Additional properties, you must enter a value in the **Key information name** field and select an option for the Key information type and Key locator reference options.

Key information name:

Specifies a name for the key information configuration.

Key information type:

Specifies the type of key information. The key information type specifies how to reference security tokens.

This product supports the following types of key information. Each type of key information is described in Web Services Security: SOAP Message Security 1.0 (WS-Security 2004)

Type	Description
Key identifier	The security token is referenced using an opaque value that uniquely identifies the token.
Key name	The security token is referenced using a name that matches an identity assertion within the token.
Security token reference	With this type, the security token is directly referenced.
Embedded token	With this type, the security token reference is embedded.
X509 issuer name and issuer serial	With this type, the security token is referenced by an issuer and serial number of an X.509 certificate

The X.509 issuer name and issuer serial is described in Web Services Security: X.509 Certificate Token Profile Version 1.0. The other types are described in Web Services Security: SOAP Message Security 1.0 (WS-Security 2004).

If you select **Key identifier** for the key information type, you can specify values in the following fields on this panel:

- Encoding method
- Calculation method
- Value type namespace URI
- Value type local name

Key locator reference:

Specifies the reference that is used to retrieve the key for digital signature and encryption.

Before specifying a key locator reference, you must configure a key locator. You can specify a signing key configuration for the following bindings:

Binding name	Cell level, server level, or application level	Path
Default generator binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Additional properties, click Key locators. 3. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.
Default consumer binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Additional properties, click Key locators. 3. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.
Default generator binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Additional properties, click Key locators. 4. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.
Default consumer binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Additional properties, click Key locators. 4. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.
Request sender binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Under Related items, click Manage modules > URI_name. 3. Click Web services: Client security bindings. Under Request sender binding, click Edit. 4. Under Additional properties, click Key locators. 5. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.
Response receiver binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Under Related items, click Manage modules > URI_name. 3. Click Web services: Client security bindings. Under Response receiver binding, click Edit. 4. Under Additional properties, click Key locators. 5. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.

Binding name	Cell level, server level, or application level	Path
Request receiver binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Under Related items, click Manage modules > <i>URI_name</i>. 3. Click Web services: Server security bindings. Under Request receiver binding, click Edit. 4. Under Additional properties, click Key locators. 5. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.
Response sender binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Under Related items, click Manage modules > <i>URI_name</i>. 3. Click Web services: Server security bindings. Under Response sender binding, click Edit. 4. Under Additional properties, click Key locators. 5. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.
Request generator (sender) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Under Related items, click Manage modules > <i>URI_name</i>. 3. Click Web services: Client security bindings. Under Request generator (sender) binding, click Edit. 4. Under Additional properties, click Key locators. 5. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.
Response consumer (receiver) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Under Related items, click Manage modules > <i>URI_name</i>. 3. Click Web services: Client security bindings. Under Response consumer (receiver) binding, click Edit custom. 4. Under Additional properties, click Key locators. 5. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.

Binding name	Cell level, server level, or application level	Path
Request consumer (receiver) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Under Related items, click Manage modules > URI_name. 3. Click Web services: Server security bindings. Under Request consumer (receiver) binding, click Edit custom. 4. Under Additional properties, click Key locators. 5. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.
Response generator (sender) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Under Related items, click Manage modules > URI_name. 3. Click Web services: Server security bindings. Under Response generator (sender) binding, click Edit custom. 4. Under Additional properties, click Key locators. 5. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.

Key name reference:

Specifies the name of the key that is used for generating digital signature and encryption.

This field is displayed for the default generator and is also displayed for the request generator and response generator for Version 6.0.x applications.

Binding name	Cell level, server level, or application level	Path
Default generator binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Additional properties, click Key locators. 3. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.
Default generator binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Additional properties, click Key locators. 4. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.

Binding name	Cell level, server level, or application level	Path
Request generator (sender) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Under Related items, click Manage modules > <i>URI_name</i>. 3. Click Web services: Client security bindings. Under Request generator (sender) binding, click Edit. 4. Under Additional properties, click Key locators. 5. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.
Response generator (sender) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Under Related items, click Manage modules > <i>URI_name</i>. 3. Click Web services: Server security bindings. Under Response generator (sender) binding, click Edit custom. 4. Under Additional properties, click Key locators. 5. Click New to create a new key locator or click the name of a configured key locator to modify its configuration.

Token reference:

Specifies the name of a token generator or token consumer that is used for processing a security token.

The application server requires this field only when you specify Security token reference or Embedded token in the **Key information type** field. The **Token reference** field is also required when you specify a key identifier type for the consumer. Before specifying a token reference, you must configure a token generator or token consumer. You can specify a token configuration for the following bindings on the following levels:

Binding name	Cell level, server level, or application level	Path
Default generator binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Default generator bindings, click Token generators. 3. Click New to create a new token generator or click the name of a configured token generator to modify its configuration.
Default consumer binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Default consumer bindings, click Token consumers. 3. Click New to create a new token generator or click the name of a configured token consumer to modify its configuration.

Binding name	Cell level, server level, or application level	Path
Default generator binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > <i>server_name</i>. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Default generator bindings, click Token generator. 4. Click New to create a new token generator or click the name of a configured token generator to modify its configuration.
Default consumer binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > <i>server_name</i>. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Default consumer bindings, click Token consumer. 4. Click New to create a new token consumer or click the name of a configured token consumer to modify its configuration.
Request generator (sender) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Under Related items, click Manage modules > <i>URI_name</i>. 3. Click Web services: Client security bindings. Under Request generator (sender) binding, click Edit custom. 4. Under Additional properties, click Token generators. 5. Click New to create a new token consumer or click the name of a configured token consumer to modify its configuration.
Response consumer (receiver) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Under Related items, click Manage modules > <i>URI_name</i>. 3. Click Web services: Client security bindings. Under Response consumer (receiver) binding, click Edit custom. 4. Under Required properties, click Token consumers. 5. Click New to create a new token consumer or click the name of a configured token consumer to modify its configuration.

Binding name	Cell level, server level, or application level	Path
Request consumer (receiver) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Under Related items, click Manage modules > <i>URI_name</i>. 3. Click Web services: Server security bindings. Under Request consumer (receiver) binding, click Edit custom. 4. Under Required properties, click Token consumers. 5. Click New to create a new token consumer or click the name of a configured token consumer to modify its configuration.
Response generator (sender) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Under Related items, click Manage modules > <i>URI_name</i>. 3. Click Web services: Server security bindings. Under Response generator (sender) binding, click Edit custom. 4. Under Additional properties, click Token generators. 5. Click New to create a new token consumer or click the name of a configured token consumer to modify its configuration.

Encoding method:

Specifies the encoding method that indicates the encoding format for the key identifier.

This field is valid when you specify Key identifier in the Key information type field. This product supports the following encoding methods:

- <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#Base64Binary>
- <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#HexBinary>

This field is available for the default generator binding only.

Calculation method:

This field is valid when you specify Key identifier in the **Key information type** field. This product supports the following calculation methods:

- <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#ITSHA1>
- <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#IT60SHA1>

This field is available for the generator binding only.

Value type namespace URI:

Specifies the namespace Uniform Resource Identifier (URI) of the value type for a security token that is referenced by the key identifier.

This field is valid when you specify Key identifier in the **Key information type** field. When you specify the X.509 certificate token, you do not need to specify this option. If you want to specify another token, specify the URI of QName for value type.

This product provides the following predefined value type URIs for the Lightweight Third Party Authentication (LTPA) token:

- <http://www.ibm.com/websphere/appserver/tokentype>
- <http://www.ibm.com/websphere/appserver/tokentype/5.0.2>

This field is available for the generator binding only.

Value type local name:

Specifies the local name of the value type for a security token that is referenced by the key identifier.

When this local name is used with the corresponding namespace URI, the information is called the *value type qualified name* or *QName*.

This field is valid when you specify Key identifier in the **Key information type** field. When you specify the X.509 certificate token, it is recommended that you use the predefined local names. When you specify the predefined local names, you do not need to specify the URI of the value type. This product provides the following predefined local names:

X.509 certificate token

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3>

X.509 certificates in a PKIPath

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1>

A list of X509 certificates and CRLs in a PKCS#7

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7>

Lightweight Third Party Authentication (LTPA)

LTPA_PROPAGATION

Attention: For LTPA, the value type local name is LTPA. If you enter LTPA for the local name, you must specify the <http://www.ibm.com/websphere/appserver/tokentype/5.0.2> URI value in the **Value type URI** field as well. For LTPA token propagation, the value type local name is LTPA_PROPAGATION. If you enter LTPA_PROPAGATION for the local name, you must specify the <http://www.ibm.com/websphere/appserver/tokentype> URI value in the **Value type URI** field as well. For the other predefined value types (User name token, X509 certificate token, X509 certificates in a PKIPath, and a list of X509 certificates and CRLs in a PKCS#7), the value for the **Value type local name** field begins with <http://>. For example, if you are specifying the user name token for the value type, enter <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken> in the **Value type local name** field and then you do not need to enter a value in the value type URI field.

When you specify a custom value type for custom tokens, you can specify the local name and the URI of the quality name (QName) of the value type. For example, you might specify Custom for the local name and <http://www.ibm.com/custom> for the URI.

This field is also available for the generator binding only.

Configuring the signing information for the generator binding on the application level

In the server-side extensions file (`ibm-webservices-ext.xmi`) and the client-side deployment descriptor extensions file (`ibm-webservicesclient-ext.xmi`), you must specify which parts of the message are

signed. Also, you must configure the key information that is referenced by the key information references on the signing information panel within the administrative console.

This task explains the required steps to configure the signing information for the client-side request generator and the server-side response generator bindings at the application level. WebSphere Application Server uses the signing information for the default generator to sign parts of the message including the body, time stamp, and user name token. The Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment. Complete the following steps to configure the signing information for the generator sections of the bindings files on the application level:

1. Locate the signing information configuration panel in the administrative console.
 - a. Click **Applications > Enterprise applications > application_name**.
 - b. Under Manage modules, click *URL_name*.
 - c. Under Web Services Security Properties, you can access the signing information for the request generator and the response generator bindings.
 - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 - d. Under Required properties, click **Signing information**.
 - e. Click **New** to create a signing information configuration, select the box next to the configuration and click **Delete** to delete an existing configuration, or click the name of an existing signing information configuration to edit its settings. If you are creating a new configuration, enter a name in the Signing information name field. For example, you might specify *gen_signinfo*.
2. Select a signature method algorithm from the Signature method field. The algorithm that is specified for the generator, which is either the request generator or the response generator configuration, must match the algorithm that is specified for the consumer, which is either the request consumer or response consumer configuration. WebSphere Application Server supports the following pre-configured algorithms:
 - <http://www.w3.org/2000/09/xmldsig#rsa-sha1>
 - <http://www.w3.org/2000/09/xmldsig#hmac-sha1>
 - <http://www.w3.org/2000/09/xmldsig#dsa-sha1>

Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP). Any `ds:SignatureMethod/@Algorithm` element in a SIGNATURE based on a symmetric key must have a value of <http://www.w3.org/2000/09/xmldsig#rsa-sha1> or <http://www.w3.org/2000/09/xmldsig#hmac-sha1>.
3. Select a canonicalization method from the Canonicalization method field. The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer. WebSphere Application Server supports the following pre-configured algorithms:
 - <http://www.w3.org/2001/10/xml-exc-c14n#>
 - <http://www.w3.org/2001/10/xml-exc-c14n#WithComments>
 - <http://www.w3.org/TR/2001/REC-xml-c14n-20010315>
 - <http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments>
4. Select a key information signature type from the Key information signature type field. WebSphere Application Server supports the following signature types:

None Specifies that the KeyInfo element is not signed.

Keyinfo

Specifies that the entire KeyInfo element is signed.

Keyinfochildelements

Specifies that the child elements of the KeyInfo element are signed.

The key information signature type for the generator must match the signature type for the consumer. You might encounter the following situations:

- If you do not specify one of the previous signature types, WebSphere Application Server uses keyinfo, by default.
 - If you select Keyinfo or Keyinfochildelements and you select <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform> as the transform algorithm in a subsequent step, WebSphere Application Server also signs the referenced token.
5. Select a signing key information reference from the Signing key information field. This selection is a reference to the signing key that the Application Server uses to generate digital signatures.
 6. Click **OK** and **Save** to save the configuration.
 7. Click the name of the new signing information configuration. This configuration is the one that you specified in a previous step.
 8. Specify the part reference, digest algorithm, and transform algorithm. The part reference specifies which parts of the message to digitally sign.
 - a. Under Additional properties, click **Part references > New** to create a new part reference, click **Part references > Delete** to delete an existing part reference, or click a part name to edit an existing part reference.
 - b. Specify a unique part name for this part reference. For example, you might specify reqint.
 - c. Select a part reference from the Part reference field.

The part reference refers to the message part that is digitally signed. The part attribute refers to the name of the <Integrity> element in the deployment descriptor when the <PartReference> element is specified for the signature. You can specify multiple <PartReference> elements within the <SigningInfo> element. The <PartReference> element has two child elements when it is specified for the signature: <DigestTransform> and <Transform>.
 - d. Select a digest method algorithm from the menu. The digest method algorithm specified within the <DigestMethod> element is used in the <SigningInfo> element.

WebSphere Application Server supports the following algorithms:

 - <http://www.w3.org/2000/09/xmlldsig#sha1>
 - <http://www.w3.org/2001/04/xmlenc#sha256>
 - <http://www.w3.org/2001/04/xmlenc#sha512>
 - e. Click **OK** to save the configuration.
 - f. Click the name of the new part reference configuration. This configuration is the one that you specified in a previous step.
 - g. Under Additional Properties, click **Transforms > New** to create a new transform, click **Transforms > Delete** to delete a transform, or click a transform name to edit an existing transform. If you create a new transform configuration, specify a unique name. For example, you might specify reqint_body_transform1.
 - h. Select a transform algorithm from the menu. The transform algorithm is that is specified within the <Transform> element and specifies the transform algorithm for the signature. WebSphere Application Server supports the following algorithms:
 - <http://www.w3.org/2001/10/xml-exc-c14n#>
 - <http://www.w3.org/TR/1999/REC-xpath-19991116>

Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use <http://www.w3.org/2002/06/xmlldsig-filter2> to ensure compliance.
 - <http://www.w3.org/2002/06/xmlldsig-filter2>
 - <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform>
 - <http://www.w3.org/2002/07/decrypt#XML>

- <http://www.w3.org/2000/09/xmldsig#enveloped-signature>

The transform algorithm that you select for the generator must match the transform algorithm that you select for the consumer.

Important: If both of the following conditions are true, WebSphere Application Server signs the referenced token:

- You previously selected the Keyinfo or the Keyinfochildelements option from the Key information signature type field on the signing information panel.
- You select <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform> as the transform algorithm.

9. Click **Apply**.
10. **Optional:** Determine whether to disable the Inclusive namespace prefix list. The Exclusive XML Canonicalization Version 1.0 specification recommends that you include all of the namespace declarations that correspond to the namespace prefix in the canonicalization form. For security reasons, WebSphere Application Server, by default, includes the prefix in the digital signature for Web services security. However, some implementations of Web services security cannot handle this prefix list. WebSphere Application Server can handle digitally signed messages that either contain or do not contain the prefix list. If you experience a signature validation failure when a signed Simple Object Access Protocol (SOAP) message is sent and you are using another vendor in your environment, it is highly recommended that you check with their Web site for a possible fix to their implementation before you disable this property. To disable this property, complete the following steps:
 - a. Under Additional properties, click **Canonicalization method properties > New**.
 - b. In the Property name field, enter the `com.ibm.wsspi.wssecurity.dsig.inclusiveNamespaces` property.
 - c. In the Property value field, enter the `false` value.
 - d. Click **OK**.

You can set this property for both the request generator and the response generator configurations.
11. Click **Save** at the top of the panel to save your configuration.

After completing these steps, the signing information is configured for the generator on the application level.

You must specify a similar signing information configuration for the consumer.

Signing information collection

Use this page to view a list of signing parameters. Signing information is used to sign and validate parts of a message including the body, time stamp, and user name token. You can also use these parameters for X.509 validation when the authentication method is IDAssertion and the ID type is X509Certificate in the server-level configuration. In such cases, you must fill in the certificate path fields only.

Note: Use Internet Explorer if you experience difficulties in the Signing Information panel using Netscape 4.7.9.

To view this administrative console page on the cell level for signing information, complete the following steps:

1. Click **Security > Web services**.
2. Under Default generator bindings or Default consumer bindings, click **Signing information**.
3. Click **New** to create a signing parameter. Click **Delete** to delete a signing parameter.

To view this administrative console page on the server level for signing information, complete the following steps:

1. Click **Servers > Application Servers > server_name**.

2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings or Default consumer bindings, click **Signing information**.
4. Click **New** to create a signing parameter. Click **Delete** to delete a signing parameter.

To view this administrative console page on the application level for signing information, complete the following steps:

1. Click **Applications > Enterprise applications > application_name**.
2. Click **Manage modules > URI_name**.
3. **Version 6 and later applications** Under Web Services Security Properties, you can access the signing information for the following bindings:
 - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
 - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
4. **Version 6 and later applications** Under Required properties, click **Signing information**.
5. **Version 5.x application** Under Additional properties, you can use this panel to configure the following bindings:
 - For the Request receiver binding, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**.
 - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**.
6. **Version 5.x application** Under Additional properties, click **Signing information**.
7. Click **New** to create a signing parameter. Click **Delete** to delete a signing parameter.

Signing information name:

Specifies the unique name that is assigned to the signing configuration.

Signature method:

Specifies the signature method algorithm that is chosen for the signing configuration.

Canonicalization method:

Specifies the canonicalization method algorithm that is chosen for the signing configuration.

Signing information configuration settings

Use this page to configure new signing parameters.

The specifications that are listed on this page for the signature method, digest method, and canonicalization method are located in the World Wide Web Consortium (W3C) document entitled, *XML Signature Syntax and Specification: W3C Recommendation 12 Feb 2002*.

To view this administrative console page on the cell level for signing information, complete the following steps:

1. Click **Security > Web services**.
2. Under Default generator bindings or Default consumer bindings, click **Signing information**.
3. Click **New** to create a signing parameter or click the name of an existing configuration to modify its settings.

To view this administrative console page on the server level for signing information, complete the following steps:

1. Click **Servers > Application Servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings or Default consumer bindings, click **Signing information**.
4. Click **New** to create a signing parameter or click the name of an existing configuration to modify its settings.

To view this administrative console page on the application level for signing information, complete the following steps:

1. Click **Applications > Enterprise applications > application_name**.
2. Click **Manage modules > URI_name**.
3. Under Web Services Security Properties, you can access the signing information for the following bindings:
 - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
 - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
4. **Version 6 and later applications** Under Required properties, click **Signing information**.
5. **Version 5.x application** Under Additional properties, you can access the signing information for the following bindings:
 - For the Request receiver binding, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**.
 - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**.
6. **Version 5.x application** Under Additional properties, click **Signing information**.
7. Click **New** to create a signing parameter or click the name of an existing configuration to modify its settings.

Signing information name:

Specifies the name that is assigned to the signing configuration.

Signature method:

Specifies the algorithm Uniform Resource Identifiers (URI) of the signature method.

The following pre-configured algorithms are supported:

- **Version 5.x or 6 application** <http://www.w3.org/2000/09/xmldsig#rsa-sha1>
- **Version 5.x or 6 application** <http://www.w3.org/2000/09/xmldsig#dsa-sha1>

Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP). Any `ds:SignatureMethod/@Algorithm` element in a signature based on a symmetric key must have a value of <http://www.w3.org/2000/09/xmldsig#rsa-sha1> or <http://www.w3.org/2000/09/xmldsig#hmac-sha1>.

- **Version 6 and later applications** <http://www.w3.org/2000/09/xmldsig#hmac-sha1>

For Version 6.0.x applications, you can specify additional signature methods on the Algorithm URI panel. To access the Algorithm URI panel, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Algorithm mappings > *algorithm_factory_engine_class_name* > Algorithm URI > New**.

When you specify the Algorithm URI, you also must specify an algorithm type. To have the algorithm display as a selection in the Signature method field on the Signing information panel, you must select **Signature** as the algorithm type.

This field is available for Version 6.0.x applications and for the request receiver and response receiver bindings for Version 5.x applications.

Digest method:

Specifies the algorithm URI of the digest method.

The <http://www.w3.org/2000/09/xmldsig#sha1> algorithm is supported.

This field is available for the request receiver and response receiver bindings for Version 5.x applications.

Canonicalization method:

Specifies the algorithm URI of the canonicalization method.

The following pre-configured algorithms are supported:

- <http://www.w3.org/2001/10/xml-exc-c14n#>
- <http://www.w3.org/2001/10/xml-exc-c14n#WithComments>
- <http://www.w3.org/TR/2001/REC-xml-c14n-20010315>
- <http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments>

This field is for Version 6.0.x applications and for the request receiver and response receiver bindings for Version 5.x applications.

Key information signature type:

Specifies how to sign a KeyInfo element if `ds:igkey` or `enckey` is specified for the signing part in the deployment descriptor.

This product supports the following keywords:

keyinfo (default)

Specifies that the entire KeyInfo element is signed.

keyinfochildelements

Specifies that the child elements of the KeyInfo element is signed.

If you do not specify a keyword, the application server uses the keyinfo value, by default.

The Key information signature type field is available for the token consumer binding.

For Version 6.0.x.x applications, this field is also available for the default consumer, request consumer, and response consumer bindings.

Signing key information:

Specifies a reference to the key information that the application server uses to generate the digital signature.

You can specify only one signing key for the default generator, request generator, and response generator bindings on the cell level and the server level. However, you can specify multiple signing keys for the default consumer, request consumer, and response consumer bindings. The signing keys for the default consumer, request consumer, and response consumer bindings are specified using the Key Information references link under Additional properties on the Signing information panel.

On the application level, you can specify only one signing key for the request generator and the response generator. You can specify multiple signing keys for the request consumer and response generator. The signing keys for the request consumer and the response consumer are specified using the Key information references link under Additional properties.

You can specify a signing key configuration for the following bindings on the following levels:

Binding name	Cell level, server level, or application level	Path
Default generator binding	Cell level	<ol style="list-style-type: none">1. Click Security > Web services.2. Under Default generator binding, click Key information.
Default consumer binding	Cell level	<ol style="list-style-type: none">1. Click Security > Web services.2. Under Default consumer binding, click Key information.
Default generator binding	Server level	<ol style="list-style-type: none">1. Click Servers > Application Servers > server_name.2. Under Security, click Web services: Default bindings for Web services security.3. Under Default generator binding, click Key information.
Default consumer binding	Server level	<ol style="list-style-type: none">1. Click Servers > Application Servers > server_name.2. Under Security, click Web services: Default bindings for Web services security.3. Under Default consumer binding, click Key information.

Certificate path:

Specifies the settings for the certificate path validation. When you select **Trust any**, this validation is skipped and all incoming certificates are trusted.

The certificate path options are available on the application level.

Trust anchor

The application server searches for trust anchor configurations on the application and server levels and lists the configurations in this menu.

In a Network Deployment environment, the application server also searches the cell level for trust anchor configurations.

Version 5.x application

You can specify trust anchors as an additional property for the response receiver binding and the request receiver binding.

You can specify a trust anchor configuration for the following bindings on the following levels:

Binding name	Cell level, server level, or application level	Path
Default generator binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Additional properties, click Trust anchors.
Default consumer binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Additional properties, click Trust anchors.
Default generator binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Additional properties, click Trust anchors > New.
Default consumer binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Additional properties, click Trust anchors > New.
Response receiver	Application level for Version 5.x applications	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Click Manage modules > URI_name. 3. Click Web services: Client security bindings. 4. Under the Response receiver binding, click Edit. 5. Under Additional properties, click Trust anchors > New.

Binding name	Cell level, server level, or application level	Path
Request receiver	Application level for Version 5.x applications	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Click Manage modules > <i>URI_name</i>. 3. Click Web services: Server security bindings. 4. Under the Request receiver binding, click Edit. 5. Under Additional properties, click Trust anchors > New.

For an explanation of the fields on the trust anchor panel, see “Trust anchor configuration settings” on page 1111.

Certificate store

The application server searches for certificate store configurations on the application and server levels and lists the configurations in this menu.

In a Network Deployment environment, the application server also searches the cell level for certificate store configurations.

You can specify a certificate store configuration for the following bindings on the following levels:

Binding name	Cell level, server level, or application level	Path
Default generator binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Additional properties, click Collection certificate store > New.
Default consumer binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Additional properties, click Collection certificate store > New.
Default generator binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > <i>server_name</i>. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Additional properties, click Collection certificate store > New.
Default consumer binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > <i>server_name</i>. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Additional properties, click Collection certificate store > New.

Binding name	Cell level, server level, or application level	Path
Response receiver	Application level for Version 5.x applications	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Click Manage modules > <i>URI_name</i>. 3. Click Web services: Client security bindings. 4. Under the Response receiver binding, click Edit. 5. Under Additional properties, click Collection certificate store > New.
Request receiver	Application level for Version 5.x applications	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Click Manage modules > <i>URI_name</i>. 3. Click Web services: Server security bindings. 4. Under the Request receiver binding, click Edit. 5. Under Additional properties, click Collection certificate store > New.

For an explanation of the fields on the collection certificate store panel, see “Collection certificate store configuration settings” on page 1116.

Part reference collection

Use this page to view the message part references for signature and encryption that are defined in the deployment descriptors.

To view this administrative console page on the cell level for signing information, complete the following steps:

1. Click **Security > Web services**.
2. Under Default generator bindings or Default consumer bindings, click **Signing information > *signing_information_name***.
3. Under Additional properties, click **Part references**.

To view this administrative console page on the server level for signing information, complete the following steps:

1. Click **Servers > Application Servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings or Default consumer bindings, click **Signing information > *signing_information_name***.
4. Under Additional properties, click **Part references**.

To view this administrative console page on the application level for signing information, complete the following steps. Part references are available through the administrative console using Version 6.x applications only.

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Services Security Properties, you can access the signing information for the following bindings:

- For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sending) binding, click **Edit custom**.
 - For Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
 - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
4. Under Required properties, click **Signing information** > *signing_information_name*.
 5. Under Additional properties, click **Part references**.

Part name:

Specifies the name that is assigned to the part reference configuration.

Part reference:

Specifies the name of the signed part that is defined in the deployment descriptor.

The Part reference field is specified in the application binding configuration only.

Digest method algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the digest method that is used for the signed part that is specified by the part reference.

Part reference configuration settings

Use this page to specify a reference to the message parts for signature and encryption that are defined in the deployment descriptors.

To view this administrative console page on the cell level for signing information, complete the following steps:

1. Click **Security** > **Web services**.
2. Under Default generator bindings or Default consumer bindings, click **Signing information** > *signing_information_name*.
3. Under Additional properties, click **Part references**.
4. Click **New** to create a part reference or click the name of an existing configuration to modify its settings.

To view this administrative console page on the server level for signing information, complete the following steps:

1. Click **Servers** > **Application Servers** > *server_name*.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings or Default consumer bindings, click **Signing information** > *signing_information_name*.
4. Under Additional properties, click **Part references**.
5. Click **New** to create a part reference or click the name of an existing configuration to modify its settings.

To view this administrative console page on the application level for signing information, complete the following steps.

Note: Part references are available through the administrative console using Version 6.0.x.x applications only.

1. Click **Applications > Enterprise applications > application_name**.
2. Click **Manage modules > URI_name**.
3. Under Web Services Security Properties, you can access the signing information for the following bindings:
 - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sending) binding, click **Edit custom**.
 - For Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
 - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
4. Under Required properties, click **Signing information > signing_information_name**.
5. Under Additional properties, click **Part references**.
6. Click **New** to create a part reference or click the name of an existing configuration to modify its settings.

You must specify a part name and select a part reference before specifying additional properties. Before specifying the digest method properties that are accessible under Additional properties, specify a digest method algorithm on this panel. If you specify **none** and click Digest method, an error message is displayed.

Part name:

Specifies the name that is assigned to the part reference configuration.

Part reference:

Specifies the name of the <integrity> or <requiredIntegrity> element for the signed part of the message or it specifies the name of the <confidentiality> or <requiredConfidentiality> element for the encrypted part of the message in the deployment descriptor.

The part names that are defined in the deployment descriptor are listed as options in this field. This field is displayed for the binding configuration on the application level only.

Digest method algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the digest method that is used for the signed part that is specified by the part reference.

This product provides the following predefined algorithm URIs:

- <http://www.w3.org/2000/09/xmlsig#sha1>
- <http://www.w3.org/2001/04/xmlenc#sha256>
- <http://www.w3.org/2001/04/xmlenc#sha512>

If you want to specify a custom algorithm, you must configure the custom algorithm in the Algorithm URI panel before setting the digest method algorithm.

To access the Algorithm URI panel, complete the following steps for the cell level:

1. Click **Security > Web services**.

2. Under Additional properties, click **Algorithm mappings** > *algorithm_factory_engine_class_name* > **Algorithm URI** > **New**.

The specified algorithms are listed as options for this field.

To access the Algorithm URI panel, complete the following steps for the server level:

1. Click **Servers** > **Application servers** > *server_name*.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Algorithm mappings** > *algorithm_factory_engine_class_name* > **Algorithm URI** > **New**.

The specified algorithms are listed as options for this field.

When you specify the Algorithm URI, you also must specify an algorithm type. To have the algorithm display as a selection in the Digest method algorithm field on the Part reference panel, you must select **Digest value calculation (Message digest)** as the algorithm type.

Transforms collection

Use this page to view the transform algorithm that is used for processing the Web services security message.

To view this administrative console page for the cell level, complete the following steps:

1. Click **Security** > **Web services**.
2. Under Default generator bindings or Default consumer bindings, click **Signing information** > *signing_information_name*.
3. Under Additional properties, click **Part references** > *part_name*.
4. Under Additional properties, click **Transforms**.

To view this administrative console page for the server level, complete the following steps:

1. Click **Application Servers** > **Servers** > *server_name*.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings or Default consumer bindings, click **Signing information** > *signing_information_name*.
4. Under Additional properties, click **Part references** > *part_name*.
5. Under Additional properties, click **Transforms**.

Version 6 and later applications

To view this administrative console page for the application level, complete the following steps.

Note: This option is available for Version 6 and later applications only.

1. Click **Applications** > **Enterprise applications** > *application_name*.
2. Click **Manage Modules** > *URI_name*.
3. Under Web Services Security Properties, you can access the transforms information for the following bindings:
 - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.

- For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
4. Under Required properties, click **Signing information** > *signing_information_name*.
 5. Under Additional properties, click **Part references** > *part_name* > **Transforms**.

Transform name:

Specifies the name that is assigned to the transform algorithm.

Transform algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the transform algorithm.

Transforms configuration settings

Use this page to specify the transform algorithm that is used for processing the Web services security message.

To view this administrative console page for the cell level, complete the following steps:

1. Click **Security** > **Web services**.
2. Under Default generator bindings or Default consumer bindings, click **Signing information** > *signing_information_name*.
3. Under Additional properties, click **Part references** > *part_name*.
4. Under Additional properties, click **Transforms**.
5. Click **New** to create a transform configuration or click the name of an existing configuration to modify its settings.

To view this administrative console page for the server level, complete the following steps:

1. Click **Application Servers** > **Servers** > *server_name*.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings or Default consumer bindings, click **Signing information** > *signing_information_name*.
4. Under Additional properties, click **Part references** > *part_name*.
5. Under Additional properties, click **Transforms**.
6. Click **New** to create a transform configuration or click the name of an existing configuration to modify its settings.

Version 6 and later applications

To view this administrative console page for the application level, complete the following steps. This option is available for Version 6.x applications only.

1. Click **Applications** > **Enterprise applications** > *application_name*.
2. Click **Manage modules** > *URI_name*.
3. Under Web Services Security Properties, you can access the transforms information for the following bindings:
 - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.

4. Under Required properties, click **Signing information** > *signing_information_name*.
5. Under Additional properties, click **Part references** > *part_name* > **Transforms**.
6. Click **New** to create a transform configuration or click the name of an existing configuration to modify its settings.

You must specify a transform name and select a transform algorithm before specifying additional properties.

Transform name:

Specifies the name that is assigned to the transform algorithm.

Transform algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the transform algorithm.

This product supports the following algorithms:

<http://www.w3.org/2001/10/xml-exc-c14n#>

This algorithm specifies the World Wide Web Consortium (W3C) Exclusive Canonicalization recommendation.

<http://www.w3.org/TR/1999/REC-xpath-19991116>

This algorithm specifies the W3C XML path language recommendation. If you specify this algorithm, you must specify the property name and value by clicking **Properties**, which is displayed under Additional properties. For example, you might specify the following information:

Property

`com.ibm.wsspi.wssecurity.dsig.XPathExpression`

Value `not(ancestor-or-self::*[namespace-uri()='http://www.w3.org/2000/09/xmlsig#' and local-name()='Signature'])`

Note: Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use <http://www.w3.org/2002/06/xmlsig-filter2> to ensure compliance.

<http://www.w3.org/2002/06/xmlsig-filter2>

This algorithm specifies the XML-Signature XPath Filter Version 2.0 proposed recommendation.

When you use this algorithm, you must specify a set of properties. You can use multiple property sets for the XPath Filter Version 2. Therefore, it is recommended that your property names end with the number of the property set, which is denoted by an asterisk in the following examples:

- To specify an XPath expression for the XPath filter2, you might use:

`name com.ibm.wsspi.wssecurity.dsig.XPath2Expression_*`

- To specify a filter type for each XPath, you might use:

`name com.ibm.wsspi.wssecurity.dsig.XPath2Filter_*`

Following this expression, you can have a value, [intersect], [subtract], or [union].

- To specify the processing order for each XPath, you might use:

`name com.ibm.wsspi.wssecurity.dsig.XPath2Order_*`

Following this expression, indicate the processing order of the XPath.

The following is a list of complete examples:

```
com.ibm.wsspi.wssecurity.dsig.XPath2Expression_2 = [XPath expression#1]
com.ibm.wsspi.wssecurity.dsig.XPath2Filter_1 = [intersect]
com.ibm.wsspi.wssecurity.dsig.XPath2Order_1 = [1]
com.ibm.wsspi.wssecurity.dsig.XPath2Expression_2 = [XPath expression#2]
com.ibm.wsspi.wssecurity.dsig.XPath2Filter_2 = [subtract]
com.ibm.wsspi.wssecurity.dsig.XPath2Order_2 = [2]
```

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform>

This algorithm specifies the enhancements to SOAP messaging that provide message integrity and confidentiality.

<http://www.w3.org/2002/07/decrypt#XML>

This algorithm specifies the W3C decryption transform for XML Signature recommendation.

<http://www.w3.org/2000/09/xmlsig#enveloped-signature>

This algorithm specifies the W3C recommendation for XML digital signatures.

Configuring the encryption information for the generator binding on the application level

Configure the key information that is referenced by the key information references in the encryption information panel.

This task provides the steps that are needed for configuring encryption information for the request generator (client side) and the response generator (server side) bindings at the application level. This encryption information is used to specify how the generators (senders) encrypt outgoing messages.

Complete the following steps to configure the encryption information for the request generator or response generator section of the bindings file on the application level:

1. Locate the encryption information configuration panel in the administrative console.
 - a. Click **Applications > Enterprise applications > application_name**.
 - b. Under Manage modules, click *URI_name*.
 - c. Under Web Services Security Properties, you can access the key information for the request generator and response generator bindings.
 - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 - d. Under Required properties, click **Encryption information**.
 - e. Click **New** to create an encryption information configuration. Click **Delete** to delete an existing configuration or click the name of an existing encryption information configuration to edit its settings. If you are creating a new configuration, enter a name in the Encryption information name field. For example, you might specify *gen_encinfo*.
2. Select a data encryption algorithm from the Data encryption algorithm field. The selection specifies the algorithm that is used to encrypt parts of the message. WebSphere Application Server supports the following pre-configured algorithms:
 - <http://www.w3.org/2001/04/xmlenc#tripleDES-cbc>
 - <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
 - <http://www.w3.org/2001/04/xmlenc#aes256-cbc>To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.
 - <http://www.w3.org/2001/04/xmlenc#aes192-cbc>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

The data encryption algorithm that you select for the generator side must match the data encryption method that you select for the consumer side.

3. Select a key encryption algorithm from the Key encryption algorithm field. This selection specifies the algorithm that is used to encrypt keys. WebSphere Application Server supports the following pre-configured algorithms:

- <http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p>.

When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this one. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5.

Restriction: This algorithm is not supported when the WebSphere Application Server is running in Federal Information Processing Standard (FIPS) mode.

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

- <http://www.w3.org/2001/04/xmlenc#sha256>
- <http://www.w3.org/2001/04/xmlenc#sha512>

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPParams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming Simple Object Access Protocol (SOAP) message.

- http://www.w3.org/2001/04/xmlenc#rsa-1_5
- <http://www.w3.org/2001/04/xmlenc#kw-tripledes>
- <http://www.w3.org/2001/04/xmlenc#kw-aes128>
- <http://www.w3.org/2001/04/xmlenc#kw-aes256>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

- <http://www.w3.org/2001/04/xmlenc#kw-aes192>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

The key encryption algorithm that you select for the generator side must match the key encryption method that you select for the consumer side.

4. Select an encryption key information reference from the Encryption key information menu. This selection is a reference to the encryption key that is used to encrypt parts of the message. To configure the key information, see “Configuring the key information for the generator binding on the application level” on page 1148.
5. Select a part reference from the Part reference field. This field specifies the name of the part reference for the generator binding element in the deployment descriptor.
6. Click **OK** and then click **Save** to save the configuration.

The encryption information is configured for the generator binding at the application level.

You must specify a similar encryption information configuration for the consumer.

Encryption information collection

Use this page to specify the configuration for the encrypting and decrypting parameters. This configuration is used to encrypt and decrypt parts of the message, including the body and user name token.

To view the administrative console panel for the encryption information on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under either Default generator bindings or Default consumer bindings, click **Encryption information**.

To view the administrative console panel for the encryption information on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under either Default generator bindings or Default consumer bindings, click **Encryption information**.

To view this administrative console page for the collection certificate store on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Services Security Properties, you can access encryption information for the following bindings:
 - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
 - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
 - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
 - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**.

4. **Version 5.x application** Under Additional properties, you can access encryption information for the following bindings:
 - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**. Under Additional properties, click **Encryption information**.
 - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**. Under Additional properties, click **Encryption information**.

Encryption information name:

Specifies the name of the encryption information.

Key locator reference:

Specifies the name of the key locator configuration that retrieves the key for XML digital signature and XML encryption.

Key encryption algorithm: Specifies the algorithm that is used to encrypt and decrypt keys.

Data encryption algorithm: Specifies the algorithm that is used to encrypt and decrypt data.

Encryption information configuration settings

Use this page to configure the encryption and decryption parameters. You can use these parameters to encrypt and decrypt various parts of the message, including the body and user name token.

To view the administrative console panel for the encryption information on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under either Default generator bindings or Default consumer bindings, click **Encryption information**.
3. Click **New** to create a new encryption configuration or click the name of an existing encryption configuration.

To view the administrative console panel for the encryption information on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under either Default generator bindings or Default consumer bindings, click **Encryption information**.
4. Click **New** to create a new encryption configuration or click the name of an existing encryption configuration.

To view this administrative console page for the collection certificate store on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Modules, click **Module update > *module_name***.
3. Under Web Services Security Properties, you can access encryption information for the following bindings:
 - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
 - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
 - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
 - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**.

4. **Version 5.x application** Under Additional properties, you can access encryption information for the following bindings:
 - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**. Under Additional properties, click **Encryption information**.
 - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**. Under Additional properties, click **Encryption information**.
5. Click either **New** to create a new encryption configuration or click the name of an existing encryption configuration.

Encryption information name:

Specifies the name for the encryption information.

Data type String

Data encryption algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the data encryption method.

The following algorithms are supported:

- <http://www.w3.org/2001/04/xmlenc#tripledes-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes256-cbc>. To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>. For more information, see “Encryption information configuration settings” on page 1185.
- <http://www.w3.org/2001/04/xmlenc#aes192-cbc>. To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>. For more information, see “Encryption information configuration settings” on page 1185.

Do not use the 192-bit data encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files. For more information, see the Key encryption algorithm field description.

Key locator reference:

Specifies the name of the key locator configuration that retrieves the key for XML digital signature and XML encryption.

The Key locator reference field is displayed for the request receiver and response receiver bindings, which are used by Version 5.x applications.

You can configure these key locator reference options on the server level, the cell level, and the application level. The configurations that are listed in the field are a combination of the configurations on these three levels.

You can specify an encryption key configuration for the following bindings on the following levels:

Binding name	Cell level, server level, or application level	Path
Default generator binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Additional properties, click Key locators.
Default consumer bindings	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Additional properties, click Key locators.
Default generator binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Additional properties, click Key locators.
Default consumer binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Additional properties, click Key locators.
Request sender	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Click Manage modules > URI_name. 3. Click Web services: Client security bindings. Under Request sender binding, click Edit. 4. Under Additional properties, click Key locators.
Request receiver	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Click Manage modules > URI_name. 3. Click Web services: Server security bindings. Under Request receiver binding, click Edit. 4. Under Additional properties, click Key locators.
Response sender	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Click Manage modules > URI_name. 3. Click Web services: Server security bindings. Under Response sender binding, click Edit. 4. Under Additional properties, click Key locators.

Binding name	Cell level, server level, or application level	Path
Response receiver	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Click Manage modules > <i>URI_name</i>. 3. Click Web services: Client security bindings. Under Response receiver binding, click Edit. 4. Under Additional properties, click Key locators.

Key encryption algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the key encryption method.

The following algorithms are provided by the application server:

- <http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p>.

When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this one. This algorithm appears in the list of supported key transport algorithms when running with Software Development Kit (SDK) Version 1.5 or later.

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

- <http://www.w3.org/2001/04/xmlenc#sha256>
- <http://www.w3.org/2001/04/xmlenc#sha512>

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPParams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming Simple Object Access Protocol (SOAP) message.

- http://www.w3.org/2001/04/xmlenc#rsa-1_5
- <http://www.w3.org/2001/04/xmlenc#kw-tripledes>
- <http://www.w3.org/2001/04/xmlenc#kw-aes128>
- <http://www.w3.org/2001/04/xmlenc#kw-aes192>

Do not use the 192-bit data encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

- <http://www.w3.org/2001/04/xmlenc#kw-aes256>

By default, the Java Cryptography Extension (JCE) ships with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files. Before downloading these policy files, back up the existing policy files (`local_policy.jar` and `US_export_policy.jar` in the `WAS_HOME/jre/lib/security/` directory) prior to overwriting them in case you want to restore the original files later. To download the policy files, complete one of the following sets of steps:

- For application server platforms using IBM Developer Kit, Java Technology Edition Version 1.4.2, including the AIX, Linux, and Windows platforms, complete the following steps to obtain unlimited jurisdiction policy files:
 1. Go to the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>
 2. Click **Java 1.4.2**
 3. Click **IBM SDK Policy files**.
The Unrestricted JCE Policy files for SDK 1.4 Web site is displayed.
 4. Enter your user ID and password or register with IBM to download the policy files. The policy files are downloaded onto your machine.
- For application server platforms using the Sun-based Java Development Kit (JDK) Version 1.4.2, including the Solaris environments and the HP-UX platform, complete the following steps to obtain unlimited jurisdiction policy files:
 1. Go to the following Web site: <http://java.sun.com/j2se/1.4.2/download.html>
 2. Click **Archive area**.
 3. Locate the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files 1.4.2 information and click **Download**. The policy file is downloaded onto your machine.

After following either of these sets of steps, two Java archive (JAR) files are placed in the Java virtual machine (JVM) `jre/lib/security/` directory.

By default, the Java Cryptography Extension (JCE) ships with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files. Before downloading these policy files, back up the existing policy files (`local_policy.jar` and `US_export_policy.jar` in the `WAS_HOME/jre/lib/security/` directory) prior to overwriting them in case you want to restore the original files later. To download the policy files, complete one of the following sets of steps:

- For application server platforms using IBM Developer Kit, Java Technology Edition Version 5, including the AIX, Linux, and Windows platforms, you can obtain unlimited jurisdiction policy files by completing the following steps:
 1. Go to the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>
 2. Click **Java 5**
 3. Click **IBM SDK Policy files**.
The Unrestricted JCE Policy files for SDK 5 Web site is displayed.
 4. Enter your user ID and password or register with IBM to download the policy files. The policy files are downloaded onto your machine.
- For application server platforms using the Sun-based Java Development Kit (JDK) Version 5, including the Solaris environments and the HP-UX platform, you can obtain unlimited jurisdiction policy files by completing the following steps:
 1. Go to the following Web site: <http://java.sun.com/j2se/1.5.0/download.jsp>
 2. Click **Archive area**.
 3. Locate the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files 1.5.1 information and click **Download**. The policy file is downloaded onto your machine.

After following either of these sets of steps, two Java archive (JAR) files are placed in the Java virtual machine (JVM) `jre/lib/security/` directory.

To specify custom algorithms on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Algorithm mappings**.
3. Click **New** to specify a new algorithm mapping or click the name of an existing configuration to modify its settings.

4. Under Additional properties, click **Algorithm URI**.
5. Click **New** to create a new algorithm URI. You must specify **Key encryption** in the **Algorithm type** field to have the configuration display in the **Key encryption algorithm** field on the Encryption information configuration settings panel.

To specify custom algorithms on the server level, complete the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Algorithm mappings**.
4. Click **New** to specify a new algorithm mapping or click the name of an existing configuration to modify its settings.
5. Under Additional properties, click **Algorithm URI**.
6. Click **New** to create a new algorithm URI. You must specify **Key encryption** in the **Algorithm type** field to have the configuration display in the **Key encryption algorithm** field on the Encryption information configuration settings panel.

Encryption key information:

Specifies the name of the key information reference that is used for encryption. This reference is resolved to the actual key by the specified key locator and defined in the key information.

Version 6 and later applications

You must specify either one or no encryption key configurations for the request generator and response generator bindings.

Version 6 and later applications

For the response consumer and the request consumer bindings, you can configure multiple encryption key references. To create a new encryption key reference, under Additional properties, click **Key information references**.

You can specify an encryption key configuration for the following bindings on the following levels:

Binding name	Cell level, server level, or application level	Path
Default generator binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Default generator binding, click Key information.
Default consumer binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Default consumer binding, click Key information.
Default generator binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Default generator binding, click Key information.

Binding name	Cell level, server level, or application level	Path
Default consumer binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Default consumer binding, click Key information.
Request generator (sender) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Click Manage modules > URI_name. 3. Under Web Services Security Properties, click Web services: Client security bindings. 4. Under Request generator (sender) binding, click Edit custom. 5. Under Required properties, click Key information.
Response generator (sender) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Click Manage modules > URI_name. 3. Under Web Services Security Properties, click Web services: Server security bindings. 4. Under Response generator (sender) binding, click Edit custom. 5. Under Required properties, click Key information.

Part Reference:

Specifies the name of the <confidentiality> element for the generator binding or the <requiredConfidentiality> element for the consumer binding element in the deployment descriptor.

This field is available on the application level only.

Encryption information configuration settings

Use this page to configure the encryption and decryption parameters.

The specifications that are listed on this page for the signature method, digest method, and canonicalization method are located in the World Wide Web Consortium (W3C) document entitled, *XML Encryption Syntax and Processing: W3C Recommendation 10 Dec 2002*.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > application_name** and complete one of the following steps:
 - Click **Manage modules > URI_file_name > Web Services: Client Security Bindings**. Under Request sender binding, click **Edit**. Under Web Service Security Properties, click **Encryption Information**.
 - Click **Manage modules > URI_file_name > Web Services: Server Security Bindings**. Under Response sender binding, click **Edit**. Under Web Service Security Properties, click **Encryption Information**.

2. Select **None** or **Dedicated encryption information**. The application server can have either one or no encryption configurations for the request sender and the response sender bindings. If you are not using encryption, select **None**. To configure encryption for either of these two bindings, select **Dedicated encryption information** and specify the configuration settings using the fields that are described in this topic.

Encryption information name:

Specifies the name of the key locator configuration that retrieves the key for XML digital signature and XML encryption.

Key locator reference:

Specifies the name that is used to reference the key locator.

You can configure these key locator reference options on the cell level, the server level, and the application level. The configurations that are listed in the field are a combination of the configurations on these three levels.

To configure the key locators on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Key locators**.

To configure the key locators on the server level, complete the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Key locators**.

To configure the key locators on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > application_name**.
2. Click **Manage modules > URI_name**.
3. Under Web Service Security Properties, you can access the key locators for the following bindings:
 - For the Request sender, click **Web services: Client security bindings**. Under Request sender binding, click **Edit**. Under Additional properties, click **Key locators**.
 - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**. Under Additional properties, click **Key locators**.
 - For the Response sender, click **Web services: Server security bindings**. Under Response sender binding, click **Edit**. Under Additional properties, click **Key locators**.
 - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**. Under Additional properties, click **Key locators**.

Encryption key name:

Specifies the name of the encryption key that is resolved to the actual key by the specified key locator.

Data type String

Key encryption algorithm:

Specifies the algorithm uniform resource identifier (URI) of the key encryption method.

The following algorithms are supported:

- <http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p>.

When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this one. This algorithm appears in the list of supported key transport algorithms when running with JDK 1.5 or later.

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is:

`com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URLs of the digest method:

- <http://www.w3.org/2001/04/xmlenc#sha256>
- <http://www.w3.org/2001/04/xmlenc#sha512>

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the `OAEPParams`. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify

`com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPParams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and `OAEPParams` properties on the generator side only. On the consumer side, these properties are read from the incoming Simple Object Access Protocol (SOAP) message.

- http://www.w3.org/2001/04/xmlenc#rsa-1_5.
- <http://www.w3.org/2001/04/xmlenc#kw-tripledes>.
- <http://www.w3.org/2001/04/xmlenc#kw-aes128>.
- <http://www.w3.org/2001/04/xmlenc#kw-aes192>.

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

- <http://www.w3.org/2001/04/xmlenc#kw-aes256>.

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file.

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files. Before downloading these policy files, back up the existing policy files (`local_policy.jar` and `US_export_policy.jar` in the `WAS_HOME/jre/lib/security/` directory) prior to overwriting them in case you want to restore the original files later. To download the policy files, complete one of the following sets of steps:

- For application server platforms using IBM Developer Kit, Java Technology Edition Version 1.4.2, including the AIX, Linux, and Windows platforms, complete the following steps to obtain unlimited jurisdiction policy files:

1. Go to the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>
2. Click **Java 1.4.2**
3. Click **IBM SDK Policy files**.

The Unrestricted JCE Policy files for SDK 1.4 Web site is displayed.

4. Enter your user ID and password or register with IBM to download the policy files. The policy files are downloaded onto your machine.
- For application server platforms using the Sun-based Java Development Kit (JDK) Version 1.4.2, including the Solaris environments and the HP-UX platform, complete the following steps to obtain unlimited jurisdiction policy files:
 1. Go to the following Web site: <http://java.sun.com/j2se/1.4.2/download.html>
 2. Click **Archive area**.

3. Locate the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files 1.4.2 information and click **Download**. The `jce_policy-1_4_1.zip` file is downloaded onto your machine.

After following either of these sets of steps, two Java archive (JAR) files are placed in the Java virtual machine (JVM) `jre/lib/security/` directory.

Data encryption algorithm:

Specifies the algorithm Uniform Resource Identifiers (URI) of the data encryption method.

The following algorithms are supported:

- <http://www.w3.org/2001/04/xmlenc#tripledes-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes192-cbc>

Do not use the 192-bit data encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

- <http://www.w3.org/2001/04/xmlenc#aes256-cbc>

By default, the JCE ships with restricted or limited strength ciphers. To use 192-bit and 256-bit AES encryption algorithms, you must apply unlimited jurisdiction policy files. For more information, see the Key encryption algorithm field description.

Configuring trust anchors for the consumer binding on the application level

You can configure trust anchors for the consumer binding at the application level.

This article does not describe how to configure trust anchors at the server or cell level. Trust anchors that are defined at the application level have a higher precedence over trust anchors that are defined at the server or cell level. For more information on creating and configuring trust anchors on the server or cell level, see “Configuring trust anchors on the server or cell level” on page 1217.

You can configure a trust anchor for the trust anchor using an assembly tool or the administrative console. This article describes how to configure the application-level trust anchor using the administrative console.

A trust anchor specifies key stores that contain trusted root Certificate Authority (CA) certificates, which validate the signer certificate. These keystores are used by the request consumer (as defined in the `ibm-webservices-bnd.xmi` file) and the response consumer (as defined in the `ibm-webservicesclient-bnd.xmi` file when a Web service is acting as a client) to validate the X.509 certificate in the SOAP message. The keystores are critical to the integrity of the digital signature validation. If the keystores are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these keystores. The binding configuration specified for the request consumer in the `ibm-webservices-bnd.xmi` file must match the binding configuration for the response consumer in the `ibm-webservicesclient-bnd.xmi` file. The trust anchor configuration for the request consumer on the server side must match the request generator configuration on the client side. Also, the trust anchor configuration for the response consumer on the client side must match the response generator configuration on the server side.

Complete the following steps to configure trust anchors for the consumer binding on the application level:

1. Locate the trust anchor panel in the administrative console.
 - a. Click **Applications > Enterprise applications > *application_name***.
 - b. Under Manage modules, click *URI_name*.
 - c. Under Web Services Security Properties you can access the trust anchor configuration for the following bindings:

- For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
- d. Under Additional properties, click **Trust anchors**.
 - e. Click **New** to create a trust anchor configuration. Select the box next to a configuration and click **Delete** to delete an existing configuration or click the name of an existing trust anchor configuration to edit its settings. If you are creating a new configuration, enter a unique name in the Trust anchor name field.
2. Specify the keystore password, the keystore location, and the keystore type. A trust anchor keystore file contains the trusted root Certificate Authority (CA) certificates that are used for validating the X.509 certificate that is used in digital signature or XML encryption.
 - a. Specify a password in the Key store password field. This password is used to access the keystore file.
 - b. Specify the location of the keystore file in the Key store path field.
 - c. Select a keystore type from the Key store type field. The Java Cryptography Extension (JCE) that is used by IBM supports the following keystore types:

JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

JCEKS
Use this option if you are using Java Cryptography Extensions.

JCERACFKS
Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

PKCS11KS (PKCS11)
Use this format if your keystore file uses the PKCS#11 file format. Keystore files that use this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)
Use this option if your keystore file uses the PKCS#12 file format.

WebSphere Application Server provides some sample keystore files in the `${USER_INSTALL_ROOT}/etc/ws-security/samples` directory. For example, you might use the `enc-receiver.jceks` keystore file for encryption keys. The password for this file is `storepass` and the type is `JCEKS`.

Attention: Do not use these keystore files in a production environment. These samples are provided for testing purposes only.

This task configures trust anchors for the consumer binding at the application level

You must specify a similar trust anchor information for the generator.

Configuring the collection certificate store for the consumer binding on the application level

A collection certificate store is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check for a valid signature in a digitally signed Simple Object Access Protocol (SOAP) message. Complete the following steps to configure a collection certificate for the consumer bindings on the application level:

1. Locate the collection certificate store configuration panel in the administrative console.
 - a. Click **Applications > Enterprise applications > *application_name***.
 - b. Under Manage modules, click *module_name*.

- c. Under Web services security properties, you can access the collection certificate store information for the response consumer and request consumer bindings.
 - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
 - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
 - d. Under Additional properties, click **Collection certificate store**.
2. Click **New** to create a collection certificate store configuration, click **Delete** to delete an existing configuration, or click the name of an existing collection certificate store configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field.

The name of the collection certificate store must be unique to the level of the application server. For example, if you create the collection certificate store for the application level, the store name must be unique to the application level. The name that is specified in the Certificate store name field is used by other configurations to refer to a predefined collection certificate store. WebSphere Application Server searches for the collection certificate store based on proximity.

For example, if an application binding refers to a collection certificate store named cert1, the Application Server searches for cert1 at the application level before searching the server level and then the cell level.
 3. Specify a certificate store provider in the Certificate store provider field. WebSphere Application Server supports the IBM CertPath certificate store provider. To use another certificate store provider, you must define the provider implementation in the provider list within the *install_dir/java/jre/lib/security/java.security* file. However, make sure that your provider supports the same requirements of the certificate path algorithm as WebSphere Application Server.
 4. Click **OK** and **Save** to save the configuration.
 5. Click the name of your certificate store configuration. After you specify the certificate store provider, you must specify either the location of a certificate revocation list or the X.509 certificates. However, you can specify both a certificate revocation list and the X.509 certificates for your certificate store configuration.
 6. Under Additional properties, click **Certificate revocation lists**.
 7. Click **New** to specify a certificate revocation list path, click **Delete** to delete an existing list reference, or click the name of an existing reference to edit the path. You must specify the fully qualified path to the location where WebSphere Application Server can find your list of certificates that are not valid. For portability reasons, it is recommended that you use the WebSphere Application Server variables to specify a relative path to the certificate revocation lists (CRL). This recommendation is especially important when you are working in a WebSphere Application Server Network Deployment environment. For example, you might use the *USER_INSTALL_ROOT* variable to define a path such as *\$USER_INSTALL_ROOT/mycertstore/mycrl1*. For a list of supported variables, click **Environment > WebSphere variables** in the administrative console. The following list provides recommendation for using certificate revocation lists:
 - If CRLs are added to the collection certificate store, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.
 - When the CRL file is updated, the new CRL does not take effect until you restart the Web service application.
 - Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.
 8. Click **OK** and **Save** to save the configuration.
 9. Return to the Collection certificate store configuration panel. See the first few steps of this article to locate the collection certificate store panel.
 10. Under Additional properties, click **X.509 certificates**.

11. Click **New** to create a new configuration for X.509 certificates, click **Delete** to delete an existing configuration, or click the name of an existing X.509 certificate configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field.
12. Specify a path in the X.509 certificate path field. This entry is the absolute path to the location of the X.509 certificates. The collection certificate store is used to validate the certificate path of incoming X.509-formatted security tokens.
 You can use the `USER_INSTALL_ROOT` variable as part of the path name. For example, you might type: `USER_INSTALL_ROOT/etc/ws-security/samples/intca2.cer`. Do not use this certificate path for production use. You must obtain your own X.509 certificate from a certificate authority before putting your WebSphere Application Server environment into production.
 Click **Environment > WebSphere variables** in the administrative console to configure the `USER_INSTALL_ROOT` variable.
13. Click **OK** and then **Save** to save your configuration.

You have configured the collection certificate store for the consumer binding.

You must configure a token consumer configuration that references this certificate store configuration.

Binary security token

The `ValueType` attribute identifies the type of the security token, for example, a Lightweight Third Party Authentication (LTPA) token. The `EncodingType` type indicates how the security token is encoded, for example, `Base64Binary`. The `BinarySecurityToken` element defines a security token that is binary encoded. The encoding is specified using the `EncodingType` attribute. The value type and space are specified using the `ValueType` attribute. The Web services security implementation for WebSphere Application Server, Version 6 and later supports both LTPA and X.509 certificate binary security tokens.

A binary security token has the following attributes that are used for interpretation:

- Value type
- Encoding type

The following example depicts an LTPA binary security token in a Web services security message header:

```
<wsse:BinarySecurityToken xmlns:ns7902342339871340177=
  "http://www.ibm.com/websphere/appserver/tokentype/5.0.2"
  EncodingType="wsse:Base64Binary"
  ValueType="ns7902342339871340177:LTPA">
  MIZ6LGPt2CzXBQfio9wZTo1VotWov0NW3Za6lU5K7Li78DSnIK6iHj3hxXgrUn6p4wZI
  8Xg26havepvmSJ8XxiACMihTJuh1t3ufsrjbfFQJ0qh5VcRvI+AKEaNmEgEV65jUYAC9
  C/iwBBWk5U/6DIk7LfXcTT0ZPAD+3D3nCS0f+6tnqMou8EG9mtMeTKccz/pJVTZjaRSO
  msu0sewsOKf1/WPsjW0bR/2g3NaVvBy18V1TFBpUbGFVGgzHRjBKAGo+ctk180n1VLIk
  TUjt/XdYvEp0r6QoddGi4okjDGPyyoDxcvKZnReXww5Usoq1pfXwN4KG9as=
</wsse:BinarySecurityToken>
</wsse:Security>
</soapenv:Header>
```

As shown in the example, the token is `Base64Binary` encoded.

Configuring token consumer on the application level

You can specify the token consumer on the application level. The token consumer information is used on the consumer side to incorporate the security token.

Complete the following steps to configure the token consumer on the application level:

1. Locate the token consumer panel in the administrative console.
 - a. Click **Applications > Enterprise applications > application_name**.

- b. Under Manage modules, click *URI_name*.
 - c. Under Web Services Security Properties you can access the token consumer for the following bindings:
 - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
 - d. Under Required properties, click **Token consumer**.
 - e. Click **New** to create a token consumer configuration, click **Delete** to delete an existing configuration, or click the name of an existing token consumer configuration to edit its settings. If you are creating a new configuration, enter a unique name in the **Token consumer name** field. For example, you might specify `con_signtgen`.
2. Specify a class name in the **Token consumer class name** field. The token consumer class must implement the `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` interface. The token consumer class name for the request consumer and the response consumer must be similar to the token generator class name for the request generator and the response generator. For example, if your application requires a user name token consumer, you can specify the `com.ibm.wsspi.wssecurity.token.UsernameTokenGenerator` class name on the Token generator panel for application level and the `com.ibm.wsspi.wssecurity.token.UsernameTokenConsumer` class name in this field.
 3. **Optional:** Select a part reference in the **Part reference** field. The part reference indicates the name of the security token that is defined in the deployment descriptor. For example, if you receive a username token in your request message, you might want to reference the token in the username token consumer.

Important: On the application level, if you do not specify a security token in your deployment descriptor, the **Part reference** field is not displayed. If you define a security token called `user_tcon` in your deployment descriptor, `user_tcon` is displayed as an option in the **Part reference** field.

4. **Optional:** In the certificate path section of the panel, select a certificate store type and indicate the trust anchor and certificate store name, if necessary. These options and fields are necessary when you specify `com.ibm.wsspi.wssecurity.token.X509TokenConsumer` as the token consumer class name. The names of the trust anchor and the collection certificate store are created in the certificate path under your token consumer. You can select one of the following options:

None If you select this option, the certificate path is not specified.

Trust any

If you select this option, any certificate is trusted. When the received token is consumed, the Application Server does not validate the certificate path.

Dedicated signing information

If you select this option, you can select a trust anchor and a certificate store configuration. When you select the trust anchor or the certificate store of a trusted certificate, you must configure the trust anchor and the certificate store before setting the certificate path.

Trust anchor

A trust anchor specifies a list of key store configurations that contain trusted root certificates. These configurations are used to validate the certificate path of incoming X.509-formatted security tokens. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath API to validate the trustworthiness of a certificate chain. You must create the keystore file using the key tool utility, which is located in the `install_dir/java/jre/bin/keytool` file.

You can configure trust anchors for the application level by completing the following steps:

- a. Click **Applications > Enterprise applications > *application_name***.
- b. Under Related Items, click **EJB Modules** or **Web Modules > *URI_name***.
- c. Access the token consumer from the following bindings:
 - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
- d. Under Additional properties, click **Trust anchors**.

Collection certificate store

A collection certificate store includes a list of untrusted, intermediary certificates and certificate revocation lists (CRLs). The collection certificate store is used to validate the certificate path of the incoming X.509-formatted security tokens. You can configure the collection certificate store for the application level by completing the following steps:

- a. Click **Applications > Enterprise applications > *application_name***.
 - b. Under Related Items, click **EJB Modules** or **Web Modules > *URI_name***.
 - c. Access the token consumer from the following bindings:
 - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
 - d. Under Additional properties, click **Collection certificate store**.
5. **Optional:** Specify a trusted ID evaluator. The trusted ID evaluator is used to determine whether to trust the received ID. You can select one of the following options:

None If you select this option, the trusted ID evaluator is not specified.

Existing evaluator definition

If you select this option, you can select one of the configured trusted ID evaluators. For example, you can select the SampleTrustedIDEvaluator, which is provided by WebSphere Application Server as an example.

Binding evaluator definition

If you select this option, you can configure a new trusted ID evaluator by specifying a trusted ID evaluator name and class name.

Trusted ID evaluator name

Specifies the name that is used by the application binding to refer to a trusted identity (ID) evaluator that is defined in the default bindings.

Trusted ID evaluator class name

Specifies the class name of the trusted ID evaluator. The specified trusted ID evaluator class name must implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface. The default `TrustedIDEvaluator` class is `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`. When you use this default `TrustedIDEvaluator` class, you must specify the name and value properties for the default trusted ID evaluator to create the trusted ID list for evaluation. To specify the name and value properties, complete the following steps:

- a. Under Additional properties, click **Properties > New**.

- b. Specify the trusted ID evaluator name in the **Property** field. You must specify the name in the form, trustedId_n where _n is an integer from 0 to n.
- c. Specify the trusted ID in the **Value** field.

For example:

```
property name="trustedId_0", value="CN=Bob,O=ACME,C=US"
property name="trustedId_1, value="user1"
```

If the distinguished name (DN) is used, the space is removed for comparison. See the programming model information in the documentation for an explanation of how to implement the com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator interface. For more information, see “Default implementations of the Web services security service provider programming interfaces” on page 1004.

Note: Define the trusted ID evaluator on the server level instead of the application level. To define the trusted ID evaluator on the server level, complete the following steps:

- a. Click **Servers > Application servers > server_name**.
- b. Under Security, click **Web services: Default bindings for Web services security**.
- c. Under Additional properties, click **Trusted ID evaluators**.
- d. Click **New** to define a new trusted ID evaluator.

The trusted ID evaluator configuration is available only for the token consumer on the server-side application level.

- 6. **Optional:** Select the **Verify nonce** option. This option indicates whether to verify a nonce in the user name token if it is specified for the token consumer. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The **Verify nonce** option is valid only when the incorporated token type is a user name token.
- 7. **Optional:** Select the **Verify timestamp** option. This option indicates whether to verify a time stamp in the user name token. The **Verify nonce** option is valid only when the incorporated token type is a user name token.
- 8. Specify the value type local name in the **Local name** field. This field specifies the local name of the value type for the consumed token. For a user name token and an X.509 certificate security token, WebSphere Application Server provides predefined local names for the value type.

Table 50. Uniform Resource Identifier (URI) and Local name combinations

URI	Local name	Description
A namespace URI is not applicable.	Specify http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3 as the local name value.	Specifies the name of an X.509 certificate token
A namespace URI is not applicable.	Specify http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1 as the local name value.	Specifies the name of the X.509 certificates in a PKI path
A namespace URI is not applicable.	Specify http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7 as the local name value.	Specifies a list of X509 certificates and certificate revocation lists (CRL) in a PKCS#7

Table 50. Uniform Resource Identifier (URI) and Local name combinations (continued)

URI	Local name	Description
Specify <code>http://www.ibm.com/websphere/appserver/tokentype/5.0.2</code> as the URI value.	Specify LTPA as the local name value.	Specifies a binary security token that contains an embedded Lightweight Third Party Authentication (LTPA) token.
Specify <code>http://www.ibm.com/websphere/appserver/tokentype</code> as the URI value.	Specify LTPA_PROPAGATION as the local name value.	Specifies a binary security token that contains an embedded propagation token.
Specify the namespace URI value as indicated by the provider.	Specify <code>http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken</code> as the local name value.	Specifies the token type that is configured to perform token validation. This local name is used to remap an incoming security token to a different security token. You can use this local name value in a situation that is similar to the following scenario: A client sends a username token to the server. The custom token consumer on the server uses the security token service to authenticate the user name information. The username token is used to create a new token type such as a Security Assertion Markup Language (SAML) token. You can use the identity from the SAML token for authentication and authorization verification in WebSphere Application Server.

9. **Optional:** Specify the value type URI in the **URI** field. This entry specifies the namespace URI of the value type for the consumed token.

Remember: If you specify the token consumer for a username token or an X.509 certificate security token, you do not need to specify a value type URI.

If you want to specify another token, you must specify both the local name and the URI. For example, if you have an implementation of your own custom token, you can specify CustomToken in the **Local name** field and `http://www.ibm.com/custom`

10. Click **OK** and **Save** to save the configuration.
11. Click the name of your token consumer configuration.
12. Under Additional properties, click **JAAS configuration**. The Java Authentication and Authorization Service (JAAS) configuration specifies the name of the JAAS configuration that is defined in the JAAS login panel. The JAAS configuration specifies how the token logs in on the consumer side.
13. Select a JAAS configuration from the **JAAS configuration name** field. The field specifies the name of the JAAS system of application login configuration. You can specify additional JAAS system and application configurations by clicking **Security > Secure administrative, applications, and infrastructure**. Under Authentication, click **Java Authentication and Authorization Service** and click either **Application logins > New** or **System logins > New**. Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module. WebSphere Application Server provides the following predefined JAAS configurations:

ClientContainer

This selection specifies the login configuration that is used by the client container

applications. The configuration uses the CallbackHandler application programming interface (API) that is defined in the deployment descriptor for the client container. To modify this configuration, see the JAAS configuration panel for application logins.

WSLogin

This selection specifies whether all of the applications can use the WSLogin configuration to perform authentication for the security run time. To modify this configuration, see the JAAS configuration panel for application logins.

DefaultPrincipalMapping

This selection specifies the login configuration that is used by Java 2 Connectors (J2C) to map users to principals that are defined in the J2C authentication data entries. To modify this configuration, see the JAAS configuration panel for application logins.

system.wssecurity.IDAssertion

This selection enables a Version 5.x application to use identity assertion to map a user name to a WebSphere Application Server credential principal. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.Signature

This selection enables a Version 5.x application to map a distinguished name (DN) in a signed certificate to a WebSphere Application Server credential principal. To modify this configuration, see the JAAS configuration panel for system logins.

system.LTPA_WEB

This selection processes login requests that are used by the Web container such as servlets and JavaServer Pages (JSPs) files. To modify this configuration, see the JAAS configuration panel for system logins.

system.WEB_INBOUND

This selection handles login requests for Web applications, which include servlets and JavaServer Pages (JSP) files. This login configuration is used by WebSphere Application Server Version 5.1.1. To modify this configuration, see the JAAS configuration panel for system logins.

system.RMI_INBOUND

This selection handles logins for inbound Remote Method Invocation (RMI) requests. This login configuration is used by WebSphere Application Server Version 5.1.1. To modify this configuration, see the JAAS configuration panel for system logins.

system.DEFAULT

This selection handles the logins for inbound requests that are made by internal authentications and most of the other protocols except Web applications and RMI requests. This login configuration is used by WebSphere Application Server Version 5.1.1. To modify this configuration, see the JAAS configuration panel for system logins.

system.RMI_OUTBOUND

This selection processes RMI requests that are sent outbound to another server when the com.ibm.CSIOutboundPropagationEnabled property is true. This property is set in the CSIv2 authentication panel.

To access the panel, click **Security > Secure administrative, applications, and infrastructure**. Under Authentication, click **RMI/IIOP security > CSIv2 Outbound authentication**. To set the com.ibm.CSIOutboundPropagationEnabled property, select **Security attribute propagation**. To modify this JAAS login configuration, see the JAAS - System logins panel.

system.wssecurity.X509BST

This selection verifies an X.509 binary security token (BST) by checking the validity of the certificate and the certificate path. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.PKCS7

This selection verifies an X.509 certificate within a PKCS7 object that might include a certificate chain, a certificate revocation list, or both. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.PkiPath

This section verifies an X.509 certificate with a public key infrastructure (PKI) path. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.UsernameToken

This selection verifies the basic authentication (user name and password) data. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.IDAssertionUsernameToken

This selection supports the use of identity assertion in Version 6.0.x applications to map a user name to a WebSphere Application Server credential principal. To modify this configuration, see the JAAS configuration panel for system logins.

system.WSS_INBOUND

This selection specifies the login configuration for inbound or consumer requests for security token propagation using Web services security. To modify this configuration, see the JAAS configuration panel for system logins.

system.WSS_OUTBOUND

This selection specifies the login configuration for outbound or generator requests for security token propagation using Web services security. To modify this configuration, see the JAAS configuration panel for system logins.

None With this selection, you do not specify a JAAS login configuration.

14. Click **OK** and then click **Save** to save the configuration.

You have configured the token consumer for the application level.

You must specify a similar token generator configuration for the application level.

Request consumer (receiver) binding configuration settings

Use this page to specify the binding configuration for the request consumer.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules**.
3. Click the Uniform Resource Identifier (URI).
4. Under Web Services Security Properties, click **Web services: Server security bindings**.
5. Under Request consumer (receiver) binding, click **Edit custom**.

The security constraints or bindings are defined using the application assembly process before the application is installed.

If the security constraints are defined in the application, you must either define the corresponding binding information or select the Use defaults option on this panel and use the default binding information for the cell or server level. The default binding that is provided by this product is a sample. Do not use this sample in a production environment without modifying the configuration. The security constraints define what is signed or encrypted in the Web services security message. The bindings define how to enforce the requirements.

Digital signature security constraint (integrity)

The following table shows the required and optional binding information when the digital signature security constraint (integrity) is defined in the deployment descriptor.

Information type	Required or optional
Signing information	Required
Key information	Required
Token consumer	Required
Key locators	Optional
Collection certificate store	Optional
Trust anchors	Optional
Properties	Optional

You can use the key locators, collection certificate stores, and trust anchors that are defined at either the server level or the cell level.

Encryption constraint (confidentiality)

The following table shows the required and optional binding information when the encryption constraint (confidentiality) is defined in the deployment descriptor.

Information type	Required or optional
Encryption information	Required
Key information	Required
Token consumer	Required
Key locators	Optional
Collection certificate store	Optional
Trust anchors	Optional
Properties	Optional

You can use the key locators, collection certificate store, and trust anchors that are defined at either the server level or the cell level.

Security token constraint

The following table shows the required and optional binding information when the security token constraint is defined in the deployment descriptor.

Information type	Required or optional
Token consumer	Required
Collection certificate store	Optional
Trust anchors	Optional
Properties	Optional

You can use the collection certificate store and trust anchors that are defined at the server level or the cell level.

Use defaults:

Select this option if you want to use the default binding information from the server or cell level.

If you select this option, the application server checks for binding information on the server level. If the binding information does not exist on the server level, the application server checks the cell level.

Port:

Specifies the port in the Web service that is defined during application assembly.

Web service:

Specifies the name of the Web service that is defined during application assembly.

Response consumer (receiver) binding configuration settings

Use this page to specify the binding configuration for the response consumer.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules**.
3. Click the Uniform Resource Identifier (URI).
4. Under Web Services Security Properties, click **Web services: Client security bindings**.
5. Under Response consumer (receiver) binding, click **Edit custom**.

The security constraints or bindings are defined using the application assembly process before the application is installed.

If the security constraints are defined in the application, you must either define the corresponding binding information or select the Use defaults option on this panel and use the default binding information for the server or cell level. The default binding that is provided by this product is a sample. Do not use this sample in a production environment without modifying the configuration. The security constraints define what is signed or encrypted in the Web services security message. The bindings define how to enforce the requirements.

Digital signature security constraint (integrity)

The following table shows the required and optional binding information when the digital signature security constraint (integrity) is defined in the deployment descriptor.

Information type	Required or optional
Signing information	Required
Key information	Required
Token consumer	Optional
Key locators	Optional
Collection certificate store	Optional
Trust anchors	Optional
Properties	Optional

You can use the key locators, collection certificate stores, and trust anchors that are defined at either the server level or the cell level.

Encryption constraint (confidentiality)

The following table shows the required and optional binding information when the encryption constraint (confidentiality) is defined in the deployment descriptor.

Information type	Required or optional
Encryption information	Required
Key information	Required
Token consumer	Optional
Key locators	Optional
Collection certificate store	Optional
Trust anchors	Optional
Properties	Optional

You can use the key locators, collection certificate store, and trust anchors that are defined at the application level, server level, or the cell level.

Security token constraint

The following table shows the required and optional binding information when the security token constraint is defined in the deployment descriptor.

Information type	Required or optional
Token consumer	Required
Collection certificate store	Optional
Trust anchors	Optional
Properties	Optional

You can use the collection certificate store and trust anchors that are defined at the application level, server level, or the cell level.

Use defaults:

Select this option if you want to use the default binding information from the cell or server level.

If you select this option, the application server checks for binding information on the server level. If the binding information does not exist on the server level, the application server checks the cell level.

Component:

Specifies the enterprise bean in an assembled Enterprise JavaBeans (EJB) module.

Port:

Specifies the port in the Web service that is defined during application assembly.

Web service:

Specifies the name of the Web service that is defined during application assembly.

JAAS configuration settings

Use this page to specify the name of the Java Authentication and Authorization Service (JAAS) configuration that is defined in the JAAS login panel.

Complete the following steps to access this page on the cell level:

1. Click **Security > Web services**.

2. Under Default consumer bindings, click **Token consumers** > *token_consumer_name* or click **New** to create a new token consumer.
3. Under Additional properties, click **JAAS configuration**.

Complete the following steps to access this page on the server level:

1. Click **Servers** > **Application Servers** > *server_name*.
2. Under Security, click **Web services: Default bindings for Web services security** .
3. Under Default consumer bindings, click **Token consumers** > *token_consumer_name* or click **New** to create a new token consumer.
4. Under Additional properties, click **JAAS configuration**.

Version 6 and later applications

Complete the following steps to access this page on the application level:

1. Click **Applications** > **Enterprise applications** > *application_name*.
2. Click **Manage modules** > *URI_name*.
3. Under Web Services Security Properties, you can access the JAAS configuration settings for the following bindings:
 - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Token consumers** > *token_consumer_name* or click **New** to create a new token consumer. Under Additional properties, click **JAAS configuration**.
 - For the Request consumer (receiver) binding, click **Web services: Server security binding**. Under Request consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Token consumers** > *token_consumer_name* or click **New** to create a new token consumer. Under Additional properties, click **JAAS configuration**.

Important: If you create a new token consumer, you must click **Apply** before you can proceed to the JAAS configuration.

JAAS configuration name:

Specifies the name of the JAAS system or application login configuration.

Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which the application server loads each module.

Preconfigured system login configurations

The following predefined system login configurations are defined on the system logins panel, which is accessible by completing the following steps:

1. Click **Security** > **Secure administration, applications, and infrastructure**.
2. Under Java Authentication and Authorization Service, click **System logins**.

Version 6 and later applications

system.wssecurity.IDAssertionUsernameToken

Enables a Version 6.0.x application to use identity assertion to map a user name to an application server credential principal.

Version 5.x application

system.wssecurity.IDAssertion

Enables a Version 5.x application to use identity assertion to map a user name to an application server credential principal.

Version 5.x application

system.wssecurity.Signature

Enables a Version 5.x application to map a distinguished name (DN) in a signed certificate to an application server credential principal.

system.LTPA_WEB

Processes login requests used by the Web container such as servlets and JavaServer Pages (JSP) files.

system.WEB_INBOUND

Handles logins for Web application requests, which include servlets and JavaServer Pages (JSP) files. This login configuration is used by WebSphere Application Server Version 5.1.1.

system.RMI_INBOUND

Handles logins for inbound Remote Method Invocation (RMI) requests. This login configuration is used by WebSphere Application Server Version 5.1.1.

system.DEFAULT

Handles the logins for inbound requests that are made by internal authentications and most of the other protocols except Web applications and RMI requests. This login configuration is used by WebSphere Application Server Version 5.1.1.

system.RMI_OUTBOUND

Processes RMI requests that are sent outbound to another server when either the `com.ibm.CSI.rmiOutboundLoginEnabled` or the `com.ibm.CSIOutboundPropagationEnabled` properties are `true`. These properties are set in the Common Secure Interoperability Version 2 (CSlv2) authentication panel.

To access the panel, click **Security > Secure administration, applications, and infrastructure**. Under RMI/IIOP security, click **CSlv2 Outbound authentication**. To set the `com.ibm.CSI.rmiOutboundLoginEnabled` property, select the **Custom outbound mapping** option. To set the `com.ibm.CSIOutboundPropagationEnabled` property, select the **Security attribute propagation** option.

system.wssecurity.X509BST

Verifies an X.509 binary security token (BST) by checking the validity of the certificate and the certificate path.

system.wssecurity.PKCS7

Verifies an X.509 certificate with a certificate revocation list in a Public Key Cryptography Standards #7 (PKCS7) object.

system.wssecurity.PkiPath

Verifies an X.509 certificate with a public key infrastructure (PKI) path.

system.wssecurity.UsernameToken

Verifies basic authentication (user name and password).

Application login configurations

The following predefined application login configurations are defined on the Application logins panel, which is accessible by completing the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Java Authentication and Authorization Service, click **Application logins**.

ClientContainer

Specifies the login configuration that is used by the client container application. This application uses the CallbackHandler API that is defined in the deployment descriptor of the client container.

WSLogin

Specifies whether all applications can use the WSLogin configuration to perform authentication for the application server security run time.

DefaultPrincipalMapping

Specifies the login configuration that is used by Java 2 Connectors (J2C) to map users to principals that are defined in the J2C authentication data entries.

Configuring the key locator for the consumer binding on the application level

The key locator information for the consumer at the application level specifies which key locator implementation is used. The key locator implementation locates the key to be used to validate the digital signature or the encryption information by the application.

Complete the following steps to configure the key locator for the consumer binding on the application level:

1. Locate the key locator configuration panel in the administrative console.
 - a. Click **Applications > Enterprise applications > application_name**.
 - b. Under Manage modules, click *URI_name*.
 - c. Under Web Services Security Properties, you can access the key information for the request consumer and response consumer bindings.
 - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
 - d. Under Additional properties, click **Key locators**.
 - e. Click **New** to create a key locator configuration, click **Delete** and select the box next to the configuration to delete an existing configuration, or click the name of an existing key locator configuration to edit its settings. If you are creating a new configuration, enter a unique name in the Key locator name field. For example, you might specify *klocator*.
2. Specify a name for the key locator class implementation. Key locators that are associated with Version 6.0.x applications must implement the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` interface. Specify a class name according to the requirements of the application. For example, if the application requires that the key is read from a keystore file, specify the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` implementation. WebSphere Application Server provides the following default key locator class implementations for Version 6.0.x applications that are available to use with the request consumer or response consumer:
 - com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator**
This implementation locates and obtains the key from the specified keystore file.
 - com.ibm.wsspi.wssecurity.keyinfo.X509TokenKeyLocator**
This implementation uses the X.509 security token from the sender message for digital signature validation and encryption. This class implementation is used by the request consumer and the response consumer.
3. Specify the keystore password, the keystore location, and the keystore type. Keystore files contain public and private keys, root certificate authority (CA) certificates, the intermediate CA certificate, and so on. Keys that are retrieved from the keystore files are used to sign and validate or encrypt and decrypt messages or message parts. If you specified the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` implementation for the key locator class implementation, you must specify a keystore password, location, and type.

- a. Specify a password in the keystore **Password** field. This password is used to access the keystore file.
- b. Specify the location of the keystore file in the keystore **Path** field.
- c. Select a keystore type from the keystore **Type** field. The Java Cryptography Extension (JCE) that is used by IBM supports the following keystore types:

JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

JCEKS

Use this option if you are using Java Cryptography Extensions.

JCERACFKS

Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

PKCS11KS (PKCS11)

Use this format if your keystore file uses the PKCS#11 file format. Keystore files that use this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)

Use this option if your keystore uses the PKCS#12 file format.

WebSphere Application Server provides some sample keystore files in the `${USER_INSTALL_ROOT}/etc/ws-security/samples` directory. For example, you might use the `enc-receiver.jceks` keystore file for encryption keys. The password for this file is `Storepass` and the type is `JCEKS`.

Attention: Do not use these keystore files in a production environment. These samples are provided for testing purposes only.

4. Click **OK** and **Save** to save the configuration.
5. Under Additional properties, click **Keys**.
6. Click **New** to create a key configuration, click **Delete** and select the box next to the configuration to delete an existing configuration, or click the name of an existing key configuration to edit its settings. This entry specifies the name of the key object within the keystore file. If you are creating a new configuration, enter a unique name in the Key name field.
It is recommended that you use a fully qualified distinguished name for the key name. For example, you might use `CN=Bob,O=IBM,C=US`.
7. Specify an alias in the Key alias field. The key alias is used by the key locator to search for key objects in the keystore file.
8. Specify a password in the Key password field. The password is used to access the key object within the keystore file.
9. Click **OK** and then click **Save** to save the configuration.

You have configured the key locator for the consumer binding at the application level.

You must specify a similar key information configuration for the generator.

Configuring the key information for the consumer binding on the application level

Configure the key locators and the token consumers that are referenced by the Key locator reference and the Token reference fields within the key information panel.

This task provides the steps that are needed for configuring the key information for the request consumer (server side) and the response consumer (client side) bindings at the application level. The key information on the consumer side is used for specifying the information about the key, which is used for validating the digital signature in the received message or for decrypting the encrypted parts of the message. Complete the following steps to configure the key information for consumer binding on the application level.

1. Locate the key information configuration panel in the administrative console.
 - a. Click **Applications > Enterprise applications > application_name**.
 - b. Under Manage modules, click *URI_name*.
 - c. Under Web Services Security Properties, you can access the key information for the request consumer and response consumer bindings.
 - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under request consumer (receiver) binding, click **Edit custom**.
 - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under response consumer (receiver) binding, click **Edit custom**.
 - d. Under Required properties, click **Key information**.
 - e. Click **New** to create a key information configuration, click **Delete** and select the box next to the configuration to delete an existing configuration, or click the name of an existing key information configuration to edit its settings. If you are creating a new configuration, enter a name in the Key information name field. For example, you might specify *con_signkeyinfo*.
2. Select a key information type from the Key information type field. The key information types specify different mechanisms for referencing security tokens using the <wsse:SecurityTokenReference> element within the <ds:KeyInfo> element. WebSphere Application Server supports the following key information types:

Key identifier

The security token is referenced using an opaque value that uniquely identifies the token. The algorithm that is used for generating the <KeyIdentifier> element value depends upon the token type. For example, you can use the identifier for the public keys that are defined in the Internet Engineering Task Force (IETF) Request for Comment (RFC) 3280. The following <KeyInfo> element is generated in the Simple Object Access Protocol (SOAP) message for this key information type:

```
<ds:KeyInfo xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
  <wsse:SecurityTokenReference>
    <wsse:KeyIdentifier ValueType="http://docs.oasis-open.org/wss/2004/01/
      oasis-200401-wss-x509-token-profile-1.0#X509v3SubjectKeyIdentifier">
      /62wX0...
    </wsse:KeyIdentifier>
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

Key name

The security token is referenced using a name that matches an identity assertion within the token. It is recommended that you do not use this key type as it might result in multiple security tokens that match the specified name. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <ds:KeyName>CN=Group1</ds:KeyName>
</ds:KeyInfo>
```

In general, use a key name when you use a Key-Hashing Message Authentication Code (HMAC) digital signature algorithm, such as <http://www.w3.org/2000/09/xmldsig#hmac-sha1>.

Security token reference

The security token is directly referenced using Universal Resource Identifiers (URIs). The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <wsse:Reference URI='#SomeCert'
      ValueType="http://docs.oasis-open.org/wss/2004/01/
        oasis-200401-wss-x509-token-profile-1.0#X509v3" />
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

Attention: As stated in the Web services Interoperability Organization (WS-I) Basic Security Profile Version 1 draft and shown in the previous example, the `wsse:Reference` element in a `SECURE_ENVELOPE` must have a `ValueType` attribute.

Embedded token

The security token is directly embedded within the `<SecurityTokenReference>` element. The following `<KeyInfo>` element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <wsse:Embedded wsu:Id="tok1" />
    ...
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

X509 issuer name and issuer serial

The security token is referenced by an issuer name and an issuer serial number of an X.509 certificate. The following `<KeyInfo>` element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
  <wsse:SecurityTokenReference>
    <ds:X509Data>
      <ds:X509IssuerSerial>
        <ds:X509IssuerName>CN=Jones, O=IBM, C=US</ds:X509IssuerName>
        <ds:X509SerialNumber>1040152879</ds:X509SerialNumber>
      </ds:X509IssuerSerial>
    </ds:X509Data>
  </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

Each type of key information is described in the Web Services Security: SOAP Message Security 1.0 (WS-Security 2004) OASIS standard, which is located at: <http://www.oasis-open.org/home/index.php> under Web services security.

3. Select a key locator reference from the Key locator reference field. The value of this field is a reference to a key locator that WebSphere Application Server uses to locate the keys that are used for digital signature and encryption. Before you can select a key locator, you must configure a key locator. For more information on configuring a key locator, see “Configuring the key locator for the consumer binding on the application level” on page 1203.
4. Select a token reference from the Token reference field. The token reference specifies a reference to a token consumer that is used for processing the security token in the message. However, WebSphere Application Server requires this field only when you select Security token reference or Embedded token in the Key information type field. Before specifying a token reference, you must configure a token consumer. For more information on configuring a token consumer, see “Configuring token consumer on the application level” on page 1191.
Select **(none)** if a token consumer is not required for this key information configuration.
5. Click **OK** and **Save** to save this configuration.

You have configured the key information for the generator binding at the application level

If you have not configured the key information for the generator binding. You must specify a similar key information configuration for the generator. After you configure the key information for both the consumer and the generator, configure the signing information or encryption information, which references the key information that is specified in this key information task.

Configuring the signing information for the consumer binding on the application level

You can configure the signing information for the server-side request consumer and the client-side response consumer bindings at the application level.

In the server-side extensions file and the client-side deployment descriptor extensions file, you must specify which parts of the message are signed. Also, you must configure the key information that is referenced by the key information references on the signing information panel within the administrative console.

WebSphere Application Server uses the signing information on the consumer side to verify the integrity of the received SOAP message by validating that the message parts are signed. Complete the following steps to configure the signing information for the server-side request consumer and client-side response consumer sections of the bindings files on the application level:

1. Access the administrative console.
To access the administrative console, enter `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.
2. Click **Applications > Enterprise applications > application_name**.
3. Under Manage modules, click *URI_name*.
4. Under Web Services Security Properties you can access the signing information for the request generator and response generator bindings.
 - To configure the request consumer signing information, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - To configure the response consumer signing information, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
5. Under Required properties, click **Signing information**.
6. Click **New** to create a signing information configuration, click **Delete** to delete an existing configuration, or click the name of an existing signing information configuration to edit its settings. If you are creating a new configuration, enter a name in the Signing information name field.
7. Select a signature method algorithm from the Signature method field. The signature method is the algorithm that is used to convert the canonicalized `<SignedInfo>` element in the binding file into the `<SignatureValue>` element. The algorithm that is specified for the consumer, which is either the request consumer or the response consumer configuration, must match the algorithm specified for the generator, which is either the request generator or response generator configuration. WebSphere Application Server supports the following pre-configured algorithms:
 - `http://www.w3.org/2000/09/xmldsig#rsa-sha1`
 - `http://www.w3.org/2000/09/xmldsig#hmac-sha1`
 - `http://www.w3.org/2000/09/xmldsig#dsa-sha1`
Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP). Any `ds:SignatureMethod/@Algorithm` element in a signature based on a symmetric key must have a value of `http://www.w3.org/2000/09/xmldsig#rsa-sha1` or `http://www.w3.org/2000/09/xmldsig#hmac-sha1`.
8. Select a canonicalization method from the Canonicalization method field. The canonicalization method algorithm is used to canonicalize the `<SignedInfo>` element before it is incorporated as part of the digital signature operation. The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer. WebSphere Application Server supports the following pre-configured algorithms:
 - `http://www.w3.org/2001/10/xml-exc-c14n#`
 - `http://www.w3.org/2001/10/xml-exc-c14n#WithComments`
 - `http://www.w3.org/TR/2001/REC-xml-c14n-20010315`

- <http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments>

9. Select a key information signature type from the Key information signature type field. The key information signature type specifies how the <KeyInfo> element in the SOAP message is digitally signed. WebSphere Application Server supports the following signature types:

None Specifies that the key is not signed.

Keyinfo

Specifies that the entire KeyInfo element is signed.

Keyinfochildelements

Specifies that the child elements of the KeyInfo element are signed.

If you do not specify one of the previous signature types, WebSphere Application Server uses keyinfo, by default. The key information signature type for the consumer must match the signature type for the generator.

10. Under Additional properties, click **Key information references**.
 - a. Click **New** to create a key information reference or click the name of an existing entry to edit its configuration. The Key information references panel is displayed.
 - b. Enter a name in the Name field.
 - c. Select a key information reference in the Key information reference field. This reference is the key information configuration name that specifies the key information that is used by this signing information configuration.
11. Return to the Signing information panel. Under Additional properties, click **Part references**. On the Part references panel, you can specify references to the message parts that are defined in the deployment descriptor extensions file.
 - a. Click **New** to create a new Part reference or click the name of an existing part reference to edit its configuration. The Part reference panel is displayed.
 - b. Enter a name in the Part name field. This name is the name of the required integrity configuration in the deployment descriptor extensions file and specifies the message parts that must be digitally signed.
 - c. Select a digest method algorithm from the Digest method algorithm field.
 WebSphere Application Server supports the following pre-configured algorithms:
 - <http://www.w3.org/2000/09/xmlsig#sha1>
 - <http://www.w3.org/2001/04/xmlenc#sha256>
 - <http://www.w3.org/2001/04/xmlenc#sha512>
 If you want to specify a custom algorithm, you must configure the custom algorithm in the Algorithm URI panel before setting the digest method algorithm.
12. Under Additional properties, click **Transforms**.
 - a. Click **New** to create a new transform or click the name of an existing transform to edit its configuration.
 - b. Enter a name in the Transform name field.
 - c. Select a transform algorithm from the Transform algorithm field. WebSphere Application Server supports the following pre-configured algorithms:
 - <http://www.w3.org/2001/10/xml-exc-c14n#>
 - <http://www.w3.org/TR/1999/REC-xpath-19991116>
 Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use <http://www.w3.org/2002/06/xmlsig-filter2> to ensure compliance.
 - <http://www.w3.org/2002/06/xmlsig-filter2>
 - <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform>

- <http://www.w3.org/2002/07/decrypt#XML>
- <http://www.w3.org/2000/09/xmldsig#enveloped-signature>

The transform algorithm that you select for the consumer must match the transform algorithm that you select for the generator. For each part reference in the signing information, specify both a digest method algorithm and a transform algorithm.

13. Click **OK**.
14. Click **Save** at the top of the panel to save your configuration.

After completing these steps, you have configured the signing information for the consumer.

You must specify a similar signing information configuration for the generator.

Key information references collection

Use this page to view the key information references that are needed for encryption or signing.

To view this administrative console page on the cell level, complete the following steps. On the cell level, you can configure the key information references for the default consumer bindings only.

1. Click **Security > Web services**.
2. Under Default consumer bindings, click either of the following links:
 - Click **Encryption information** > *encryption_information_name*.
 - Click **Signing information** > *signing_information_name*.
3. Under Additional properties, click **Key information references**.

To view this administrative console page on the server level, complete the following steps. On the server level, you can configure the key information references for the default consumer bindings only.

1. Click **Servers > Application Servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default consumer bindings, click either of the following links:
 - Click **Encryption information** > *encryption_information_name*.
 - Click **Signing information** > *signing_information_name*.
4. Under Additional properties, click **Key information references**.

To view this administrative console page on the application level, complete the following steps. On the application level, you can configure the key information reference for the consumer bindings only.

1. Click **Applications > Enterprise applications > application_name**.
2. Click **Manage modules > URI_name**.
3. Under Web Services Security properties, you can access the signing information for the following bindings:
 - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**. Click **New** to create a new encryption configuration or click the name of a configuration to modify its settings.
 - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**. Click **New** to create a new encryption configuration or click the name of a configuration to modify its settings.

Name:

Specifies the name of the Key information reference.

Key information reference:

Specifies a reference to the message parts that are signed or encrypted.

The value of this field is the name of the <requiredIntegrity> or the <requiredConfidentiality> element in the deployment descriptor.

Key information reference configuration settings

Use this page to specify a reference to the message parts for signature and encryption that is defined in the deployment descriptors.

To view this administrative console page on the cell level for the key information references, complete the following steps. On the cell level, you can configure the key information references for the default consumer bindings only.

1. Click **Security > Web services**.
2. Under Default consumer bindings, click either of the following links:
 - Click **Encryption information** > *encryption_information_name*.
 - Click **Signing information** > *signing_information_name*.
3. Under Additional properties, click **Key information references**.
4. Click **New** to create a key information reference or click the name of an existing configuration to modify its settings.

To view this administrative console page on the server level for the key information references, complete the following steps. On the server level, you can configure the key information references for the default consumer bindings only.

1. Click **Servers > Application Servers** > *server_name*.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default consumer bindings, click either of the following links:
 - Click **Encryption information** > *encryption_information_name*.
 - Click **Signing information** > *signing_information_name*.
4. Under Additional properties, click **Key information references**.
5. Click **New** to create a key information reference or click the name of an existing configuration to modify its settings.

To view this administrative console page on the application level, complete the following steps:

1. Click **Applications > Enterprise applications** > *application_name*.
2. Click **Manage modules** > *URI_name*.
3. Under Web Services Security Properties, you can access the key information references for the following bindings:
 - For the Response consumer (sender) binding, click **Web services: Client security bindings**. Under Response consumer (sender) binding, click **Edit custom**. Under Required properties, click **Encryption information** > *encryption_information_name*. Under Additional properties, click **Key information references**.
 - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information** > *encryption_information_name*. Under Additional properties, click **Key information references**.
4. Click **New** to create a key information reference or click the name of an existing configuration to modify its settings.

Name:

Specifies the name of the key information reference.

Key information reference:

Specifies a reference to the message parts that are signed or encrypted.

The value of this field is the name of the <requiredIntegrity> or the <requiredConfidentiality> element in the deployment descriptor. You can specify a signing key configuration for the following bindings:

Binding name	Cell level, Server level, or application level	Path
Default consumer binding	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Default consumer binding, click Key information.
Default consumer binding	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application Servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Default consumer binding, click Key information.
Response consumer (receiver) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Click Manage modules > URI_name. 3. Under Web Services Security Properties, click Web services: Client security bindings. 4. Under Response consumer (receiver) binding, click Edit custom. 5. Under Required properties, click Key information.
Request consumer (receiver) binding	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Click Manage modules > URI_name. 3. Under Web Services Security Properties, click Web services: Server security bindings. 4. Under Request consumer (receiver) binding, click Edit custom. 5. Under Required properties, click Key information.

Configuring the encryption information for the consumer binding on the application level

Configure the key information that is referenced in the encryption information panel. For more information, see “Configuring the key information for the consumer binding on the application level” on page 1204.

This task provides the steps that are needed for configuring the encryption information for the request consumer (server side) and response consumer (client side) bindings at the application level. The encryption information on the consumer side is used for decrypting the encrypted message parts in the incoming Simple Object Access Protocol (SOAP) message.

Complete the following steps to configure the encryption information for the request consumer or response consumer section of the bindings file on the application level:

1. Locate the Encryption information configuration panel in the administrative console.
 - a. Click **Applications > Enterprise applications > *application_name***.
 - b. Under Manage modules, click *URI_name*.
 - c. Under Web Services Security Properties you can access the encryption information for the request consumer and response consumer bindings.
 - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
 - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
 - d. Under Required properties, click **Encryption information**.
 - e. Click **New** to create an encryption information configuration, click **Delete** to delete an existing configuration, or click the name of an existing encryption information configuration to edit its settings. If you are creating a new configuration, enter a name in the Encryption information name field. For example, you might specify *cons_encinfo*.
2. Select a data encryption algorithm from the Data encryption algorithm field. The data encryption algorithm is used for encrypting or decrypting parts of a SOAP message such as the SOAP body or the username token. WebSphere Application Server supports the following pre-configured algorithms:
 - <http://www.w3.org/2001/04/xmlenc#tripledes-cbc>
 - <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
 - <http://www.w3.org/2001/04/xmlenc#aes256-cbc>To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.
 - <http://www.w3.org/2001/04/xmlenc#aes192-cbc>To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

The data encryption algorithm that you select for the consumer side must match the data encryption method that you select for the generator side.
3. Select a key encryption algorithm from the Key encryption algorithm field. The key encryption algorithm is used for encrypting the key that is used for encrypting the message parts within the SOAP message. Select (**none**) if the data encryption key, which is the key that is used for encrypting the message parts, is not encrypted. WebSphere Application Server supports the following pre-configured algorithms:
 - <http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p>.When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this one. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5.

Restriction: This algorithm is not supported when the WebSphere Application Server is running in Federal Information Processing Standard (FIPS) mode.

 - http://www.w3.org/2001/04/xmlenc#rsa-1_5
 - <http://www.w3.org/2001/04/xmlenc#kw-tripledes>
 - <http://www.w3.org/2001/04/xmlenc#kw-aes128>
 - <http://www.w3.org/2001/04/xmlenc#kw-aes256>

To use the <http://www.w3.org/2001/04/xmlenc#aes256-cbc> algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site:
<http://www.ibm.com/developerworks/java/jdk/security/index.html>.

- <http://www.w3.org/2001/04/xmlenc#kw-aes192>

To use the <http://www.w3.org/2001/04/xmlenc#kw-aes192> algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site:
<http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

The key encryption algorithm that you select for the consumer side must match the key encryption method that you select for the generator side.

4. **Optional:** Select a part reference in the Part reference field. The part reference specifies the name of the message part that is encrypted and is defined in the deployment descriptor. For example, you can encrypt the bodycontent message part in the deployment descriptor. The name of this Required Confidentiality part is conf_con. This message part is shown as an option in the Part reference field.
5. Under Additional properties, click **Key information references**.
6. Click **New** to create a key information configuration, click **Delete** to delete an existing configuration, or click the name of an existing key information configuration to edit its settings. If you are creating a new configuration, enter a name in the name field. For example, you might specify con_ekeyinfo. This entry is the name of the <encryptionKeyInfo> element in the binding file.
7. Select a key information reference from the Key information reference field. This reference is the value of the keyinfoRef attribute of the <encryptionKeyInfo> element and it is the name of the <keyInfo> element that is referenced by this key information reference. Each key information reference entry generates an <encryptionKeyInfo> element under the <encryptionInfo> element in the binding configuration file. For example, if you enter con_ekeyinfo in the Name field and dec_keyinfo in the Key information reference field, the following <encryptionKeyInfo> element is generated in the binding file:

```
<encryptionKeyInfo xmi:id="EncryptionKeyInfo_1085092248843"
keyinfoRef="dec_keyinfo" name="con_ekeyinfo"/>
```
8. Click **OK** and then click **Save** to save the configuration.

You have configured the encryption information for the consumer binding at the application level

You must specify a similar encryption information configuration for the generator.

Hardware cryptographic device support for Web Services Security

In IBM WebSphere Application Server Version 6.1 or later, Web services security supports the use of cryptographic hardware devices. There are two ways in which to use hardware cryptographic devices with Web services security as described in this article.

Enabling cryptographic operations on hardware devices

You can enable cryptographic operations on hardware devices. The keys that are used can be stored in a Java keystore file; it is not necessary to store them on the hardware device. The decision to use enable cryptographic operations on hardware devices is made at the server level only, not at the application level.

If cryptographic operations on hardware device is enabled, the Web service security run time first attempts to use the hardware device for cryptographic operations. If the attempt to use the hardware device fails, or the algorithm is not supported by the hardware device, the run time uses a software provider from the security providers list.

Enabling this feature might improve the performance depending on the hardware device.

For more information on how to enable cryptographic operations on hardware devices, see “Configuring hardware cryptographic devices for Web Services Security” on page 1215.

Secure keys

Cryptographic keys can be stored on the hardware cryptographic device and never leave the device. These secure keys are confined to the hardware cryptographic device for security considerations rather than performance considerations. The option to select whether to use keys stored in a hardware cryptographic device or a Java keystore file can be made at the application level.

If the keystore reference is specified to be a hardware device configuration, the Web services security run time first attempts to obtain the cryptographic algorithm from the hardware device. If the algorithm is not supported or fails, the run time uses a software provider from the security providers list.

Limitations

The hardware cryptographic device support for Web Services Security currently has the following limitations:

- There is no support for a Web services client running as a J2EE Application Client.
- There is no support for hardware cryptographic devices on iSeries.
- Versions 5.x and 6.0 Web services security applications can run in a Version 6.1 WebSphere Application Server, but they cannot take advantage of the hardware cryptographic support. Only Version 6.1 and later Web services security applications can take advantage of the hardware cryptographic support.

Enabling hardware cryptographic devices for Web Services Security

A cryptographic token is a hardware or software device with a built-in keystore implementation. Cryptographic devices are used to manage certificates stored on the cryptographic tokens. These devices are also called smartcards.

You can enable Web Services Security using cryptographic hardware devices for both Web service clients and Web service providers running in the WebSphere Application Server environment.

Web services security using cryptographic hardware devices is supported for both Web (JavaServer Pages (JSP) or servlet) and Enterprise JavaBeans (EJB) Web service clients. Individual applications have the option to select whether to use keys stored in hardware devices or in a Java keystore file.

There are two ways to enable hardware cryptographic devices for Web service security:

- Enable cryptographic operations on hardware devices for Web services security. For more information, see “Configuring hardware cryptographic devices for Web Services Security” on page 1215.
- Enable cryptographic keys that are stored in hardware devices for Web services security. For more information, see “Enabling cryptographic keys stored in hardware devices in Web Services Security” on page 1215

Note: Hardware cryptographic devices for Web Services Security are not supported on the Java 2 Platform, Enterprise Edition (J2EE) Application Client on distributed platform.

Related concepts

“Hardware cryptographic device support for Web Services Security” on page 1213

In IBM WebSphere Application Server Version 6.1 or later, Web services security supports the use of cryptographic hardware devices. There are two ways in which to use hardware cryptographic devices with Web services security as described in this article.

Related tasks

“Configuring hardware cryptographic devices for Web Services Security”

You can configure a hardware cryptographic device in Web Service Security. The key for the cryptographic operation can be stored in an ordinary Java key store file, and does not need to be stored on the hardware devices.

“Enabling cryptographic keys stored in hardware devices in Web Services Security”

You can enable individual Web service applications to use cryptographic keys stored in hardware devices in Web Services Security.

Configuring hardware cryptographic devices for Web Services Security

You can configure a hardware cryptographic device in Web Service Security. The key for the cryptographic operation can be stored in an ordinary Java key store file, and does not need to be stored on the hardware devices.

You must first configure a hardware cryptographic device using the Secure Sockets Layer (SSL) certificate and key management panels in the administrative console.

1. In the administrative console, click **Servers > Application servers** and then select the server name.
2. Under **Security**, select **Web services: default bindings for Web services security**.
3. Under Cryptographic Hardware, select **Enable cryptographic operations on hardware device** and then specify the name of the hardware cryptographic device configuration name. For more information, see “Configuring a hardware cryptographic keystore” on page 467.
4. Click **OK**.

This procedure configures a hardware cryptographic device for all Web services security applications running on the WebSphere Application Server.

Related concepts

“Hardware cryptographic device support for Web Services Security” on page 1213

In IBM WebSphere Application Server Version 6.1 or later, Web services security supports the use of cryptographic hardware devices. There are two ways in which to use hardware cryptographic devices with Web services security as described in this article.

Related tasks

“Enabling hardware cryptographic devices for Web Services Security” on page 1214

“Enabling cryptographic keys stored in hardware devices in Web Services Security”

You can enable individual Web service applications to use cryptographic keys stored in hardware devices in Web Services Security.

“Configuring a hardware cryptographic keystore” on page 467

You can create a hardware cryptographic keystore that WebSphere Application Server can use to provide cryptographic token support in the server configuration.

Enabling cryptographic keys stored in hardware devices in Web Services Security

You can enable individual Web service applications to use cryptographic keys stored in hardware devices in Web Services Security.

You must first configure the hardware acceleration device using the key management panels in the administrative console. See “Configuring hardware cryptographic devices for Web Services Security”

1. In the administrative console, click **Servers > Application servers** and then select the server name.
2. Under **Security**, click **Web services: default bindings for Web services security**.
3. Under **Additional properties**, click **key locators**.
4. Select the key locator name.
5. Under **Key store**, specify the name of the keystore configuration.

If the keystore reference is specified to a hardware device configuration, the Web Services Security run time first attempts to obtain the cryptographic algorithm from the hardware device. If the hardware device is not supported or if it fails, the run time for Web services security obtains the cryptographic

algorithm from the security providers list. See “Creating a keystore configuration” on page 465 for more information about how to create the name of a keystore configuration.

6. Click **OK**.

If the name of the keystore reference is a Java keystore file, a hardware acceleration device configured at the application server level (`ws-security.xml`) is used for cryptographic operations.

Retrieving tokens from the JAAS Subject in a server application

In WebSphere Application Server Version 6.1, the security handlers are responsible for propagating security tokens. These security tokens are embedded in the SOAP security header and passed to downstream servers. The security tokens are encapsulated in the implementation classes for the `com.ibm.wsspi.wsssecurity.auth.token.Token` interface. You can retrieve the security token data from either a server application or a client application.

With a server application, the application acts as the request consumer and the response generator, is deployed, and runs in the Java 2 Platform, Enterprise Edition (J2EE) container. The consumer component for Web services security stores the security tokens that it receives in the Java Authentication and Authorization Service (JAAS) Subject of the current thread. You can retrieve the security tokens from the JAAS Subject that is maintained as a local thread in the container. Complete the following steps to retrieve the security token data from a server application:

1. Obtain the JAAS Subject of the current thread using the `WSSubject` utility class. If you enable Java 2 security on the Secure administration, applications, and infrastructure panel in the administrative console, access to the JAAS Subject is denied if the application code is not granted the `javax.security.auth.AuthPermission("wsssecurity.getCallerAsSubject")` permission. The following code sample shows how to obtain the JAAS subject:

```
javax.security.auth.Subject subj;
try {
    subj = com.ibm.websphere.security.auth.WSSubject.getCallerSubject();
} catch (com.ibm.websphere.security.WSSecurityException e) {
    ...
}
```

2. Obtain a set of private credentials from the Subject. For more information, see the application programming interface (API) `com.ibm.websphere.security.auth.WSSubject` class through the information center. To access this information within the information center, click **Reference > Developer > API Documentation > Application Programming Interfaces**. In the Application Programming Interfaces article, click **com.ibm.websphere.security.auth > WSSubject**.

Attention: When Java 2 security is enabled, you might need to use the `AccessController` class to avoid a security violation that is caused by operating the security objects in the J2EE container.

The following code sample shows how to set the `AccessController` class and obtain the private credentials:

```
Set s = (Set) AccessController.doPrivileged(
    new PrivilegedAction() {
        public Object run() {
            return subj.getPrivateCredentials();
        }
    });
```

3. Search the targeting token class in the private credentials. You can search the targeting token class by using the `java.util.Iterator` interface. The following example shows how to retrieve a username token

with a certain token ID value in the security header. You can also use other method calls to retrieve security tokens. For more information, see the application programming interface (API) documents for the `com.ibm.wsspi.wssecurity.auth.token.Token` interface or custom token classes.

```
com.ibm.wsspi.wssecurity.auth.token.UsernameToken unt;
Iterator it = s.iterator();
while (it.hasNext()) {
    Object obj = it.next();
    if (obj != null &&
        obj instanceof com.ibm.wsspi.wssecurity.auth.token.UsernameToken) {
        unt =(com.ibm.wsspi.wssecurity.auth.token.UsernameToken) obj;
        if (unt.getId().equals("...")) break;
    } else continue;
}
```

After completing these steps, you have retrieved the security tokens from the JAAS Subject in a server application

Retrieving tokens from the JAAS Subject in an application

The security handlers are responsible for propagating security tokens. These security tokens are embedded in the SOAP security header and passed to downstream servers.

The security tokens are encapsulated in the implementation classes for the `com.ibm.wsspi.wssecurity.auth.token.Token` interface. You can retrieve the security token data from either a server application or a client application.

With a client application, the application serves as the request generator and the response consumer and runs as the Java 2 Platform, Enterprise Edition (J2EE) client application. The consumer component for Web services security stores the security tokens that it receives in one of the properties of the `MessageContext` object for the current Web services call. You can retrieve a set of token objects through the `javax.xml.rpc.Stub` interface of that Web Services call. You must know which security tokens to retrieve and their token IDs in case multiple security tokens are included in the SOAP security header. Complete the following steps to retrieve the security token data from a client application:

1. Use the `com.ibm.wsspi.wssecurity.token.tokenProperagation` key string to obtain the `Hashtable` for the tokens through a property value in the `javax.xml.rpc.Stub` interface. The following example shows how to obtain the `Hashtable`:

```
java.util.Hashtable t;
javax.xml.rpc.Service serv = ...;
MyWSPortType pt = (MyWSPortType)serv.getPort(MyWSPortType.class);
t = (Hashtable)((javax.xml.rpc.Stub)pt)._getProperty(
    com.ibm.wsspi.wssecurity.Constants.WSSECURITY_TOKEN_PROPERGATION);
```

2. Search the targeting token objects in the `Hashtable`. Each token object in the `Hashtable` is set with its token ID as a key. You must have prior knowledge of the security token IDs to retrieve the security tokens. The following example shows how to retrieve a username token from the security header with a certain token ID value:

```
com.ibm.wsspi.wssecurity.auth.token.UsernameToken unt;
if (t != null) {
    unt = (com.ibm.wsspi.wssecurity.auth.token.UsernameToken)t.get("...");
}
```

After completing these steps, you have retrieved the security tokens from the JAAS Subject in a client application

Configuring trust anchors on the server or cell level

Prior to completing the steps to configure trust anchors, you must create the keystore file using the key tool. WebSphere Application Server provides the key tool in the `install_dir/java/jre/bin/keytool` file.

This task provides the steps that are needed to configure a list of keystore objects that contain trusted root certificates. These objects are used for certificate path validation of incoming X.509-formatted security tokens. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath application programming interface (API) to determine whether to trust a certificate chain.

You can configure trust anchors on the server level and the cell level. In the following steps, use the first step to access the server-level default bindings and use the second step to access the cell-level bindings.

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > *server_name***.
 - b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Additional properties, click **Trust anchors**.
4. Click **New** to create a trust anchor configuration, click **Delete** to delete an existing configuration, or click the name of an existing trust anchor configuration to edit its settings. If you are creating a new configuration, enter a unique name for the trust anchor in the Trust anchor name field.
5. Specify a password in the Key store password field that is used to access the keystore file.
6. Specify the absolute location of the keystore file in the Key store path field. It is recommended that you use the *USER_INSTALL_ROOT* variable as a portion of the keystore path. To change this predefined variable, click **Environment > WebSphere variables**. The *USER_INSTALL_ROOT* variable might display on the second page of variables.
7. Specify the type of keystore file in the key store type field. WebSphere Application Server supports the following keystore types:
 - JKS** Use this option if you are not using Java Cryptography Extensions (JCE) and your keystore file uses the Java Key Store (JKS) format.
 - JCEKS** Use this option if you are using Java Cryptography Extensions.
 - JCERACFKS** Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).
 - PKCS11KS (PKCS11)** Use this option if your keystore file uses the PKCS#11 file format. Keystore files that use this format might contain Rivest Shamir Adleman (RSA) keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.
 - PKCS12KS (PKCS12)** Use this option if your keystore file uses the PKCS#12 file format.
8. Click **OK** and **Save** to save your configuration.

You have configured trust anchors at the server or cell level.

Configuring the collection certificate store for the server or cell-level bindings

Collection certificate stores contain untrusted, intermediary certificate files awaiting validation. You can configure a collection certificate store on the server level.

Validation might consist of checking for a valid signature in a digitally signed SOAP message to see if the certificate is on a certificate revocation list (CRLs), checking that the certificate is not expired, and checking that the certificate is issued by a trusted signer.

In the following steps, use the first step to configure the collection certificate store for the server level and use the second step to configure the collection certificate store for the cell level:

1. Access the default bindings for the server level.

- a. Click **Servers > Application servers > server_name** .
- b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Additional properties, click **Collection certificate store**.
4. Click **New** to create a collection certificate store configuration, click **Delete** to delete an existing configuration, or click the name of an existing collection certificate store configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field. For example, you might name your certificate store `sig_certstore`.

The name of the collection certificate store must be unique to the level of the application server. For example, if you create the collection certificate store for the server level, the store name must be unique to the server level. The name that is specified in the Certificate store name field is used by other configurations to refer to a predefined collection certificate store. WebSphere Application Server searches for the collection certificate store based on proximity.

For example, if an application binding refers to a collection certificate store named `cert1`, the Application Server searches for `cert1` at the application level before searching the server level and then the cell level.

5. Specify a certificate store provider in the Certificate store provider field. WebSphere Application Server supports the `IBMCertPath` certificate store provider. To use another certificate store provider, you must define the provider implementation in the provider list within the `install_dir/java/jre/lib/security/java.security` file. However, make sure that your provider supports the same requirements of the certificate path algorithm as WebSphere Application Server.
6. Click **OK** and **Save** to save the configuration.
7. Click the name of your certificate store configuration. After you specify the certificate store provider, you must specify either the location of a certificate revocation list or the X.509 certificates. However, you can specify both a certificate revocation list and the X.509 certificates for your certificate store configuration.
8. Under Additional properties, click **Certificate revocation lists**. For the generator binding, a certificate revocation list (CRL) is used when it is included in a generated security token. For example, a security token might be wrapped in a PKCS#7 format with a CRL. For more information on certificate revocation lists, see “Certificate revocation list” on page 1032.
9. Click **New** to specify a certificate revocation list path, click **Delete** to delete an existing list reference, or click the name of an existing reference to edit the path. You must specify the fully qualified path to the location where WebSphere Application Server can find your list of certificates that are not valid. WebSphere Application Server uses the certificate revocation list to check the validity of the sender certificate.

For portability reasons, it is recommended that you use the WebSphere Application Server variables to specify a relative path to the certificate revocation lists. This recommendation is especially important when you are working in a WebSphere Application Server Network Deployment environment.

For example, you might use the `USER_INSTALL_ROOT` variable to define a path such as `$USER_INSTALL_ROOT/mycertstore/mycrl1` where `mycertstore` represents the name of your certificate store and `mycrl1` represents the certificate revocation list. For a list of supported variables, click **Environment > WebSphere variables** in the administrative console. The following list provides recommendations for using certificate revocation lists:

- If CRLs are added to the collection certificate store, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.
- When the CRL file is updated, the new CRL does not take effect until you restart the Web service application.

- Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.
10. Click **OK** and then **Save** to save the configuration.
 11. Return to the Collection certificate store configuration panel.
 12. Under Additional properties, click **X.509 certificates**. The X.509 certificate configuration specifies intermediate certificate files that are used for certificate path validation of incoming X.509-formatted security tokens.
 13. Click **New** to create an X.509 certificate configuration, click **Delete** to delete an existing configuration, or click the name of an existing X.509 certificate configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field.
 14. Specify a path in the X.509 certificate path field. This entry is the absolute path to the location of the X.509 certificate. The collection certificate store is used to validate the certificate path of the incoming X.509-formatted security tokens.
 You can use the `USER_INSTALL_ROOT` variable as part of path name. For example, you might type: `$USER_INSTALL_ROOT/etc/ws-security/samples/intca2.cer`. Do not use this certificate path for production use. You must obtain your own X.509 certificate from a certificate authority before putting your WebSphere Application Server environment into production.
 Click **Environment > WebSphere variables** in the administrative console to configure the `USER_INSTALL_ROOT` variable.
 15. Click **OK** and then **Save** to save your configuration.
 16. Return to the Collection certificate store collection panel and click **Update run time** to update the Web services security run time with the default binding information, which is located in the `ws-security.xml` file. When you click **Update run time**, the configuration changes made to other Web services are also updated in the run time for Web services security.

You have configured the collection certificate store for the server or cell level.

Distributed nonce caching

The *distributed nonce caching* feature enables you to distribute the cache for a nonce to different servers in a cluster.

In previous releases of WebSphere Application Server, the nonce was cached locally. To use this feature, you must complete the following actions:

- Configure cache replication.
- Verify that you created an appropriate domain setting when you form a cluster.
- Verify that replication domain is properly secured. The nonce cache is crucial to the integrity of the nonce validation process. If the nonce cache is compromised, then you cannot trust the result of the validation process.
- In the administrative console for the cell level, select the **Distribute nonce caching** option. You can enable the option by completing the following steps:
 1. Click **Servers > Application servers > server_name**.
 2. Under Security, click **Web services: Default bindings for Web services security**.
 3. Select the **Distribute nonce caching** option.
- Verify that the dynamic cache service is enabled for each one of the application servers in you cluster. To access the dynamic cache service through the administrative console, complete the following steps:
 1. Click **Servers > Application servers > server_name**.
 2. Under Container settings, click **Container services > Dynamic cache service**.
 3. Confirm that the **Enable service at server startup** option is selected.

- In the administrative console for the server level, select the **Distribute nonce caching** option. You can enable the option by completing the following steps:
 1. Click **Security > Web services**.
 2. Select the **Distribute nonce caching** option.
- Restart the servers within your cluster.

When you select the **Distribute nonce caching** option in the administrative console, the nonce is propagated to other servers in your environment. However, the nonce might be subject to a one-second delay in propagation and subject to any network congestion.

For more information on distributed nonce caching, see “Web services security enhancements” on page 979.

Configuring a nonce on the server or cell level

You can configure nonce for the cell level using the WebSphere Application Server administrative console.

Nonce is a randomly generated, cryptographic token that is used to prevent replay attacks of user name tokens that are used with SOAP messages. Typically, nonce is used with the user name token.

You can configure nonce at the application level, the server level, and the cell level. However, you must consider the order of precedence. The following list shows the order of precedence:

1. Application level

The application level settings for the nonce maximum age and nonce clock skew fields are specified through the additional properties.
2. Server level
3. Cell level

If you configure nonce on the application level and the server level, the values that are specified for the application level take precedence over the values that are specified for the server level. Likewise, the values that are specified for the application level take precedence over the values that are specified for the server level and the cell level. In the WebSphere Application Server Network Deployment environment, the Nonce cache timeout, Nonce maximum age, and Nonce clock skew fields are required to use nonce effectively. However, these fields are optional on the server level.

You can configure a nonce on the server level and the cell level. In the following steps, use the first step to access the server-level default bindings and use the second step to access the cell-level bindings.

Complete the following steps to configure a nonce on the server or cell level:

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > server_name**.
 - b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Specify a value, in seconds, for the Nonce cache timeout field. The value that is specified for the Nonce cache timeout field indicates how long the nonce remains cached before it is discarded. You must specify a minimum of 300 seconds. However, if you do not specify a value, the default is 600 seconds. This field is optional on the server level, but required on the cell level.
4. Specify a value, in seconds, for the Nonce maximum age field. The value that is specified for the Nonce maximum age field indicates how long the nonce is valid. You must specify a minimum of 300 seconds, but the value cannot exceed the number of seconds that is specified for the Nonce cache timeout field in the previous step. If you do not specify a value, the default is 300 seconds.

In a Network Deployment environment, this field is optional on the server level, but it is required on the cell level.

5. Specify a value, in seconds, for the Nonce clock skew field. The value that is specified for the Nonce clock skew field specifies the amount of time, in seconds, to consider when the message receiver checks the freshness of the value. Consider the following information when you set this value:
 - Difference in time between the message sender and the message receiver, if the clocks are not synchronized.
 - Time that is needed to encrypt and transmit the message.
 - Time that is needed to get through network congestion.

At a minimum, you must specify 0 seconds in this field. However, the maximum value cannot exceed the number of seconds indicated in the Nonce maximum age field. If you do not specify a value, the default is 0 seconds. This field is optional on the server level, but required on the cell level.
6. Select the **Distribute nonce caching** option. This option enables you to distribute the caching for a nonce using a Data Replication Service (DRS). In previous releases of WebSphere Application Server, the nonce was cached locally. By selecting this option, the nonce is propagated to other servers in your environment. However, the nonce might be subject to a one-second delay in propagation and subject to any network congestion.
7. Enable the dynamic cache service for each one of the application servers in your cluster. To access the dynamic cache service through the administrative console, complete the following steps:
 - a. Click **Servers > Application servers > *server_name***.
 - b. Under Container settings, click **Container services > Dynamic cache service**.
 - c. Confirm that the **Enable service at server startup** option is selected.
8. Specify the number of replication domains. To specify the number of replicas, click **Environment > Replication domains**. In a Network Deployment environment, it is recommended that you select the **Entire domain** option for the number of replicas.
9. Restart the server. If you change the Nonce cache timeout value and do not restart the server, the change is not recognized by the server.

Configuring token generators on the server or cell level

The token generator on the server or cell level is used to specify the information for the token generator if these bindings are not defined at the application level. The signing information and the encryption information can share the token generator information, which is why they are all defined at the same level.

WebSphere Application Server provides default values for bindings. You must modify the defaults for a production environment.

You can configure the token generator on the server level and the cell level. In the following steps, use the first step to access the server-level default bindings and use the second step to access the cell-level bindings.

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > *server_name***.
 - b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Default generator bindings, click **Token generators**.
4. Click **New** to create a token generator configuration, click **Delete** to delete an existing configuration, or click the name of an existing token generator configuration to edit its settings. If you are creating a new configuration, enter a unique name for the token generator configuration in the **Token generator name** field. For example, you might specify `sig_tgen`. This field specifies the name of the token generator element.
5. Specify a class name in the **Token generator class name** field. The token generator class must implement the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface. The token generator class name must be similar to the token consumer class name. For example, if your application requires an X.509 certificate token consumer, you can specify the

com.ibm.wsspi.wssecurity.token.X509TokenConsumer class name on the Token consumer panel and the com.ibm.wsspi.wssecurity.token.X509TokenGenerator class name in this field. WebSphere Application Server provides the following default token generator class implementations:

com.ibm.wsspi.wssecurity.token.UsernameTokenGenerator

This implementation generates a username token.

com.ibm.wsspi.wssecurity.token.X509TokenGenerator

This implementation generates an X.509 certificate token.

com.ibm.wsspi.wssecurity.token.LTPATokenGenerator

This implementation generates a Lightweight Third Party Authentication (LTPA) token.

6. Select a certificate path option. The certificate path specifies the certificate revocation list (CRL), which is used for generating a security token that is wrapped in a PKCS#7 with a CRL. WebSphere Application Server provides the following certificate path options:

None Select this option in case the CRL is not used for generating a security token. You must select this option when the token generator does not use the PKCS#7 token type.

Dedicated signing information

If the CRL is wrapped in a security token, select **Dedicated signing information** and select a collection certificate store name from the **Certificate store** field. The **Certificate store** field shows the names of collection certificate stores already defined. To define a collection certificate store on the cell level, see “Configuring the collection certificate store for the server or cell-level bindings” on page 1218.

7. Select the **Add nonce** option to include a nonce in the user name token for the token generator. Nonce is a unique cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The **Add nonce** option is available if you specify a user name token for the token generator.
8. Select the **Add timestamp** option to include a time stamp in the user name token for the token generator.
9. Specify a value type local name in the **Local name** field. This entry specifies the local name of the value type for a security token that is referenced by the key identifier. This attribute is valid when **Key identifier** is selected as Key information type. To specify the Key information type, see “Configuring the key information for the generator binding on the server or cell level” on page 1236. WebSphere Application Server provides the following predefined X.509 certificate token configurations:

X.509 certificate token

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3>

X.509 certificates in a PKIPath

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1>

A list of X.509 certificates and CRLs in a PKCS#7

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7>

LTPA For LTPA, the value type local name is LTPA. If you enter LTPA for the local name, you must specify the <http://www.ibm.com/websphere/appserver/tokentype/5.0.2> uniform resource identifier (URI) value in the **Value type URI** field as well.

LTPA_PROPAGATION

For LTPA token propagation, the value type local name is LTPA_PROPAGATION. If you enter LTPA_PROPAGATION for the local name, you must specify the <http://www.ibm.com/websphere/appserver/tokentype> URI value in the **Value type URI** field as well.

For example, when an X.509 certificate token is specified, you can use <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3> for the local name.

10. Specify the value type URI in the **URI** field. This entry specifies the namespace URI of the value type for a security token that is referenced by the key identifier. This attribute is valid when **Key identifier**

is selected as Key information type on the Key information panel for the default generator. When the X.509 certificate token is specified, you do not need to specify the namespace URI. If another token is specified, you must specify the namespace URI of the value type.

11. Click **OK** and then **Save** to save the configuration.
12. Click the name of your token generator configuration.
13. Under Additional properties, click **Callback handler** to configure the callback handler properties. The callback handler specifies how to acquire the security token that is inserted in the Web services security header within the SOAP message. The token acquisition is a pluggable framework that leverages the Java Authentication and Authorization Service (JAAS) `javax.security.auth.callback.CallbackHandler` interface for acquiring the security token.
 - a. Specify a callback handler class implementation in the **Callback handler class name** field. This attribute specifies the name of the Callback handler class implementation that is used to plug in a security token framework. The specified callback handler class must implement the `javax.security.auth.callback.CallbackHandler` class. WebSphere Application Server provides the following default callback handler implementations:

`com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler`

This callback handler uses a login prompt to gather the user name and password information. However, if you specify the user name and password on this panel, a prompt is not displayed and WebSphere Application Server returns the user name and password to the token generator. Use this implementation for a Java 2 Platform, Enterprise Edition (J2EE) application client only.

`com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`

This callback handler does not issue a prompt and returns the user name and password if it is specified in the basic authentication section of this panel. You can use this callback handler when the Web service is acting as a client.

`com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`

This callback handler uses a standard-in prompt to gather the user name and password. However, if the user name and password is specified in the basic authentication section of this panel, WebSphere Application Server does not issue a prompt, but returns the user name and password to the token generator. Use this implementation for a Java 2 Platform, Enterprise Edition (J2EE) application client only.

`com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`

This callback handler is used to obtain the Lightweight Third Party Authentication (LTPA) security token from the Run As invocation Subject. This token is inserted in the Web services security header within the SOAP message as a binary security token. However, if the user name and password are specified in the basic authentication section of this panel, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token. It obtains the security token this way rather than obtaining it from the Run As Subject. Use this callback handler only when the Web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a J2EE application client.

`com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler`

This callback handler is used to create the X.509 certificate that is inserted in the Web services security header within the SOAP message as a binary security token. A keystore file and a key definition are required for this callback handler.

`com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler`

This callback handler is used to create X.509 certificates that are encoded with the PKCS#7 format. The certificate is inserted in the Web services security header in the SOAP message as a binary security token. A keystore file is required for this callback handler. You must specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format. For more

information on configuring the collection certificate store, see “Configuring the collection certificate store for the server or cell-level bindings” on page 1218.

com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler

This callback handler is used to create X.509 certificates that are encoded with the PkiPath format. The certificate is inserted in the Web services security header within the SOAP message as a binary security token. A keystore file is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used.

For an X.509 certificate token, you might specify the `com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler` implementation.

- b. **Optional:** Select the **Use identity assertion** option. Select this option if you have identity assertion that is defined in the IBM extended deployment descriptor. This option indicates that only the identity of the initial sender is required and inserted into the Web services security header within the SOAP message. For example, WebSphere Application Server sends only the user name of the original caller for a user name token generator. For an X.509 token generator, the application server sends the original signer certification only.
 - c. **Optional:** Select the **Use RunAs identity** option. Select this option if the following conditions are true:
 - You have identity assertion defined in the IBM extended deployment descriptor.
 - You want to use the Run As identity instead of the initial caller identity for identity assertion for a downstream call.
 - d. **Optional:** Specify a basic authentication user ID and password in the **User ID** and **Password** fields. This entry specifies the user name and password that is passed to the constructors of the callback handler implementation. The basic authentication user ID and password are used if you specify one of the following default callback handler implementations that are provided by WebSphere Application Server:
 - `com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler`
 - `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`
 - `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`
 - `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`
 - e. **Optional:** Specify a keystore password and path. The keystore and its related information are necessary when the key or certificate is used for generating a token. For example, the keystore information is required if you select one of the following default callback handler implementations that are provided by WebSphere Application Server:
 - `com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler`
 - `com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler`
 - `com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler`The keystore files contain public and private keys, root certificate authority (CA) certificates, intermediate CA certificates, and so on. Keys that are retrieved from the keystore file are used to sign and validate or encrypt and decrypt messages or message parts. To retrieve a key from a keystore file, you must specify the keystore password, the keystore path, and the keystore type.
14. Select a keystore type from the **Type** field. WebSphere Application Server provides the following options:
- JKS** Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.
 - JCEKS** Use this option if you are using Java Cryptography Extensions.
 - JCERACFKS** Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

PKCS11KS (PKCS11)

Use this format if your keystore file uses the PKCS#11 file format. Key store files using this format might contain RSA keys on cryptographic hardware or might encrypt the keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)

Use this option if your keystore file uses the PKCS#12 file format.

15. Click **OK** and then **Save** to save the configuration.
16. Click the name of your token generator configuration.
17. Under Additional properties, click **Callback handler > Keys**.
18. Click **New** to create a key configuration, click **Delete** to delete an existing configuration, or click the name of an existing key configuration to edit its settings. If you are creating a new configuration, enter a unique name for the key configuration in the **Key name** field. This name refers to the name of the key object that is stored within the keystore file.
19. Specify an alias for the key object in the **Key alias** field. Use the alias when the key locator searches for the key objects in the keystore.
20. Specify the password that is associated with the key in the **Key password** field.
21. Click **OK** and **Save** to save the configuration.

You have configured the token generators at the server or the cell level.

You must specify a similar token consumer configuration.

Token generator collection

Use this page to view the token generators. The information is used on the generator side only to generate the security token.

To view this administrative console page for the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Default generator bindings, click **Token generators**.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings, click **Token generators**.

Token generator name:

Specifies the name of the token generator configuration.

Token generator class name:

Specifies the name of the token generator implementation class.

This class must implement the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface.

Token generator configuration settings

Use this page to specify the information for the token generator. The information is used at the generator side only to generate the security token.

To view this administrative console page for the cell level, complete the following steps:

1. Click **Security > Web services**.

2. Under Default generator bindings, click **Token generators** > *token_generator_name* or click **New** to create a new token generator.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers** > **Application servers** > *server_name* .
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings, click **Token generators** > *token_generator_name* or click **New** to create a new token generator.
 1. Click **Applications** > **Enterprise applications** > *application_name* .
 2. Under Related items, click **Manage modules**> *URI_name* .
 3. Under Additional properties, you can access the token generator information for the following bindings:
 - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
 4. Click **New** to create a new token generator or click the name of an existing token generator name to specify its settings.

To view this administrative console page for the application level, complete the following steps:

1. Click **Applications** > **Enterprise applications** > *application_name* .
2. Click **Manage modules** > *URI_name* .
3. Under Web Services Security Properties, click **Web services: Client security bindings**.
4. Under Request generator (sender) binding, click **Edit custom**.
5. Under Additional properties, click **Token generators** > **New**.

Before specifying additional properties, specify a value in the **Token generator name** and the **Token generator class name** fields.

Token generator name:

Specifies the name of the token generator configuration.

Token generator class name:

Specifies the name of the token generator implementation class.

This class must implement the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface.

Certificate path:

Specifies the certificate revocation list (CRL) that is used for generating a security token wrapped in a PKCS#7 token type with CRL.

When the token generator is not for a PKCS#7 token type, you must select **None**. When the token generator is for the PKCS#7 token type and you want to package CRL in the security token, select **Dedicated signing information** and specify the CRL for the collection certificate store.

You can specify a certificate store configuration for the following bindings on the following levels:

Binding name	Cell level, server level, or application level	Path
Default generator bindings	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Additional properties, click Collection certificate store.
Default generator bindings	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Additional properties, click Collection certificate store.

Using the collection certificate store, you can configure a related certificate revocation list by clicking **Certificate revocation list** under Additional properties.

Add nonce:

Indicates whether nonce is included in the user name token for the token generator. *Nonce* is a unique cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens.

On the application level, if you select the **Add nonce** option, you can specify the following properties under Additional properties:

Table 51. Additional nonce properties

Property name	Default value	Explanation
com.ibm.ws.wssecurity.config.token.BasicAuth.Nonce.cacheTimeout	600 seconds	Specifies the timeout value, in seconds, for the nonce value that is cached on the server.
com.ibm.ws.wssecurity.config.token.BasicAuth.Nonce.clockSkew	0 seconds	Specifies the time, in seconds, before the nonce time stamp expires.
com.ibm.ws.wssecurity.config.token.BasicAuth.Nonce.maxAge	300 seconds	Specifies the clock skew value, in seconds, to consider when the application server checks the timeliness of the message.

These properties are available on the administrative console at the cell and server level. However, on the application level, you can configure the properties under Additional properties.

This option is displayed on the cell, server, and application levels. This option is valid only when the generated token type is a user name token.

Add timestamp:

Specifies whether to insert the time stamp into the user name token.

This option is displayed on the cell, server, and application levels. This option is valid only when the generated token type is a user name token.

Value type local name:

Specifies the local name of the value type for the generated token.

For a user name token and an X.509 certificate security token, this product provides predefined value types. When you specify the following local names, you do not need to specify the Uniform Resource Identifier (URI) of value type.

Username token

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken>

X509 certificate token

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509>

X509 certificates in a PKIPath

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1>

A list of X509 certificates and CRLs in a PKCS#7

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7>

Lightweight Third Party Authentication (LTPA)

LTPA_PROPAGATION

Important: For LTPA, the value type local name is LTPA. If you enter LTPA for the local name, you must specify the <http://www.ibm.com/websphere/appserver/tokentype/5.0.2> URI value in the Value type URI field as well. For LTPA token propagation, the value type local name is LTPA_PROPAGATION. If you enter LTPA_PROPAGATION for the local name, you must specify the <http://www.ibm.com/websphere/appserver/tokentype> URI value in the Value type URI field as well. For the other predefined value types (Username token, X509 certificate token, X509 certificates in a PKIPath, and a list of X509 certificates and CRLs in a PKCS#7), the value for the local name field begins with <http://>. For example, if you are specifying the user name token for the value type, enter <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken> in the Value type local name field and then you do not need to enter a value in the Value type URI field.

When you specify a custom value type for custom tokens, you can specify the local name and the URI of the quality name (QName) of the value type. For example, you might specify Custom for the local name and <http://www.ibm.com/custom> for the URI.

Value type URI:

Specifies the namespace URI of the value type for the generated token.

When you specify the token generator for the user name token or the X.509 certificate security token, you do not need to specify this option. If you want to specify another token, specify the URI of the QName of the value type.

The application server provides the following predefined value type URIs:

- For the LTPA token: <http://www.ibm.com/websphere/appserver/tokentype/5.0.2>
- For the LTPA token propagation: <http://www.ibm.com/websphere/appserver/tokentype>

Algorithm URI collection

Use this page to view a list of uniform resource identifier (URI) algorithms for XML digital signature or XML encryption that are mapped to an algorithm factory engine class. With algorithm mappings, service providers can use other cryptographic algorithms for digest value calculation, digital signature signing and verification, data encryption and decryption, and key encryption and decryption.

To view this administrative console page on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Algorithm mappings**.

3. Under Additional properties, click **Algorithm URI**.

To view administrative console page on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Algorithm mappings**.
4. Under Additional properties, click **Algorithm URI**.

Algorithm URI:

Specifies the algorithm uniform resource identifier (URI) for the specified algorithm type.

Algorithm type:

Specifies the algorithm type.

Algorithm URI configuration settings

Use this page to specify the algorithm uniform resource identifier (URI) and its usage type.

This product supports the following algorithm URI types:

Message digest

Specifies the algorithm URI that is used for digest value calculation.

Signature

Specifies the algorithm URI that is used for digital signature, including both signature and signing verification.

Data encryption

Specifies the algorithm URI that is used for both encrypting and decrypting data.

Key encryption

Specifies the algorithm URI that is used for encrypting and decrypting the encryption key.

If the URI is used for multiple usage types, then you must define a mapping of the URI to each usage type.

To view this administrative console page on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Algorithm mappings**.

Note: The Algorithm mappings feature is not supported when the **Use the Federal Information Processing Standard (FIPS)** option has been selected on the SSL certificate and key management panel of the administrative console. When this option is selected, the **New** button in the Algorithm mappings panel is not available.

4. Click **New**.
5. Under Additional properties, click **Algorithm URI > *algorithm_URI_name***

Algorithm URI:

Specifies the algorithm uniform resource identifier (URI) for the specified algorithm type.

The algorithm URI that is defined on this page is available to the various binding configurations. For example, if you specify an algorithm URI and select **Signature** from the Algorithm type field, the URI displays in the Signature method field on the signing information panel.

Algorithm type:

Specifies the type of algorithm that is specified in the Algorithm URI field.

The following types of algorithms are supported by this product. The following list shows where configurations that are specified on this panel are displayed for a binding configuration:

Algorithm type	Explanation	Location of the configuration
Signature	This algorithm type is used for digital signatures.	This configuration displays in the Signature method field on the Signing information panel. For information on how to access the Signing information panel, see “Signing information configuration settings” on page 1164.
Digest value calculation (message digest)	This algorithm type is used for calculating the digest value.	This configuration displays in the Digest method algorithm field on the Part references panel. For information on how to access the Part references panel, see “Part reference configuration settings” on page 1171.
Data encryption	This algorithm type is used for encrypting data.	This configuration displays in the Data encryption algorithm field on the Encryption information panel. For information on how to access the Encryption information panel, see “Encryption information configuration settings” on page 1179.
Key encryption	This algorithm type is used for encrypting the key that is used for data encryption.	This configuration displays in the Key encryption algorithm field on the Encryption information panel. For information on how to access the Encryption information panel, see “Encryption information configuration settings” on page 1179.

The actual implementation of the algorithm is done in the implementation class for the engine factory.

Algorithm mapping collection

You can view a list of custom uniform resource identifier (URI) algorithms for digest value calculation, signature, key encryption, and data encryption. The application server maps these algorithms to an implementation of the algorithm factory engine interface. With algorithm mappings, service providers can extend the cryptographic algorithms for XML digital signature and XML encryption.

To view this administrative console page on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Algorithm mappings**.

To view this administrative console page on the server level, complete the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Algorithm mappings**.

Algorithm factory engine class:

Specifies the custom class that implements the engine factory implementation class for the algorithm factory engine.

The implementation class for the engine factory implements the cryptographic functions of the defined uniform resource identifier (URI).

Note: The Algorithm mappings feature is not supported when the **Use the Federal Information Processing Standard (FIPS) algorithms** option has been selected on the Global security panel of the administrative console. When this option is selected, the **New** button in the Algorithm mappings panel is not available.

Algorithm mapping configuration settings

Use this page to view a list of custom uniform resource identifier (URI) algorithms for digest value calculation, signature, key encryption, and data encryption. The application server maps these algorithms to an implementation of the algorithm factory engine interface. With algorithm mappings, service providers can extend the cryptographic algorithms for XML digital signature and XML encryption.

To view this administrative console page on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Algorithm mappings > *algorithm_factory_engine_class_name***.

Note: The Algorithm mappings feature is not supported when the **Use the Federal Information Processing Standard (FIPS)** option has been selected on the Global security panel of the administrative console. When this option is selected, the **New** button in the Algorithm mappings panel is not available.

Note: The Algorithm mappings feature is not supported when the **Use the Federal Information Processing Standard (FIPS)** option has been selected on the SSL certificate and key management panel of the administrative console. When this option is selected, the **New** button in the Algorithm mappings panel is not available.

4. Click **New**.

Algorithm factory engine class:

Specifies the custom class that implements the engine factory interface.

To use this algorithm mapping feature, you must specify a custom algorithm class in the Algorithm factory engine class field for digital signature, data encryption, digest value calculation, and key encryption. The algorithm factory engine provides a plug-in point for service providers to provide their implementation for digest value calculation, digital signature, key encryption, and data encryption that is based on a specified algorithm uniform resource identifier (URI). By clicking **Algorithm URI** under Additional properties, you can specify the algorithm URI and its usage type. This product supports the following algorithm types:

Message digest

Specifies the algorithm URI that is used for digest value calculation.

Signature

Specifies the algorithm URI that is used for digital signatures including both signing and signature verification.

Data encryption

Specifies the algorithm URI that is used for both encrypting and decrypting data.

Key encryption

Specifies the algorithm URI that is used for both encrypting and decrypting the encryption key.

If the URI is used for multiple usage types, then you must define a mapping of the URI to each usage type. The actual implementation of the algorithm is provided by the custom class that implements the engine factory interface. For more information, refer to the information center documentation on how to implement a factory class.

Default bindings for Web services security

Use this page to specify the configuration on the cell level in a WebSphere Application Server Network Deployment environment. In addition, use this page to define the default generator bindings, default consumer bindings, and additional properties such as key locators, the collection certificate store, trust anchors, trusted ID evaluators, algorithm mappings, and login mappings.

To view this administrative console page for the cell level, click **Security > Web Services**.

To define the server-side configuration, click **Servers > Application Servers > *server_name***. Under Security, click **Web Services: Default bindings for Web Services Security**.

Nonce is a unique cryptographic number embedded in a message to help stop repeated, unauthorized attacks of user name tokens. In a WebSphere Application Server Network Deployment environment, you must specify values for the Nonce cache timeout, the Nonce maximum age, and the Nonce clock skew fields for the cell level.

The default binding configuration provides a central location where reusable binding information is defined. The application binding file can reference the information in the default binding configuration.

Nonce cache timeout:

Specifies the timeout value, in seconds, for the nonce value that is cached on the server. Nonce is a randomly generated value.

The maximum value for the Nonce maximum age field cannot exceed the number of seconds that is specified for this Nonce cache timeout field.

The Nonce cache timeout field is required for the cell level. If you make changes to the field value, you must restart WebSphere Application Server for the changes to take effect.

Default	600 seconds
Minimum	300 seconds

Nonce maximum age:

Specifies the time, in seconds, before the nonce time stamp expires. Nonce is a randomly generated value.

The value that is specified in this cell-level field is the maximum value that you can specify for the Nonce maximum age field for the server level. You can specify the Nonce maximum age value for the server level by clicking **Servers > Application servers > *server_name***. Under Additional Properties, click **Web Services: Default bindings for Web services security**.

The Nonce maximum age field is required for the cell level.

Default	300 seconds
Range	300 to the Nonce cache timeout value in seconds

Nonce clock skew:

Specifies the clock skew value, in seconds, to consider when WebSphere Application Server checks the timeliness of the message. Nonce is a randomly generated value.

The Nonce clock skew field is required for the cell level.

Default	0 seconds
Range	0 to the Nonce maximum age value, in seconds

Distribute nonce caching:

Enables distributed caching for nonce using a Data Replication Service (DRS). In previous releases of WebSphere Application Server, the nonce was cached locally. By selecting this option, the nonce is propagated to other servers in your environment. However, the nonce might be subject to a one-second delay in propagation and subject to any network congestion.

Configuring the key locator on the server or cell level

The key locator information for the default generator bindings specifies which key locator implementation is used to locate the key that is used for signature and encryption information if these bindings are not defined at the application level. The key locator information for the default consumer bindings specifies which key locator implementation is used to locate the key that is used for signature validation or decryption if these bindings are not defined at the application level. WebSphere Application Server provides default values for the bindings. However, you must modify the defaults for a production environment.

You can configure the key locator on the server level and the cell level. In the following steps, use the first step to access the server-level default bindings and use the second step to access the cell-level bindings.

Complete the following steps to configure the key locator on the server or cell level:

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > server_name**.
 - b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Additional properties, click **Key locator**. You can configure the key locator configurations for both the default generator and the default consumer in this location.
4. Click **New** to create a key locator configuration, click **Delete** to delete an existing configuration, or click the name of an existing key locator configuration to edit its settings. If you are creating a new configuration, enter a unique name for the key locator configuration in the Key locator name field. For example, you might specify sig_klocator.
5. Specify a name for the key locator class implementation in the Key locator class name field. The key locators that are associated with Version 6.0.x applications must implement the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` interface. WebSphere Application Server provides the following default key locator class implementations for Version 6.0.x applications:

`com.ibm.wsspi.wssecurity.keyinfo.KeyStoreLeyLocator`

This implementation locates and obtains the key from a specified keystore file.

`com.ibm.wsspi.wssecurity.keyinfo.SignerCertKeyLocator`

This implementation uses the public key from the certificate of the signer. This class implementation is used by the response generator.

`com.ibm.wsspi.wssecurity.keyinfo.X509TokenKeyLocator`

This implementation uses the X.509 security token from the sender message for digital signature validation and encryption. This class implementation is used by the request consumer and the response consumer.

For example, you might specify the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreLeyLocator` implementation if you need the configuration to be the key locator for signing information.

6. Specify the keystore password, the keystore location, and the keystore type. Keystore files contain public and private keys, root certificate authority (CA) certificates, the intermediate CA certificate, and so on. Keys that are retrieved from the keystore file are used to sign and validate or encrypt and decrypt messages or message parts. If you specified the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` implementation for the key locator class implementation, you must specify a key store password, location, and type.
 - a. Specify a password in the Key store password field. This password is used to access the keystore file.
 - b. Specify the location of the keystore file in the Key store path field.
 - c. Select a keystore type from the Key store type field. The Java Cryptography Extension (JCE) that is used supports the following key store types:

JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

JCEKS

Use this option if you are using Java Cryptography Extensions.

JCERACFKS

Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

PKCS11

Use this format if your keystore file uses the PKCS#11 file format. Keystore files that use this format might contain Rivest Shamir Adleman (RSA) keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12

Use this option if your keystore file uses the PKCS#12 file format.

WebSphere Application Server provides some sample keystore files in the `${USER_INSTALL_ROOT}/etc/ws-security/samples` directory. For example, you might use the `enc-receiver.jceks` keystore file for encryption keys. The password for this file is `storepass` and the type is `JCEKS`.

Attention: Do not use these keystore files in a production environment. These samples are provided for testing purposes only.

7. Click **OK** and **Save** to save the configuration.
8. Under Additional properties, click **Keys**.
9. Click **New** to create a key configuration, click **Delete** to delete an existing configuration, or click the name of an existing key configuration to edit the settings. This entry specifies the name of the key object within the keystore file. If you are creating a new configuration, enter a unique name in the Key name field.

You must use a fully qualified distinguished name for the key name. For example, you might use `CN=Bob,O=IBM,C=US`.
10. Specify an alias in the Key alias field. The key alias is used by the key locator to search for key objects in the keystore file.
11. Specify a password in the Key password field. The password is used to access the key object within the keystore file.
12. Click **OK** and then click **Save** to save the configuration.

You have configured the key locator for the server or cell level.

Configure the key information for the default generator and the default consumer bindings that reference this key locator.

Configuring the key information for the generator binding on the server or cell level

Use the key information for the default generator to specify the key that is used by the signing or the encryption information configurations if these bindings are not defined at the application level. The signing and encryption information configurations can share the same key information, which is why they are both defined on the same level. WebSphere Application Server provides default values for these bindings. However, an administrator must modify these values for a production environment.

You can configure the key information for the generator binding on the server level and the cell level. In the following steps, use the first step to configure the key information on the server level or use the second step to configure the key information on the cell level:

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > *server_name***.
 - b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Default generator bindings, click **Key information**.
4. Click **New** to create a key information configuration, click **Delete** to delete an existing configuration, or click the name of an existing key information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the key configuration in the Key information name field. For example, you might specify `sig_keyinfo`.
5. Select a key information type from the Key information type field. WebSphere Application Server supports the following types of key information:

Key identifier

This key information type is used when two parties agree on how to create a key identifier. For example, a field of X.509 certificates can be used for the key identifier according to the X.509 profile.

Key name

This key information type is used when the sender and receiver agree on the name of the key.

Security token reference

This key information type is typically used when an X.509 certificate is used for digital signature.

Embedded token

This key information type is used to embed a security token in an embedded element.

X509 issuer name and issuer serial

This key information type specifies an X.509 certificate with its issuer name and serial number.

Select **Security token reference** if you are using an X.509 certificate for the digital signature. In these steps, it is assumed that **Security token reference** is selected for this field.

Important: This key information type must match the key information type that is specified for the consumer.

6. Select a key locator reference from the Key locator reference menu. In these steps, assume that the key locator reference is called `sig_klocator`. The key locator reference is the name of the key locator that is used to generate the key for digital signature. You must configure a key locator before you can select it in this field. For more information on configuring the key locator, see “Configuring the key locator on the server or cell level” on page 1234.

7. Click **Get keys** to view a list of key name references. After you click **Get keys**, the key names that are defined in the sig_klocator element are shown in the key name reference menu. If you change the key locator reference, you must click **Get keys** again to display the list of key names that are associated with the new key locator.
8. Select a key name reference from the Key name reference menu. The key name reference specifies the name of the key that is used for generating the digital signature or for encryption. The Key name reference menu displays a list of key names that are defined for the selected key locator in the Key locator reference field. For example, select **signerkey**. It is assumed that signer key is a key name that is defined for the sig_klocator key locator.
9. Select a token reference from the Token reference field. The token reference refers to the name of a configured token generator. When a security token is required in the deployment descriptor, the token reference attribute is required. If you select **Security token reference** in the Key information type field, the token reference is required and you can specify an X.509 token generator. To specify an X.509 token generator, you must have an X.509 token generator configured. To configure an X.509 token generator, see “Configuring token generators on the server or cell level” on page 1222. For the remaining steps, it is assumed that an X.509 token generator that is named gen_tcon is already configured.
10. **Optional:** Select an encoding method from the Encoding method field. This field specifies the encoding format for the key identifier. The encoding method attribute is valid when you select **Key identifier** as the key information type. WebSphere Application Server supports the following encoding methods:
 - <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#Base64Binary>
 - <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#HexBinary>
11. **Optional:** Select a calculation method from the Calculation method field. The calculation method specifies the calculation algorithm that is used for the key identifier. This attribute is valid when you select **Key identifier** as the key information type. WebSphere Application Server supports the following calculation methods:
 - <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#ITSHA1>
 - <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#IT60SHA1>
12. **Optional:** Specify a Uniform Resource Identifier (URI) of the value type for a security token from the Namespace URI field. The namespace URI is referenced by the key identifier. This attribute is valid when you select **Key identifier** as the key information type. When you specify the X.509 certificate token, you do not need to specify the namespace URI. If another token is specified, you must specify the namespace URI. For example, you can specify <http://www.ibm.com/websphere/appserver/tokentype/5.0.2> for the Lightweight Third Party Authentication (LTPA) token and <http://www.ibm.com/websphere/appserver/tokentype> for the LTPA_PROPAGATION token.
13. **Optional:** Specify the local name of the value type for a security token in the Local name field. The local name is referenced by the key identifier. This attribute is valid when you select **Key identifier** as the key information type. WebSphere Application Server supports the following local names:

For an X.509 certificate token

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3>

For X.509 certificates in a PKIPath

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1>

For a list of X.509 certificates and CRLs in a PKCS#7

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7>

For LTPA

LTPA

For LTPA_PROPAGATION

LTPA_PROPAGATION

14. Click **OK** and **Save** to save the configuration.

You have configured the key information for the generator binding at the server or cell level.

You must specify a similar key information configuration for the consumer.

Configuring the signing information for the generator binding on the server or cell level

In the server-side extensions file (`ibm-webservices-ext.xmi`) and the client-side deployment descriptor extensions file (`ibm-webservicesclient-ext.xmi`), you must specify which parts of the message are signed. Also, you need to configure the key information that is referenced by the key information references on the Signing information panel within the administrative console.

This task explains the steps that are needed for you to configure the signing information for the client-side request generator and the server-side response generator bindings at the server or cell level. WebSphere Application Server uses the signing information for the default generator to sign parts of the message that include the body, time stamp, and user name token if these bindings are not defined at the application level. The Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

You can configure the signing information for the generator binding on the server level and the cell level. In the following steps, use the first step to configure the signing information for the server level and use the second step to configure the signing information on the cell level:

Complete the following steps to configure the signing information for the generator sections of the bindings files on the server level:

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > *server_name***.
 - b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Default generator bindings, click **Signing information**.
4. Click **New** to create a signing information configuration, click **Delete** to delete an existing configuration, or click the name of an existing signing information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the signing configuration in the Signing information name field. For example, you might specify `gen_signinfo`.
5. Select a signature method algorithm from the Signature method field. The algorithm that is specified for the default generator must match the algorithm that is specified for the default consumer. WebSphere Application Server supports the following pre-configured algorithms:
 - `http://www.w3.org/2000/09/xmldsig#rsa-sha1`
 - `http://www.w3.org/2000/09/xmldsig#hmac-sha1`
 - `http://www.w3.org/2000/09/xmldsig#dsa-sha1`Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP). Any `ds:SignatureMethod/@Algorithm` element in a SIGNATURE based on a symmetric key must have a value of `http://www.w3.org/2000/09/xmldsig#rsa-sha1` or `http://www.w3.org/2000/09/xmldsig#hmac-sha1`.
6. Select a canonicalization method from the Canonicalization method field. The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer. WebSphere Application Server supports the following pre-configured canonical XML and exclusive XML canonicalization algorithms:
 - `http://www.w3.org/2001/10/xml-exc-c14n#`
 - `http://www.w3.org/2001/10/xml-exc-c14n#WithComments`

- <http://www.w3.org/TR/2001/REC-xml-c14n-20010315>
 - <http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments>
7. Select a key information signature type from the Key information signature type field. The key information signature type determines how to digitally sign the key. WebSphere Application server supports the following signature types:

None Specifies that the KeyInfo element is not signed.

Keyinfo

Specifies that the entire KeyInfo element is signed.

Keyinfochildelements

Specifies that the child elements of the KeyInfo element are signed.

The key information signature type for the generator must match the signature type for the consumer. You might encounter the following situations:

- If you do not specify one of the previous signature types, WebSphere Application Server uses keyinfo, by default.
 - If you select Keyinfo or Keyinfochildelements and you select <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform> as the transform algorithm in a subsequent step, WebSphere Application Server also signs the referenced token.
8. Select a signing key information reference from the Signing key information field. This selection is a reference to the signing key that the Application Server uses to generate digital signatures. In the binding files, this information is specified within the <signingKeyInfo> tag. The key that is used for signing is specified by the key information element, which is defined at the same level as the signing information. For more information, see “Configuring the key information for the generator binding on the server or cell level” on page 1236.
9. Click **OK** to save the configuration.
10. Click the name of the new signing information configuration. This configuration is the one that you specified in the previous steps.
11. Specify the part reference, digest algorithm, and transform algorithm. The part reference specifies which parts of the message to digitally sign.
- Under Additional Properties, click **Part references > New** to create a new part reference, click **Part references > Delete** to delete an existing part reference, or click a part name to edit an existing part reference.
 - Specify a unique part name for the message part that needs signing. This message part is specified on both the server side and the client side. You must specify an identical part name for both the server side and the client side. For example, you might specify reqint for both the generator and the consumer.

Important: You do not need to specify a value for the Part reference in the default bindings like you specify on the application level because the part reference on the application level points to a particular part of the message that is signed. Because the default bindings for the server and cell levels are applicable to all of the services that are defined on a particular server, you cannot specify this value.

- Select a digest method algorithm in the Digest method algorithm field. The digest method algorithm that is specified in the binding files within the <DigestMethod> element is used in the <SigningInfo> element.

WebSphere Application Server supports the following algorithms:

- <http://www.w3.org/2000/09/xmlsig#sha1>
 - <http://www.w3.org/2001/04/xmllenc#sha256>
 - <http://www.w3.org/2001/04/xmllenc#sha512>
- d. Click **OK** and **Save** to save the configuration.

- e. Click the name of the new part reference configuration. This configuration is the one that you specified in the previous steps.
- f. Under Additional properties, click **Transforms > New** to create a new transform, click **Transforms > Delete** to delete a transform, or click a transform name to edit an existing transform. If you create a new transform configuration, specify a unique name. For example, you might specify `reqint_body_transform1`.
- g. Select a transform algorithm from the menu. The transform algorithm is specified within the `<Transform>` element. This algorithm element specifies the transform algorithm for the digital signature. WebSphere Application Server supports the following algorithms:
 - <http://www.w3.org/2001/10/xml-exc-c14n#>
 - <http://www.w3.org/TR/1999/REC-xpath-19991116>
Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use <http://www.w3.org/2002/06/xmldsig-filter2> to ensure compliance.
 - <http://www.w3.org/2002/06/xmldsig-filter2>
 - <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform>
 - <http://www.w3.org/2002/07/decrypt#XML>
 - <http://www.w3.org/2000/09/xmldsig#enveloped-signature>

The transform algorithm that you select for the generator must match the transform algorithm that you select for the consumer.

Important: If both of the following conditions are true, WebSphere Application Server signs the referenced token:

- You previously selected the Keyinfo or the Keyinfochildelements option from the Key information signature type field on the signing information panel.
- You select <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform> as the transform algorithm.

12. Click **Apply**.
13. **Optional:** Determine whether to disable the Inclusive namespace prefix list. The Exclusive XML Canonicalization Version 1.0 specification recommends that you include all of the namespace declarations that correspond to the namespace prefix in the canonicalization form. For security reasons, WebSphere Application Server, by default, includes the prefix in the digital signature for Web services security. However, some implementations of Web services security cannot handle this prefix list. WebSphere Application Server can handle digitally signed messages that either contain or do not contain the prefix list. If you experience a signature validation failure when a signed Simple Object Access Protocol (SOAP) message is sent and you are using another vendor in your environment, it is highly recommended that you check with their Web site for a possible fix to their implementation before you disable this property. To disable this property, complete the following steps:
 - a. Under Additional properties, click **Canonicalization method properties > New**.
 - b. In the Property name field, enter the `com.ibm.wsspi.wssecurity.dsig.inclusiveNamespaces` property.
 - c. In the Property value field, enter the `false` value.
 - d. Click **OK**.
14. Click **Save** at the top of the panel to save your configuration.

After completing these steps, you have configured the signing information for the generator on the server or the cell level.

You must specify a similar signing information configuration for the consumer.

Configuring the encryption information for the generator binding on the server or cell level

The encryption information for the default generator specifies how to encrypt the information on the sender side if these bindings are not defined at the application level. WebSphere Application Server provides default values for the bindings. However, an administrator must modify the defaults for a production environment.

You can configure the encryption information for the generator binding on the server level and the cell level. In the following steps, use the first step to configure the encryption information for the server level and use the second step to configure the encryption information for the cell level:

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > *server_name***.
 - b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Default generator bindings, click **Encryption information**.
4. Click **New** to create an encryption information configuration, click **Delete** to delete an existing configuration, or click the name of an existing encryption information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the encryption configuration in the Encryption information name field. For example, you might specify `gen_encinfo`.

5. Select a data encryption algorithm from the Data encryption algorithm field. This algorithm is used to encrypt the data. WebSphere Application Server supports the following pre-configured algorithms:

- <http://www.w3.org/2001/04/xmlenc#tripledes-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
- <http://www.w3.org/2001/04/xmlenc#aes256-cbc>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

- <http://www.w3.org/2001/04/xmlenc#aes192-cbc>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use this algorithm, the 192-bit key encryption algorithm, if you want your configured application to be in compliance with the Basic Security Profile (BSP).

The data encryption algorithm that you select for the generator side must match the data encryption algorithm that you select for the consumer side.

6. Select a key encryption algorithm from the Key encryption algorithm field. This algorithm is used to encrypt the key. WebSphere Application Server supports the following pre-configured algorithms:

- <http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p>.

When running with JDK 1.4, the list of supported key transport algorithms will not include this one. This algorithm will appear in the list of supported key transport algorithms when running with JDK 1.5.

Restriction: This algorithm is not supported when the WebSphere Application Server is running in Federal Information Processing Standard (FIPS) mode.

By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

- <http://www.w3.org/2001/04/xmlenc#sha256>
- <http://www.w3.org/2001/04/xmlenc#sha512>

By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming Simple Object Access Protocol (SOAP) message.

- http://www.w3.org/2001/04/xmlenc#rsa-1_5
- <http://www.w3.org/2001/04/xmlenc#kw-tripledes>
- <http://www.w3.org/2001/04/xmlenc#kw-aes128>
- <http://www.w3.org/2001/04/xmlenc#kw-aes256>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

- <http://www.w3.org/2001/04/xmlenc#kw-aes192>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use this algorithm, the 192-bit key encryption algorithm, if you want your configured application to be in compliance with the Basic Security Profile (BSP).

If you select **None**, the key is not encrypted.

The key encryption algorithm that you select for the generator side must match the key encryption algorithm that you select for the consumer side.

7. Select an encryption key configuration from the Encryption key information field. This attribute specifies the name of the key that is used to encrypt the message. To configure the key information, see “Configuring the key information for the generator binding on the server or cell level” on page 1236.
8. Click **OK** and then click **Save** to save the configuration.

You have configured the encryption information for the generator binding at the server or cell level.

You must specify a similar encryption information configuration for the consumer.

Configuring trusted ID evaluators on the server or cell level

You can configure trusted identity (ID) evaluators. The trusted ID evaluator determines whether or not to trust the identity-asserting authority.

This task provides the steps that are needed to configure trusted identity (ID) evaluators. The trusted ID evaluator determines whether to trust the identity-asserting authority. After the ID is trusted, the WebSphere Application Server issues the proper credentials based on the identity, which are used in a downstream call to another server for invoking resources. The trusted ID evaluator implements the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface.

You can configure the trusted ID evaluators on the server level and the cell level. In the following steps, use the first step to access the server-level default bindings and use the second step to access the cell-level bindings:

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > *server_name***.

- b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Additional properties, click **Trusted ID evaluators**.
4. Click **New** to create a trusted ID evaluator configuration, click **Delete** to delete an existing configuration, or click the name of an existing configuration to edit the settings. If you are creating a new configuration, enter a unique name for the trusted ID evaluator configuration in the Trusted ID evaluator name field. This field specifies the name that is used by the application binding to refer to a trusted identity (ID) evaluator that is defined in the default binding.
5. Specify a class name in the Trusted ID evaluator class name field. The default class name is `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`. The specified trusted ID evaluator class name must implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` class. When you use the default `TrustedIDEvaluator` class, you must specify the name and value properties for the default trusted ID evaluator to create the trusted ID list for evaluation.
6. Under Additional properties, click **Properties > New**.
7. Specify the trusted ID evaluator name as a property name. You must specify the trusted ID evaluator name in the form, `trustedId_n`, where `_n` is an integer from zero (0) to n.
8. Specify the trusted ID as a property value.

```
property name="trustedId_0", value="CN=Bob,0=ACME,C=US"
property name="trustedId_1, value="user1"
```

If a distinguished name (DN) is used, the space is removed for comparison.
9. Click **OK** and then **Save**.

You have configured the trusted ID evaluators at the server or cell level.

Trusted ID evaluator collection

Use this page to view a list of trusted identity (ID) evaluators. The trusted ID evaluator determines whether to trust the identity-asserting authority. After the ID is trusted, the application server issues the proper credentials based on the identity, which are used in a downstream call for invoking resources. The trusted ID evaluator implements the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface.

To view this administrative console page for trusted ID evaluators on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Trusted ID evaluators**.
3. Click **New** to create a trusted ID evaluator or click **Delete** to delete a trusted ID evaluator.

To view this administrative console page for trusted ID evaluators on the server level, complete the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Trusted ID evaluators**.
4. Click **New** to create a trusted ID evaluator or click **Delete** to delete a trusted ID evaluator.

Version 6 and later applications

To view this administrative console page for trusted ID evaluators on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > application_name**.
2. Under Related items, click **EJB modules** or **Web modules**.
3. Click *URI_name*.
4. Under Additional properties, click **Web services: Server security bindings**.
5. Under Request consumer (receiver) binding, click **Edit custom**.

6. Click **Trusted ID evaluators**.
7. Click **New** to create a trusted ID evaluator or click **Delete** to delete a trusted ID evaluator.

Version 5.x application

To view this administrative console page for trusted ID evaluators on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Service Security Properties, click **Web services: Server security bindings**.
4. Click **Edit** under Request receiver binding.
5. Click **Trusted ID evaluators**.
6. Click **New** to create a trusted ID evaluator or click **Delete** to delete a trusted ID evaluator.

Important: Trusted ID evaluators are only required for the request receiver (Version 5.x applications) and the request consumer (Version 6.0.x.x applications), if identity assertion is configured.

Using this trusted ID evaluator collection panel, complete the following steps:

1. Specify a trusted ID evaluator name and a trusted ID evaluator class name.
2. Save your changes by clicking **Save** in the messages section at the top of the administrative console.
3. Click **Update run time** to update the Web services security run time with the default binding information, which is found in the `ws_security.xml` file. The configuration changes made to the other Web services also are updated in the Web services security run time.

Trusted ID evaluator name:

Specifies the unique name of the trusted ID evaluator.

Trusted ID evaluator class name:

Specifies the class name of the trusted ID evaluator.

Trusted ID evaluator configuration settings

Use this information to configure trust identity (ID) evaluators.

To view this administrative console page for trusted ID evaluators on the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Additional properties, click **Trusted ID evaluators**.
3. Click **New** to create a trusted ID evaluator or click the name of an existing configuration to modify its settings.

To view this administrative console page for trusted ID evaluators on the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Trusted ID evaluators**.
4. Click **New** to create a trusted ID evaluator or click the name of an existing configuration to modify the settings.

Version 6 and later applications

To view this administrative console page for trusted ID evaluators on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules**.
3. Click the *URI_name*.
4. Under Web Services Security Properties, click **Web services: Server security bindings**.
5. Under Request consumer (receiver) binding, click **Edit custom**.
6. Click **Trusted ID evaluators**.
7. Click **New** to create a trusted ID evaluator or click **Delete** to delete a trusted ID evaluator.

Version 5.x application

To view this administrative console page for trusted ID evaluators on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Under Related items, click **EJB modules** or **Web modules > *URI_name***.
3. Under Additional properties, click **Web services: Server security bindings**.
4. Click **Edit** under Request receiver binding.
5. Click **Trusted ID evaluators**.
6. Click **New** to create a trusted ID evaluator or click **Delete** to delete a trusted ID evaluator.

Important: Trusted ID evaluators are only required for the request receiver (Version 5.x applications) and the request consumer (Version 6.x applications), if identity assertion is configured.

You can specify one of the following options:

None Choose this option if you are not specifying a trusted ID evaluator.

Existing evaluator definition

Choose this option to specify a currently defined trusted ID evaluator.

Binding evaluator definition

Choose this option to specify a new trusted ID evaluator. A description of the required fields follows.

Trusted ID evaluator name:

Specifies the name that is used by the application binding to refer to a trusted identity (ID) evaluator that is defined in the default binding.

Trusted ID evaluator class name:

Specifies the class name of the trusted ID evaluator.

The specified trusted ID evaluator class name must implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface. The default `TrustedIDEvaluator` class is `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`. When you use this default `TrustedIDEvaluator` class, you must specify the name and the value properties for the default trusted ID evaluator to create the trusted ID list for evaluation.

To specify the name and value properties, complete the following steps:

1. Under Additional properties, click **Properties > New**.

2. Specify the trusted ID evaluator name as a property name. You must specify the trusted ID evaluator name in the form, `trustedId_n`, where `_n` is an integer from zero (0) to `n`.
3. Specify the trusted ID as a property value.

For example:

```
property name="trustedId_0", value="CN=Bob,O=ACME,C=US"  
property name="trustedId_1", value="user1"
```

If a distinguished name (DN) is used, the space is removed for comparison.

Default

`com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`

See the programming model information in the documentation for an explanation of how to implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface.

Configuring token consumers on the server or cell level

The token consumer on the server or cell level is used to specify the information that is needed to process the security token if it is not defined at the application level. WebSphere Application Server provides default values for bindings. You must modify the defaults for a production environment.

You can configure the token consumers on the server level and the cell level. In the following steps, use the first step to access the server-level default bindings and use the second step to access the cell-level bindings.

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > *server_name***.
 - b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Default consumer bindings, click **Token consumers**.
4. Click **New** to create a token consumer configuration, click **Delete** to delete an existing configuration, or click the name of an existing token consumer configuration to edit its settings. If you are creating a new configuration, enter a unique name for the token consumer configuration in the Token consumer name field. For example, you might specify `sig_cgen`. This field specifies the name of the token consumer element.
5. Specify a class name in the Token consumer class name field. The token consumer class must implement the `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` interface. The token consumer class name must be similar to the token generator class name.

For example, if your application requires an X.509 certificate token consumer, you can specify the `com.ibm.wsspi.wssecurity.token.X509TokenGenerator` class name on the Token generator panel and the `com.ibm.wsspi.wssecurity.token.X509TokenConsumer` class name in this field. WebSphere Application Server provides the following default token consumer class implementations:

`com.ibm.wsspi.wssecurity.token.UsernameTokenConsumer`

This implementation integrates a user name token.

`com.ibm.wsspi.wssecurity.token.X509TokenConsumer`

This implementation integrates an X.509 certificate token.

`com.ibm.wsspi.wssecurity.token.LTPATokenConsumer`

This implementation integrates a Lightweight Third Party Authentication (LTPA) token.

`com.ibm.wsspi.wssecurity.token.IDAssertionUsernameTokenConsumer`

This implementation integrates an IDAssertionUsername token.

A corresponding token generator class does not exist for this implementation.

6. Select a certificate path option. The certificate path specifies the certificate revocation list (CRL) that is used for generating a security token wrapped in a PKCS#7 with a CRL. WebSphere Application Server provides the following certificate path options:

None If you select this option, the certificate path is not specified.

Trust any

If you select this option, any certificate is trusted. When the received token is consumed, the certificate path validation is not processed.

Dedicated signing information

If you select this option, you can specify a trust anchor and a certificate store. When you select the trust anchor or the certificate store of a trusted certificate, you must configure the collection certificate store before setting the certificate path. To define a collection certificate store on the server or cell level, see “Configuring the collection certificate store for the server or cell-level bindings” on page 1218.

- a. Select a trust anchor in the Trust anchor field. WebSphere Application Server provides two sample trust anchors. However, it is recommended that you configure your own trust anchors for a production environment. For information on configuring a trust anchor, see “Configuring trust anchors on the server or cell level” on page 1217.
 - b. Select a collection certificate store in the Certificate store field. WebSphere Application Server provides a sample collection certificate store. If you select **None**, the collection certificate store is not specified. For information on specifying a list of certificate stores that contain untrusted, intermediary certificate files awaiting validation, see “Configuring trusted ID evaluators on the server or cell level” on page 1242.
7. Select a trusted ID evaluator from the Trusted ID evaluation reference field. This field specifies a reference to the Trusted ID evaluator class name that is defined in Trusted ID evaluators panel. The trusted ID evaluator is used for evaluating whether the received ID is trusted. If you select **None**, the trusted ID evaluator is not referenced in this token consumer configuration. To configure a trusted ID evaluator, see “Configuring trusted ID evaluators on the server or cell level” on page 1242.
 8. Select the **Verify nonce** option if a nonce is included in a user name token on the generator side. Nonce is a unique cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The **Verify nonce** option is available if you specify a user name token for the token consumer and nonce is added to the user name token on the generator side.
 9. Select the **Verify timestamp** option if a time stamp is included in the user name token on the generator side. The **Verify Timestamp** option is available if you specify a user name token for the token consumer and a time stamp is added to the user name token on the generator side.
 10. Specify the local name of the value type for the integrated token. This entry specifies the local name of the value type for a security token that is referenced by the key identifier. This attribute is valid when **Key identifier** is selected as the key information type. To specify the key information type, see “Configuring the key information for the consumer binding on the server or cell level” on page 1254. WebSphere Application Server has predefined value type local names for the user name token and the X.509 certificate security token. Enter one of the following local names for the user name token and the X.509 certificate security token. When you specify the following local names, you do not need to specify the URI of the value type:

Username token

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken>

X.509 certificate token

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3>

X.509 certificates in a PKIPath

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1>

A list of X.509 certificates and CRLs in a PKCS#7

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7>

Note: To specify Lightweight Third Party Authentication (LTPA) or token propagation (LTPA_PROPAGATION), you must specify both the value type local name and the Uniform Resource Identifier (URI). For LTPA, specify LTPA for the local name and <http://www.ibm.com/websphere/appserver/tokentype/5.0.2> for the URI. For LTPA token propagation, specify LTPA_PROPAGATION for the local name and <http://www.ibm.com/websphere/appserver/tokentype> for the URI.

For example, when an X.509 certificate token is specified, you can use <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3> for the local name. When you specify the local name of another token, you must specify a value type QName. For example: `uri=http://www.ibm.com/custom, localName=CustomToken`

11. Specify the value type uniform resource identifier (URI) in the URI field. This entry specifies the namespace URI of the value type for a security token that is referenced by the key identifier. This attribute is valid when **Key identifier** is selected as the key information type on the Key information panel for the default generator. When you specify the token consumer for the user name token or an X.509 certificate security token, you do not need to specify this option. If you specify another token, you need to specify the URI of the QName for the value type.
12. Click **OK** and then **Save** to save the configuration. After saving the token generator configuration, you can specify a Java Authentication and Authorization Service (JAAS) configuration for your token consumer.
13. Click the name of your token generator configuration.
14. Under Additional properties, click **JAAS configuration**.
15. Select a JAAS configuration from the JAAS configuration name field. The field specifies the name of the JAAS system for application login configuration. You can specify additional JAAS system and application configurations by clicking **Security > Global security**. Under Authentication, click **JAAS configuration** and either **Application logins > New** or **System logins > New**. Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module. WebSphere Application Server provides the following predefined JAAS configurations:

ClientContainer

This selection specifies the login configuration that is used by the client container applications. The configuration uses the CallbackHandler application programming interface (API) that is defined in the deployment descriptor for the client container. To modify this configuration, see the JAAS configuration panel for application logins.

WSLogin

This selection specifies whether all of the applications can use the WSLogin configuration to perform authentication for the security run time. To modify this configuration, see the JAAS configuration panel for application logins.

DefaultPrincipalMapping

This selection specifies the login configuration that is used by Java 2 Connectors (J2C) to map users to principals that are defined in the J2C authentication data entries. To modify this configuration, see the JAAS configuration panel for application logins.

system.wssecurity.IDAssertion

This selection enables a Version 5.x application to use identity assertion to map a user name to a WebSphere Application Server credential principal. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.Signature

This selection enables a Version 5.x application to map a distinguished name (DN) in a signed certificate to a WebSphere Application Server credential principal. To modify this configuration, see the JAAS configuration panel for system logins.

system.LTPA_WEB

This selection processes login requests that are used by the Web container such as servlets and JavaServer Pages (JSP) files. To modify this configuration, see the JAAS configuration panel for system logins.

system.WEB_INBOUND

This selection handles login requests for Web applications, which include servlets and JavaServer Pages (JSP) files. This login configuration is used by WebSphere Application Server Version 5.1.1. To modify this configuration, see the JAAS configuration panel for system logins.

system.RMI_INBOUND

This selection handles logins for inbound Remote Method Invocation (RMI) requests. This login configuration is used by WebSphere Application Server Version 5.1.1. To modify this configuration, see the JAAS configuration panel for system logins.

system.DEFAULT

This selection handles the logins for inbound requests that are made by internal authentications and most of the other protocols except Web applications and RMI requests. This login configuration is used by WebSphere Application Server Version 5.1.1. To modify this configuration, see the JAAS configuration panel for system logins.

system.RMI_OUTBOUND

This selection processes RMI requests that are sent outbound to another server when the `com.ibm.CSIOutboundPropagationEnabled` property is true. This property is set in the CSIv2 authentication panel. To access the panel, click **Security > Secure administrative, applications, and infrastructure**. Under Authentication, click **RMI/IIOP security** and click **CSIv2 outbound authentication**. To set the `com.ibm.CSIOutboundPropagationEnabled` property, select **Security attribute propagation**. To modify this JAAS login configuration, see the JAAS - System logins panel.

system.wssecurity.X509BST

This section verifies an X.509 binary security token (BST) by checking the validity of the certificate and the certificate path. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.PKCS7

This selection verifies an X.509 certificate with a certificate revocation list in a PKCS7 object. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.PkiPath

This section verifies an X.509 certificate with a public key infrastructure (PKI) path. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.UsernameToken

This selection verifies the basic authentication (user name and password) data. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.IDAssertionUsernameToken

This selection enables Version 6 and later applications to use identity assertion to map a user name to a WebSphere Application Server credential principal. To modify this configuration, see the JAAS configuration panel for system logins.

system.WSS_INBOUND

This selection specifies the login configuration for inbound or consumer requests for security token propagation using Web services security. To modify this configuration, see the JAAS configuration panel for system logins.

system.WSS_OUTBOUND

This selection specifies the login configuration for outbound or generator requests for security token propagation using Web services security. To modify this configuration, see the JAAS configuration panel for system logins.

None With this selection, you do not specify a JAAS login configuration.

16. Click **OK** and then **Save** to save the configuration.

You have configured the token consumer at the server or cell level.

You must specify a similar token generator configuration for the server or cell level.

Token consumer collection

Use this page to view the token consumer. The information is used on the consumer side only to process the security token.

To view this administrative console page for the cell level, complete the following steps:

1. Click **Security > Web services**.
2. Under Default consumer bindings, click **Token consumers**.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default generator bindings, click **Token consumers**.

To view this administrative console page for Version 6 and later applications on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Services Security Properties, you can access the signing information for the following bindings:
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. Under Required properties, click **Token consumers**.
 - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Token consumers**.

Token consumer name:

Specifies the name of the token consumer configuration.

Token consumer class name:

Specifies the name of the token consumer implementation class.

This class must implement the `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` interface.

Token consumer configuration settings

Use this page to specify the information for the token consumer. The information is used at the consumer side only to process the security token.

To view this administrative console page, complete the following steps:

1. Click **Security > Web services**.
2. Under Default consumer bindings, click **Token consumers > *token_consumer_name*** or click **New** to create a new token consumer.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Default consumer bindings, click **Token consumers > *token_consumer_name*** or click **New** to create a new token consumer.

To view this administrative console page for Version 6 and later applications on the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Services Security Properties, you can access the signing information for the following bindings:
 - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. Under Required properties, click **Token consumers**.
 - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Token consumers**.
4. Click **New** to specify a new configuration or click the name of an existing configuration to modify its settings.

Before specifying additional properties, specify a value in the Token consumer name, the Token consumer class name, and the Value type local name fields.

Token consumer name:

Specifies the name of the token consumer configuration.

Token consumer class name:

Specifies the name of the token consumer implementation class.

This class must implement the `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` interface.

Part reference:

Specifies a reference to the name of the security token that is defined in the deployment descriptor.

On the application level, when the security token is not specified in the deployment descriptor, the Part reference field is not displayed.

Certificate path:

Specifies the trust anchor and the certificate store.

You can select the following options:

None If you select this option, the certificate path is not specified.

Trust any

If you select this option, any certificate is trusted. When the received token is incorporated, the certificate path validation is not processed.

Dedicated signing information

If you select this option, you can specify the trust anchor and the certificate store. When you select the trust anchor or the certificate store of a trusted certificate, you must configure the collection certificate store before setting the certificate path.

Trust anchor

You can specify a trust anchor for the following bindings on the following levels:

Binding name	Cell level, server level, or application level	Path
Default consumer binding	Cell level	<ol style="list-style-type: none">1. Click Security > Web services.2. Under Additional properties, click Trust anchors.
Default consumer binding	Server level	Click Servers > Application servers > server_name . Under Security, click Web services: Default bindings for Web services security . Under Additional properties, click Trust anchors .

Certificate store

You can specify a certificate path configuration for the following bindings on the following levels:

Binding name	Cell level, server level, or application level	Path
Default consumer binding	Cell level	<ol style="list-style-type: none">1. Click Security > Web services.2. Under Additional properties, click Collection certificate store.
Default consumer binding	Server level	<ol style="list-style-type: none">1. Click Servers > Application servers > server_name.2. Under security, click Web services: Default bindings for Web services security.3. Under Additional properties, click Collection certificate store.

Trusted ID evaluator reference:

Specifies the reference to the Trusted ID evaluator class name that is defined in the Trusted ID evaluators panel. The trusted ID evaluator is used for determining whether the received ID is trusted.

You can select the following options:

None If you select this option, the trusted ID evaluator is not specified.

Existing evaluator definition

If you select this option, you can select one of the configured trusted ID evaluators.

You can specify a certificate path configuration for the following bindings on the following levels:

Binding name	Cell level, server level, or application level	Path
Default consumer binding	Cell level	<ol style="list-style-type: none">1. Click Security > Web services.2. Under Additional properties, click Trusted ID evaluators.
Default consumer binding	Server level	<ol style="list-style-type: none">1. Click Servers > Application servers > server_name.2. Under security, click Web services: Default bindings for Web services security.3. Under Additional properties, click Trusted ID evaluators.

Binding evaluator definition

If you select this option, you can specify a new trusted ID evaluator and its class name.

When you select a trusted ID evaluator reference, you must configure the trusted ID evaluators before setting the token consumer.

The Trusted ID evaluator field is displayed in the default binding configuration and the application server binding configuration.

Verify nonce:

Specifies whether the nonce of the user name token is verified.

This option is displayed on the cell, server, and application levels. This option is valid only when the type of incorporated token is the user name token.

Verify timestamp:

Specifies whether the time stamp of user name token is verified.

This option is displayed on the cell, server, and application levels. This option is valid only when the type of incorporated token is the user name token.

Value type local name:

Specifies the local name of value type for the consumed token.

This product has predefined value type local names for the user name token and the X.509 certificate security token. Use the following local names for the user name token and the X.509 certificate security token. When you specify the following local names, you do not need to specify the Uniform Resource Identifier (URI) of the value type:

Username token

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken>

X509 certificate token

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509>

X509 certificates in a PKIPath

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1>

A list of X509 certificates and CRLs in a PKCS#7

<http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7>

Lightweight Third Party Authentication (LTPA)

LTPA_PROPAGATION

Important: For Lightweight Third Party Authentication (LTPA), the value type local name is LTPA. If you enter LTPA for the local name, you must specify the <http://www.ibm.com/websphere/appserver/tokentype/5.0.2> URI value in the Value type URI field as well. For LTPA token propagation, the value type local name is LTPA_PROPAGATION. If you enter LTPA_PROPAGATION for the local name, you must specify the <http://www.ibm.com/websphere/appserver/tokentype> URI value in the Value type URI field as well. For the other predefined value types (Username token, X509 certificate token, X509 certificates in a PKIPath, and a list of X509 certificates and CRLs in a PKCS#7), the value for the local name field begins with `http://`. For example, if you are specifying the username token for the value type, enter <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken> in the value type local name field and then you do not need to enter a value in the value type URI field.

When you specify a custom value type for custom tokens, you can specify the local name and the URI of the Quality name (QName) of the value type. For example, you might specify Custom for the local name and <http://www.ibm.com/custom> for the URI.

Value type URI:

Specifies the namespace URI of the value type for the integrated token.

When you specify the token consumer for the user name token or the X.509 certificate security token, you do not need to specify this option. If you want to specify another token, specify the URI of the QName for the value type.

The application server provides the following predefined value type URIs:

- For the LTPA token: <http://www.ibm.com/websphere/appserver/tokentype/5.0.2>
- For the LTPA token propagation: <http://www.ibm.com/websphere/appserver/tokentype>

Configuring the key information for the consumer binding on the server or cell level

The key information for the default consumer is used to specify the key that is used by the signing or the encryption information configurations if these bindings are not defined at the application level. The signing and encryption information configurations can share the same key information, which is why they are both defined on the same level. WebSphere Application Server provides default values for these bindings. However, an administrator must modify these values for a production environment.

You can configure the key information for the consumer binding on the server level and the cell level. In the following steps, use the first step to access the server-level default bindings and use the second step to access the cell-level bindings:

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > server_name**.
 - b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Default consumer bindings, click **Key information**.

4. Click **New** to create a key information configuration, click **Delete** to delete an existing configuration, or click the name of an existing key information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the key configuration in the Key information name field. For example, you might specify `con_signkeyinfo`.
5. Select a key information type from the Key information type field. WebSphere Application Server supports the following types of key information:

Key identifier

This key information type is used when two parties agree on how to create a key identifier. For example, a field of X.509 certificates can be used for the key identifier according to the X.509 profile.

Key name

This key information type is used when the sender and receiver agree on the name of the key.

Security token reference

This key information type is typically used when an X.509 certificate is used for digital signature.

Embedded token

This key information type is used to embed a security token in an embedded element.

X509 issuer name and issuer serial

This key information type specifies an X.509 certificate with its issuer name and serial number.

Select **Security token reference** if you are using an X.509 certificate for the digital signature. In these steps, it is assumed that **Security token reference** is selected for this field.

Important: This key information type must match the key information type that is specified for the generator.

6. Select a key locator reference from the Key locator reference menu. In these steps, assume that the key locator reference is called `sig_klocator`. You must configure a key locator before you can select it in this field. For more information on configuring the key locator, see “Configuring the key locator on the server or cell level” on page 1234.
7. Select a token reference from the Token reference field. The token reference refers to the name of a configured token consumer. When a security token is required in the deployment descriptor, the token reference attribute is required. If you select **Security token reference** in the Key information type field, the token reference is required and you can specify an X.509 token consumer. To specify an X.509 token consumer, you must have an X.509 token consumer configured. To configure an X.509 token consumer, see “Configuring token consumers on the server or cell level” on page 1246.
8. Click **OK** and **Save** to save the configuration.

You have configured the key information for the consumer binding at the server or cell level.

You must specify a similar key information configuration for the generator

Configuring the signing information for the consumer binding on the server or cell level

In the server-side extensions file (`ibm-webservices-ext.xmi`) and the client-side deployment descriptor extensions file (`ibm-webservicesclient-ext.xmi`), you must specify which parts of the message are signed. Also, you need to configure the key information that is referenced by the key information references on the signing information panel within the administrative console.

This task explains the steps that are needed for you to configure the signing information for the client-side request generator and server-side response generator bindings at the server or cell level. WebSphere Application Server uses the signing information for the default generator to sign parts of the message

including the body, time stamp, and user name token, if these bindings are not defined at the application level. The Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

You can configure the signing information for the consumer binding on the server level and the cell level. In the following steps, use the first step to access the server-level default bindings and use the second step to access the cell-level bindings.

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > *server_name***.
 - b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Default consumer bindings, click **Signing information**.
4. Click **New** to create a signing information configuration, click **Delete** to delete an existing configuration, or click the name of an existing signing information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the signing configuration in the Signing information name field. For example, you might specify `gen_signinfo`.
5. Select a signature method algorithm from the Signature method field. The algorithm that is specified for the default consumer must match the algorithm that is specified for the default generator. WebSphere Application Server supports the following pre-configured algorithms:
 - <http://www.w3.org/2000/09/xmldsig#rsa-sha1>
 - <http://www.w3.org/2000/09/xmldsig#hmac-sha1>
 - <http://www.w3.org/2000/09/xmldsig#dsa-sha1>Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP). Any `ds:SignatureMethod/@Algorithm` element in a SIGNATURE based on a symmetric key must have a value of <http://www.w3.org/2000/09/xmldsig#rsa-sha1> or <http://www.w3.org/2000/09/xmldsig#hmac-sha1>.
6. Select a canonicalization method from the Canonicalization method field. The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer. WebSphere Application Server supports the following pre-configured canonical XML and exclusive XML canonicalization algorithms:
 - <http://www.w3.org/2001/10/xml-exc-c14n#>
 - <http://www.w3.org/2001/10/xml-exc-c14n#WithComments>
 - <http://www.w3.org/TR/2001/REC-xml-c14n-20010315>
 - <http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments>
7. Select a key information signature type from the Key information signature type field. The key information signature type determines how to digitally sign the key. WebSphere Application Server supports the following signature types:

None Specifies that the KeyInfo element is not signed.

Keyinfo

Specifies that the entire KeyInfo element is signed.

Keyinfochildelements

Specifies that the child elements of the KeyInfo element are signed.

The key information signature type for the consumer must match the signature type for the generator. You might encounter the following situations:

- If you do not specify one of the previous signature types, WebSphere Application Server uses `keyinfo`, by default.
- If you select `Keyinfo` or `Keyinfochildelements` and you select <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform> as the transform algorithm in a subsequent step, WebSphere Application Server also signs the referenced token.

8. Click **OK** to save the configuration.
9. Click the name of the new signing information configuration. This configuration is the one that you specified in the previous steps.
10. Specify the key information reference, part reference, digest algorithm, and transform algorithm.
 - a. Under Additional properties, click **Key information references > New** to create a new reference, click **Key information references > Delete** to delete an existing reference, or click a reference name to edit an existing key information reference.
 - b. Enter a name for the configuration in the Name field. For example, enter `con_skeyinfo`.
 - c. Select a key information reference from the Key information reference field. The key Information reference points to the key that WebSphere Application Server uses for digital signing. In the binding files, the reference is specified within the `<signingKeyInfo>` element. The key that is used for signing is specified by the Key information element, which is defined at the same level as the signing information. For more information, see “Configuring the key information for the consumer binding on the application level” on page 1204.
 - d. Click **OK** and **Save** to save the configuration.
 - e. Under Additional Properties, click **Part references > New** to create a new part reference, click **Part references > Delete** to delete an existing part reference, or click a part name to edit an existing part reference. The part reference specifies which parts of the message to digitally sign. The part attribute refers to the name of the `<RequiredIntegrity>` element in the deployment descriptor when `<PartReference>` is specified for the digital signature. WebSphere Application Server enables you to specify multiple `<PartReference>` elements for the `<SigningInfo>` element. The `<PartReference>` element has two child elements: `<DigestMethod>` and `<Transform>`.
 - f. Specify a unique part name for this part reference. For example, you might specify `reqint`.

Important: We do not need to specify a value for the Part Reference field like you specify on the application level because the part reference on the application level points to a particular part of the message that is signed. Because the default bindings for the server and cell levels are applicable to all of the services defined on a particular server, you cannot specify this value.

- g. Select a digest method algorithm in the Digest method algorithm field. The digest method algorithm specified within the `<DigestMethod>` element that is used in the `<SigningInfo>` element. WebSphere Application Server supports the following algorithms:
 - <http://www.w3.org/2000/09/xmlsig#sha1>
 - <http://www.w3.org/2001/04/xmlenc#sha256>
 - <http://www.w3.org/2001/04/xmlenc#sha512>
- h. Click **OK** and **Save** to save the configuration.
- i. Click the name of the new part reference configuration. This configuration is the one that you specified in the previous steps.
- j. Under Additional properties, click **Transforms > New** to create a new transform, click **Transforms > Delete** to delete a transform, or click a transform name to edit an existing transform. If you create a new transform configuration, specify a unique name. For example, you might specify `reqint_body_transform1`.
- k. Select a transform algorithm from the menu. The transform algorithm is specified within the `<Transform>` element. It specifies the transform algorithm for the signature. WebSphere Application Server supports the following algorithms:
 - <http://www.w3.org/2001/10/xml-exc-c14n#>
 - <http://www.w3.org/TR/1999/REC-xpath-19991116>
Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use <http://www.w3.org/2002/06/xmlsig-filter2> to ensure compliance.
 - <http://www.w3.org/2002/06/xmlsig-filter2>

- <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform>
- <http://www.w3.org/2002/07/decrypt#XML>
- <http://www.w3.org/2000/09/xmlsig#enveloped-signature>

The transform algorithm that you select for the consumer must match the transform algorithm that you select for the generator.

Important: If both of the following conditions are true, WebSphere Application Server signs the referenced token:

- You previously selected the Keyinfo or the Keyinfochildelements option from the Key information signature type field on the signing information panel.
- You select <http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform> as the transform algorithm.

11. Click **OK**.
12. Click **Save** at the top of the panel to save your configuration.

After completing these steps, you have configured the signing information for the consumer on the server or cell level.

You must specify a similar signing information configuration for the generator.

Configuring the encryption information for the consumer binding on the server or cell level

The encryption information for the default consumer specifies how to process the encryption information on the receiver side if these bindings are not defined at the application level. WebSphere Application Server provides default values for the bindings. However, an administrator must modify the defaults for a production environment.

You can configure the encryption information for the consumer binding on the server level and the cell level. In the following steps, use the first step to access the server-level default bindings and use the second step to access the cell-level bindings.

1. Access the default bindings for the server level.
 - a. Click **Servers > Application servers > *server_name***.
 - b. Under Security, click **Web services: Default bindings for Web services security**.
2. Click **Security > Web services** to access the default bindings on the cell level.
3. Under Default consumer bindings, click **Encryption information**.
4. Click **New** to create an encryption information configuration, click **Delete** to delete an existing configuration, or click the name of an existing encryption information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the encryption configuration in the Encryption information name field. For example, you might specify `con_encinfo`.
5. Select a data encryption algorithm from the Data encryption algorithm field. This algorithm is used to encrypt the data. WebSphere Application Server supports the following pre-configured algorithms:
 - <http://www.w3.org/2001/04/xmlenc#tripleDES-cbc>
 - <http://www.w3.org/2001/04/xmlenc#aes128-cbc>
 - <http://www.w3.org/2001/04/xmlenc#aes256-cbc>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

 - <http://www.w3.org/2001/04/xmlenc#aes192-cbc>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

The data encryption algorithm that you select for the consumer side must match the data encryption algorithm that you select for the generator side.

6. Select a key encryption algorithm from the Key encryption algorithm field. This algorithm is used to encrypt the key. WebSphere Application Server supports the following pre-configured algorithms:

- <http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p>.

When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this one. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5.

Restriction: This algorithm is not supported when the WebSphere Application Server is running in Federal Information Processing Standard (FIPS) mode.

- http://www.w3.org/2001/04/xmlenc#rsa-1_5
- <http://www.w3.org/2001/04/xmlenc#kw-tripledes>
- <http://www.w3.org/2001/04/xmlenc#kw-aes128>
- <http://www.w3.org/2001/04/xmlenc#kw-aes256>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

- <http://www.w3.org/2001/04/xmlenc#kw-aes192>

To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>.

Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

If you select **None**, the key is not encrypted.

The key encryption algorithm that you select for the consumer side must match the key encryption algorithm that you select for the generator side.

7. Under Additional properties, click **Key information references**.
8. Click **New** to create a key information configuration, click **Delete** to delete an existing configuration, or click the name of an existing key information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the key information configuration in the name field. For example, you might specify `con_enckeyinfo`.
9. Select a key information reference from the Key information reference field. This selection refers to the name of the key information that is used for encryption. For more information, see “Configuring the key information for the consumer binding on the server or cell level” on page 1254.
10. Click **OK** and **Save** to save the configuration.

You have configured the encryption information for the consumer binding at the server and the cell level.

You must specify a similar encryption information configuration for the generator.

Tuning Web services security for Version 6.1 applications

The Java Cryptography Extension (JCE) is integrated into the software development kit (SDK) version 1.4.x and is no longer an optional package. However, the default Java Cryptography Extension (JCE) jurisdiction policy file shipped with the SDK enables you to use cryptography to enforce this default policy.

The Java Cryptography Extension (JCE) is integrated into the software development kit (SDK) version 1.4.x and is no longer an optional package. However, due to export and import regulations, the default Java Cryptography Extension (JCE) jurisdiction policy file shipped with the SDK enables you to use strong, but limited, cryptography only. To enforce this default policy, WebSphere Application Server uses a JCE jurisdiction policy file that might introduce a performance impact. The default JCE jurisdiction policy might have a performance impact on the cryptographic functions that are supported by Web services security. If you have Web services applications that use transport level security for XML encryption or digital signatures, you might encounter performance degradation over previous releases of WebSphere Application Server. However, IBM and Sun Microsystems provide versions of these jurisdiction policy files that do not have restrictions on cryptographic strengths. If you are permitted by your governmental import and export regulations, download one of these jurisdiction policy files. After downloading one of these files, the performance of JCE and Web services security might improve.

For WebSphere Application Server platforms using IBM Developer Kit, Java Technology Edition Version 5, including the AIX, Linux, and Windows platforms, you can obtain unlimited jurisdiction policy files by completing the following steps:

1. Go to the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>
2. Click **J2SE 5.0**
3. Scroll down and click **IBM SDK Policy files**.
The Unrestricted JCE Policy files for the SDK Web site is displayed.
4. Click **Sign in** and provide your IBM intranet ID and password.
5. Select the appropriate Unrestricted JCE Policy files and then click **Continue**.
6. View the license agreement and then click **I Agree**.
7. Click **Download Now**.

For WebSphere Application Server platforms using the Sun-based Java Development Kit (JDK) Version 5, including the Solaris environments and the HP-UX platform, you can obtain unlimited jurisdiction policy files by completing the following steps:

1. Go to the following Web site: <http://java.sun.com/j2se/1.5.0/download.jsp>
2. Click **Other Downloads**.
3. Locate the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files 1.5.1 information and click **Download**. The policy files are downloaded onto your machine.

In IBM WebSphere Application Server Version 6.1, Web services security supports the use of cryptographic hardware devices. There are two ways in which to use hardware cryptographic devices with Web services security.

See “Hardware cryptographic device support for Web Services Security” on page 1213 for more information.

After following either of these sets of steps, two Java Archive (JAR) files are placed in the JVM `jre/lib/security/` directory.

Securing Web services for Version 5.x applications based on WS-Security

Web services security for WebSphere Application Server is based on standards included in the Web services security (WS-Security) specification. These standards address how to provide protection for messages exchanged in a Web service environment.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

The specification defines the core facilities for protecting the integrity and confidentiality of a message and provides mechanisms for associating security-related claims with the message. Web services security is a message-level standard based on securing SOAP messages through XML digital signature, confidentiality through XML encryption, and credential propagation through security tokens.

Use the deprecated "Securing Apache SOAP Web services" topics in the WebSphere Application Server, Version 5 documentation if you are still using Apache SOAP Version 2.3.

To secure Web services, you must consider a broad set of security requirements, including authentication, authorization, privacy, trust, integrity, confidentiality, secure communications channels, federation, delegation, and auditing across a spectrum of application and business topologies. One of the key requirements for the security model in today's business environment is the ability to inter-operate between formerly incompatible security technologies, such as public key infrastructure and Kerberos in heterogeneous environments like Microsoft .NET and environments that are based on the Java 2 Platform, Enterprise Edition (J2EE) standards. The complete Web services security protocol stack and technology roadmap is described in *Security in a Web Services World: A Proposed Architecture and Roadmap*.

Specification: Web Services Security (WS-Security) proposes a standard set of SOAP extensions that you can use to build secure Web services. These standards confirm integrity and confidentiality, which are generally provided with digital signature and encryption technologies. In addition, Web services security provides a general purpose mechanism for associating security tokens with messages. A typical example of the security token is a user name and password token, in which a user name and password are included as text. Web services security defines how to encode binary security tokens using methods such as X.509 certificates and Kerberos tickets.

To establish a managed environment and to enforce constraints for Web services security, you must perform a Java Naming and Directory Interface (JNDI) lookup on the client to resolve the service reference.

An administrator can use any of the following methods to integrate message-level security into a WebSphere Application Server environment:

- "Securing Web services for Version 5.x applications using XML digital signature" on page 1290
- "Securing Web services for Version 5.x applications using XML encryption" on page 1346
- "Securing Web services for Version 5.x applications using basicauth authentication" on page 1365
- "Securing Web services for Version 5.x applications using identity assertion authentication" on page 1373
- "Securing Web services for version 5.x applications using signature authentication" on page 1379
- "Securing Web services for version 5.x applications using a pluggable token" on page 1392

Web services security specification—a chronology

This chronology describes the process that has been used to develop the Web services security specifications. The chronology includes both the Organization for the Advancement of Structured Information Standards (OASIS) and non-OASIS activities.

Non-OASIS activities

Important: There is an important distinction between Version 5.x and Version 6.0.x applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x applications.

In April 2002, IBM, Microsoft, and VeriSign proposed the *Web Services Security (WS-Security) specification* on their Web sites. This specification included the basic ideas of security token, XML signature, and XML encryption. The specification also defined the format for user name tokens and encoded binary security tokens. After some discussion and an interoperability test that was based on the specification, the following issues were noted:

- The specification requires that the Web services security processors understand the schema correctly so that the processor distinguishes between the ID attribute for XML signature and XML encryption.
- The freshness of the message, which indicates whether the message complies with predefined time constraints, cannot be determined.
- Digested password strings do not strengthen security.

In August 2002, IBM, Microsoft, and VeriSign published the *Web Services Security Addendum*, which attempted to address the previously listed issues. The following solutions were put in the addendum:

- Require a global ID attribute for XML signature and XML encryption.
- Use time stamp header elements that indicate the time of the creation, receipt, or expiration of the message.
- Use password strings that are digested with a timestamp and nonce (randomly generated token).

OASIS activities

In June 2002, OASIS received a proposed Web services security specification from IBM, Microsoft, and Verisign. The Web Services Security Technical Committee (WSS TC) was organized at OASIS soon after the submission. The technical committee included many companies including IBM, Microsoft, VeriSign, Sun Microsystems, and BEA Systems.

In September 2002, WSS TC published its first specification, *Web Services Security Core Specification, Working Draft 01*. This specification included the contents of both the original Web services security specification and its addendum.

The coverage of the technical committee became larger as the discussion proceeded. Since the Web Services Security Core Specification allows arbitrary types of security tokens, proposals were published as profiles. The profiles described the method for embedding tokens, including Security Assertion Markup Language (SAML) tokens and Kerberos tokens imbedded into the Web services security messages. Subsequently, the definitions of the usage for user name tokens and X.509 binary security tokens, which were defined in the original Web Services Security Specification, were divided into the profiles.

WebSphere Application Server supports the following specifications:

- Web Services Security: SOAP Message Security Draft 13 (formerly Web Services Security Core Specification)
- Web Services Security: Username Token Profile Draft 2

The following figure shows the various Web services security-related specifications. As indicated in the figure, the current support level for Web services security: SOAP message security is based on Draft 13 from May 2003. The current support level for Web services security user name token profiles, is based on Draft 2 from February 2003.

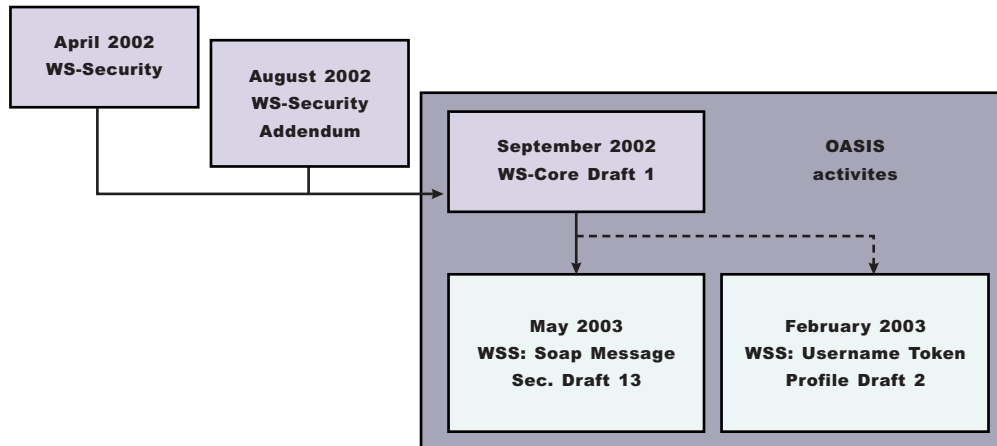

Figure 8. Web services security specification support

Web services security support

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

WebSphere Application Server, Versions 4.x, 5, and 5.0.1 support digital signature for Apache SOAP Version 2.x. Beginning with WebSphere Application Server, Version 5.0.2, IBM supports *Web services security*, which is an extension of the IBM Web services engine to provide a quality of service. The IBM implementation is based on the Web services security specification, "Web Services Security (WS-Security)", originally proposed by IBM, Microsoft, and VeriSign in April 2002. Early versions of the proposed draft specification can be found in Web Services Security (WS-Security) Version 1.0 05 April 2002 and Web Services Security Addendum 18 August 2002. The WebSphere Application Server implementation is based on the Organization for the Advancement of Structured Information Standards (OASIS) working Draft 13 specification. (See the OASIS Web Services Security TC Web site for the latest working specification.) However, not all the features in the OASIS working Draft 13 specification are implemented.

The WebSphere Application Server security infrastructure fully integrates Web services security with the Java 2 Platform, Enterprise Edition (J2EE) security specification. Web services security is not supported in a pure Java client or a nonmanaged client. When a user ID and password are embedded in a request message, authentication is performed with the user ID and password. If authentication is successful, a user identity is established and further resource access is authorized based on that identity. After the user ID and password are authenticated by the Web services security run time, a J2EE container performs authorization.

WebSphere Application Server provides an implementation of the key features of Web services security based on the following specifications:

- Specification: Web Services Security (WS-Security) Version 1.0 05 April 2002
- Web Services Security Addendum 18 August 2002
- Web Services Security: SOAP Message Security Working 13 May 2003
- Web Services Security: Username Token Profile Draft

The following table provides a summary of Web services security elements supported by WebSphere Application Server:

Table 52. Web services security elements

Element	Notes
UsernameToken	Both the user name and password for the BasicAuth authentication method and the user name for the identity assertion authentication method are supported. WebSphere Application Server supports nonce, a randomly generated value.
BinarySecurityToken	X.509 certificates and Lightweight Third Party Authentication (LTPA) can be embedded, but there is no implementation to embed Kerberos tickets. However, the binary token generation and validation are pluggable and are based on the Java Authentication and Authorization Service (JAAS) Application Programming Interfaces (APIs). You can extend this implementation to generate and validate other types of binary security tokens.
Signature	The X.509 certificate is embedded as a binary security token and can be referenced by the SecurityTokenReference. WebSphere Application Server does not support shared, key-based signature.
Encryption	Both the EncryptedKey and ReferenceList XML tags are supported. KeyIdentifier specifies public keys and KeyName identifies the secret keys. WebSphere Application Server has the capability to map an authenticated identity to a key for encryption or use the signer certificate to encrypt the response message.
Timestamp	WebSphere Application Server supports the Created and Expires attributes. The freshness of the message, which indicates whether the message complies with predefined time constraints, is checked only if the Expires attribute is present in the message. WebSphere Application Server does not support the Received attribute, which is defined in the addendum. Instead, WebSphere Application Server uses the TimestampTrace Received attribute, which is defined in the OASIS specification.
XML based token	You can insert and validate an arbitrary format of XML tokens into a message. This format mechanism is based on the JAAS APIs.

Signing and encrypting attachments is not supported by WebSphere Application Server. However, WebSphere Application Server signs and encrypts the following elements for the request message.

Method	Element
XML digital signature	<ul style="list-style-type: none"> • Body • Securitytoken • Timestamp
XML encryption	<ul style="list-style-type: none"> • Bodycontent • Usenametoken

Method	Element
AuthMethod	<ul style="list-style-type: none"> • BasicAuth • IDAssertion (From WebSphere Application Server to another WebSphere Application Server) • Signature • Lightweight Third Party Authentication (LTPA) on the server side • Other customer tokens

WebSphere Application Server signs and encrypts the following elements for the response message:

Method	Element
XML digital signature	<ul style="list-style-type: none"> • Body • Timestamp
XML encryption	<ul style="list-style-type: none"> • Bodycontent

The namespaces used for sending a message were published by OASIS in draft 13 (<http://schemas.xmlsoap.org/ws/2003/06/secext>). However, the Web services security run time in WebSphere Application Server can accept any of the following namespaces:

April 2002 specification

<http://schemas.xmlsoap.org/ws/2002/04/secext>

August 2002 addendum

<http://schemas.xmlsoap.org/ws/2002/07/secext>

<http://schemas.xmlsoap.org/ws/2002/07/utility>

OASIS draft published on draft 13 May 2003

<http://schemas.xmlsoap.org/ws/2003/06/secext>

<http://schemas.xmlsoap.org/ws/2003/06/utility>

Note: WebSphere Application Server only uses the previously mentioned two name spaces for sending out requests and responses. However, the product can process all other mentioned name spaces for incoming requests and responses.

WebSphere Application Server provides the following capabilities for Web services security:

- Integrity of the message
- Authenticity of the message
- Confidentiality of the message
- Privacy of the message
- Transport level security: provided by Secure Sockets Layer (SSL)
- Security token propagation (pluggable)
- Identity assertion

See the previous table titled, "Web services security elements," for a description of capabilities that are not supported.

Web services security and Java 2 Platform, Enterprise Edition security relationship

This article describes the relationship between Web services security (message level security) model and the Java 2 Platform, Enterprise Edition (J2EE) security model. It also includes information on J2EE role-based authorization checks.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

WebSphere Application Server supports Java Specification Requests (JSR) 101 and JSR 109. For more information, see *Developing Web services applications*. JSRs 101 and 109 define Web services for the J2EE architecture so that you can develop and run Web services on the J2EE component architecture.

Important: *Web services security* refers to the Web services security: SOAP Message Security specification. For more information, see “Web services security support” on page 1263.

Securing Web services with WebSphere Application Server security (J2EE role-based security)

You can secure Web services using the existing security infrastructure of WebSphere Application Server, J2EE role-based security, and Secure Sockets Layer (SSL) transport level security.

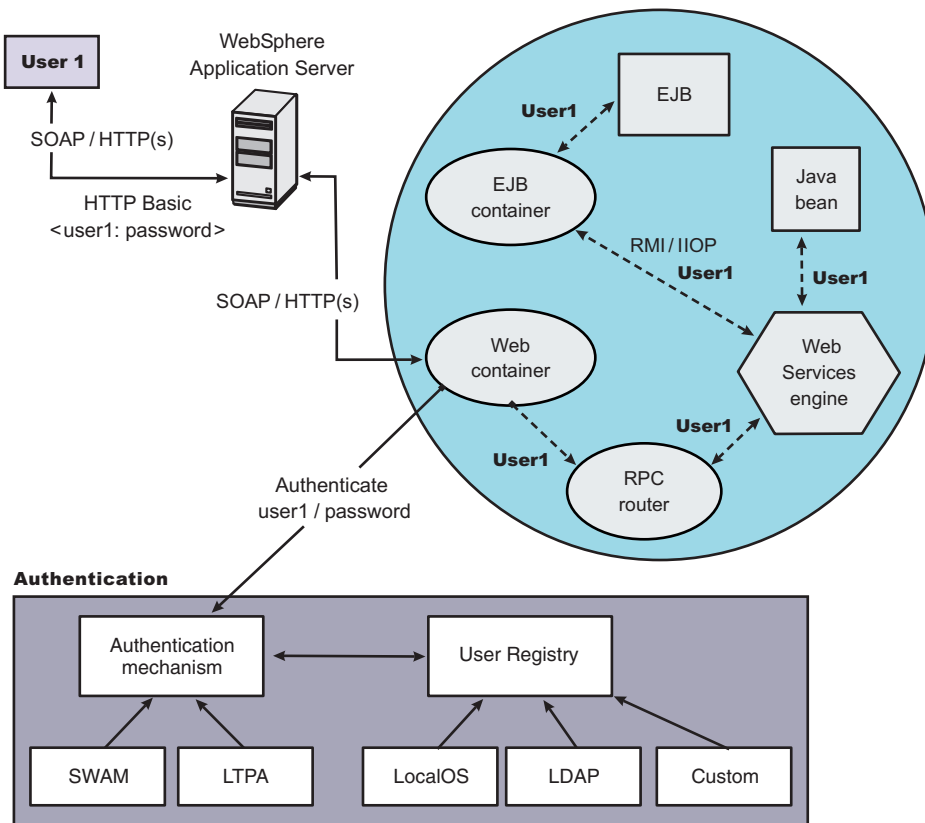

Figure 9. SOAP message flow using existing security infrastructure of WebSphere Application Server

The Web services port can be secured using J2EE role-based security. The Web services sender sends the basic authentication data using the HTTP header. SSL (HTTPS) can be used to secure the transport. When the WebSphere Application Server receives the SOAP message, the Web container authenticates the user (in this example, user1) and sets the security context for the call. After the security context is set, the SOAP router servlet sends the request to the implementation of the Web services (the implementation can be JavaBeans or enterprise bean files). For enterprise bean implementations, the EJB container performs an authorization check against the identity of user1.

The Web services port also can be secured using the J2EE role. Then, authorization is performed by the Web container before the SOAP request is dispatched to the Web services implementation.

Securing Web services with Web services security at the message level

You can also secure Web services using Web services security at the message level. In this case, you can digitally sign or encrypt a certain part of the message. Web services security also supports security token propagation within the SOAP message. The following scenario assumes that the Web services port is not secured with J2EE role-based security and the enterprise bean is secured with J2EE role-based security.

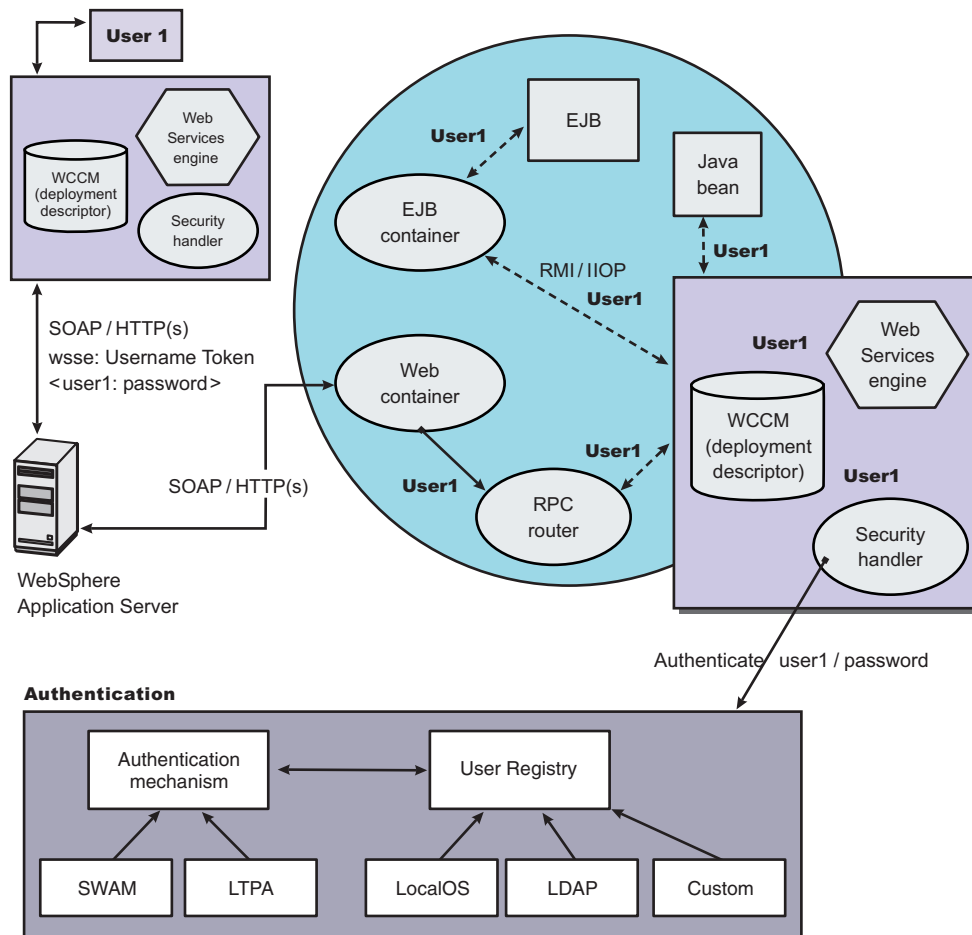

Figure 10. SOAP message flow using Web services security

In this case, the Web services port is not secured with J2EE role-based security. The Web services engine processes the SOAP message before the client sends the message to the Web services port. The Web services security run time acts on the security constraints, such as digitally signing, encrypting, or

generating (and inserting) a security token in the SOAP header. In this case `<wsse:UsernameToken>` is generated using `user1` and the password. On the server-side (receiving), the Web services process the incoming message and Web services security enforces security constraints. This enforcement includes making sure that messages are properly signed, properly encrypted, and decrypted, authenticating the security token, and setting up the security context with the authenticated identity. (In this case, `user1` is the authenticated identity.) Finally, the SOAP message is dispatched to the Web services implementation (if the implementation is an enterprise beans file, the Enterprise JavaBeans (EJB) container performs an authorization check against `user1`). SSL also might be used in this scenario.

Mixing the two

The second scenario shows that Web services security can complement J2EE role-based security. For example, SSL can be enabled at the transport level to provide a secure channel. Furthermore, if the Web services implementation is an enterprise beans file, you can leverage the EJB role-based authorization by performing authorization checks. Web services security run time leverages the security infrastructure to set the authenticated identity in the security context. The authenticated identity can be used in the downstream call to J2EE resources (or other resource types).

There are subtle consequences of combining the two scenarios. For example, if the HTTP transport is sending basic authentication data with `user1` and password in the HTTP header, but `<wsse:UsernameToken>` with `user99` and `letmein` also is inserted into the SOAP header. In the previous scenarios, there are two authentications performed. One authentication is performed by the Web container for authenticating `user1`, and the other is performed by Web services security for authenticating `user99`. The Web services security run time runs after the Web container runs and `user99` is the authenticated identity that is set in the security context.

Web services security can also propagate security tokens from the sender to the receiver for SOAP over a Java Message Service (JMS) transport.

J2EE role-based authorization checks

A standard for authorization does not exist for Web services. However, IBM, in conjunction with Microsoft Corporation, jointly published a security white paper road map for Web services called *Security in a Web Services World: A Proposed Architecture and Roadmap* in which a proposal exists for the WS-Authorization specification. However, the WS-Authorization specification has not been published.

The existing implementation of Web services security is based upon the Web Services for J2EE specification or the Java Specification Requirements (JSR) 109 specification. The implementation of Web services security leverages the J2EE role-based authorization checks. For conceptual information on role-based authorization, see “Role-based authorization” on page 334. If you develop a Web service that requires method-level authorization checks, then you must use stateless session beans to implement your Web service. For more information on using stateless session beans to implement a Web service, see *Developing a Web service from an enterprise bean* and “Securing enterprise bean applications” on page 943. If you develop a Web service that is implemented as a servlet, you can use coarse-grained or URL-based authorization in the Web container. However, in this situation, you cannot use the identity from Web services security for authorization checks. Instead, you can use the identity from the transport. If you use SOAP over HTTP, then the identity is in the HTTP transport.

Web services security model in WebSphere Application Server

The Web services security model used by WebSphere Application Server is the declarative model. WebSphere Application Server does not include any application programming interfaces (APIs) for programmatically interacting with Web services security. However, a few Server Provider Interfaces (SPIs) are available for extending some security-related behaviors.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

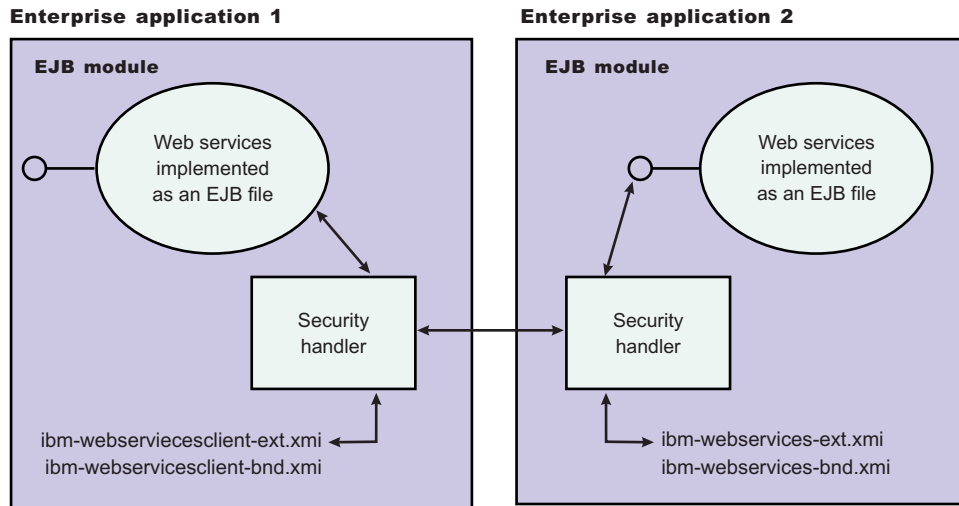

Figure 11. Web services security model

The security constraints for Web services security are specified in IBM deployment descriptor extensions for Web services. The Web services security run time acts on the constraints to enforce Web services security for the SOAP message. The scope of the IBM deployment descriptor extension is at the enterprise bean (EJB) or Web module level. Bindings are associated with each of the following IBM deployment descriptor extensions:

Client (Might be either a Java 2 Platform, Enterprise Edition (J2EE) client (application client container) or Web services acting as a client)

ibm-webservicesclient-ext.xmi
ibm-webservicesclient-bnd.xmi

Server

ibm-webservices-ext.xmi
ibm-webservices-bnd.xmi

It is recommended that you use the tools provided by IBM (the Application Server Toolkit and Rational Web Developer) to create the IBM deployment descriptor extension and bindings. After the bindings are created, you can use the administrative console or an assembly tool to specify the bindings.

Important: The binding information is collected after application deployment rather than during application deployment. The alternative is to specify the required binding information before deploying your application.

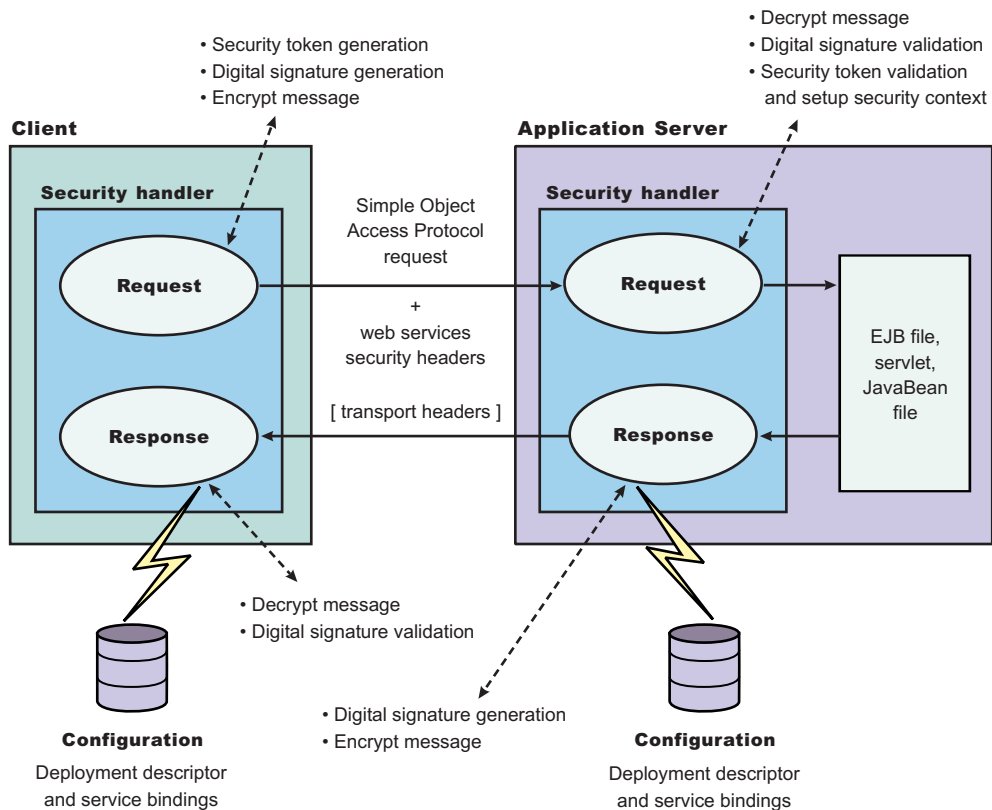

Figure 12. Web services security message interpretation

The Web services security run time enforces Web services security based on the defined security constraints in the deployment descriptor and binding files. Web services security has the following four points where it intercepts the message and acts on the security constraints defined:

Message points	Description
Request sender (defined in the <code>ibm-webservicesclient-ext.xmi</code> and <code>ibm-webservicesclient-bnd.xmi</code> files)	<ul style="list-style-type: none"> Applies the appropriate security constraints to the SOAP message (such as signing or encryption) before the message is sent, generating the time stamp or the required security token.
Request receiver (defined in the <code>ibm-webservices-ext.xmi</code> and <code>ibm-webservices-bnd.xmi</code> files)	<ul style="list-style-type: none"> Verifies that the Web services security constraints are met. Verifies the freshness of the message based on the time stamp. The freshness of the message indicates whether the message complies with predefined time constraints. Verifies the required signature. Verifies that the message is encrypted and decrypts the message if encrypted. Validates the security tokens and sets up the security context for the downstream call.
Response sender (defined in the <code>ibm-webservices-ext.xmi</code> and <code>ibm-webservices-bnd.xmi</code> files)	<ul style="list-style-type: none"> Applies the appropriate security constraints to the SOAP message response, like signing the message, encrypting the message, or generating the time stamp.

Message points	Description
Response receiver (defined in the <code>ibm-webservicesclient-ext.xmi</code> or <code>ibm-webservicesclient-bnd.xmi</code> files)	<ul style="list-style-type: none"> • Verifies that the Web services security constraints are met. • Verifies the freshness of the message based on the time stamp. The freshness of the message indicates whether the message complies with predefined time constraints. • Verifies the required signature. • Verifies that the message is encrypted and decrypts the message, if encrypted.

Web services: Default bindings for the Web services security collection

Use this page to configure the settings for nonce on the server level and to manage the default bindings for the signing information, encryption information, key information, token generators, token consumers, key locators, collection certificate store, trust anchors, trusted ID evaluators, algorithm mappings, and login mappings.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers > Application Servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.

Read the Web services documentation before you begin defining the default bindings for Web services security.

Nonce is a unique cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens.

In WebSphere Application Server and WebSphere Application Server Express, you must specify values for the Nonce cache timeout, Nonce maximum age, and Nonce clock skew fields for the server level.

The default binding configuration provides a central location where reusable binding information is defined. The application binding file can reference the information that is contained in the default binding configuration.

Nonce cache timeout

Specifies the timeout value, in seconds, for the nonce cached on the server. Nonce is a randomly generated value.

The Nonce cache timeout field is not required on the server level, but it is required on the cell level. To specify a value for the field on the cell level, click **Security > Web services**.

If you make changes to the value for the Nonce cache timeout field, you must restart the application server for the changes to take effect.

Default	600 seconds
Minimum	300 seconds

Nonce maximum age

Specifies the default time, in seconds, before the nonce timestamp expires. Nonce is a randomly generated value.

The maximum value cannot exceed the number of seconds that is specified in the Nonce cache timeout field for the server level.

The Nonce maximum age field is not required on the server level, but it is required on the cell level. The value set for this Nonce maximum age field on the server level must not exceed the value for the Nonce maximum age field on the cell level. To specify a value for the Nonce maximum age field on the cell level, click **Security > Web services**.

Default	300 seconds
Range	300 to the value that is specified, in seconds, in the Nonce cache timeout field.

Nonce clock skew

Specifies the default clock skew value, in seconds, to consider when the application server checks the timeliness of the message. Nonce is a randomly generated value.

The maximum value cannot exceed the number of seconds that is specified in the Nonce maximum age field.

The Nonce clock skew field is not required on the server level, but it is required on the cell level. To specify a value for the Nonce clock skew field on the cell level, click **Security > Web services**.

Default	0 seconds
Range	0 to the value that is specified, in seconds, in the Nonce maximum age field.

Distribute nonce caching

Enables distributed caching for the nonce value using a Data Replication Service (DRS).

transition: In previous releases of WebSphere Application Server, the nonce value was cached locally.

By selecting this option, the nonce value is propagated to other servers in your environment. However, the nonce value might be subject to a one-second delay in propagation and subject to any network congestion.

Enable cryptographic operations on hardware device

Enables cryptographic operations on hardware devices. Enabling this feature might improve the performance, depending on the hardware device.

Cryptographic hardware configuration name

Specifies the name of the hardware device configuration name defined in the keystore settings in the secure communications.

This value is necessary only if **Hardware acceleration** has been selected.

Usage scenario for propagating security tokens

This sample shows propagating security tokens using Web services security, the security infrastructure of the WebSphere Application Server, and Java 2 Platform, Enterprise Edition (J2EE) security.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

A sample scenario

This document describes a usage scenario for Web services security.

In scenario 1, Client 1 invokes Web services 1. Then Web services 1 calls the Enterprise JavaBeans (EJB) file 2. The EJB file 2 calls Web services 3 and Web services 3 calls Web services 4.

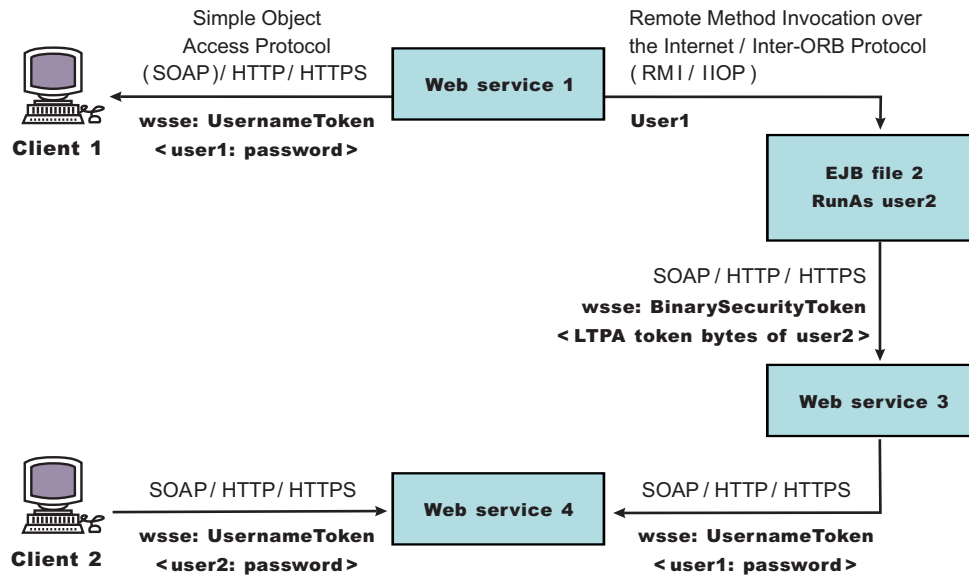

Figure 13. Propagating security tokens

The previous scenario shows how to propagate security tokens using Web services security, the security infrastructure of the WebSphere Application Server, and Java 2 Platform, Enterprise Edition (J2EE) security. Web services 1 is configured to accept `<wsse:UsernameToken>` only and use the BasicAuth authentication method. However, Web services 4 is configured to accept either `<wsse:UsernameToken>` using the BasicAuth authentication method or Lightweight Third Party Authentication (LTPA) as `<wsse:BinarySecurityToken>`. The following steps describe the scenario shown in the previous figure:

1. Client 1 sends a SOAP message to Web services 1 with user1 and password in the `<wsse:UsernameToken>` element.
2. The user1 and password values are authenticated by the Web services security run time and set in the current security context as the Java Authentication and Authorization Service (JAAS) Subject.
3. Web services 1 invokes EJB file 2 using the Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) protocol.
4. The user1 identity is propagated to the downstream call.
5. The EJB container of EJB file 2 performs an authorization check against user1.
6. EJB file 2 calls Web services 3 and Web services 3 is configured to accept LTPA tokens.
7. The RunAs role of EJB file 2 is set to user2.
8. The LTPA CallbackHandler implementation extracts the LTPA token from the current JAAS Subject in the security context and Web services security run time inserts the token as `<wsse: BinarySecurityToken>` in the SOAP header.
9. The Web services security run time in Web services 3 calls the JAAS login configuration to validate the LTPA token and set it in the current security context as the JAAS Subject.

10. Web services 3 is configured to send LTPA security to Web services 4. In this case, assume that the RunAs role is not configured for Web services 3. The LTPA token of user2 is propagated to Web services 4.
11. Client 2 uses the <wsse:UsernameToken> element to propagate the basic authentication data to Web services 4.

Web services security complements the WebSphere Application Server security run time and the J2EE role-based security. This scenario demonstrates how to propagate security tokens across multiple resources such as Web services and EJB files.

Web services security constraints

The Web services security model that is used by WebSphere Application Server is the declarative model. A version 5.x application must be secured with Web services security by defining the security constraints in the IBM extension deployment descriptors and in IBM extension bindings.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

No Application Programming Interfaces (APIs) exist in WebSphere Application Server for programmatically interacting with Web services security. However, Service Provider Programming Interfaces (SPIs) are available for extending some security run-time behaviors. You can secure an application with Web services security by defining security constraints in the IBM extension deployment descriptors and in IBM extension bindings.

The development life cycle of a Web services security-enabled application is similar to the Java 2 Platform, Enterprise Edition (J2EE) programming model. See the following figure for more details.

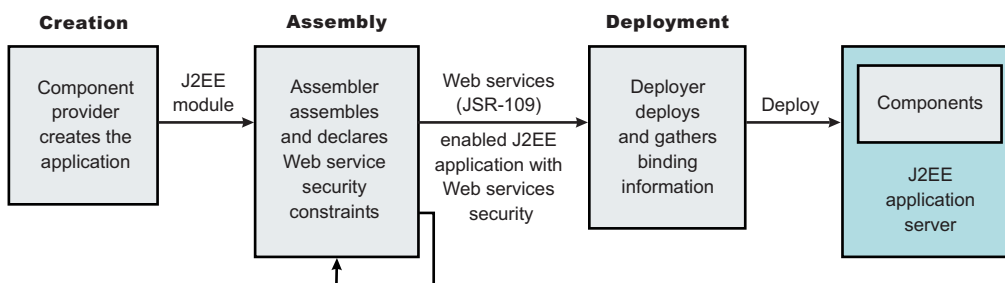

Figure 14. Application development life cycle

The Web services security constraints are defined by the assembler during the application assembly phase if the J2EE application is Web services-enabled. Create, define, and edit the Web services security constraints with an assembly tool. For more information, see Assembly tools.

Web services security constraints

The security constraints for Web services security are specified in the IBM deployment descriptor extension for Web services. The assembler defines these constraints during the application assembly phase, if the J2EE application is Web services enabled. Define the Web services security constraints using an assembly tool. For more information, see Assembling applications.

The Web services security run time acts on the constraints to enforce Web services security for the SOAP message. The scope of the IBM deployment descriptor extension is at the Enterprise JavaBeans (EJB) module or Web module level. There also are bindings associated with each of the following IBM deployment descriptor extensions:

Client (might be either a J2EE client (application client container) or Web services acting as a client)

- `ibm-webservicesclient-ext.xml`
- `ibm-webservicesclient-bnd.xml`

Server

- `ibm-webservices-ext.xml`
- `ibm-webservices-bnd.xml`

The IBM extension deployment descriptor and bindings are associated with each EJB module or Web module. See Figure 2 for more information. If Web services is acting as a client, then it contains the client IBM extension deployment descriptors and bindings in the EJB module or Web module.

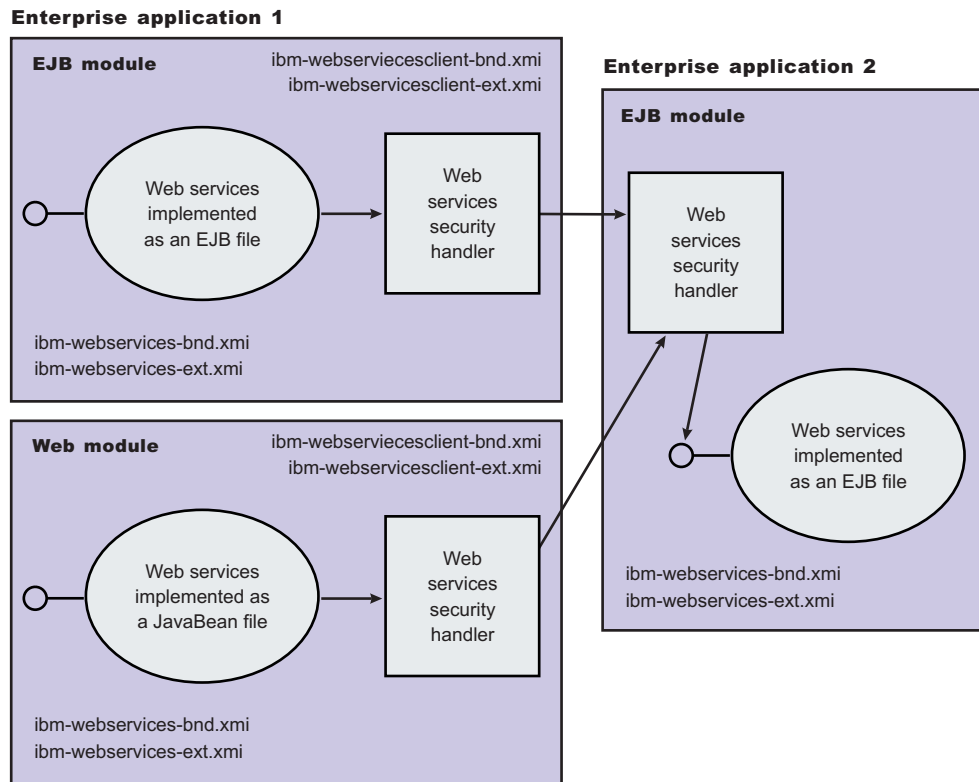

Figure 15. IBM extension deployment descriptors and bindings

The Web services security handler acts on the security constraints defined in the IBM extension deployment descriptor and enforces the security constraints accordingly. There are outbound and inbound configurations in both the client and server security constraints.

In a SOAP request, the following message points exist:

- Sender outbound
- Receiver inbound

- Receiver outbound
- Sender inbound

These message points correspond to the following four security constraints:

- Request sender (sender outbound)
- Request receiver (receiver inbound)
- Response sender (receiver outbound)
- Response receiver (sender inbound)

The security constraints of request sender and request receiver must match. Also, the security constraints of the response sender and response receiver must match. For example, if you specify integrity as a constraint in the request receiver, then you must configure the request sender to have integrity applied to the SOAP message. Otherwise, the request is denied because the SOAP message does not include the integrity specified in the request constraint.

The four security constraints are shown in the following figure of Web services security constraints.

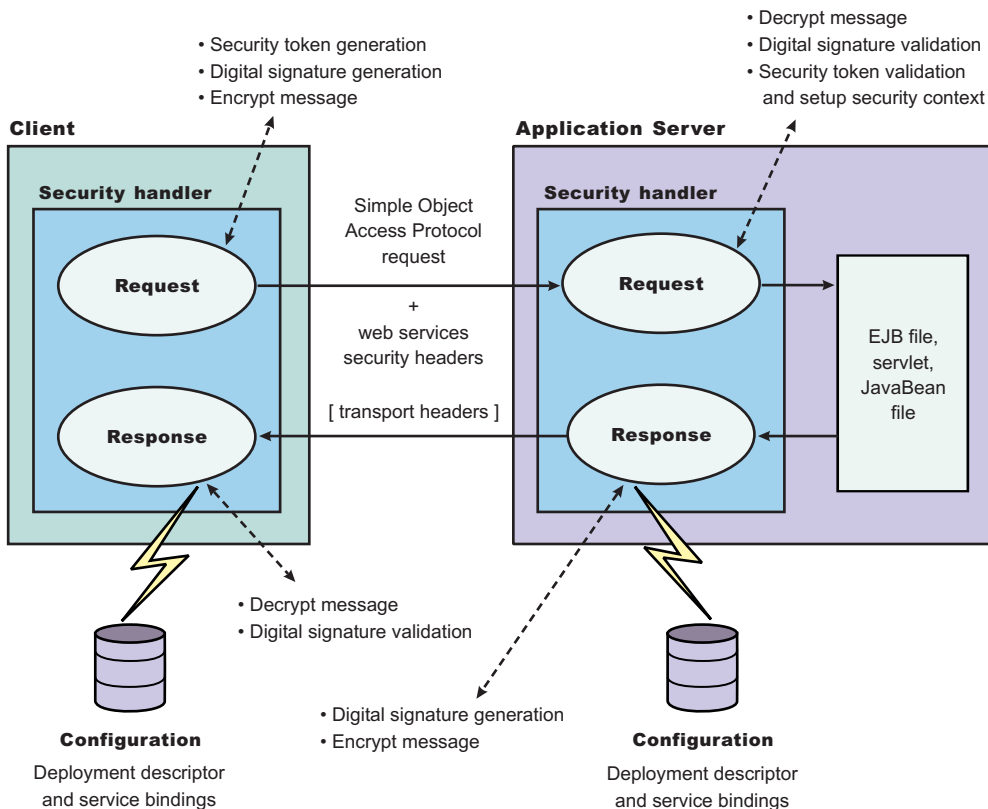

Figure 16. Web services security constraints

Sample configuration for Web services security for a version 5.x application

To secure a version 5.x application with Web services security, you must define the security constraints in the IBM extension deployment descriptors and in IBM extension bindings. Sample keystore files and default binding information are provided for a sample configuration to demonstrate what IBM deployment descriptor extensions and bindings can do.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

WebSphere Application Server provides the following sample keystores for sample configurations. These sample keystores are for testing and sample purposes only. Do not use them in a production environment.

- `${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-sender.ks`
 - The keystore password is `client`
 - Trusted certificate with alias name, `soapca`
 - Personal certificate with alias name, `soaprequester` and key password `client` issued by intermediary certificate authority `Int CA2`, which is, in turn, issued by `soapca`
- `${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-receiver.ks`
 - The keystore password is `server`
 - Trusted certificate with alias name, `soapca`
 - Personal certificate with alias name, `soapprovider` and key password `server`, issued by intermediary certificate authority `Int CA2`, which is, in turn, issued by `soapca`
- `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-sender.jceks`
 - The keystore password is `storepass`
 - Secret key `CN=Group1`, alias name `Group1`, and key password `keypass`
 - Public key `CN=Bob`, `O=IBM`, `C=US`, alias name `bob`, and key password `keypass`
 - Private key `CN=Alice`, `O=IBM`, `C=US`, alias name `alice`, and key password `keypass`
- `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-receiver.jceks`
 - The keystore password is `storepass`
 - Secret key `CN=Group1`, alias name `Group1`, and key password `keypass`
 - Private key `CN=Bob`, `O=IBM`, `C=US`, alias name `bob`, and key password `keypass`
 - Public key `CN=Alice`, `O=IBM`, `C=US`, alias name `alice`, and key password `keypass`
- `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`
 - The intermediary certificate authority is `Int CA2`.

Default binding (cell and server level)

WebSphere Application Server provides the following default binding information:

Trust anchors

Used to validate the trust of the signer certificate.

- `SampleClientTrustAnchor` is used by the response receiver to validate the signer certificate.
- `SampleServerTrustAnchor` is used by the request receiver to validate the signer certificate.

Collection Certificate Store

Used to validate the certificate path.

- `SampleCollectionCertStore` is used by the response receiver and the request receiver to validate the signer certificate path.

Key Locators

Used to locate the key for signature, encryption, and decryption.

- `SampleClientSignerKey` is used by the requesting sender to sign the Simple Object Access Protocol (SOAP) message. The signing key name is `clientsignerkey`, which can be referenced in the signing information as the signing key name.

- `SampleServerSignerKey` is used by the responding sender to sign the SOAP message. The signing key name is `serversignerkey`, which can be referenced in the signing information as the signing key name.
- `SampleSenderEncryptionKeyLocator` is used by the sender to encrypt the SOAP message. It is configured to use the `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-sender.jceks` keystore and the `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator` keystore key locator.
- `SampleReceiverEncryptionKeyLocator` is used by the receiver to decrypt the encrypted SOAP message. The implementation is configured to use the `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-receiver.jceks` keystore and the `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator` keystore key locator. The implementation is configured for symmetric encryption (DES or TRIPLEDES). However, to use it for asymmetric encryption (RSA), you must add the private key `CN=Bob, O=IBM, C=US`, alias name `bob`, and key password `keypass`.
- `SampleResponseSenderEncryptionKeyLocator` is used by the response sender to encrypt the SOAP response message. It is configured to use the `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-receiver.jceks` keystore and the `com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator` key locator. This key locator maps an authenticated identity (of the current thread) to a public key for encryption. By default, WebSphere Application Server is configured to map to public key `alice`, and you must change WebSphere Application Server to the appropriate user. The `SampleResponseSenderEncryptionKeyLocator` key locator also can set a default key for encryption. By default, this key locator is configured to use public key `alice`.

Trusted ID Evaluator

Used to establish trust before asserting to the identity in identity assertion.

`SampleTrustedIDEvaluator` is configured to use the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl` implementation. The default implementation of `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` contains a list of trusted identities. The list is defined as properties with `trustedId_*` as the key and the value as the trusted identity. Define this information for the server level in the administration console by completing the following steps:

1. Click **Servers > Application Servers > *server1***.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security > Trusted ID Evaluators > *SampleTrustedIDEvaluator***

For the cell level, click **Security > Web Services > Trusted ID Evaluators > *SampleTrustedIDEvaluator***.

Login Mapping

Used to authenticate the incoming security token in the Web services security SOAP header of a SOAP message.

- The `BasicAuth` authentication method is used to authenticate user name security token (user name and password).
- The signature authentication method is used to map a distinguished name (DN) into a WebSphere Application Server Java Authentication and Authorization Server (JAAS) Subject.
- The `IDAssertion` authentication method is used to map a trusted identity into a WebSphere Application Server JAAS Subject for identity assertion.
- The `Lightweight Third Party Authentication (LTPA)` authentication method is used to validate a LTPA security token.

The previous default bindings for trust anchors, collection certificate stores, and key locators are for testing or sample purpose only. Do not use them for production.

A sample configuration

The following examples demonstrate what IBM deployment descriptor extensions and bindings can do. The unnecessary information was removed from the examples to improve clarity. Do not copy and paste these examples into your application deployment descriptors or bindings. These examples serve as reference only and are not representative of the recommended configuration.

Use the following tools to create or edit IBM deployment descriptor extensions and bindings:

- Use an assembly tool to create or edit the IBM deployment descriptor extensions.
- Use an assembly tool or the administrative console to create or edit the bindings file.

The following example illustrates a scenario that:

- Signs the SOAP body, time stamp, and security token.
- Encrypts the body content and user name token.
- Sends the user name token (basic authentication data).
- Generates the time stamp for the request.

For the response, the SOAP body and time stamp are signed, the body content is encrypted, and the SOAP message freshness is checked using the time stamp. The freshness of the message indicates whether the message complies with predefined time constraints.

The request sender and the request receiver are a pair. Similarly, the response sender and the response receiver are a pair.

Tip: It is recommended that you use the WebSphere Application Server variables for specifying the path to the key stores. In the administrative console, click **Environment > Manage WebSphere Variables**. These variables often help with platform differences such as file system naming conventions. In the following examples, `$$ {USER_INSTALL_ROOT}` is used for specifying the path to the key stores.

Client-side IBM deployment descriptor extension

The client-side IBM deployment descriptor extension describes the following constraints:

Request Sender

- Signs the SOAP body, time stamp and security token
- Encrypts the body content and user name token
- Sends the basic authentication token (user name and password)
- Generates the time stamp to expire in three minutes

Response Receiver

- Verifies that the SOAP body and time stamp are signed
- Verifies that the SOAP body content is encrypted
- Verifies that the time stamp is present (also check for message freshness)

Example 1: Sample client IBM deployment descriptor extension

The `xmi:id` statements are removed for readability. These statements must be added for this example to work.

Important: In the following code sample, lines 2 through 4 were split into three lines due to the width of the printed page.

```

```

Client-side IBM extension bindings

Example 2 shows the client-side IBM extension binding for the security constraints described previously in the discussion on client-side IBM deployment descriptor extensions.

The signer key and encryption (decryption) key for the message can be obtained from the keystore key locator implementation (`com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator`). The signer key is used for encrypting the response. The sample is configured to use the Java Certification Path API to validate the certificate path of the signer of the digital signature. The user name token (basic authentication) data is collected from the standard in (stdin) prompts using one of the default JAAS implementations `:javax.security.auth.callback.CallbackHandler` implementation (`com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`).

Example 2: Sample client IBM extension binding

Server-side IBM deployment descriptor extension

The client-side IBM deployment descriptor extension describes the following constraints:

Request Receiver (ibm-webservices-ext.xmi and ibm-webservices-bnd.xmi)

- Verifies that the SOAP body, time stamp, and security token are signed.
- Verifies that the SOAP body content and user name token are encrypted.
- Verifies that the basic authentication token (user name and password) is in the Web services security SOAP header.
- Verifies that the time stamp is present (also check for message freshness). The freshness of the message indicates whether the message complies with predefined time constraints.

Response Sender (ibm-webservices-ext.xmi and ibm-webservices-bnd.xmi)

- Signs the SOAP body and time stamp
- Encrypts the SOAP body content
- Generates the time stamp to expire in 3 minutes

Example 3: Sample server IBM deployment descriptor extension

Important: In the following code sample, several lines were split into multiple lines due to the width of the printed page. See the close bracket for an indication of where each line of code ends.

```

          </confidentiality>
          <addCreatedTimestamp flag="true" expires="PT3M"/>
        </securityResponseSenderServiceConfig>
      </serverServiceConfig>
    </pcBinding>
  </wsDescExt>
</com.ibm.etools.webservice.wsext:WsExtension>

```

```

    </serverServiceConfig>
  </pcBinding>
</wsDescExt>
</com.ibm.etools.webservice.wsext:WsExtension>

```

Server-side IBM extension bindings

The following binding information reuses some of the default binding information defined either at the server level or the cell level, which depends upon the installation. For example, request receiver is referencing the SampleCollectionCertStore certification store and the SampleServerTrustAnchor trust store is defined in the default binding. However, the encryption information in the request receiver is referencing a SampleReceiverEncryptionKeyLocator key locator defined in the application-level binding (the same `ibm-webservices-bnd.xmi` file). The response sender is configured to use the signer key of the digital signature of the request to encrypt the response using one of the default key locator (`com.ibm.wsspi.wssecurity.config.CertInRequestKeyLocator`) implementations.

Example 4: Sample server IBM extension binding

```

Overview of authentication methods

The Web services security implementation for WebSphere Application Server supports the following authentication methods: BasicAuth, Lightweight Third Party Authentication (LTPA), digital signature, and identity assertion.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

When the WebSphere Application Server is configured to use the BasicAuth authentication method, the sender attaches the Lightweight Third Party Authentication (LTPA) token as a BinarySecurityToken from the current security context or from basic authentication data configuration in the binding file in the SOAP message header. The Web services security message receiver authenticates the sender by validating the user name and password against the configured user registry. With the LTPA method, the sender attaches the LTPA BinarySecurityToken it previously received in the SOAP message header. The receiver authenticates the sender by validating the LTPA token and the token expiration time. With the Digital Signature authentication method, the sender attaches a BinarySecurityToken from a X509 certificate to the Web services security message header along with a digital signature of the message body, time stamp, security token, or any combination of the three. The receiver authenticates the sender by verifying the validity of the X.509 certificate and the digital signature using the public key from the verified certificate.

The identity assertion authentication method is different from the other three authentication methods. This method establishes the security credential of the sender based on the trust relationship. You can use the identity assertion authentication method, for example, when an intermediary server must invoke a service from a downstream server on behalf of the client, but does not have the client authentication information. The intermediary server might establish a trust relationship with the downstream server and then assert the client identity to the same downstream server.

Web Services Security supports the following trust modes:

- BasicAuth
- Digital signature
- Presumed trust

When you use the BasicAuth and digital signature trust modes, the intermediary server passes its own authentication information to the downstream server for authentication. The presumed trust mode establishes a trust relationship using some external mechanism. For example, the intermediary server might pass SOAP messages through a Secure Socket Layers (SSL) connection with the downstream server and transport layer client certificate authentication.

The Web services security implementation for WebSphere Application Server validates the trust relationship by following this procedure:

1. The downstream server validates the authentication information of the intermediary server.
2. The downstream server verifies whether the authenticated intermediary server is authorized for identity assertion. For example, the intermediary server must be in the trust list for the downstream server.

The client identity might be represented by a name string, a distinguished name (DN), or an X.509 certificate. The client identity is attached in the Web services security message in a UsernameToken with just a user name, DN, or in a BinarySecurityToken of a certificate. The following table summarizes the type of security token that is required for each authentication method.

Table 53. Authentication methods and their security tokens

Authentication method	Security token
BasicAuth	BasicAuth requires <wsse:UsernameToken> with <wsse:Username> and <wsse:Password>.
Signature	Signature requires <ds:Signature> and <wsse:BinarySecurityToken>.
IDAssertion	IDAssertion requires <wsse:UsernameToken> with <wsse:Username> or <wsse:BinarySecurityToken> with a X.509 certificate for client identity depending on <idType>. This method also requires other security tokens according to the <trustMode>: <ul style="list-style-type: none"> • If the <trustMode> is BasicAuth, IDAssertion requires <wsse:UsernameToken> with <wsse:Username> and <wsse:Password>. • If the <trustMode> is Signature, IDAssertion requires <wsse:BinarySecurityToken>.
LTPA	LTPA requires <wsse:BinarySecurityToken> with an LTPA token.

A Web service can support multiple authentication methods simultaneously. The receiver side of the Web services deployment descriptor can specify all the authentication methods that are supported in the `ibm-webservices-ext.xmi` XML file. The Web services receiver-side, as shown in the following example, is configured to accept all the authentication methods described previously:

```
<loginConfig xmi:id="LoginConfig_1052760331326">
  <authMethods xmi:id="AuthMethod_1052760331326" text="BasicAuth"/>
  <authMethods xmi:id="AuthMethod_1052760331327" text="IDAssertion"/>
  <authMethods xmi:id="AuthMethod_1052760331336" text="Signature"/>
  <authMethods xmi:id="AuthMethod_1052760331337" text="LTPA"/>
</loginConfig>
<idAssertion xmi:id="IDAssertion_1052760331336" idType="Username" trustMode="Signature"/>
```

You can define only one authentication method in the sender-side Web services deployment descriptor. A Web service client can use any of the authentication methods that are supported by the particular Web services application. The following example illustrates an identity assertion authentication method configuration in the `ibm-webservicesclient-ext.xmi` deployment descriptor extension of the Web service client:

```
<loginConfig xmi:id="LoginConfig_1051555852697">
  <authMethods xmi:id="AuthMethod_1051555852698" text="IDAssertion"/>
</loginConfig>
<idAssertion xmi:id="IDAssertion_1051555852697" idType="Username" trustMode="Signature"/>
```

As shown in the previous example, the client identity type is Username and the trust mode is digital signature.

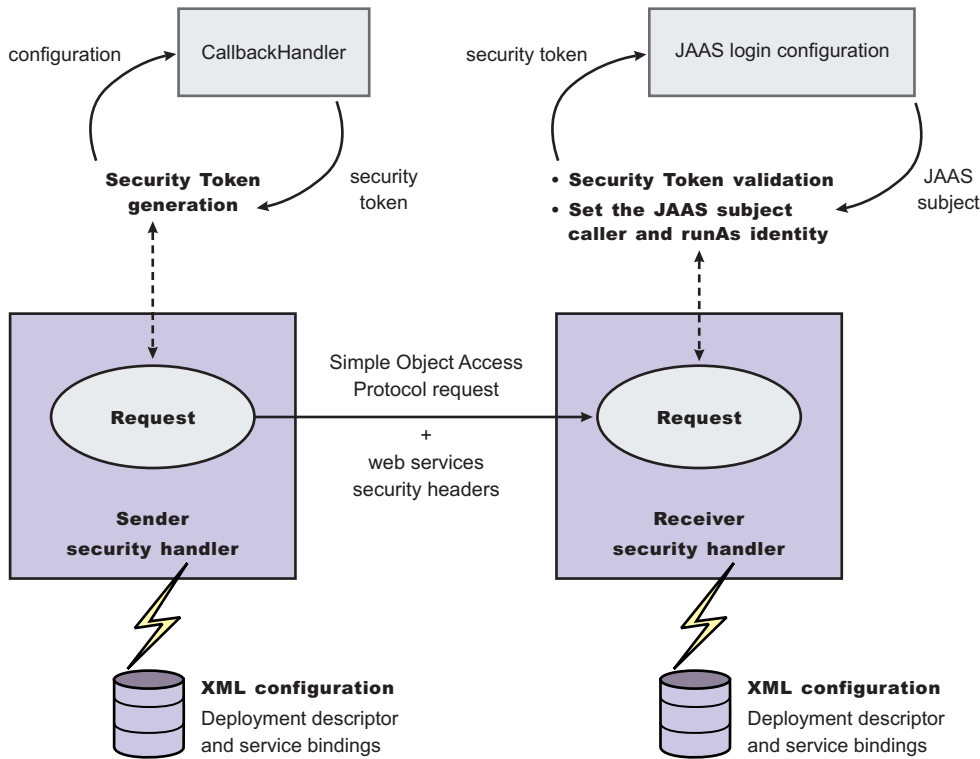

Figure 17. Security token generation and validation

The sender security handler invokes the `handle()` method of an implementation of the `javax.security.auth.callback.CallbackHandler` interface. The `javax.security.auth.callback.CallbackHandler` interface creates the security token and passes it back to the sender security handler. The sender security handler constructs the security token based on the authentication information in the callback array and inserts the security token into the Web services security message header.

The receiver security handler compares the token type in the message header with the expected token types configured in the deployment descriptor. If none of the expected token types are found in the Web services security header of the SOAP message, the request is rejected with a SOAP fault exception. Otherwise, the token type is used to map to a Java Authentication and Authorization Service (JAAS) login configuration for validating the token. If the authentication is successful, a JAAS Subject is created and associated with the running thread. Otherwise, the request is rejected with a SOAP fault exception.

XML digital signature

XML-Signature Syntax and Processing (XML signature) is a specification that defines XML syntax and processing rules to sign and verify digital signatures for digital content. The specification was developed jointly by the World Wide Web Consortium (W3C) and the Internet Engineering Task Force (IETF).

XML signature does not introduce new cryptographic algorithms. WebSphere Application Server uses XML signature with existing algorithms such as RSA, HMAC, and SHA1. XML signature defines many methods for describing key information and enables the definition of a new method.

XML canonicalization (c14n) is often needed when you use XML signature. Information can be represented in various ways within serialized XML documents. For example, although their octet representations are different, the following examples are identical:

- `<person first="John" last="Smith"/>`
- `<person last="Smith" first="John"></person>`

C14n is a process used to canonicalize XML information. Select an appropriate c14n algorithm because the information that is canonicalized is dependent upon this algorithm. One of the major c14n algorithms, Exclusive XML Canonicalization, canonicalizes the character encoding scheme, attribute order, namespace declarations, and so on. The algorithm does not canonicalize white space outside tags, namespace prefixes, or data type representation.

XML signature in the Web Services Security-Core specification

The Web Services Security-Core (WSS-Core) specification defines a standard way for SOAP messages to incorporate an XML signature. You can use almost all of the XML signature features in WSS-Core except enveloped signature and enveloping signature. However, WSS-Core has some recommendations such as exclusive canonicalization for the c14n algorithm and some additional features such as `SecurityTokenReference` and `KeyIdentifier`. The `KeyIdentifier` is the value of the `SubjectKeyIdentifier` field within the X.509 certificate. For more information on the `KeyIdentifier`, see "Reference to a Subject Key Identifier" within the OASIS Web Services Security X.509 Certificate Token Profile documentation.

By including XML signature in SOAP messages, the following are realized:

Message integrity

A message receiver can confirm that attackers or accidents have not altered parts of the message after these parts are signed by a key.

Authentication

You can assume that a valid signature is *proof of possession*. A message with a digital certificate issued by a certificate authority and a signature in the message that is validated successfully by a public key in the certificate, is proof that the signer has the corresponding private key. The receiver can authenticate the signer by checking the trustworthiness of the certificate.

XML signature in the current implementation

XML signature is supported in Web services security, however, an application programming interface (API) is not available. The current implementation has many hardcoded behaviors and has some user-operable configuration items. To configure the client for digital signature, see [Configuring the client for response digital signature verification: Verifying the message parts](#). To configure the server for digital signature, see [Configuring the server for request digital signature verification: Verifying the message parts](#).

Security considerations

In a replay attack, an attacker taps the lines, receives a signed message, and then returns the message to the receiver. In this case, the receiver receives the same message twice and might process both of them if the signatures are valid. Processing both messages can cause damage to the receiver if the message is a claim for money. If you have the signed generation time stamp and the signed expiration time in a message replay, attacks might be reduced. However, this is not a complete solution. A message must have a nonce value to prevent these attacks and the receiver must reject a message that contains a processed nonce. The current implementation does not provide a standard way to generate and check nonces in messages. In WebSphere Application Server, Version 5.1, nonce is supported in username tokens only. The username token profile contains concrete nonce usage scenarios for username tokens. Applications handle nonces (such as serial numbers) and they need to be signed.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Signing parameter configuration settings

Use this page to configure new signing parameters.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

The specifications that are listed on this page for the signature method, digest method, and canonicalization method are located in the World Wide Web Consortium (W3C) document entitled, *XML Signature Syntax and Specification: W3C Recommendation 12 Feb 2002*.

To view this administrative console page, complete the following steps:

1. Click **Enterprise Applications** > *application_name*.
2. Click **Manage modules** > *URI_file_name*
3. **Version 5.x application** Under Additional properties, you can access the signing information for the following bindings:
 - a. For the Request sender binding, click **Web services: Client security bindings**. Under Request sender binding, click **Edit**. Under Additional properties, click **Signing information**.
 - b. For the Response sender binding, click **Web services: Server security bindings**. Under Response sender binding, click **Edit**. Under Additional properties, click **Signing information**.
4. In the Request Sender Binding column, click **Edit** > **Signing Information**.

If the signing information is not available, select **None**.

If the signing information is available, select **Dedicated Signing Information** and specify the configuration in the following fields:

Signature method:

Specifies the algorithm Uniform Resource Identifiers (URI) of the signature method.

The following algorithms are supported:

- <http://www.w3.org/2000/09/xmlsig#rsa-sha1>
- <http://www.w3.org/2000/09/xmlsig#dsa-sha1>
- <http://www.w3.org/2000/09/xmlsig#hmac-sha1>

You can also add custom algorithms.

Digest method:

Specifies the algorithm URI of the digest method.

WebSphere Application Server supports the <http://www.w3.org/2000/09/xmlsig#sha1> algorithm.

Canonicalization method:

Specifies the algorithm URI of the canonicalization method.

The following algorithms are supported:

- <http://www.w3.org/2001/10/xml-exc-c14n#>
- <http://www.w3.org/2001/10/xml-exc-c14n#WithComments>
- <http://www.w3.org/TR/2001/REC-xml-c14n-20010315>
- <http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments>

Key name:

Specifies the name of the key object found in the keystore file.

Key locator reference:

Specifies the name used to reference the key locator

You can configure these key locator reference options on the cell level, the server level, and the application level. The configurations that are listed in the field are a combination of the configurations on these three levels.

You can specify a key locator configuration for the following bindings on the following levels:

Binding name	Cell level, server level, or application level	Path
N/A	Cell level	<ol style="list-style-type: none"> 1. Click Security > Web services. 2. Under Additional properties, click Key locators.
N/A	Server level	<ol style="list-style-type: none"> 1. Click Servers > Application servers > server_name. 2. Under Security, click Web services: Default bindings for Web services security. 3. Under Additional properties, click Key locators.
Request sender	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Click Manage modules > URI_name. 3. Click Web services: Client security bindings. 4. Under Request sender binding, click Edit. 5. Under Additional properties, click Key locators.
Request receiver	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Click Manage modules > URI_name. 3. Click Web services: Server security bindings. 4. Under Request receiver binding, click Edit. 5. Under Additional properties, click Key locators.
Response sender	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > application_name. 2. Click Manage modules > URI_name. 3. Click Web services: Server security bindings. 4. Under Response sender binding, click Edit. 5. Under Additional properties, click Key locators.

Binding name	Cell level, server level, or application level	Path
Response receiver	Application level	<ol style="list-style-type: none"> 1. Click Applications > Enterprise applications > <i>application_name</i>. 2. Click Manage modules > <i>URL_name</i>. 3. Click Web services: Client security bindings. 4. Under Response receiver binding, click Edit. 5. Under Additional properties, click Key locators.

Securing Web services for Version 5.x applications using XML digital signature

XML digital signature is one of the methods WebSphere Application Server provides to secure your Web services. It provides message integrity and authentication capabilities when used with SOAP messages

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

WebSphere Application Server provides several different methods to secure your Web services; XML digital signature is one of these methods. You might secure your Web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

XML digital signature provides both message integrity and authentication capabilities when it is used with SOAP messages. A message receiver can verify that attackers or accidents have not altered parts of the message after the message was signed by a key. If a message has a digital certificate issued by a certificate authority (CA) and a signature in the message is validated successfully by a public key in the certificate, it is proof that the signer has the corresponding private key. To use XML digital signature to secure Web services, complete the following steps:

1. Define the security constraints or extensions. To configure the security constraints, you must use an assembly tool. For more information, see Assembly tools.
 - a. Configure the client to digitally sign a message request. To configure the client, complete the following steps to specify which parts of the SOAP message to digitally sign and define the method used to digitally sign the message. The client in these steps is the request sender.
 - 1) Specify the message parts by following the steps found in Configuring the client for request signing: digitally signing message parts.
 - 2) Select the method used to digitally sign the request message. You can select the digital signature method by following the steps in Configuring the client for request signing: choosing the digital signature method.
 - b. Configure the server to verify the digital signature that is used in the message request. To configure the server, you must specify which parts of the SOAP message, sent by the request

sender, contain digitally signed information and which method was used to digitally sign the message. The settings chosen for the request receiver, or the server in this step, must match the settings chosen for the request sender in the previous step.

- 1) Define the message parts by following the steps found in Configuring the server for request digital signature verification: verifying message parts.
 - 2) Select the same method used by the request sender to digitally sign the message. You can select the digital signature method by following the steps in Configuring the server for request digital signature verification: choosing the verification method
- c. Configure the server to digitally sign a message response. To configure the server, complete the following steps to specify which parts of the SOAP message to digitally sign and define the method used to digitally sign the message. The sender in these steps is the response sender.
- 1) Specify which message parts to digitally sign by following the steps found in Configuring the server for response signing: digitally signing message parts.
 - 2) Select the method used to digitally sign the response message. You can select the digital signature method by following the steps in Configuring the server for response signing: choosing the digital signature method
- d. Configure the client to verify the digital signature that is used in the message response. To configure the client, you must specify which parts of the SOAP message sent by the response sender contain digitally signed information and which method was used to digitally sign the message. The settings chosen for the response receiver, or client in this step, must match the settings chosen for the response sender in the previous step.
- 1) Define the message parts by following the steps found in Configuring the client for response digital signature verification: verifying message parts
 - 2) Select the same method used by the response sender to digitally sign the message. You can select the digital signature method by following the steps in Configuring the client for response digital signature verification: choosing the verification method
2. Define the client security bindings. To configure the client security bindings, complete the steps in either of the following topics:
- Configuring the client security bindings using the Application Server Toolkit
 - Configuring the client security bindings using the administrative console
3. Define the server security bindings. To configure the server security bindings, complete the steps in either of the following topics:
- Configuring the server security bindings using the Application Server Toolkit
 - Configuring the server security bindings using the administrative console

After completing these steps, you have secured your Web services using XML digital signature.

Default binding

The default binding information is defined in the `ws-security.xml` file and can be administered by either the administrative console or by scripting.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Certain applications can share certain binding information. This information includes truststores, keystores, and authentication methods (token validation). WebSphere Application Server provides support for default binding information. Administrators can define binding information at:

- The cell level

Applications can refer to this binding information.

You can define the following binding information in the `ws-security.xml` file:

Trust anchors (truststore)

- *Trust anchors* contain key store configuration information that has the root-trusted certificates. Trust anchors are used for certificate path validation of the incoming X.509-formatted security tokens.
- The Trust Anchor Name is used in the binding file (`ibm-webservices-bnd.xmi` and `ibm-webservicesclient-bnd-xmi` when Web services is running as a client) to refer to the trust anchor defined in the default binding information. The trust anchor name must be unique in the trust anchor collection.

Collection certificate store

- The *collection certificate store* specifies a list of untrusted, intermediate certificates and is used for certificate path validation of incoming X.509-formatted security tokens. The default provider is `IBMCertPath`.
- The Certificate Store Name is used in the binding file (`ibm-webservices-bnd.xmi` and `ibm-webservicesclient-bnd-xmi` when Web services is running as a client) to refer to the certificate store defined in the default binding information. The Certificate Store Name must be unique to the collection certificate store collection.

Key locators

- *Key locators* specify implementation of the `com.ibm.wsspi.wssecurity.config.KeyLocator` interface. This interface is used to retrieve keys for signature or encryption. Customer implementations can extend the key locator interface to retrieve keys using other methods. WebSphere Application Server provides implementations to retrieve a key from the key store, map an authenticated identity to a key in the key store, or retrieve a key from the signer certificate (mapping and retrieving actions are used for encrypting the response).
- The Key Locator Name is used in the binding file (`ibm-webservices-bnd.xmi` and `ibm-webservicesclient-bnd-xmi` when Web services is running as a client) to refer to the key locator defined in the default binding information. The Key Locator Name must be unique to the key locators collection in the default binding information.

Trusted ID evaluators

- *Trusted ID evaluators* are an implementation of the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface. This interface is used to make sure the identity (ID)-asserting authority is trusted. Additionally, you can extend the trusted identity evaluator to validate the trust. WebSphere Application Server provides a default implementation for validating trust based on a predefined list of identities.
- The Trusted ID Evaluator Name is used in the binding file (`ibm-webservices-bnd.xmi`) to refer to the trusted identity evaluator defined in the default binding information. The Trusted ID Evaluator Name must be unique to the Trusted ID Evaluator collection.

Login mappings

- *Login mappings* define the mapping of the authentication method to the Java Authentication and Authorization Service (JAAS) login configuration. The mappings are used to authenticate the incoming security token embedded in the Web services security SOAP message header. The JAAS login configuration is defined in the administrative console under **Security > Secure administration, applications, and infrastructure > Java Authentication and Authorization Service > Application logins**.
- WebSphere Application Server defines the following authentication methods:

BasicAuth

Authenticates user name and password.

Signature

Maps the subject distinguished name (DN) in the certificate to a WebSphere Application Server credential.

IDAssertion

Maps the identity to a WebSphere Application Server credential.

LTPA Authenticates a Lightweight Third Party Authentication (LTPA) token.

After identity authentication, the associated credential is used in the downstream call.

- This method can be extended to authenticate custom security tokens by providing a custom JAAS login configuration and by using the `com.ibm.wsspi.wssecurity.auth.module.WSSecurityMappingModule` to create the principal and credential required by WebSphere Application Server.
- If `LoginConfig (AuthMethod)` is defined in the IBM extension deployment descriptor (`ibm-webservices-ext.xmi`), but there are no login mapping bindings (`ibm-webservices-bnd.xmi`) defined for the `AuthMethod`, Web services security run time uses the login mapping defined in the default binding information.

Default configuration for WebSphere Application Server Network Deployment

WebSphere Application Server Network Deployment installation uses the `ws-security.xml` file to define the default binding information for Web services security for an entire cell.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

In the WebSphere Application Server Network Deployment installation, the `ws-security.xml` file is at the cell level and defines the default binding information for Web services security for the entire cell. But each application server can have its own `ws-security.xml` file to override the cell default; similarly, each Web service can override the default in its binding files. The following list contains the defaults defined in `ws-security.xml` file:

Trust anchors

Identifies the trusted root certificates for signature verification.

Collection certificate stores

Contains certificate revocation lists (CRLs) and nontrusted certificates for verification.

Key locators

Locates the keys for digital signature and encryption.

Trusted ID evaluators

Evaluates the trust of the received identity before identity assertion.

Login mappings

Contains the Java Authentication and Authorization Service (JAAS) configurations for `AuthMethod` token validation.

The Web services security run time reads the configuration from the application bindings first, then tries the server-level, and finally tries the cell level. The following figure depicts the run-time configuration process.

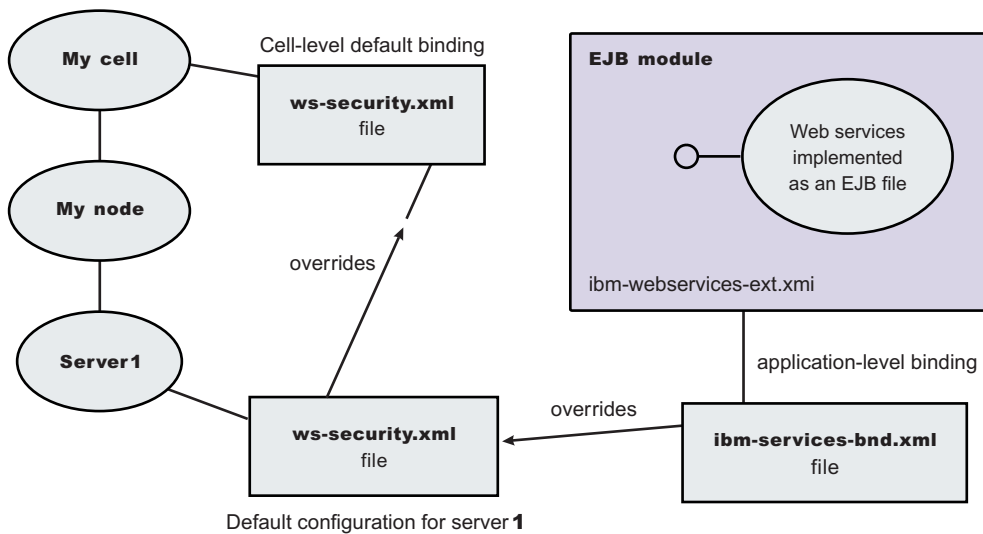

Figure 18. Run-time configuration

Trust anchors

A trust anchor specifies keystores that contain trusted root certificates that validate the signer certificate. The request receiver and the response receiver use these keystores to validate the signer certificate of the digital signature.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

The request receiver (as defined in the `ibm-webservices-bnd.xmi` file) and the response receiver (as defined in the `ibm-webservicesclient-bnd.xmi` file when Web services is acting as client) use these keystores to validate the signer certificate of the digital signature. The keystores are critical to the integrity of the digital signature validation. If they are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these keystores. The binding configuration specified for the request receiver in the `ibm-webservices-bnd.xmi` file must match the binding configuration for the response receiver in the `ibm-webservicesclient-bnd.xmi` file.

The trust anchor is defined as `javax.security.cert.TrustAnchor` in the Java CertPath application programming interface (API). The Java CertPath API uses the trust anchor and the certificate store to validate the incoming X.509 certificate that is embedded in the SOAP message.

The Web services security implementation in WebSphere Application Server supports this trust anchor. In WebSphere Application Server, the trust anchor is represented as a Java keystore object. The type, path, and password of the keystore are passed to the implementation through the administrative console or by scripting.

Configuring trust anchors using an assembly tool

Use an assembly tool to configure trust anchors (that specify key stores which contain trusted root certificates to validate the signer certificate) or trust stores at the application level.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

This document describes how to configure trust anchors or trust stores at the application level. It does not describe how to configure trust anchors at the server or cell level. Trust anchors defined at the application level have a higher precedence over trust anchors defined at the server or cell level. You can configure an application-level trust anchor using an assembly tool or the administrative console. This document describes how to configure the application-level trust anchor using an assembly tool. For more information on creating and configuring trust anchors at the server or cell level, see either “Configuring the server security bindings using an assembly tool” on page 1339 or “Configuring the server security bindings using the administrative console” on page 1342.

A trust anchor specifies key stores that contain trusted root certificates, which validate the signer certificate. These key stores are used by the request receiver (as defined in the `ibm-webservices-bnd.xml` file) and the response receiver (as defined in the `application-client.xml` file when Web services is acting as client) to validate the signer certificate of the digital signature. The key stores are critical to the integrity of the digital signature validation. If they are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these key stores. The binding configuration specified for the request receiver in the `ibm-webservices-bnd.xml` file must match the binding configuration for the response receiver in the `application-client.xml` file.

Complete the following steps to configure trust anchors using an assembly tool.

1. Configure an assembly tool to work with a Java 2 Platform, Enterprise Edition (J2EE) enterprise application. For more information, see *Assembling applications*
 2. Create a Web services-enabled J2EE enterprise application. If you have not created a Web services-enabled J2EE enterprise application, see *Developing Web services applications*. Also, see either “Configuring the server security bindings using an assembly tool” on page 1339 or “Configuring the server security bindings using the administrative console” on page 1342 for an introduction on how to manage Web services security binding information on the server.
 3. Configure the client-side response receiver, which is defined in the `ibm-webservicesclient-bnd.xml` bindings extensions file.
 - a. Use an assembly tool to import your J2EE application.
 - b. Click **Windows > Open Perspective > Other > J2EE**.
 - c. Click **Application Client projects > application_name > appClientModule > META-INF**
 - d. Right-click the `application-client.xml` file, select **Open with > Deployment Descriptor Editor**, and click the WS Binding tab. The Client Deployment Descriptor is displayed.
 - e. Locate the Port qualified name binding section and either select an existing entry or click **Add**, to add a new port binding. The Web services client port binding editor displays for the selected port.
 - f. Locate the Trust anchor section and click **Add**. The Trust anchor dialog box is displayed.
 - 1) Enter a unique name within the port binding for the **Trust anchor name**.
The name is used to reference the trust anchor that is defined.
 - 2) Enter the key store password, path, and key store type.
The supported key store types are the Java Cryptography Extension (JCE) and Java Cryptography Extension Key Stores (JCEKS) types.
- Click **Edit** to edit the selected trust anchor.
- Click **Remove** to remove the selected trust anchor.
- When you start the application, the configuration is validated in the run time while the binding information is loading.
- g. Save the changes.

4. Configure the server-side request receiver, which is defined in the `ibm-webservices-bnd.xmi` bindings extensions file.
 - a. Click **Windows > Open perspective > J2EE**.
 - b. Select the Web services enabled Enterprise JavaBeans (EJB) or Web module.
 - c. In the Package Explorer window, click the META-INF directory for an EJB module or the WEB-INF directory for a Web module.
 - d. Right-click the `webservices.xml` file, select **Open with > Web services editor**, and click the bindings tab. The Web services bindings editor is displayed.
 - e. Locate the Web service description bindings section and either select an existing entry or click **Add** to add a new Web services descriptor.
 - f. Click **Binding configurations**. The Web services binding configurations editor is displayed for the selected Web services descriptor.
 - g. Locate the Trust anchor section and click **Add**. The Trust anchor dialog box is displayed.
 - 1) Enter a unique name within the binding for the **Trust anchor name**.
This unique name is used to reference the trust anchor defined.
 - 2) Enter the key store password, path, and key store type. The supported key store types are JCE and JCEKS.Click **Edit** to edit the selected trust anchor.
Click **Remove** to remove the selected trust anchor.
When you start the application, the configuration is validated in the run time while the binding information is loading.
 - h. Save the changes.

This procedure defines trust anchors that can be used by the request receiver or the response receiver (if the Web services is acting as client) to verify the signer certificate.

The request receiver or the response receiver (if the Web service is acting as a client) uses the defined trust anchor to verify the signer certificate. The trust anchor is referenced using the trust anchor name.

To complete the signing information configuration process for request receiver, complete the following tasks:

1. "Configuring the server for request digital signature verification: Verifying the message parts" on page 1324
2. "Configuring the server for request digital signature verification: choosing the verification method" on page 1326

To complete the process for the response receiver, if the Web services is acting as a client, complete the following tasks:

1. "Configuring the client for response digital signature verification: verifying the message parts" on page 1331
2. "Configuring the client for response digital signature verification: choosing the verification method" on page 1333

Configuring trust anchors using the administrative console

Use the WebSphere Application Server administrative console to configure trust anchors that specify key stores which contain trusted root certificates to validate the signer certificate.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

This document describes how to configure trust anchors or trust stores at the application level. It does not describe how to configure trust anchors at the server or cell level. Trust anchors defined at the application level have a higher precedence over trust anchors defined at the server or cell level. For more information on creating and configuring trust anchors at the server or cell level, see either “Configuring the server security bindings using an assembly tool” on page 1339 or “Configuring the server security bindings using the administrative console” on page 1342.

You can configure an application-level trust anchor using an assembly tool or the administrative console. This document describes how to configure the application-level trust anchor using the administrative console.

A trust anchor specifies key stores that contain trusted root certificates, which validate the signer certificate. These key stores are used by the request receiver (as defined in the `ibm-webservices-bnd.xmi` file) and the response receiver (as defined in the `ibm-webservicesclient-bnd.xmi` file when Web services is acting as client) to validate the signer certificate of the digital signature. The keystores are critical to the integrity of the digital signature validation. If they are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these keystores. The binding configuration specified for the request receiver in the `ibm-webservices-bnd.xmi` file must match the binding configuration for the response receiver in the `ibm-webservicesclient-bnd.xmi` file.

The following steps are for the client-side response receiver, which is defined in the `ibm-webservicesclient-bnd.xmi` file and the server-side request receiver, which is defined in the `ibm-webservices-bnd.xmi` file.

1. Configure an assembly tool to work with a Java 2 Platform, Enterprise Edition (J2EE) enterprise application. For more information, see *Assembling applications*
2. Create a Web services-enabled J2EE enterprise application. If you have not created a Web services-enabled J2EE enterprise application, see *Developing Web services applications*. Also, see either “Configuring the server security bindings using an assembly tool” on page 1339 or “Configuring the server security bindings using the administrative console” on page 1342 for an introduction on how to manage Web services security binding information on the server.
3. Click **Applications > Enterprise applications > *enterprise_application***.
4. Under Manage modules, click *URI_name*.
5. Under Web Services Security Properties, click **Web services: client security bindings** to edit the response receiver binding information, if Web services is acting as a client.
 - a. Under Response receiver binding, click **Edit**.
 - b. Under Additional properties, click **Trust anchors**.
 - c. Click **New** to create a new trust anchor.
 - d. Enter a unique name within the request receiver binding for the Trust anchor name field. The name is used to reference the trust anchor that is defined.
 - e. Enter the key store password, path, and key store type.
 - f. Click the trust anchor name link to edit the selected trust anchor.
 - g. Click **Remove** to remove the selected trust anchor or anchors.

When you start the application, the configuration is validated in the run time while the binding information is loading.
6. Return to the Web services-enabled module panel accessed in step 2.
7. Under Web Services Security Properties, click **Web services: server security bindings** to edit the request receiver binding information.
 - a. Under Request receiver binding, click **Edit**.
 - b. Under Additional properties, click **Trust anchors**.
 - c. Click **New** to create a new trust anchor

Enter a unique name within the request receiver binding for the Trust anchor name field. The name is used to reference the trust anchor that is defined.

Enter the key store password, path, and key store type.

Click the trust anchor name link to edit the selected trust anchor.

Click **Remove** to remove the selected trust anchor or anchors.

When you start the application, the configuration is validated in the run time while the binding information is loading.

8. Save the changes.

This procedure defines trust anchors that can be used by the request receiver or the response receiver (if the Web services is acting as client) to verify the signer certificate.

The request receiver or the response receiver (if the Web service is acting as a client) uses the defined trust anchor to verify the signer certificate. The trust anchor is referenced using the trust anchor name.

To complete the signing information configuration process for request receiver, complete the following tasks:

1. “Configuring the server for request digital signature verification: Verifying the message parts” on page 1324
2. “Configuring the server for request digital signature verification: choosing the verification method” on page 1326

To complete the process for the response receiver, if the Web services is acting as client, complete the following tasks:

1. “Configuring the client for response digital signature verification: verifying the message parts” on page 1331
2. “Configuring the client for response digital signature verification: choosing the verification method” on page 1333

Collection certificate store

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check the signature of a digitally signed SOAP message.

Important: There is an important distinction between Version 5.x and Version 6.0.x applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x applications.

The collection certificate stores are used when processing a received SOAP message. This collection is configured in the `securityRequestReceiverBindingConfig` section of the binding file for servers and in the `securityResponseReceiverBindingConfig` section of the binding file for clients.

A collection certificate store is one kind of certificate store. A certificate store is defined as `javax.security.cert.CertStore` in the Java `CertPath` application programming interface (API). The Java `CertPath` API defines the following types of certificate stores:

Collection certificate store

A collection certificate store accepts the certificates and CRLs as Java collection objects.

Lightweight Directory Access Protocol certificate store

The Lightweight Directory Access Protocol (LDAP) certificate store accepts certificates and CRLs as LDAP entries.

The CertPath API uses the certificate store and the trust anchor to validate the incoming X.509 certificate that is embedded in the SOAP message.

The Web services security implementation in the WebSphere Application Server supports the collection certificate store. Each certificate and CRL is passed as an encoded file. This configuration is done using either the administrative console or by scripting.

Configuring the client-side collection certificate store using an assembly tool

You can configure the client-side collection certificate store using the assembly tool.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

A collection certificate store is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message.

You can configure the collection certificate either by using an assembly tool or the WebSphere Application Server administrative console. Complete the following steps to configure the client-side collection certificate store using the assembly tool.

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client projects > application_name > appClientModule > META-INF**
4. Right-click the `application-client.xml` file, select **Open with > Deployment Descriptor Editor**, and click the WS Binding tab. The Client Deployment Descriptor is displayed.
5. Click the Port binding tab in deployment descriptor editor within the assembly tool. The Web services client port binding window is displayed.
6. Select one of the Port qualified name binding entries.
7. Expand the **Security response receiver binding configuration > certificate store list > Collection certificate store** section.
8. Click **Add** to create a new collection certificate store, click **Edit** to edit an existing certificate store, or click **Remove** to delete an existing certificate store.
9. Enter a name in the Name field. This name is referenced in the Certificate store reference field in the Signing info dialog box.
10. Leave the Provider field as `IBMCertPath`.
11. Click **Add** to enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have additional certificate store paths, click **Add** to add the paths.
12. Click **OK** when you finish adding paths.

Configuring the client-side collection certificate store using the administrative console

You can configure the client-side collection certificate store by using the administrative console.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message.

You can configure the collection certificate either by using the assembly tools or the WebSphere Application Server administrative console. Complete the following steps to configure the client-side collection certificate store using the administrative console.

1. Connect to the WebSphere Application Server administrative console.
You can connect to the administrative console by typing `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.
2. Click **Applications > Enterprise applications > application_name**.
3. Under Manage modules, click *URI_name*.
4. Under Additional properties, click either **Web services: client security bindings** to add the collection certificate store to the client security bindings. If you do not see any entries, return to the assembly tool and configure the security extensions for either the client or the server.
To configure the security extensions for the client, see the following topics:
 - “Configuring the client for response digital signature verification: verifying the message parts” on page 1331
 - “Configuring the client for response digital signature verification: choosing the verification method” on page 1333
5. Under Response receiver binding, click **Edit** to edit the client security bindings.
6. Click **Collection certificate store**.
7. Click a Certificate store name to edit an existing certificate store or click **New** to add a new certificate store name.
8. Enter a name in the Certificate store name field. The name entered in this field is a name that is referenced in the Certificate store field on the Signing information configuration page.
9. Leave the Certificate store provider field value as `IBMCertPath`.
10. Click **Apply**.
11. Under Additional properties, click **X.509 certificates > New**.
12. Enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have any additional certificate store paths to enter, click **New** and add the path names.
13. Click **OK**.

Configuring the server-side collection certificate store using an assembly tool

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collections of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message. You can configure the server-side collection certificate store by using an assembly tool.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

You can configure the collection certificate either by using an assembly tool or by using the WebSphere Application Server administrative console. Complete the following steps to configure the server-side collection certificate store using an assembly tool.

1. Start an assembly tool.
For more information on the assembly tools, see “Starting WebSphere Application Server Toolkit” in the Application Server Toolkit documentation.

2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB projects > *application_name* > ejbModule > META-INF**
4. Right-click the `webservices.xml` file, select **Open with > Web Services Editor**.
5. Click the Binding configurations tab in the Web services editor within the assembly tool. The Web Service Binding Configuration window is displayed.
6. Select one of the Web service description binding entries under the Port Component Binding section.
7. Expand the **Request receiver binding configuration details > Certificate store list > Collection certificate store** section.
8. Click **Add** to create a new collection certificate store, click **Edit** to edit an existing certificate store, or click **Remove** to delete an existing certification store.
9. Enter a name in the **Name** field. This name is referenced in the **Certificate store reference** field in the Signing info dialog.
10. Leave the **Provider** field as `IBMCertPath`.
11. Click **Add** to enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have additional certificate store paths, click **Add** to add the paths.
12. Click **OK** when you finish adding paths.

Configuring the server-side collection certificate store using the administrative console

You can configure the collection certificate either by using an assembly tool or the WebSphere Application Server administrative console.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check the signature of a digitally signed SOAP message.

Complete the following steps to configure the server-side collection certificate store using the administrative console.

1. Connect to the WebSphere Application Server administrative console.
You can connect to the administrative console by typing `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.
2. Click **Applications > Enterprise applications > *application_name***.
3. Under Manage modules, click *URI_name*
4. Under Web Services Security Properties, click **Web services: server security bindings** to add the collection certificate store to the server security bindings. If you do not see any entries, return to the assembly tool and configure the security extensions for the server.
To configure the security extensions for the server, see the following topics:
 - “Configuring the server for request digital signature verification: Verifying the message parts” on page 1324
 - “Configuring the server for request digital signature verification: choosing the verification method” on page 1326
5. Click **Edit** under Request Receiver Binding to edit the server security bindings.
6. Click **Collection certificate store**.

7. Click a Certificate store name to edit an existing certificate store or click **New** to add a new certificate store name.
8. Enter a name in the Certificate store name field. The name entered in this field is a name that is referenced in the Certificate store field on the Signing information configuration page.
9. Leave the Certificate store provider field as IBM CertPath.
10. Click **Apply**.
11. Under Additional Properties, click **X.509 Certificates > New**.
12. Enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have any additional certificate store paths to enter, click **New** and add the path names.
13. Click **OK**.

Configuring default collection certificate stores at the server level in the WebSphere Application Server administrative console

You can define a single collection certificate store for all of the applications that need to use the same certificates. Use the WebSphere Application Server administrative console to configure the default collection certificate store at the server level.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message. A certificate store typically refers to a certificate store located in the file system. The location of the certificate store can vary from machine to machine, so you might configure a default collection certificate store for a specific machine and reference it from within the signing information. The signing information is found within the binding configurations of any application installed on the machine. This suggestion enables you to define a single collection certificate store for all of the applications that need to use the same certificates. You also can specify the default binding information at the cell level.

Complete the following steps to configure the default collection certificate store at the server level using the WebSphere Application Server administrative console:

1. Connect to the administrative console.
You can access the administrative console by typing `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.
2. Click **Servers > Application servers > server_name**.
3. Under Security, click **Web Services: Default bindings for Web Services Security**.
4. Under Additional properties, click **Collection certificate store**.
5. Enter a name in the **Certificate store name** field. This name is referenced in the **Certificate store** field on the Signing information configuration page.
6. Leave the **Certificate store provider** field value as IBM CertPath.
7. Click **Apply**.
8. Under Additional properties, click **X.509 certificates > New**.
9. Enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`.
If you have any additional certificate store paths to enter, click **New** and add the path names.
10. Click **OK**.

Configuring default collection certificate stores at the cell level in the WebSphere Application Server administrative console

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check the signature of a digitally signed Simple Object Access Protocol (SOAP) message. A certificate store typically refers to a certificate store located in the file system. The location of the certificate store can vary from machine to machine, so you might configure a default collection certificate store for a specific machine and reference it from within the signing information. The signing information is found within the binding configurations of any application installed on the machine. This suggestion enables you to define a single collection certificate store for all of the applications that need to use the same certificates. You also can specify the default binding information at the server level.

Complete the following steps to configure the default collection certificate store at the cell level using the WebSphere Application Server administrative console:

1. Connect to the administrative console.
You can access the administrative console by typing `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.
2. Click **Security > Web services**.
3. Under Additional properties, click **Collection certificate store**.
4. Click the name of a certificate store name to edit an existing store, or click **New** to add a new store. This name is referenced in the Certificate store field on the Signing information configuration page.
5. Leave the Certificate store provider field value as `IBMCertPath`.
6. Click **Apply**.
7. Under Additional properties, click **X.509 certificates > New**.
8. Enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`
If you have any additional certificate store paths to enter, click **New** and add the path names.
9. Click **OK**.

Key locator

A *key locator* (`com.ibm.wsspi.wssecurity.config.KeyLocator`) is an abstraction of the mechanism that retrieves the key for digital signature and encryption.

You can use any of the following infrastructure from which to retrieve the keys depending upon the implementation:

- Java keystore file
- Database
- Lightweight Third Party Authentication (LTPA) server

Key locators search the key using some type of a clue. The following types of clues are supported:

- A string label of the key, which is explicitly passed through the application programming interface (API). The relationships between each key and its name (string label) is maintained inside the key locator.
- The execution context of the key locator; explicit information is not passed to the key locator. A key locator determines the appropriate key according to the execution context.

Current versions of key locators do not support the retrieval of verification keys because current Web services security implementations do not support the secret key-based signature. Because the key locators support the public key-based signature only, the key for verification is embedded in the X.509 certificate as a <BinarySecurityToken> element in the incoming message.

For example, key locators can obtain the identity of the caller from the context and can retrieve the public key of the caller for response encryption.

Usage scenarios

This section describes the usage scenarios for key locators.

Signing

The name of the signing key is specified in the Web services security configuration. This value is passed to the key locator and the actual key is returned. The corresponding X.509 certificate also can be returned.

Verification

As described previously, key locators are not used in signature verification.

Encryption

The name of the encryption key is specified in the Web services security configuration. This value is passed to the key locator and the actual key is returned.

Decryption

The Web services security specification recommends using the key identifier instead of the key name. However, while the algorithm for computing the identifier for the public keys is defined in Internet Engineering Task Force (IETF) Request for Comment (RFC) 3280, there is no agreed upon algorithm for the secret keys. Therefore, the current implementation of Web services security uses the identifier only when public key-based encryption is performed. Otherwise, the ordinal key name is used.

When you use public key-based encryption, the value of the key identifier is embedded in the incoming encrypted message. Then, the Web services security implementation searches for all the keys managed by the key locator and decrypts the message using the key whose identifier value matches the one in the message.

When you use secret key-based encryption, the value of the key name is embedded in the incoming encrypted message. The Web services security implementation asks the key locator for the key with the name that matches the name in the message and decrypts the message using the key.

Important: There is an important distinction between Version 5.x and Version 6.0.x applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x applications.

Keys

Keys are used for XML signature and encryption.

There are two predominant kinds of keys used in the current Web services security implementation:

- Public key - such as Rivest Shamir Adleman (RSA) encryption and Digital Signature Algorithm (DSA) encryption
- Secret key - such as Data Encryption Standard (DES) encryption

In public key-based signature, a message is signed using the sender private key and is verified using the sender public key. In public key-based encryption, a message is encrypted using the receiver public key and is decrypted using the receiver private key. In secret key-based signature and encryption, the same key is used by both parties.

While the current implementation of Web services security can support both kinds of keys, there are a few items to note:

- Secret key-based signature is not supported.
- The format of the message differs slightly between public key-based encryption and secret key-based encryption.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Web services security service provider programming interfaces

Several Service Provider Interfaces (SPIs) are provided to extend the capability of the Web services security runtime.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

The following list contains the SPIs that are available for WebSphere Application Server:

- `com.ibm.wsspi.wssecurity.config.KeyLocator` is an abstract for obtaining the keys for digital signature and encryption. The following list contains the default implementations:
 - `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator`
Implements the Java key store.
 - `com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator`
Provides a mapping of the authenticated identity to a key for encryption. Or, the implementation uses the default key that is specified. This implementation is typically used in the response sender configuration.
 - `com.ibm.wsspi.wssecurity.config.CertInRequestKeyLocator`
Provides the capability of using the signer key for encryption in the response message. This implementation is typically used in the response sender configuration.
- `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` is an interface that is used to evaluate the trust for identity assertion. The default implementation is `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`, which enables you to define a list of trusted identities.
- The Java Authentication and Authorization Service (JAAS) `CallbackHandler` application programming interfaces (APIs) are used for token generation by the request sender. This interface can be extended to generate a custom token that can be inserted in the Web services security header. The following list contains the default implementations that are provided by WebSphere Application Server:
 - `com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler`
Presents a login prompt to gather the basic authentication data. Use this implementation in the client environment only.
 - `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`
Collects the basic authentication data in the standard in (stdin) prompt. Use this implementation in the client environment only.
 - `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`

Reads the basic authentication data from the application binding file. This implementation might be used on the server side to generate a user name token.

- `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`

Generates a Lightweight Third Party Authentication (LTPA) token in the Web services security header as a binary security token. If basic authentication data is defined in the application binding file, it is used to perform a login, to extract the LTPA token from the WebSphere credentials, and to insert the token in the Web services security header. Otherwise, it will extract the LTPA security token from the invocation credentials (RunAs identity) and insert the token in the Web services security header.

The JAAS LoginModule API is used for token validation on the request receiver side of the message. You can implement a custom LoginModule API to perform validation of the custom token on the request receiver of the message. After the token is verified and validated, the token is set as the caller and then run as the identity in the WebSphere Application Server runtime. The identity is used for authorization checks by the containers before a Java 2 Platform, Enterprise Edition (J2EE) resource is invoked. The following list presents the default AuthMethod configurations provided by WebSphere Application Server:

BasicAuth

Validates a user name token.

Signature

Maps the distinguished name (DN) of a verified certificate to a Java Authentication and Authorization Service (JAAS) subject.

IDAssertion

Maps a trusted identity to a JAAS subject.

LTPA Validates an LTPA token that is received in the message and creates a JAAS subject.

Configuring key locators using an assembly tool

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

This task provides instructions on how to configure key locators using an assembly tool. You can configure key locators in various locations within the assembly tool. This task provides instructions on how to configure key locators at any of these locations because the concept is the same.

1. Start an assembly tool. For more information on the assembly tools, see [Assembly tools](#).
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client projects > application_name > appClientModule > META-INF**
4. Right-click the `application-client.xml` file, select **Open with > Deployment Descriptor Editor**, and click the WS Binding tab. The Client Deployment Descriptor is displayed.
5. Click the WS Binding tab in deployment descriptor editor within the assembly tool or the Binding configurations tab in the Web services editor within the assembly tool.
6. Expand one of the **Binding configuration** sections.
7. Expand the **Key locators** section.
8. Click **Add** to create a new key locator, click **Edit** to edit an existing key locator, or click **Remove** to delete an existing key locator.
9. Enter a key locator name. The name entered for the **Key locator name** is used to refer to the key locator from the Encryption information and Signing Information sections.
10. Enter a key locator class. The key locator class is the implementation of the KeyLocator interface. When using default implementations, select a class from the menu.

11. Determine whether to click **Use key store**. Select this option when you use the default implementations as they use key stores. If you click **Use key store**, complete the following steps:
 - a. Enter a value in the key store storepass field. The key store storepass is the password used to access the key store.
 - b. Enter a path name in the key store path field. The key store path is the location on the file system where the key store resides. Make sure that the location can be found wherever you deploy the application.
 - c. Enter a type value in the key store type field. The valid types to enter are JKS and JCEKS. JKS is used when you are not using the Java Cryptography Extensions (JCE) policy. JCEKS is used when you are using JCE. Although the JCEKS type is more secure, it might decrease performance.
 - d. Click **Add** to create an entry for a key in the key store.
 - 1) Enter a value in the Alias field.
The key alias is a reference to this particular key from the Signing Information section.
 - 2) Enter a value in the Key pass field.
The key pass is the password associated with the certificate which is created using the Development Kit, Java Technology Edition keytool.exe file.
 - 3) Enter a value in the Key name field.
The key name refers to the alias of the certificate as found in the key store.
12. Click **Add** to create a custom property. The property can be used by custom key locator implementations. For example, you can use properties with the WSIIdKeyStoreMapKeyLocator default implementation. The key locator implementation has the following property names:
 - *id_*, which maps to a credential user ID.
 - *mappedName_*, which maps to the key alias to use for this user name.
 - *default*, which maps to a key alias to use when a credential does not have an associated *id_* entry.

A typical set of properties for this key locator might be: `id_1=user1, mappedName_1=key1, id_2=user2, mappedName_2=key2, default=key3`. If user1 or user2 authenticates, then the associated key1 or key2 is used, respectively. However, if none of the user properties authenticate or the user is not user1 or user2, then key3 is used.

 - a. Enter a name in the Name field. The name entered is the property name.
 - b. Enter a value in the Value field. This value entered is the property value.

Configuring key locators using the administrative console

You can configure binding information and key locators using the WebSphere Application Server administrative console.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

This task provides instructions on how to configure key locators using the WebSphere Application Server administrative console. You can configure binding information in the administrative console. You must use an assembly tool to configure extensions. The following steps are used to configure a key locator in the administrative console for a specific application:

1. Open the administrative console.
Type `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.
2. Click **Applications > Enterprise Applications > application_name**.
3. Under Related Items, click either **Web Modules** or **EJB Modules**, depending on the type of module you are securing.

4. Click the name of the module you are securing.
5. Under Additional Properties, click either **Web services: Client security bindings** or **Web services: Server security bindings**, depending on whether you are adding the key locator to the client security bindings or to the server security bindings. If you do not see any entries, return to the assembly tool and configure the security extensions.
6. Edit the Request Sender Binding, Response Receiver Binding, Request Receiver Binding, or Response Sender Binding.
 - If you are editing your client security bindings, click **Edit** for either the Request Sender Binding or the Response Receiver Binding.
 - If you are editing your server security bindings, click **Edit** for either the Request Receiver Binding or the Response Sender Binding.
7. Click **Key Locators**.
8. Click **New** to configure a new key locator, select the box next to a key locator name and click **Delete** to delete a key locator, or click the name of a key locator to edit its configuration. If you are configuring a new key locator or editing an existing one, complete the following steps:
 - a. Specify a name for the key locator in the **Key Locator Name** field.
 - b. Specify a name for the key locator class implementation in the **Key Locator Classname** field. WebSphere Application Server has the following default key locator class implementations:

com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator

This class is used by the response sender to map an authenticated identity to a key. If encryption is used, this class is used to locate a key to encrypt the response message. The `com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator` class has the capability to map an authenticated identity from the invocation credential of the current thread to a key that is used to encrypt the message. If an authenticated identity is present on the current thread, the class maps the ID to the mapped name. For example, `user1` is mapped to `mappedName_1`. Otherwise, `name="default"`. When a matching key is not found, the authenticated identity is mapped to the default key specified in the binding file.

com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator

This class is used by the response receiver, the request sender, and the request receiver to map a name to an alias. Encryption uses this class to obtain a key to encrypt a message and digital signature uses this class to obtain a key to sign a message. The `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator` class maps a logical name to a key alias in the key store file. For example, `key #105115176771` maps to `CN=Alice, O=IBM, C=US`.

- c. Specify the password used to access the key store password in the **Key Store Password** field. This field is optional because the key locator does not use a key store.
- d. Specify the path name used to access the key store in the **Key Store Path** field. This field is optional because the key locator does not use a key store. Use `${USER_INSTALL_ROOT}` because this path expands to the WebSphere Application Server path on your machine.
- e. Select a keystore type from the **Key Store Type** field. This field is optional because the key locator does not use a key store. Use the **JKS** option if you are not using the Java Cryptography Extensions (JCE) policy and use **JCEKS** if you are using the JCE policy.

Configuring server and cell level key locators using the administrative console

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

A key locator typically locates a key store in the file system. The location of key stores can vary from machine to machine so it is often helpful to configure a default key locator for a specific machine and

reference it from within the encryption or signing information. This information is found within the binding configurations of any application installed on the machine. This suggestion enables you to define a single key locator for all applications that need to use the same keys. In a Network Deployment environment, you also can specify the default binding information at the cell level.

This task provides instructions on how to configure server and cell-level key locators for a specific application using the WebSphere Application Server administrative console. You can configure binding information in the administrative console, but for extensions, you must use the Application Server Toolkit.

- Configure default key locators at the server level

1. Open the administrative console.

Type `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.

2. Click **Servers > Application servers > server_name**.
3. Under Security, click **Web services: Default bindings for Web services security**.
4. Under Additional properties, click **Key locators**

5. Click **New** to configure a new key locator; select the box next to a key locator name and click **Delete** to delete a key locator; or click the name of a key locator to edit its configuration. If you are configuring a new key locator or editing an existing one, complete the following steps:

- a. Specify a name for the key locator in the Key locator name field.
- b. Specify a name for the key locator class implementation in the Key locator class name field.

WebSphere Application Server has the following default key locator class implementations:

com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator

This class, used by the response sender, maps an authenticated identity to a key. If encryption is used, this class is used to locate a key to encrypt the response message. The `com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator` class has the capability to map an authenticated identity from the invocation credential of the current thread to a key that is used to encrypt the message. If an authenticated identity is present on the current thread, the class maps the ID to the mapped name. For example, `user1` is mapped to `mappedName_1`. Otherwise, `name="default"`. When a matching key is not found, the authenticated identity is mapped to the default key specified in the binding file.

com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator

This class, used by the response receiver, request sender, and request receiver, maps a name to an alias. Encryption uses this class to obtain a key to encrypt a message and digital signature uses this class to obtain a key to sign a message. The `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator` class maps a logical name to a key alias in the key store file. For example, key `#105115176771` is mapped to `CN=Alice, O=IBM, c=US`.

- c. Specify the password used to access the keystore password in the Key store password field.

This field is optional is the key locator does not use a keystore.

- d. Specify the path name used to access the keystore in the Key store path field.

This field is optional is the key locator does not use a keystore. Use `${USER_INSTALL_ROOT}` as this path expands to the WebSphere Application Server path on your machine.

- e. Select a keystore type from the Key store type field.

This field is optional is the key locator does not use a keystore. Use the **JKS** option if you are not using the Java Cryptography Extensions (JCE) keystore type and use **JCEKS** if you are using the JCE type.

- Configure default key locators at the cell level.

1. Open the administrative console.

Type `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.

2. Click **Security > Web services**.
3. Under Additional properties, click **Key locators**.
4. Click **New** to configure a new key locator; select the box next to a key locator name and click **Delete** to delete a key locator; or click the name of a key locator to edit its configuration. If you are configuring a new key locator or editing an existing one, complete the following steps:
 - a. Specify a name for the key locator in the Key locator name field.
 - b. Specify a name for the key locator class implementation in the Key locator class name field.

WebSphere Application Server has the following default key locator class implementations:

com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator

This class, used by the response sender, maps an authenticated identity to a key. If encryption is used, this class is used to locate a key to encrypt the response message. The `com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator` class has the capability to map an authenticated identity from the invocation credential of the current thread to a key that is used to encrypt the message. If an authenticated identity is present on the current thread, the class maps the ID to the mapped name. For example, `user1` is mapped to `mappedName_1`. Otherwise, `name="default"`. When a matching key is not found, the authenticated identity is mapped to the default key specified in the binding file.

com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator

This class, used by the response receiver, request sender, and request receiver, maps a name to an alias. Encryption uses this class to obtain a key to encrypt a message and digital signature uses this class to obtain a key to sign a message. The `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator` class maps a logical name to a key alias in the key store file. For example, key `#105115176771` is mapped to `CN=Alice, O=IBM, c=US`.

- c. Specify the password used to access the keystore password in the Key store password field. This field is optional if the key locator does not use a keystore.
- d. Specify the path name used to access the keystore in the Key store path field. This field is optional if the key locator does not use a keystore. Use `${USER_INSTALL_ROOT}` as this path expands to the WebSphere Application Server path on your machine.
- e. Select a keystore type from the Key store type field. This field is optional if the key locator does not use a keystore. Use the **JKS** option if you are not using the Java Cryptography Extensions (JCE) keystore type and use **JCEKS** if you are using the JCE type.

Trusted ID evaluator

The trusted ID evaluator is an abstraction of the mechanism that evaluates whether the given ID name is to be trusted. The trusted ID evaluator is typically used by the eventual receiver in a multi-hop environment.

Important: There is an important distinction between Version 5.x and Version 6.0.x applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x applications.

Depending upon the implementation, you can use various types of infrastructure to store a list of the trusted IDs, such as:

- Plain text file
- Database

- Lightweight Directory Access Protocol (LDAP) server

The Web services security implementation (`com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator`) invokes the trusted ID evaluator and passes the identity name of the intermediary as a parameter. If the identity is evaluated and deemed trustworthy, the procedure continues. Otherwise, an exception is created and the procedure is stopped.

Login mappings

Login mappings, found in the `ibm-webservices-bnd.xmi` Extended Markup Language (XML) file, contains a mapping configuration. This mapping configuration defines how the Web services security handler maps the token `<ValueType>` element that is contained within the security token extracted from the message header, to the corresponding authentication method. The token `<ValueType>` element is contained within the security token extracted from a Simple Object Access Protocol (SOAP) message header.

The sender-side Web services security handler generates and attaches security tokens based on the `<AuthMethods>` element that is specified in the deployment descriptor. For example, if the authentication method is `BasicAuth`, the sender-side security handler generates and attaches `UsernameToken` (with both user name and password) to the SOAP message header. The Web services security run time uses the Java Authentication and Authorization Service (JAAS) `javax.security.auth.callback.CallbackHandler` interface as a security provider to generate security tokens on the client side (or when Web services is acting as client).

The sender security handler invokes the `handle()` method of a `javax.security.auth.callback.CallbackHandler` interface implementation. This implementation creates the security token and passes the token back to the sender security handler. The senders security handler constructs the security token based on the authentication information in the callback array. The security handler then inserts the security token into the Web Services Security message header.

The `CallbackHandler` interface implementation that you use to generate the required security token is defined in the `<loginBinding>` element in the `ibm-webservicesclient-bnd.xmi` Web services security binding file. For example,

```
<loginBinding xmi:id="LoginBinding_1052760331526" authMethod="BasicAuth"
  callbackHandler="com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler"/>
```

The `<loginBinding>` element associates the `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler` interface with the `BasicAuth` authentication method. WebSphere Application Server provides the following set of `CallbackHandler` interface implementations you can use to create various security token types:

`com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler`

If there is no basic authentication data defined in the login binding information (this information is not the same as the HTTP basic authentication information), the previous token type prompts for user name and password through a login panel. The implementation uses the basic authentication data defined in the login binding. Use this `CallbackHandler` with the `BasicAuth` authentication method. Do not use this `CallbackHandler` implementation on the server because it prompts you for login binding information.

`com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`

If basic authentication data is not defined in the login binding (this information is not the same as the HTTP basic authentication information), the implementation prompts for the user name and password using standard in (`stdin`). The implementation uses the basic authentication data defined in the login binding. Use this `CallbackHandler` implementation with the `BasicAuth` authentication method. Do not use this `CallbackHandler` implementation on the server because it prompts you for login binding information.

`com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`

This `CallbackHandler` implementation does not prompt. Rather, it uses the basic authentication data defined in the login binding (this information is not the same as the HTTP basic

authentication information). This CallbackHandler implementation is meant for use with the BasicAuth authentication method. You must define the basic authentication data in the login binding information for this CallbackHandler implementation. You can use this implementation when Web services is running as a client and needs to send basic authentication (<wsse:UsernameToken>) to the downstream call.

com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler

The CallbackHandler generates Lightweight Third Party Authentication (LTPA) tokens from the run as JAAS Subject (invocation Subject) of the current WebSphere Application Server security context. However, if basic authentication data is defined in the login binding information (not the HTTP basic authentication information), the implementation uses the basic authentication data and LTPA token generated. The **Token Type URI** and **Token Type Local Name** values must be defined in the login binding information for this CallbackHandler implementation. The token value type is used to validate the token to the request sender and request receiver binding configuration. The Web services security run time inserts the LTPA token as a binary security token (<wsse:BinarySecurityToken>) into the message SOAP header. The value type is mandatory. (See LTPA for more information). Use this CallbackHandler implementation with the LTPA authentication method.

Figure 1 shows the sender security handler in the request sender message process.

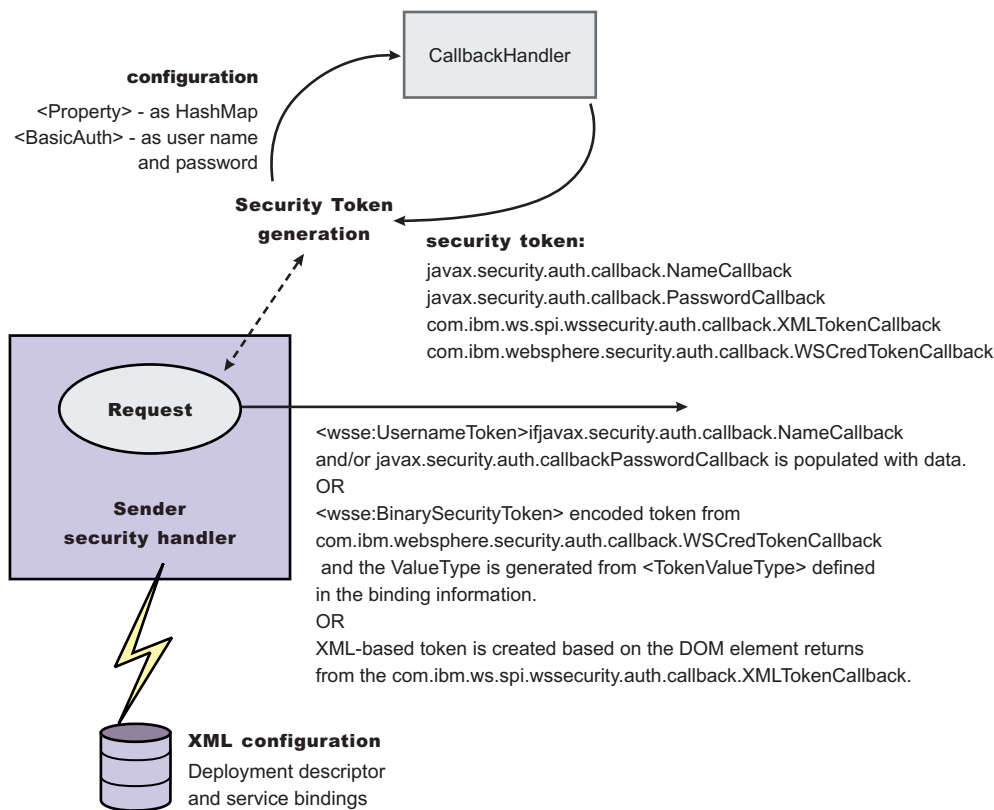

Figure 19. Request sender SOAP message process

You can configure the receiver-side security server to support multiple authentication methods and multiple types of security tokens. The following steps describe the request sender SOAP message process:

1. After receiving a message, the receiver Web services security handler compares the token type (in the message header) with the expected token types configured in the deployment descriptor.

- The Web services security handler extracts the security token from the message header and maps the token <ValueType> element to the corresponding authentication method. The mapping configuration is defined in the <loginMappings> element in the `ibm-webservices-bnd.xml` XML file. For example:

```
<loginMappings xmi:id="LoginMapping_1051977980074" authMethod="LTPA"
  configName="WSLogin">
  <callbackHandlerFactory xmi:id="CallbackHandlerFactory_1051977980081"
    classname="com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl"/>
  <tokenValueType xmi:id="TokenValueType_1051977980081"
    uri="http://www.ibm.com/websphere/appserver/tokentype/5.0.2" localName="LTPA"/>
</loginMappings>
```

The `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` interface is a factory for `javax.security.auth.callback.CallbackHandler`.

- The Web services security run time initiates the factory implementation class and passes the authentication information from Web services security header to the factory class through the `set` methods.
- The Web services security run time invokes the `newCallbackHandler()` method to obtain the `javax.security.auth.CallbackHandler` object, which generates the required security token.
- When the security handler receives an LTPA `BinarySecurityToken`, it uses the `WSLogin` JAAS login configuration and the `newCallbackHandler()` method to validate the security token. If none of the expected token types are found in the SOAP message Web services security header, the request is rejected with an SOAP fault. Otherwise, the token type is used to map to a JAAS login configuration for token validation. If authentication is successful, a JAAS `Subject` is created and associated with the running thread. Otherwise, the request is rejected with a SOAP fault.

The following table shows the authentication methods and the JAAS login configurations.

Authentication method	JAAS login configuration
BasicAuth	WSLogin
Signature	system.wssecurity.Signature
LTPA	WSLogin
IDAssertion	system.wssecurity.IDAssertion

Figure 2 shows the receiver security handler in the request receiver message process.

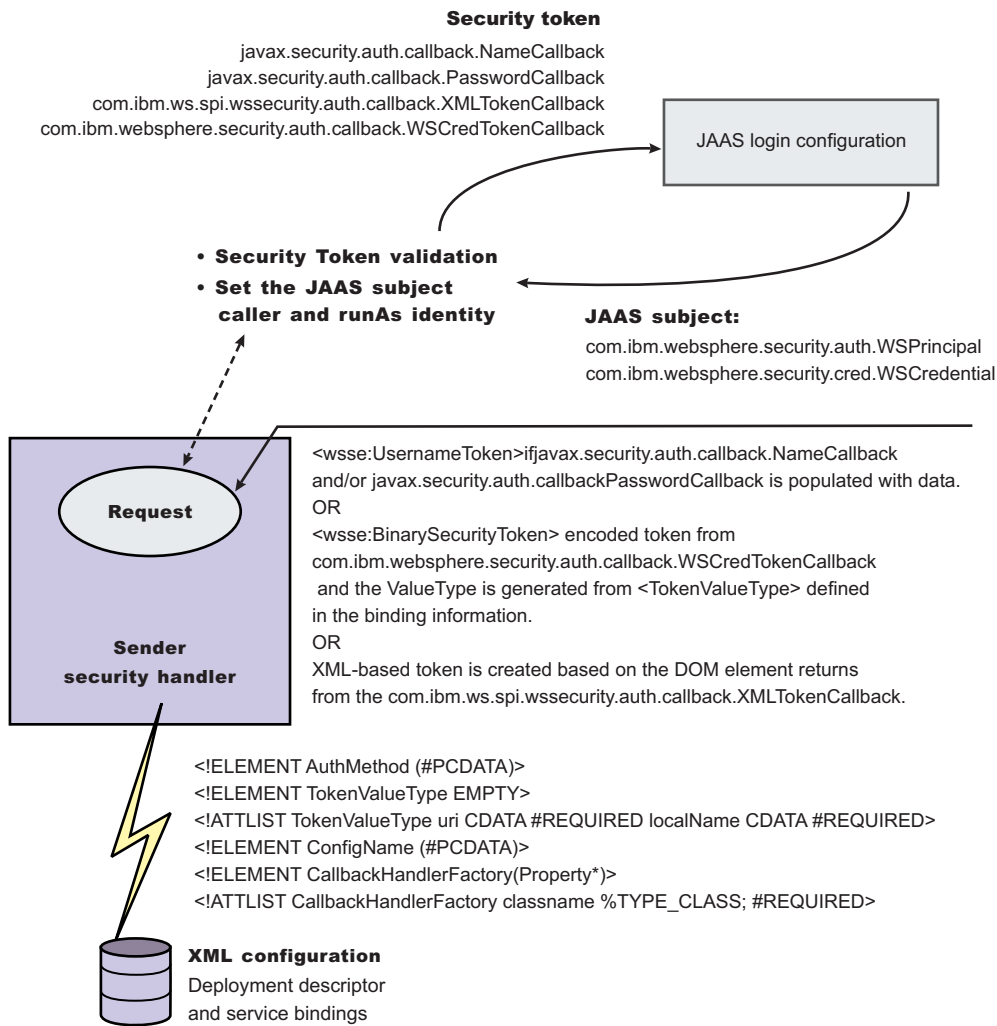

Figure 20. Request receiver SOAP message process

The default <LoginMapping> is defined in the following files:

- Server-level ws-security.xml file
- Cell-level ws-security.xml and server-level ws-security.xml files

If nothing is defined in the binding file information, the ws-security.xml default is used. However, an administrator can override the default by defining a new <LoginMapping> element in the binding file.

6. The client reads the default binding information in the `${install_dir}/properties/ws-security.xml` file.
7. The server run-time component loads the following files if they exist:
 - Server-level ws-security.xml file
 - Cell-level ws-security.xml file and the server-level ws-security.xml file. The two files are merged in the run time to form one effective set of default binding information.

On a base application server, the server run time component only loads the server-level ws-security.xml file. The server-side ws-security.xml file and the application Web services security binding information are managed using the administrative console and the WSADMIN command. You can specify the binding information during application deployment either through the administrative console or through the WSADMIN command. The Web services security policy is defined in the

deployment descriptor extension (`ibm-webservicesclient-ext.xml`) and the bindings are stored in the IBM binding extension (`ibm-webservicesclient-bnd.xml`). However, the `${install_dir}/properties/ws-security.xml` file defines the default binding value for the client. If the binding information is not specified in the binding file, the run time reads the binding information from the default `${install_dir}/properties/ws-security.xml` file.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Login mappings collection:

Use this page to view a list of configurations for validating security tokens within incoming messages. Login mappings map an authentication method to a Java Authentication and Authorization Service (JAAS) login configuration to validate the security token. Four authentication methods are predefined in the WebSphere Application Server: BasicAuth, Signature, IDAssertion, and Lightweight Third Party Authentication (LTPA).

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

To view this administrative console page for the cell level, complete the following steps:

1. Click **Security > Web services**
2. Under Additional properties, click **Login mappings**.
3. Click **New** to create a new login mapping or click an existing configuration to modify its settings.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers > Application servers > *server_name***.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Login mappings**.
4. Click either **New** to create a new login mapping configuration or click the name of an existing configuration.

To view this administrative console page for the application level, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_name***.
3. Under Web Services Security properties, click **Web services: Server security bindings**.
4. Click **Edit** under Request receiver binding.
5. Click **Login mappings**.

If you click **Update runtime**, the Web services security run time is updated with the default binding information, which is contained in the `ws-security.xml` file that was previously saved. After you specify the authentication method, the JAAS configuration name, and the Callback Handler Factory class name on this panel, you must complete the following steps:

1. Click **Save** in the messages section at the top of the administrative console.
2. Click **Update runtime**. When you click **Update runtime**, the configuration changes made to the other Web services also are updated in the Web services security run time.

Important: If the login mapping configuration is not found on the application level, the Web services run time searches for the login mapping configuration on the server level. If the configuration is not found on the server level, the Web services run time searches the cell.

Authentication method:

Specifies the authentication method used for validating the security tokens.

The following authentication methods are available:

BasicAuth

The basic authentication method includes both a user name and a password in the security token. The information in the token is authenticated by the receiving server and is used to create a credential.

Signature

The signature authentication method sends an X.509 certificate as a security token. For Lightweight Directory Access Protocol (LDAP) registries, the distinguished name (DN) is mapped to a credential, which is based on the LDAP certificate filter settings. For local OS registries, the first attribute of the certificate, usually the common name (CN) is mapped directly to a user name in the registry.

IDAssertion

The identity assertion method maps a trusted identity (ID) to a WebSphere Application Server credential. This authentication method only includes a user name in the security token. An additional token is included in the message for trust purposes. When the additional token is trusted, the IDAssertion token user name is mapped to a credential.

LTPA Lightweight Third Party Authentication (LTPA) validates an LTPA token.

JAAS configuration name:

Specifies the name of the Java Authentication and Authorization Service (JAAS) configuration.

Callback handler factory class name:

Specifies the name of the factory for the CallbackHandler class.

Login mapping configuration settings:

Use this page to specify the Java Authentication and Authorization Service (JAAS) login configuration settings that are used to validate security tokens within incoming messages.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

To view this administrative console page for the cell level, complete the following steps:

1. Click **Security > Web services**
2. Under Additional properties, click **Login mappings**.
3. Click either **New** to create a new login mapping configuration or click the name of an existing configuration.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers > Application servers > server_name**.
2. Under Security, click **Web services: Default bindings for Web services security**.
3. Under Additional properties, click **Login mappings**.

4. Click either **New** to create a new login mapping configuration or click the name of an existing configuration.

To use this administrative console page for the application level, complete the following steps:

1. Click **Applications > Enterprise applications > application_name**.
2. Click **Manage modules > URI_name**.
3. Under Web Services Security Properties, click **Web services: Server security bindings**.
4. Click **Edit** under Request receiver binding.
5. Click **Login mappings**.
6. Click either **New** to create a new login mapping configuration or click the name of an existing configuration.

Important: If the login mapping configuration is not found on the application level, the Web services run time searches for the login mapping configuration on the server level. If the configuration is not found on the server level, the Web services run time searches the cell.

Authentication method:

Specifies the method of authentication.

You can use any string, but the string must match the element in the service-level configuration. The following words are reserved and have special meanings:

BasicAuth

Uses both a user name and a password.

IDAssertion

Uses only a user name, but requires that additional trust is established on the receiving server using a TrustedIDEvaluator mechanism.

Signature

Uses the distinguished name (DN) of the signer.

LTPA Validates a token.

JAAS configuration name:

Specifies the name of the Java Authentication and Authorization Service (JAAS) configuration.

You can use the following predefined system login configurations:

system.wssecurity.IDAssertion

Enables a version 5.x application to use identity assertion to map a user name to a WebSphere Application Server credential principal.

system.wssecurity.Signature

Enables a version 5.x application to map a distinguished name (DN) in a signed certificate to a WebSphere Application Server credential principal.

system.LTPA_WEB

Processes login requests that are used by the Web container such as servlets and JavaServer Pages (JSP) files.

system.WEB_INBOUND

Handles logins for Web application requests, which include servlets and JavaServer Pages. This login configuration is used by WebSphere Application Server Version 5.1.1.

system.RMI_INBOUND

Handles logins for inbound Remote Method Invocation (RMI) requests. This login configuration is used by WebSphere Application Server Version 5.1.1.

system.DEFAULT

Handles the logins for inbound requests made by internal authentications and most of the other protocols except Web applications and RMI requests. This login configuration is used by WebSphere Application Server Version 5.1.1.

system.RMI_OUTBOUND

Processes RMI requests that are sent outbound to another server when the `com.ibm.CSIOutboundPropagationEnabled` property is `true`. This property is set in the CSiv2 authentication panel. To access the panel, click **Security > Global security > Authentication protocol > CSiv2 Outbound authentication**. To set the `com.ibm.CSIOutboundPropagationEnabled` property, select **Security attribute propagation**.

Version 6 and later applications

system.wssecurity.X509BST

Verifies an X.509 binary security token (BST) by checking the validity of the certificate and the certificate path.

Version 6 and later applications

system.wssecurity.PKCS7

Verifies an X.509 certificate with a certificate revocation list in a PKCS7 object.

Version 6 and later applications

system.wssecurity.PkiPath

Verifies an X.509 certificate with a public key infrastructure (PKI) path.

Version 6 and later applications

system.wssecurity.UsernameToken

Verifies basic authentication (user name and password).

These system login configurations are defined on the System logins panel, which is accessible by completing the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Java Authentication and Authorization Service, click **System logins**.

Attention: The predefined system login configurations are listed on the System logins configuration panel without the system prefix. For example, the `system.wssecurity.UsernameToken` configuration listed in the Java Authentication and Authorization Service (JAAS) configuration name option corresponds to the `wssecurity.UsernameToken` configuration that is on the System logins configuration panel.

You can use the following predefined application login configurations:

ClientContainer

Specifies the login configuration that is used by the client container application, which uses the `CallbackHandler` API that is defined in the deployment descriptor of the client container.

WSLogin

Specifies whether all applications can use the `WSLogin` configuration to perform authentication for the WebSphere Application Server security run time.

DefaultPrincipalMapping

Specifies the login configuration used by Java 2 Connectors (J2C) to map users to principals that are defined in the J2C authentication data entries.

These application login configurations are defined on the Application logins panel, which is accessible by completing the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under Java Authentication and Authorization Service, click **Application logins**.

Do not remove these predefined system or application login configurations. Within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module.

Callback handler factory class name:

Specifies the name of the factory for the CallbackHandler class.

You must implement the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` class in this field.

Token type URI:

Specifies the namespace Uniform Resource Identifiers (URI), which denotes the type of security token that is accepted.

If binary security tokens are accepted, the value denotes the ValueType attribute in the element. The ValueType element identifies the type of security token and its namespace. If Extensible Markup Language (XML) tokens are accepted, the value denotes the top-level element name of the XML token.

If the reserved words are specified previously in the Authentication method field, this field is ignored.

Data type:

Unicode characters except for non-ASCII characters, but including the number sign (#), the percent sign (%), and the square brackets ([]).

Token type local name:

Specifies the local name of the security token type, for example, X509v3.

If binary security tokens are accepted, the value denotes the ValueType attribute in the element. The ValueType attribute identifies the type of security token and its namespace. If Extensible Markup Language (XML) tokens are accepted, the value denotes the top-level element name of the XML token.

If the reserved words are specified previously in the Authentication method field, this field is ignored.

Nonce maximum age:

Specifies the time, in seconds, before the nonce timestamp expires. Nonce is a randomly generated value.

You must specify a minimum of 300 seconds for the Nonce maximum age field. However, the maximum value cannot exceed the number of seconds specified in the Nonce cache timeout field for either the server level or the cell level.

You can specify the Nonce maximum age value for the cell level by completing the following steps:

1. Click **Security > Web services**.

You can specify the Nonce maximum age value for the server level by completing the following steps:

1. Click **Servers > Application Servers > server_name**.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security**.

Important: The Nonce maximum age field on this panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt

to specify values for this field, the following error message displays and you must remove the specified value: Nonce is not supported for authentication methods other than BasicAuth.

If you specify the BasicAuth method, but do not specify values for the Nonce maximum age field, the Web services security run time searches for a Nonce maximum age value on the server level. If a value is not found on the server level, the run time searches the cell level. If a value is not found on either the server level or the cell level, the default is 300 seconds.

Default	300 seconds
Range	300 to Nonce cache timeout seconds

Nonce clock skew:

Specifies the clock skew value, in seconds, to consider when WebSphere Application Server checks the freshness of the message. Nonce is a randomly generated value.

You can specify the Nonce clock skew value for the cell level by completing the following steps:

1. Click **Security > Web services**.

You can specify the **Nonce clock skew** value for the server level by completing the following steps:

1. Click **Servers > Application Servers > server_name**.
2. Under Additional Properties, click **Web Services: Default bindings for Web Services Security**.

You must specify a minimum of zero (0) seconds for the Nonce Clock Skew field. However, the maximum value cannot exceed the number of seconds that is specified in the Nonce maximum age field on this Login mappings panel.

Important: The Nonce clock skew field on this panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt to specify values for this field, the following error message displays and you must remove the specified value: Nonce is not supported for authentication methods other than BasicAuth.

Note: If you specify BasicAuth, but do not specify values for the Nonce clock skew field, WebSphere Application Server searches for a Nonce clock skew value on the server level. If a value is not found on the server level, the run time searches the cell level. If a value is not found on either the server level or the cell level, the default is zero (0) seconds.

Default	0 seconds
Range	0 to Nonce Maximum Age seconds

Configuring the client for request signing: digitally signing message parts

To configure the client for request signing, specify which message parts to digitally sign when configuring the client.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **Security Extensions** tab and the **Port Binding** tab in the Web Services Client Editor within an assembly tool, such as the Application Server Toolkit or Rational Web Developer.

- “Configuring the client security bindings using an assembly tool” on page 1335
- “Configuring the security bindings on a server acting as a client using the administrative console” on page 1338

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to specify which message parts to digitally sign when configuring the client for request signing:

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*
2. Click **Windows > Open perspective > Other > J2EE**.
3. Click **Application Client projects > application_name > appClientModule > META-INF**
4. Right-click the `application-client.xml` file, select **Open with > Deployment Descriptor Editor**, and click the WS Extension tab. The Client Deployment Descriptor is displayed.
5. Expand **Request sender configuration > Integrity**. *Integrity* refers to digital signature while *confidentiality* refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet. For more information on digitally signing SOAP messages, see “XML digital signature” on page 1286.
6. Indicate which parts of the message to sign by clicking **Add** and selecting **body**, **timestamp**, or **SecurityToken**. The following list contains descriptions of the message parts

body The body is the user data portion of the message.

timestamp

The time stamp determines if the message is valid based on the time that the message is sent and then received. If **timestamp** is selected, proceed to the next step and select **Add created time stamp** to add a time stamp to a message.

SecurityToken

The security token authenticates the client. If this option is selected, the message is signed.

You can choose to digitally sign the message using a time stamp if **Add created time stamp** is selected and configured. You can digitally sign the message using a security token if a login configuration authentication method is selected.

7. **Optional:** Expand the **Add created time stamp** section and select this option if you want a time stamp added to the message. You can specify an expiration time for the time stamp, which helps defend against replay attacks. The lexical representation for duration is the [ISO 8601] extended format *PnYnMnDTnHnMnS*, where:
 - *nY* represents the number of years
 - *nM* represents the number of months
 - *nD* represents the number of days
 - *T* is the date and time separator
 - *nH* represents the number of hours
 - *nM* represents the number of minutes
 - *nS* represents the number of seconds. The number of seconds can include decimal digits to arbitrary precision.

For example, to indicate a duration of 1 year, 2 months, 3 days, 10 hours, and 30 minutes, the format is: `P1Y2M3DT10H30M`. Typically, you configure a message time stamp for about 10 to 30 minutes, for example, 10 minutes is represented as: `P0Y0M0DT0H10M0S`. The *P* character precedes time and date values.

Important: If you configure the client and server signing information correctly, but receive a Soap body not signed error when executing the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within the assembly tool (such as the Application Server Toolkit or Rational Web Developer):

- Click **Security extensions > Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions > Request sender configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web Services Editor within the WebSphere Application Server Toolkit:

- Click **Security extensions > Server service configuration**.
- Click **Security extensions > Response sender service configuration details > Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the **Actor** fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **Actor** fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server **Actor** fields are synchronized.

After you have specified which message parts to digitally sign, you must specify which method is used to digitally sign the message. See “Configuring the client for request signing: choosing the digital signature method” for more information.

Configuring the client for request signing: choosing the digital signature method

To configure the client for request signing, specify which message parts to digitally sign when configuring the client.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the Security extensions tab and the **Port binding** tab in the Web services client editor within an assembly tool, such as the Application Server Toolkit or Rational Web Developer:

- “Configuring the client security bindings using an assembly tool” on page 1335
- “Configuring the security bindings on a server acting as a client using the administrative console” on page 1338

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively. You must specify which parts of the message sent by the client must be digitally signed. See “Configuring the client for request signing: digitally signing message parts” on page 1320 for more information.

Complete the following steps to specify which message parts to digitally sign when configuring the client for request signing:

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Windows > Open perspective > Other > J2EE**.
3. Click **Application Client projects > application_name > appClientModule > META-INF**

4. Right-click the application-client.xml file, select **Open with > Deployment Descriptor Editor**, and click the **WS Binding** tab. The Client Deployment Descriptor is displayed.
5. Expand **Security request sender binding configuration > Signing information**.
6. Select **Edit** to view the signing information and select a digital signature method from the **Signature method algorithm** field. The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following Web site <http://www.w3.org/TR/xmlsig-core>.

Name	Purpose
Canonicalization method algorithm	Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation.
Digest method algorithm	Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. Signing the <DigestValue> element binds the resource content to the signer key. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.
Signature method algorithm	Converts the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.
Signing key name	Represents the key entry associated with the signing key locator. The key entry refers to an alias of the key, which is found in the key store and is used to sign the request.
Signing key locator	Represents a reference to a key locator implementation class that locates the correct key store where the alias and the certificate exist.

7. **Optional:** Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the **Digest method algorithm** and **Signature method algorithm** drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the WebSphere administrative console.

Important: If you configure the client and server signing information correctly, but receive a Soap body not signed error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web services client editor within an assembly tool:

- Click **Security extensions > Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions > Request sender configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web services editor within an assembly tool:

- Click **Security extensions > Server service configuration**.
- Click **Security extensions > Response sender service configuration details > Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **Actor** fields might be different when you have Web

services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which method is used to digitally sign a message when the client sends a message to a server.

After you configure the client to digitally sign the message, you must configure the server to verify the digital signature. See “Configuring the server for request digital signature verification: Verifying the message parts” for more information.

Configuring the server for request digital signature verification: Verifying the message parts

Configure the server for request digital signature verification by modifying the extensions to indicate which parts of the request to verify.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the Extensions tab and the Binding Configurations tab in the Web services editor within the assembly tool such as the Application Server Toolkit or Rational Web Developer:

- “Configuring the server security bindings using an assembly tool” on page 1339
- “Configuring the server security bindings using the administrative console” on page 1342

You can use these two tabs to configure the Web services security extensions and the Web services security bindings, respectively. Also, you must specify which parts of the message sent by the client must be digitally signed. See “Configuring the client for request signing: digitally signing message parts” on page 1320 to determine which message parts are digitally signed. The message parts specified for the client request sender must match the message parts specified for the server request receiver.

Complete the following steps to configure the server for request digital signature verification. The steps describe how to modify the extensions to indicate which parts of the request to verify.

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Windows > Open perspective > Other > J2EE**.
3. Click **EJB Projects > application_name > ejbModule > META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Extensions tab in the Web services editor.
6. Expand the **Request receiver service configuration details > Required integrity** section. Required integrity refers to the parts of the message that require digital signature verification. The purpose of digital signature verification is to make sure that the message parts have not been modified while transmitting across the Internet.
7. Indicate parts of the message to verify by clicking **Add**, and selecting one of the following three parts: `body`, `timestamp`, or `SecurityToken`. You can determine which parts of the message to verify by looking at the Web service request sender configuration in the client application. To view the Web service

request sender configuration information in the Web services client editor, click the Security extensions tab and expand **Request sender configuration > Integrity**. The following includes a list and description of the message parts:

Body This is the user data portion of the message.

Timestamp

The timestamp determines if the message is valid based on the time that the message is sent and then received. If timestamp option is selected, proceed to the next step to Add Created Time Stamp to the message.

Securitytoken

The security token authenticates the client. If the SecurityToken is selected, the message is signed.

8. **Optional:** Expand the **Add received time stamp** section. The Add Received Time Stamp value indicates to validate the Add Created Time Stamp option configured by the client. You must select this option if you selected the Add Created Time Stamp on the client. The time stamp ensures message integrity by indicating the timeliness of the request. This option helps defend against replay attacks.

Important: If you configure the client and server signing information correctly, but receive a Soap body not signed error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within the Application Server Toolkit:

- Click **Security extensions > Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions > Request sender configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web Services Editor within the Application Server Toolkit:

- Click **Security extensions > Server service configuration**.
- Click **Security extensions > Response sender service configuration details > Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **actor** fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts are digitally signed and must be verified by the server when the client sends a message to a server.

After you specify which message parts contain a digital signature that must be verified by the server, you must configure the server to recognize the digital signature method used to digitally sign the message. See “Configuring the server for request digital signature verification: choosing the verification method” on page 1326 for more information.

Configuring the server for request digital signature verification: choosing the verification method

To configure the server for request digital signature verification, use an assembly tool to modify the extensions and indicate which digital signature method the server will use during verification.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the Extensions tab and the Binding Configurations tab in the Web Services Editor within the assembly tool such as the Application Server Toolkit or Rational Web Developer:

- “Configuring the server security bindings using an assembly tool” on page 1339
- “Configuring the server security bindings using the administrative console” on page 1342

You can use these two tabs to configure the Web services security extensions and Web services security bindings, respectively. You must specify which message parts contain digital signature information that must be verified by the server. See “Configuring the server for request digital signature verification: Verifying the message parts” on page 1324. The message parts specified for the client request sender must match the message parts specified for the server request receiver. Likewise, the digital signature method chosen for the client must match the digital signature method used by the server.

Complete the following steps to configure the server for request digital signature verification. The steps describe how to modify the extensions to indicate which digital signature method the server will use during verification.

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Windows > Open perspective > Other > J2EE**.
3. Click **EJB Projects > application_name > ejbModule > META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Binding Configurations tab.
6. Expand the **Security request receiver binding configuration details > Signing information** section.
7. Click **Edit** to edit the signing information. The signing information dialog is displayed, select or enter the following information:
 - Canonicalization method algorithm
 - Digest method algorithm
 - Signature method algorithm
 - Use certificate path reference
 - Trust anchor reference
 - Certificate store reference
 - Trust any certificate

For more conceptual information on digitally signing SOAP messages, see *XML digital signature*. The following table describes the purpose for each of these selections. Some of the following definitions are based on the XML-Signature specification, which is located at the following Web address: <http://www.w3.org/TR/xmlsig-core>.

Name	Purpose
Canonicalization method algorithm	Canonicalizes the <SignedInfo> element before it is digested as part of the signature operation. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration.
Digest method algorithm	Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. The signing of the <DigestValue> element binds resource content to the signer key. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration.
Signature method algorithm	Converts the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the server request receiver configuration must match the algorithm selected in the client request sender configuration.
Use certificate path reference or Trust any certificate	Validates a certificate or signature sent with a message. When a message is signed, the public key used to sign it is sent with the message. This public key or certificate might not be validated at the receiving end. By selecting User certificate path reference , you must configure a trust anchor reference and a certificate store reference to validate the certificate sent with the message. By selecting Trust any certificate , the signature is validated by the certificate sent with the message without the certificate itself being validated.
Use certificate path reference: Trust anchor reference	Refers to a key store that contains trusted, self-signed certificates and certificate authority (CA) certificates. These certificates are trusted certificates that you can use with any applications in your deployment.
Use certificate path reference: Certificate store reference	Contains a collection of X.509 certificates. These certificates are not trusted for all applications in your deployment, but might be used as an intermediary to validate certificates for an application.

8. **Optional:** Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Signature method algorithm and Digest method algorithm drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms.** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

Important: If you configure the client and server signing information correctly, but receive a Soap body not signed error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within the Application Server Toolkit:

- Click **Security extensions > Client service configuration details** and indicate the actor information in the Actor URI field.
- Click **Security extensions > Request sender configuration > Details** and indicate the actor information in the Actor field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web Services Editor within the WebSphere Application Server Toolkit:

- Click **Security extensions > Server service configuration**.
- Click **Security extensions > Response sender service configuration details > Details** and indicate the actor information in the Actor field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **actor** fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified the method that the server uses to verify the digital signature in the message parts.

After you configure the client for request signing and the server for request digital signature verification, you must configure the server and the client to handle the response. Next, specify the response signing for the server. See “Configuring the server for response signing: digitally signing message parts” for more information.

Configuring the server for response signing: digitally signing message parts

Use an assembly tool to specify which message parts to digitally sign when configuring the server for response signing.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the Extensions tab and the Binding configurations tab in the Web services editor within an assembly tool such as the Application Server Toolkit or Rational Web Developer:

- “Configuring the server security bindings using an assembly tool” on page 1339
- “Configuring the server security bindings using the administrative console” on page 1342

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to specify which message parts to digitally sign when configuring the server for response signing:

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Windows > Open perspective > Other > J2EE**.
3. Click **EJB Projects > application_name > ejbModule > META-INF**
4. Right-click the `webservices.xml` file and click **Open with > Web services editor**.
5. Click the Extensions tab, which is located at the bottom of the Web Services Editor within the assembly tool.
6. Expand **Response sender service configuration details > Integrity**. Integrity refers to digital signature while confidentiality refers to encryption. Integrity decreases the risk of data modification while the data is transmitted across the Internet. For more information on digitally signing SOAP messages, see XML digital signature.

7. Indicate the parts of the message to sign by clicking **Add**, and selecting **Body**, **Timestamp**, or **Securitytoken**.

The following list contains descriptions of the message parts:

Body The body is the user data portion of the message.

Timestamp

The time stamp determines if the message is valid based on the time that the message is sent and then received. If **timestamp** is selected, proceed to the next step and click **Add Created Time Stamp**, which indicates that the time stamp is added to the message.

Securitytoken

The security token is used for authentication. If this option is selected, the authentication information is added to the message.

8. **Optional:** Expand the **Add created time stamp** section. Select this option if you want a time stamp added to the message. You can specify an expiration time for the time stamp, which helps defend against replay attacks. The lexical representation for duration is the ISO 8601 extended format, *PnYnMnDTnHnMnS*, where:

- *nY* represents the number of years.
- *nM* represents the number of months.
- *nD* represents the number of days.
- *T* is the date and time separator.
- *nH* represents the number of hours.
- *nM* represents the number of minutes.
- *nS* represents the number of seconds. The number of seconds can include decimal digits to arbitrary precision.

For example, to indicate a duration of 1 year, 2 months, 3 days, 10 hours, and 30 minutes, the format is: P1Y2M3DT10H30M. Typically, you configure a message time stamp for about 10 to 30 minutes. 10 minutes is represented as: P0Y0M0DT0H10M0S. The *P* character precedes time and date values.

Important: If you configure the client and server signing information correctly, but receive a Soap body not signed error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web Services Client Editor within the assembly tool:

- Click **Security extensions > Client service configuration details** and indicate the actor information in the **Actor URI** field.
- Click **Security extensions > Request sender configuration > Details** and indicate the actor information in the **Actor** field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web Services Editor within the WebSphere Application Server Toolkit:

- Click **Security extensions > Server service configuration**.
- Click **Security extensions > Response sender service configuration details > Details** and indicate the actor information in the **Actor** field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The **actor** fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct

actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts to digitally sign when the server sends a response to the client.

After you specifying which message parts to digitally sign, you must specify which method is used to digitally sign the message. See “Configuring the server for response signing: choosing the digital signature method” for more information.

Configuring the server for response signing: choosing the digital signature method

Use an assembly tool to specify which digital signature method to use when configuring the server for response signing.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the Extensions tab and the Binding configurations tab in the Web services editor within the assembly tools such as the Application Server Toolkit or Rational Web Developer:

- “Configuring the server security bindings using an assembly tool” on page 1339
- “Configuring the server security bindings using the administrative console” on page 1342

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to specify which digital signature method to use when configuring the server for response signing:

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects > *application_name* > ejbModule > META-INF**
4. Right-click the `webservices.xml` file and click **Open with > Web services editor**.
5. Click the Binding Configurations tab.
6. Expand **Response sender binding configuration details > Signing information**.
7. Click **Edit** to choose a signing method. The signing info dialog is displayed and either select or enter the following information:
 - **Canonicalization method algorithm**
 - **Digest method algorithm**
 - **Signature method algorithm**
 - **Signing key name**
 - **Signing key locator**

The following table describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following address: <http://www.w3.org/TR/xmlsig-core>.

Name	Purpose
Canonicalization method algorithm	Canonicalizes the <SignedInfo> element before the information is digested as part of the signature operation. Use the same algorithm on the client response receiver. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.
Digest method algorithm	Applies to the data after transforms are applied, if specified, to yield the <DigestValue> element. Signing the <DigestValue> binds resource content to the signer key. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.
Signature method algorithm	Converts the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.
Signing key name	Represents the key entry associated with the signing key locator. The key entry refers to an alias of the key, which is found in the key store and is used to sign the request.
Signing key locator	Represents a reference to a key locator implementation class that locates the correct key store where the alias and certificate exists. For more information on configuring key locators, see any of the following files: <ul style="list-style-type: none"> • “Configuring key locators using an assembly tool” on page 1306 • “Configuring key locators using the administrative console” on page 1307

8. **Optional:** Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Signature method algorithm and Digest method algorithm drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

You have specified which method is used to digitally sign a message when the server sends a message to a client.

After you configure the server to digitally sign the response message, you must configure the client to verify the digital signature contained in the response message. See “Configuring the client for response digital signature verification: verifying the message parts” for more information.

Configuring the client for response digital signature verification: verifying the message parts

To configure the Web services security extensions and the Web services security bindings, use the WS Extension tab and the WS Binding tab in the Client Deployment Descriptor within an assembly tool such as the Application Server Toolkit or Rational Web Developer.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the WS Extension tab and the WS Binding tab in the Client Deployment Descriptor within the assembly tool such as the Application Server Toolkit or Rational Web Developer:

- “Configuring the client security bindings using an assembly tool” on page 1335
- “Configuring the security bindings on a server acting as a client using the administrative console” on page 1338

You can use these two tabs to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to configure the client for response digital signature verification. The steps describe how to modify the extensions to indicate which parts of the response to verify.

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Windows > Open perspective > Other > J2EE**.
3. Click **Application Client projects > *application_name* > appClientModule > META-INF**.
4. Right-click the `application-client.xml` file and click **Open With > Deployment descriptor editor**.
5. Click the WS extension tab.
6. Expand the **Response receiver configuration > Required integrity** section. Required integrity refers to parts that require digital signature verification. Digital signature verification decreases the risk that the message parts have been modified while the message is transmitted across the Internet.
7. Indicate the parts of the message that must be verified. You can determine which parts of the message to verify by looking at the Web service response sender configuration. Click **Add** and select one of the following parts:

Body The body is the user data portion of the message.

Timestamp

The time stamp determines if the message is valid based on the time that the message is sent and then received. If the time stamp option is selected, proceed to the next step to add a received time stamp to the message.

Securitytoken

The security token authenticates the client. If Securitytoken option is selected, the message is signed.

8. **Optional:** Expand the **Add received time stamp** section. Select **Add received time stamp** to add the received time stamp to the message.

Important: If you configure the client and server signing information correctly, but receive a Soap body not signed error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web services client editor within an assembly tool:

- Click **Security extensions > Client service configuration details** and indicate the actor information in the Actor URI field.
- Click **Security extensions > Request sender configuration > Details** and indicate the actor information in the Actor field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web services editor within an assembly tool:

- Click **Security extensions > Server service configuration**.
- Click **Security extensions > Response sender service configuration details > Details** and indicate the actor information in the Actor field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which message parts are digitally signed and must be verified by the client when the server sends a response message to the client.

After you specify which message parts contain a digital signature that must be verified by the client, you must configure the client to recognize the digital signature method used to digitally sign the message. See “Configuring the client for response digital signature verification: choosing the verification method” for more information.

Configuring the client for response digital signature verification: choosing the verification method

You can configure the Web services security extensions and Web services security bindings using the WS extension tab and the WS binding tab in the Web services editor within an assembly tool such as the Application Server Toolkit or Rational Web Developer.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the WS extension tab and the WS binding tab in the Web services editor within an assembly tool such as the Application Server Toolkit or Rational Web Developer:

- “Configuring the server security bindings using an assembly tool” on page 1339
- “Configuring the server security bindings using the administrative console” on page 1342

You can use these two tabs to configure the Web services security extensions and Web services security bindings, respectively. Also, you must specify which message parts contain digital signature information that must be verified by the client. See “Configuring the client for response digital signature verification: verifying the message parts” on page 1331 to specify which message parts are digitally signed by the server and must be verified by the client. The message parts specified for the server response sender must match the message parts specified for the client response receiver. Likewise, the digital signature method chosen for the server must match the digital signature method used by the client.

Complete the following steps to configure the client for response digital signature verification. The steps describe how to modify the extensions to indicate which digital signature method the client will use during verification.

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Windows > Open perspective > Other > J2EE**.
3. Click **Application Client Projects > *application_name* > appClientModule > META-INF**.
4. Right-click the `application-client.xml` file, select **Open with > Deployment descriptor editor**.
5. Click the WS Binding tab.
6. Expand the **Security response receiver binding configuration > Signing information** section.

7. Click **Edit** to select a digital signature method. The signing info dialog displays and either select or enter the following information:

- **Canonicalization method algorithm**
- **Digest method algorithm**
- **Signature method algorithm**
- **Signing key name**
- **Signing key locator**

For more conceptual information on digitally signing SOAP messages, see XML digital signature. The following table describes the purpose for each of these selections. Some of the following definitions are based on the XML-Signature specification, which can be found at: <http://www.w3.org/TR/xmlsig-core>.

Name	Purpose
Canonicalization method algorithm	The canonicalization method algorithm is used to canonicalize the <SignedInfo> element before it is digested as part of the signature operation.
Digest method algorithm	The digest method algorithm is the algorithm applied to the data after transforms are applied, if specified, to yield the <DigestValue>. The signing of the <DigestValue> binds resource content to the signer key. The algorithm selected for the client response receiver configuration must match the algorithm selected in the server response sender configuration.
Signature method algorithm	The signature method is the algorithm that is used to convert the canonicalized <SignedInfo> element into the <SignatureValue> element. The algorithm selected for the client response receiver configuration must match the algorithm selected in the server response sender configuration.
Use certificate path reference or Trust any certificate	When a message is signed, the public key used to sign it is transmitted with the message. To validate this public key at the receiving end, configure a certificate path reference. By selecting User certificate path reference , you must configure a trust anchor reference and certificate store reference to validate the certificate sent with the message. By selecting trust any certificate , the signature is validated by the certificate sent with the message without the certificate itself being validated.
Use certificate path reference: Trust anchor reference	A trust anchor is a configuration that refers to a keystore that contains trusted, self-signed certificates and certificate authority (CA) certificates. These certificates are trusted certificates that you can use with any applications in your deployment.
Use certificate path reference: Certificate store reference	A certificate store is a configuration that has a collection of X.509 certificates. These certificates are not trusted for all applications in your deployment, but might be used as an intermediary to validate certificates for an application.

8. **Optional:** Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Signature method algorithm and Digest method algorithm drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

Important: If you configure the client and server signing information correctly, but receive a Soap body not signed error when running the client, you might need to configure the actor. You can configure the actor in the following locations on the client in the Web services client editor within an assembly tool:

- Click **Security extensions > Client service configuration details** and indicate the actor information in the Actor URI field.
- Click **Security extensions > Request sender configuration > Details** and indicate the actor information in the Actor field.

You must configure the same actor strings for the Web service on the server, which processes the request and sends the response back. Configure the actor in the following locations in the Web services editor within an assembly tool:

- Click **Security extensions > Server service configuration**.
- Click **Security extensions > Response sender service configuration details > Details** and indicate the actor information in the Actor field.

The actor information on both the client and server must refer to the same exact string. When the actor fields on the client and server match, the request or response is acted upon instead of being forwarded downstream. The actor fields might be different when you have Web services acting as a gateway to other Web services. However, in all other cases, make sure that the actor information matches on the client and server. When Web services are acting as a gateway and they do not have the same actor configured as the request passing through the gateway, Web services do not process the message from a client. Instead, these Web services send the request downstream. The downstream process that contains the correct actor string processes the request. The same situation occurs for the response. Therefore, it is important that you verify that the appropriate client and server actor fields are synchronized.

You have specified which method the client uses to verify the digital signature in the message parts.

After you configure the server for response signing and the client for request digital signature verification, verify that you have configured the client and the server to handle the message request.

Configuring the client security bindings using an assembly tool

Use the Web services client editor within an assembly tool to include the binding information, that describes how to run the security specifications found in the extensions, in the client enterprise archive (EAR) file.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

When configuring a client for Web services security, the bindings describe how to run the security specifications found in the extensions. Use the Web services client editor within an assembly tool to include the binding information in the client enterprise archive (EAR) file.

You can configure the client-side bindings from a pure client accessing a Web service or from a Web service accessing a downstream Web service. This document focuses on the pure client situation. However, the concepts, and in most cases the steps, also apply when a Web service is configured to communicate downstream to another Web service that has client bindings. Complete the following steps to edit the security bindings on a pure client (or server acting as a client) using an assembly tool:

1. Import the Web services client EAR file into an assembly tool. When you edit the client bindings on a server acting as a client, the same basic steps apply. Refer to the Assembly tools documentation for additional information.

2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > application_name > appClientModule > META-INF**.
4. Right-click the application-client.xml file, select **Open with > Deployment descriptor editor**. The Client Deployment Descriptor is displayed.
5. Click the WS Extension tab.
6. On the WS extension tab, select the Port QName Bindings that you want to configure. The Web services security extensions are configured for outbound requests and inbound responses. You need to configure the following information for Web services security extensions. These topics are discussed in more detail in other sections of the documentation.

Key locators

“Configuring key locators using an assembly tool” on page 1306

Important: When configuring the security request sender binding configuration, you must synchronize the information used to perform the specified security with the security request receiver binding configuration, which is configured in the server EAR file. These two configurations must be synchronized in all respects because there is no negotiation during run time to determine the requirements of the server.

For example, when configuring the encryption information in the security request sender binding Configuration, you must use the public key from the server for encryption. Therefore, the key locator that you choose must contain the public key from the server configuration. The server must contain the private key to decrypt the message. This example illustrates the important relationship between the client and server configuration. Additionally, when configuring the security response receiver binding configuration, the server must send the response using security information known by this client security response receiver binding configuration.

The following table shows the related configurations between the client and the server. The client request sender and the server request receiver are relative configurations that must be synchronized with each other. The server response sender and the client response receiver are related configurations that must be synchronized with each other. Note that the related configurations are end points for any request or

response. One end point must communicate its actions with the other end point because run time requirements are not negotiated.

Table 54. Related configurations

Client configuration	Server configuration
Request sender	Request receiver
Response receiver	Response sender

Configuring the security bindings on a server acting as a client using the administrative console

Use the Web services client editor within an assembly tool to include the binding information, that describes how to run the security specifications found in the extensions, in the client enterprise archive (EAR) file.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

When configuring a client for Web services security, the bindings describe how to run the security specifications found in the extensions. Use the Web services client editor within an assembly tool to include the binding information in the client enterprise archive (EAR) file.

You can configure the client-side bindings from a pure client accessing a Web service or from a Web service accessing a downstream Web service. Complete the following steps to find the location in which to edit the client bindings from a Web service that is running on the server. When a Web service communicates with another Web service, you must configure client bindings to access the downstream Web service.

1. Deploy the Web service using the WebSphere Application Server administrative console. Click **Applications > Install New Application**.

You can access the administrative console by typing `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.

See also [Installing a new application](#).

2. Click **Applications > Enterprise applications > application_name**.
3. Under Manage modules, click *URI_name*.
4. Under Web Services Security Properties, click **Web Services: Client security bindings**. A table displays with the following columns:
 - Component Name
 - Port
 - Web Service
 - Request Sender Binding
 - Request Receiver Binding
 - HTTP Basic Authentication
 - HTTP SSL Configuration

For Web services security, you must edit the request sender binding and response receiver binding configurations. You can use the defaults for some of the information at the server level and at the cell level in Network Deployment environments. Default bindings are convenient because you can configure commonly reused elements such as key locators once and then reference their aliases in the application bindings.

5. View the default bindings for the server using the administrative console by clicking **Servers > Application server > server_name**. Under Additional Properties, click **Web Services: Default**

bindings for Web services security. You can configure the following sections. These topics are discussed in more detail in other sections of the documentation.

- Request sender binding
 - “Signing parameter configuration settings” on page 1288
 - “Encryption information configuration settings” on page 1185
 - “Key locator configuration settings” on page 1145
 - “Login bindings configuration settings” on page 1347
- Response receiver binding
 - “Signing information configuration settings” on page 1164
 - “Encryption information configuration settings” on page 1179
 - “Trust anchor configuration settings” on page 1111
 - “Collection certificate store configuration settings” on page 1116
 - “Key locator configuration settings” on page 1145

Important: When configuring the security request sender binding configuration, you must synchronize the information used to perform the specified security with the security request receiver binding configuration, which is configured in the server EAR file. These two configurations must be synchronized in all respects because there is no negotiation during run time to determine the requirements of the server. For example, when configuring the encryption information in the security request sender binding configuration, you must use the public key from the server for encryption. Therefore, the key locator that you choose must contain the public key from the server configuration. The server must contain the private key to decrypt the message. This example illustrates the important relationship between the client and server configuration. Additionally, when configuring the security response receiver binding configuration, the server must send the response using security information known by this client security response receiver binding configuration.

The following table shows the related configurations between the client and the server. The client request sender and the server request receiver are relative configurations that must be synchronized with each other. The server response sender and the client response receiver are related configurations that must be synchronized with each other. Note that related configurations are end points for any request or response. One end point must communicate its actions with the other end point because run time requirements are not required.

Table 55. Related configurations

Client configuration	Server configuration
Request sender	Request receiver
Response receiver	Response sender

Configuring the server security bindings using an assembly tool

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Create an Enterprise JavaBeans (EJB) file Java archive (JAR) file or a Web archive (WAR) file containing the security binding file (`ibm-webservices-bnd.xmi`) and the security extension file (`ibm-webservices-ext.xmi`). If this archive is acting as a client to a downstream service, you also need the client-side binding file (`ibm-webservicesclient-bnd.xmi`) and the client-side extension file (`ibm-webservicesclient-ext.xmi`). These files are generated using the WSDL2Java command. You can edit these files using the Web services editor in the Assembly tools.

When configuring server-side security for Web services security, the security extensions configuration specifies what security is performed, the security bindings configuration indicates how to perform what is specified in the security extensions configuration. You can use the defaults for some elements at the cell and server levels in the bindings configuration, including key locators, trust anchors, the collection certificate store, trusted ID evaluators, and login mappings and reference these elements from the WAR and JAR binding configurations.

Prior to importing the Web services enterprise archive (EAR) file into the assembly tool, make sure that you have already run the `wsdl2java` command on your Web service to enable your Java 2 Platform, Enterprise Edition (J2EE) application. You must import the Web services EAR file into the assembly tool.

Open the Web services editor in an assembly tool to begin editing the server security extensions and bindings. The following steps can locate the server security extensions and bindings. Other tasks specify how to configure each section of the extensions and bindings in more detail.

1. Launch an assembly tool. For more information on the assembly tools, see [Assembly tools](#).
2. Switch to the J2EE perspective. Click **Window > Open Perspective > J2EE**.
3. Configure the server for inbound requests and outbound responses security configuration. To configure the server for inbound requests and outbound responses, complete the following steps:
 - a. Click **EJB Projects > application_name > ejbModule > META-INF**.
 - b. Right-click the `webservices.xml` file and click **Open with > Web services editor**. The `webservices.xml` file represents the server-side (inbound) Web services configuration. The `webservicesclient.xml` file represents the client-side (outbound) Web services configuration.
4. In the Web services editor (for the `webservices.xml` file and inbound requests and outbound responses Web services configuration), there are several tabs at the bottom of the editor including Web Services, Port Components, Handlers, Security Extensions, Bindings, and Binding Configurations. The security extensions are edited using the Security Extensions tab. The security bindings are edited using the Security Bindings tab.
 - a. Click the WS Extensions tab and select the port component binding to edit. The Web services security extensions are configured for inbound requests and outbound responses. You need to configure the following information for Web services security extensions. These topics are discussed in more detail in other topics in the documentation.

Request receiver service configuration details

Key locators

“Configuring key locators using an assembly tool” on page 1306

Configure the client for outbound requests and inbound responses security configuration by right-clicking the `webservicesclient.xml` file and clicking **Open With > Deployment descriptor editor**. For more information, see “Configuring the client security bindings using an assembly tool” on page 1335.

Configuring the server security bindings using the administrative console

Use the WebSphere Application Server administrative console to edit bindings for a Web service after these bindings are deployed on a server.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Create an Enterprise JavaBeans (EJB) file Java archive (JAR) file or Web archive (WAR) file containing the security binding file (`ibm-webservices-bnd.xmi`) and the security extension file (`ibm-webservices-ext.xmi`). If this archive is acting as a client to a downstream service, you also need the client-side binding file (`ibm-webservicesclient-bnd.xmi`) and the client-side extension file (`ibm-webservicesclient-ext.xmi`). These files are generated using the `WSDL2Java` command command. You can edit these files using the Web Services Editor in the Assembly tools.

When configuring server-side security for Web services security, the security extensions configuration specifies what security is to be performed while the security bindings configuration indicates how to perform what is specified in the security extensions configuration. You can use the defaults for some elements at the cell and server levels in the bindings configuration, including key locators, trust anchors, the collection certificate store, trusted ID evaluators, and login mappings and reference them from the WAR and JAR binding configurations.

The following steps describe how to edit bindings for a Web service after these bindings are deployed on a server. When one Web service communicates with another Web service, you also must configure the client bindings to access the downstream Web service.

1. Deploy the Web service using the WebSphere Application Server administrative console.
Type `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.
After you log into the administration console, click **Applications > Install new application** to deploy the Web service. For more information, see [Installing application files with the console](#).
2. After you deploy the Web service, click **Applications > Enterprise applications > application_name**.
3. Under Manage modules, click *URI_name*.
4. Under Web Services Security Properties, click **Web services: client security bindings** for outbound requests and inbound responses. Click **Web services: server security bindings** for inbound requests and outbound responses.
5. If you click **Web services: server security bindings**, the following sections can be configured. These topics are discussed in more detail in other sections of the documentation.
 - Request receiver binding
 - Signing information

- Encryption information
- Trust anchors
- Collection certificate store
- Key locator
- Trusted ID evaluator
- Login mappings
- Response sender binding
 - Signing parameters
 - Encryption information
 - Key locator

XML encryption

Extensible Markup Language (XML) encryption is a specification developed by World Wide Web (WWW) Consortium (W3C) in 2002 that contains the steps to encrypt data, the steps to decrypt encrypted data, the syntax to represent XML encrypted data, the information used to decrypt the data, and a list of encryption algorithms such as triple Data Encryption Standard (DES), Advanced Encryption Standard (AES), and Rivest-Shamir-Adleman algorithm (RSA).

You can apply XML encryption to an XML element, XML element content, and arbitrary data, including an XML document. For example, suppose that you need to encrypt the CreditCard element shown in the example 1.

Example 1: Sample XML document

```
<PaymentInfo xmlns='http://example.org/paymentv2'>
  <Name>John Smith</Name>
  <CreditCard Limit='5,000' Currency='USD'>
    <Number>4019 2445 0277 5567</Number>
    <Issuer>Example Bank</Issuer>
    <Expiration>04/02</Expiration>
  </CreditCard>
</PaymentInfo>
```

Example 2: XML document with a common secret key

Example 2 shows the XML document after encryption. The EncryptedData element represents the encrypted CreditCard element. The EncryptionMethod element describes the applied encryption algorithm, which is triple DES in this example. The KeyInfo element contains the information to retrieve a decryption key, which is a KeyName element in this example. The CipherValue element contains the ciphertext obtained by serializing and encrypting the CreditCard element.

```
<PaymentInfo xmlns='http://example.org/paymentv2'>
  <Name>John Smith</Name>
  <EncryptedData Type='http://www.w3.org/2001/04/xmlenc#Element'
    xmlns='http://www.w3.org/2001/04/xmlenc#'>
    <EncryptionMethod
      Algorithm='http://www.w3.org/2001/04/xmlenc#tripleDES-cbc' />
    <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
      <KeyName>John Smith</KeyName>
    </KeyInfo>
    <CipherData>
      <CipherValue>ydUNqHkMrD...</CipherValue>
    </CipherData>
  </EncryptedData>
</PaymentInfo>
```

Example 3: XML document encrypted with the public key of the recipient

In example 2, it is assumed that both the sender and recipient have a common secret key. If the recipient has a public and private key pair, which is most likely the case, the CreditCard element can be encrypted as shown in example 3. The EncryptedData element is the same as the EncryptedData element found in Example 2. However, the KeyInfo element contains an EncryptedKey .

```
<PaymentInfo xmlns='http://example.org/paymentv2'>
  <Name>John Smith</Name>
  <EncryptedData Type='http://www.w3.org/2001/04/xmlenc#Element'
    xmlns='http://www.w3.org/2001/04/xmlenc#'>
    <EncryptionMethod
      Algorithm='http://www.w3.org/2001/04/xmlenc#tripleDES-cbc' />
    <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
      <EncryptedKey xmlns='http://www.w3.org/2001/04/xmlenc#'>
        <EncryptionMethod
          Algorithm='http://www.w3.org/2001/04/xmlenc#rsa-1_5' />
        <KeyInfo xmlns='http://www.w3.org/2000/09/xmldsig#'>
          <KeyName>Sally Doe</KeyName>
        </KeyInfo>
        <CipherData>
          <CipherValue>yMTEy0TA1M...</CipherValue>
        </CipherData>
      </EncryptedKey>
    </KeyInfo>
    <CipherData>
      <CipherValue>ydUNqHkMrD...</CipherValue>
    </CipherData>
  </EncryptedData>
</PaymentInfo>
```

XML Encryption in the WSS-Core

WSS-Core specification is under development by Organization for the Advancement of Structured Information Standards (OASIS). The specification describes enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. The message confidentiality is realized by encryption based on XML Encryption.

The WSS-Core specification supports encryption of any combination of body blocks, header blocks, their sub-structures, and attachments of a SOAP message. The specification also requires that when you encrypt parts of a SOAP message, you prepend a reference from the security header block to the encrypted parts of the message. The reference can be a clue for a recipient to identify which encrypted parts of the message to decrypt.

The XML syntax of the reference varies according to what information is encrypted and how it is encrypted. For example, suppose that the CreditCard element in example 4 is encrypted with either a common secret key or the public key of the recipient.

Example 4: Sample SOAP message

```
<SOAP-ENV:Envelope
  SOAP-ENV:encodingStyle='http://schemas.xmlsoap.org/soap/encoding/'
  xmlns:SOAP-ENV='http://schemas.xmlsoap.org/soap/envelope/'>
  <SOAP-ENV:Body>
    <PaymentInfo xmlns='http://example.org/paymentv2'>
      <Name>John Smith</Name>
      <CreditCard Limit='5,000' Currency='USD'>
        <Number>4019 2445 0277 5567</Number>
        <Issuer>Example Bank</Issuer>
        <Expiration>04/02</Expiration>
      </CreditCard>
    </PaymentInfo>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

The resulting SOAP messages are shown in Examples 5 and 6. In these example, the ReferenceList and EncryptedKey elements are used as references, respectively.

Example 5: SOAP message encrypted with a common secret key

```
<SOAP-ENV:Envelope
  SOAP-ENV:encodingStyle='http://schemas.xmlsoap.org/soap/encoding/'
  xmlns:SOAP-ENV='http://schemas.xmlsoap.org/soap/envelope/'>
  <SOAP-ENV:Header>
    <Security SOAP-ENV:mustUnderstand='1'
      xmlns='http://schemas.xmlsoap.org/ws/2003/06/secext'>
      <ReferenceList xmlns='http://www.w3.org/2001/04/xmlenc#'>
        <DataReference URI='#ed1' />
      </ReferenceList>

```

Relationship to digital signature

The WSS-Core specification also provides message integrity, which is realized by a digital signature based on the XML-Signature specification.

A combination of encryption and digital signature over common data introduces cryptographic vulnerabilities.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Securing Web services for Version 5.x applications using XML encryption

XML encryption is one method that WebSphere Application Server provides to secure your Web services. It enables you to encrypt an XML element, the content of an XML element, or arbitrary data such as an XML document.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

WebSphere Application Server provides several different methods to secure your Web services. XML encryption is one of these methods. You can secure your Web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

XML encryption enables you to encrypt an XML element, the content of an XML element, or arbitrary data such as an XML document. Like XML digital signature, a message is sent by the client as the request sender to the server as the request receiver. The response is sent by the server as the response sender to the client as the request receiver. Unlike XML digital signature, which verifies the authenticity of the sender, XML encryption scrambles the message content using a key, which can be unscrambled by a receiver that possesses the same key. You can use XML encryption in conjunction with XML digital signature to scramble the content while verifying the authenticity of the message sender.

To use XML encryption to secure Web services, you must use an assembly tool. For more information, see [Assembly tools](#)

To securing Web services for Version 5.x applications using XML encryption, complete the following steps:

1. Specify the encryption settings for the request sender. The message parts and the encryption method settings chosen for the request sender on the client must match the message parts and the method settings chosen for the request receiver on the server. To specify the encryption settings for the request sender:
 - a. “Configuring the client for request encryption: Encrypting the message parts” on page 1351.
 - b. “Configuring the client for request encryption: choosing the encryption method” on page 1352.
2. Specify the encryption settings for the request receiver. The decryption settings chosen for the request receiver must match the encryption settings chosen for the request sender.
To specify the decryption settings for the request receiver:
 - a. “Configuring the server for request decryption: decrypting the message parts” on page 1355.
 - b. “Configuring the server for request decryption: choosing the decryption method” on page 1356.
3. Specify the encryption settings for the response sender. The message parts and the encryption method settings chosen for the response sender on the server must match the message parts and the method settings chosen for the response receiver on the client. To specify the encryption settings for the response sender:
 - a. “Configuring the server for response encryption: encrypting the message parts” on page 1359.
 - b. “Configuring the server for response encryption: choosing the encryption method” on page 1360.
4. Specify the encryption settings for the response receiver.

Remember: The decryption settings chosen for the response receiver must match the encryption settings chosen for the response sender.

To specify the decryption settings for the response receiver, complete the following steps:

- a. “Configuring the client for response decryption: decrypting the message parts” on page 1362.
- b. “Configuring the client for response decryption: choosing a decryption method” on page 1363.

After completing these steps, you have secured your Web services using XML encryption.

Login bindings configuration settings

Use this page to configure the encryption and decryption parameters.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

The pluggable token uses the Java Authentication and Authorization Service (JAAS) `CallbackHandler` (`javax.security.auth.callback.CallbackHandler`) interface to generate the token that is inserted into the message. The following list describes the `Callback` support implementations:

com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback

This implementation is used for generating binary tokens inserted as `<wsse:BinarySecurityToken/@ValueType>` in the message.

javax.security.auth.callback.NameCallback and javax.security.auth.callback.PasswordCallback

This implementation is used for generating user name tokens inserted as `<wsse:UsernameToken>` in the message.

com.ibm.wsspi.wssecurity.auth.callback.XMLTokenSenderCallback

This implementation is used to generate Extensible Markup Language (XML) tokens and is inserted as the `<SAML: Assertion>` element in the message.

com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback

This implementation is used to obtain properties that are specified in the binding file.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise Applications > *application_name***.

2. Under Related Items, click **Manage modules** > *URI_file_name* > **Web Services: Client security bindings**.
3. Under Request Sender Bindings, click **Edit**.
4. Under Additional properties, click **Login binding**.

If the encryption information is not available, select **None**.

If the encryption information is available, select **Dedicated login binding** and specify the configuration in the following fields:

Authentication method:

Specifies the unique name for the authentication method.

You can use any string to name the authentication method. However, the string must match the element in the server-level configuration. The following words are reserved by WebSphere Application Server:

BasicAuth

This method uses both a user name and a password.

IDAssertion

This method uses a user name, but it requires that additional trust is established by the receiving server using a trusted ID evaluator mechanism.

Signature

This method uses the distinguished name (DN) of the signer.

LTPA This method validates the token.

Callback handler:

Specifies the name of the callback handler. The callback handler must implement the `javax.security.auth.callback.CallbackHandler` interface.

Basic authentication user ID:

Specifies the user name for basic authentication. With the basic authentication method, you can define a user name and a password in the binding file.

Basic authentication password:

Specifies the password for basic authentication.

Token type URI:

Specifies the namespace Uniform Resource Identifiers (URI), which denotes the type of security token that is accepted.

The value of this field is impacted by the following conditions:

- If binary security tokens are accepted, the value denotes the `ValueType` attribute in the element. The `ValueType` element identifies the type of security token and its namespace.
- If Extensible Markup Language (XML) tokens are accepted, the value denotes the top-level element name of the XML token.
- The Token type URI field is ignored if the reserved words, which are listed in the description of the Authentication method field, are specified.

This information is inserted as `<wsse:BinarySecurityToken>/ValueType` for the `<SAML: Assertion>` XML token.

Token type local name:

Specifies the local name of the security token type. For example, X509v3.

The value of this field if is impacted by the following conditions:

- If binary security tokens are accepted, the value denotes the ValueType attribute in the element. The ValueType element identifies the type of security token and its namespace.
- If Extensible Markup Language (XML) tokens are accepted, the value denotes the top-level element name of the XML token.
- The Token type URI field is ignored if the reserved words, which are listed in the description of the Authentication method field, are specified.

This information is inserted as `<wsse:BinarySecurityToken>/ValueType` for the `<SAML: Assertion>` XML token.

Request sender

The security handler on the request sender side of the SOAP message enforces the security constraints, located in the `ibm-webservicesclient-ext.xmi` file, and bindings, located in the `ibm-webservicesclient-bnd.xmi` file. These constraints and bindings apply both to Java 2 Platform, Enterprise Edition (J2EE) application clients or when Web services is acting as a client. The security handler acts on the security constraints before sending the SOAP message. For example, the security handler might digitally sign the message, encrypt the message, create a time stamp, or insert a security token.

The security handler on the request sender side of the SOAP message enforces the security constraints, located in the `ibm-webservicesclient-ext.xmi` file, and the bindings, located in the `ibm-webservicesclient-bnd.xmi` file. These constraints and bindings apply both to J2EE application clients or when Web services is acting as a client. The security handler acts on the security constraints before sending the SOAP message. Request sender security constraints must match the security constraint requirements defined in the request receiver. For example, the security handler might digitally sign the message, encrypt the message, create a time stamp, or insert a security token. You can specify the following security requirements for the request sender and apply them to the SOAP message:

Integrity (digital signature)

You can select multiple parts of a message to sign digitally. The following list contains the integrity options:

- Body
- Time stamp
- Security token

Confidentiality (encryption)

You can select multiple parts of a message to encrypt. The following list contains the confidentiality options:

- Body content
- Username token

Security token

You can insert only one token into the message. The following list contains the security token options:

- Basic authentication, which requires both a user name and a password
- Identity assertion, which requires a user name only
- X.509 binary security token
- Lightweight Third Party Authentication (LTPA) binary security token

- Custom token , which is pluggable and supports custom-defined tokens in the SOAP message

Timestamp

You can have a time stamp to indicate the timeliness of the message.

- Timestamp

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Request sender binding collection:

Use this page to specify the binding configuration to send request messages for Web services security.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > application_name**.
2. Click **Manage modules > URI_file_name**
3. Under Web Services Security Properties, click **Web services: Client security bindings**.
4. Under Request sender binding, click **Edit**.

Web services security namespace: Specifies the namespace that is used by Web services security to send a request. However, this field configures the namespace value only and does not enforce the semantics of the specification related to the namespace. Web services security uses the processing semantic only in draft 13 of the OASIS specification. The following schemas are available:

- <http://schemas.xmlsoap.org/ws/2003/06/secext>
- <http://schemas.xmlsoap.org/ws/2002/07/secext>
- <http://schemas.xmlsoap.org/ws/2002/04/secext>
- None

The namespace used by the response sender is based on the namespace of the incoming message in the request receiver.

Signing information:

Specifies the configuration for the signing parameters. Signing information is used to sign and validate parts of the message including the body and time stamp.

You can also use these parameters for X.509 validation when the Authentication method is IDAssertion and the ID Type is X509Certificate, in the server-level configuration. In such cases, you must fill in the Certificate Path fields only.

Encryption information:

Specifies the configuration for the encrypting and decrypting parameters. Encryption information is used for encrypting and decrypting various parts of a message, including the body and user name token.

Key locators:

Specifies a list of key locator objects that retrieve the keys for digital signature and encryption from a keystore file or a repository. The key locator maps a name or a logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

Login mappings:

Specifies a list of configurations for validating tokens within incoming messages.

Login mappings map the authentication method to the Java Authentication and Authorization Service (JAAS) configuration.

To configure JAAS, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under the Java Authentication and Authorization Service field, select **Application logins** or **System logins**.

Configuring the client for request encryption: Encrypting the message parts

To configure the client for request encryption, specify which message parts to encrypt when configuring the client.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to familiarize yourself with the **WS Extensions** tab and the **WS Binding** tab in the Client Deployment Descriptor Editor within an assembly tool:

- “Configuring the client security bindings using an assembly tool” on page 1335
- “Configuring the security bindings on a server acting as a client using the administrative console” on page 1338

These two tabs are used to configure the Web services security extensions and Web services security bindings, respectively.

Complete the following steps to specify which message parts to encrypt when configuring the client for request encryption:

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > application_name > appClientModule > META-INF**.
4. Right-click the `application-client.xml` file, select **Open with > Deployment descriptor editor**.
5. Click the **WS extensions** tab, which is located at the bottom of Client Deployment Descriptor Editor within the assembly tool.
6. Expand **Request sender configuration > Confidentiality**. Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the message is encrypted before it is sent and decrypted when it is received at the correct target. For more information on encrypting, see *XML encryption*.
7. Select the parts of the message that you want to encrypt by clicking **Add**. You can select one of the following parts:

Bodycontent

User data portion of the message

Usenametoken

Basic authentication information, if selected

After you specify which message parts to encrypt, you must specify which method to use to encrypt the request message. See “Configuring the client for request encryption: choosing the encryption method” for more information.

Configuring the client for request encryption: choosing the encryption method

To configure the client for request encryption, specify which encryption method to use when configuring the client.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to familiarize yourself with the **WS Extensions** tab and the **WS Binding** tab in the Client Deployment Descriptor editor within an assembly tool:

- “Configuring the client security bindings using an assembly tool” on page 1335
- “Configuring the security bindings on a server acting as a client using the administrative console” on page 1338

These two tabs are used to configure the Web services security extensions and Web services security bindings, respectively.

Complete the following steps to specify which encryption method to use when configuring the client for request encryption:

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > application_name > appClientModule > META-INF**.
4. Right-click the application-client.xml file, select **Open with > Deployment descriptor editor**.
5. Click the WS binding tab, which is located at the bottom of the Client Deployment Descriptor editor within the assembly tool.
6. Expand **Security request sender binding configuration > Encryption information**.
7. Select an encryption option and click **Edit** to view the encryption information or click **Add** to add another option. The following table describes the purpose of this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following Web address: <http://www.w3.org/TR/xmlenc-core>

Encryption name

Refers to the name of the encryption information entry.

Data encryption method algorithm

Encrypts and decrypts data in fixed size, multiple octet blocks.

Key encryption method algorithm

Represents public key encryption algorithms that are specified for encrypting and decrypting keys.

Encryption key name

Represents a Subject (**Owner** field of the certificate) from a public key certificate found by the encryption key locator, which is used by the key encryption method algorithm to encrypt the private key. The private key is used to encrypt the data.

The key chosen must be a public key of the target. Encryption must be done using the public key and decryption must be done by the target using the private key (the personal certificate of the target).

Encryption key locator

Represents a reference to a key locator implementation class that locates the correct key store where the alias and the certificate exist. For more information on configuring key locators, see “Configuring key locators using an assembly tool” on page 1306 and “Configuring key locators using the administrative console” on page 1307.

8. **Optional:** Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the **Data Encryption method algorithm** and **Key Encryption method algorithm** drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the WebSphere administrative console.

For more information, see “Configuring key locators using an assembly tool” on page 1306 and “Configuring key locators using the administrative console” on page 1307.

You must specify which parts of the request message to encrypt. See “Configuring the client for request encryption: Encrypting the message parts” on page 1351 if you have not previously specified this information.

Request receiver

The request receiver defines the security requirement of the SOAP message. The security handler on the request receiver side of the SOAP message enforces the security specifications that are defined in the IBM extension deployment descriptor (`ibm-webservices-ext.xmi`) and bindings (`ibm-webservices-bnd.xmi`).

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

The security constraint for request sender must match the security requirement of the request receiver for the server to accept the request. If the incoming SOAP message does not meet all the security requirements defined, then the request is rejected with the appropriate fault code returned to the sender. For security tokens, the token is validated using Java Authentication and Authorization Service (JAAS) login configuration and authenticated identity is set as the identity for the downstream invocation.

For example, if there is a security requirement to have the SOAP body digitally signed by Joe Smith and if the SOAP body of the incoming SOAP message is not signed by Joe Smith, then the request is rejected.

You can define the following security requirements for the request receiver:

Required integrity (digital signature)

You can select multiple parts of a message to sign digitally. The following list contains the integrity options:

- Body
- Time stamp
- Security token

Required confidentiality (encryption)

You can select multiple parts of a message to encrypt. The following list contains the confidentiality options:

- Body content
- Token

You can have multiple security tokens. The following list contains the security token options:

- Basic authentication, which requires both a user name and a password
- Identity assertion, which requires a user name only
- X.509 binary security token
- Lightweight Third Party Authentication (LTPA) binary security token
- Custom token, which is pluggable and supports custom-defined tokens validated by the JAAS login configuration

Received time stamp

You can have a time stamp for checking the timeliness of the message.

- Time stamp

Request receiver binding collection:

Use this page to specify the binding configuration to receive request messages for Web services security.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_file_name***
3. Under Web Services Security Properties, click **Web services: Server security bindings**.
4. Under Request receiver binding, click **Edit**.

Signing information:

Specifies the configuration for the signing parameters. Signing information is used to sign and validate parts of a message including the body, the timestamp, and the user name token.

You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID Type is X509Certificate in the server-level configuration. In such cases, you must fill in the Certificate Path fields only.

Encryption information:

Specifies the configuration for the encrypting and decrypting parameters. This configuration is used to encrypt and decrypt parts of the message that include the body and the user name token.

Trust anchors:

Specifies a list of keystore objects that contain the trusted root certificates that are issued by a certificate authority (CA).

The certificate authority authenticates a user and issues a certificate. The CertPath API uses the certificate to validate the certificate chain of incoming, X.509-formatted security tokens or trusted, self-signed certificates.

Collection certificate store:

Specifies a list of the untrusted, intermediate certificate files.

The collection certificate store contains a chain of untrusted, intermediate certificates. The CertPath API attempts to validate these certificates, which are based on the trust anchor.

Key locators:

Specifies a list of key locator objects that retrieve the keys for digital signature and encryption from a keystore file or a repository. The key locator maps a name or a logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

Trusted ID evaluators:

Specifies a list of trusted ID evaluators that determine whether to trust the identity-asserting authority or message sender.

The trusted ID evaluators are used to authenticate additional identities from one server to another server. For example, a client sends the identity of user A to server 1 for authentication. Server 1 calls downstream to server 2, asserts the identity of user A, and includes the user name and password of server 1. Server 2 attempts to establish trust with server 1 by authenticating its user name and password and checking the trust based on the TrustedIDEvaluator implementation. If the authentication process and the trust check are successful, server 2 trusts that server 1 authenticated user A and a credential is created for user A on server 2 to invoke the request.

Login mappings:

Specifies a list of configurations for validating tokens within incoming messages.

Login mappings map the authentication method to the Java Authentication and Authorization Service (JAAS) configuration.

To configure JAAS, complete the following steps:

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Under the Java Authentication and Authorization Service field, select **Application logins** or **System logins**.

Configuring the server for request decryption: decrypting the message parts

Use the WS Extensions tab and the WS Binding configurations tab to specify which parts of the request message must be decrypted by the server.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Complete this task to specify which parts of the request message must be decrypted by the server. You must know which parts of the request message the client encrypts because the server must decrypt the same message parts.

Prior to completing these steps, read either of the following topics to become familiar with the WS Extensions tab and the WS Binding configurations tab:

- “Configuring the server security bindings using an assembly tool” on page 1339
- “Configuring the server security bindings using the administrative console” on page 1342

These two tabs are used to configure the Web services security extensions and Web services security bindings, respectively.

Complete the following steps to configure the request receiver extensions:

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects > application_name > ejbModule > META_INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Extensions tab, which is located at the bottom of the Web services editor within the assembly tool.
6. Expand the **Request receiver service configuration details > Required confidentiality** section.
7. Select the parts of the message to decrypt. The message parts selected for the request decryption on the server must match the message parts selected for the message encryption on the client. Click **Add** and select either of the following message parts:

bodycontent

The user data section of the message.

usnametoken

This token is the basic authentication information.

After you specify which parts of the request message to decrypt, you must specify the method to use decrypt the message. See “Configuring the server for request decryption: choosing the decryption method” for more information.

Configuring the server for request decryption: choosing the decryption method

Use the WS Extensions tab and the WS Bindings tab to configure the Web services security extensions and Web services security bindings.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the WS Extensions tab and the WS Bindings tab:

- “Configuring the server security bindings using an assembly tool” on page 1339
- “Configuring the server security bindings using the administrative console” on page 1342

These two tabs are used to configure the Web services security extensions and Web services security bindings, respectively.

Complete this task to specify which decryption method is used by the server to decrypt the request message. You must know which decryption method the client uses because the server must use the same method.

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects > application_name > ejbModule > META_INF**.
4. Right-click the `webservices.xml` file, select **Open with > Web services editor**.
5. Click the Binding Configurations tab, which is located at the bottom of the Web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details > Encryption information** section.

7. Click **Edit** to view the encryption information. The following table describes the purpose for each of these selections. Some definitions are taken from the XML-Encryption specification , which is located at the following Web address: <http://www.w3.org/TR/xmlenc-core>

Encryption name

Represents the name of this encryption information entry; an alias for the entry.

Data encryption method algorithm

Encrypts and decrypts data in fixed size, multiple octet blocks. This algorithm must be the same as the algorithm selected in the client request sender configuration.

Key encryption method algorithm

Represents algorithms specified for encrypting and decrypting keys. This algorithm must be the same as the algorithm selected in the client request sender configuration.

Encryption key name

Represents a Subject from a personal certificate, which is typically a distinguished name (DN) that is found by the encryption key locator. The subject is used by the key encryption method algorithm to decrypt the secret key, and the secret key is used to decrypt the data.

The key chosen must be a private key in the key store configured by the key locator. The key requires the same Subject used by the client to encrypt the data. Encryption must be done using the public key and decryption by using the private key (personal certificate). To ensure that the client encrypts the data with the correct public or private key, you must extract the public key from the server key store and add it to the key store specified in the encryption configuration information for the client request sender.

For example, the personal certificate of a server is CN=Bob, O=IBM, C=US. Therefore the server contains the public and private key pair. The client sending the request should encrypt the data using the public key for CN=Bob, O=IBM, C=US. The server decrypts the data using the private key for CN=Bob, O=IBM, C=US.

Encryption key locator

Represents a reference to a key locator implementation class that finds the correct keystore where the alias and the certificate exist. For more information on configuring key locators, go to the following sections: “Configuring key locators using an assembly tool” on page 1306 and “Configuring key locators using the administrative console” on page 1307.

8. **Optional:** Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Data Encryption method algorithm and Key Encryption method algorithm drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

It is important to note that for decryption, the encryption key name chosen must refer to a personal certificate that can be located by the key locator of the server referenced in the encryption information. Enter the Subject of the personal certificate here, which is typically a Distinguished Name (DN). The Subject uses the default key locator to find the key. If a custom key locator is written, the encryption key name can be anything used by the key locator to find the correct encryption key. The encryption key locator references the implementation class that finds the correct key store where this alias and certificate exist. Refer to “Configuring key locators using an assembly tool” on page 1306 and “Configuring key locators using the administrative console” on page 1307 for more information.

You must specify which parts of the request message to decrypt. See “Configuring the server for request decryption: decrypting the message parts” on page 1355 if you have not previously specified this information.

Response sender

The response sender defines the security requirements of the SOAP response message. The security handler acts on the security constraints that are defined for the response in the IBM extension deployment descriptors.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

The IBM extension deployment descriptors are located in the `ibm-webservices-ext.xmi` file and the bindings, located in the `ibm-webservices-bnd.xmi` file. The security handler signs, encrypts, or generates the time stamp for the SOAP response message before the response is send to the caller.

Integrity constraints (digital signature)

You can select which parts of the message are digitally signed.

- Body
- Time stamp

Confidentiality (encryption)

You can encrypt the body content of the message.

Time stamp

You can have a time stamp for checking the timeliness of the message.

The security constraints that apply to the SOAP response message must match the security requirements defined in the response receiver. Otherwise, the response is rejected by the response receiver (caller).

Response sender binding collection:

Use this page to specify the binding configuration for sender response messages for Web services security.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_file_name***
3. Under Web Services Security Properties, click **Web services: Server security bindings**.
4. Under Response sender binding, click **Edit**.

Signing information:

Specifies the configuration for the signing parameters.

You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID Type is X509Certificate in the server-level configuration. In such cases, you must fill-in the Certificate Path fields only.

Encryption information:

Specifies the configuration for the encryption and decryption parameters.

Key locators:

Specifies a list of key locator objects that retrieve the keys for a digital signature and encryption from a keystore file or a repository. The key locator maps a name or logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

Configuring the server for response encryption: encrypting the message parts

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the WS Extensions tab and the WS Bindings tab in the Web services editor within an assembly tool:

- “Configuring the server security bindings using an assembly tool” on page 1339
- “Configuring the server security bindings using the administrative console” on page 1342

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to specify which parts of the response message to encrypt when configuring the server for response encryption:

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects > application_name ejbModule > META_INF**.
4. Right-click the `webservices.xml` file, select **Open with > Web services editor**.
5. Click the Extensions tab, which is located at the bottom of the Web Services Editor within the assembly tool.
6. Expand **Response sender service configuration details > Confidentiality**. Confidentiality refers to encryption while integrity refers to digital signing. Confidentiality reduces the risk of someone understanding the message flowing across the Internet. With confidentiality specifications, the response is encrypted before it is sent and decrypted when it is received at the correct target. For more information on encrypting, see “XML encryption” on page 1343.
7. Select the parts of the response that you want to encrypt by clicking **Add** and selecting **Bodytoken** or **Usenametoken**. The following information describes the message parts:

Bodycontent

User data portion of the message.

Usenametoken

Basic authentication information, if selected.

A user name token does not appear in the response so you do not need to select this option for the response. If you select this option, make sure that you also select it for the client response receiver. If you do not select this option, make sure that you do not select it for the client response receiver.

After you specify which message parts to encrypt, you must specify which method to use message encryption. See “Configuring the server for response encryption: choosing the encryption method” on page 1360 for more information.

Configuring the server for response encryption: choosing the encryption method

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the Extensions tab and the Binding configurations tab in the Web services editor within an assembly tool:

- “Configuring the server security bindings using an assembly tool” on page 1339
- “Configuring the server security bindings using the administrative console” on page 1342

These two tabs are used to configure the Web services security extensions and Web services security bindings, respectively.

Complete the following steps to specify which method the server uses to encrypt the response message:

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects > *application_name* > ejbModule > META_INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Binding Configurations tab, which is located at the bottom of the Web Services Editor within the assembly tool.
6. Expand **Response sender binding configuration details > Encryption information**.
7. Click **Edit** to view the encryption information. The following table describes the purpose of this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following Web address: <http://www.w3.org/TR/xmlenc-core>

Encryption name

Refers to the name of the encryption information entry.

Data encryption method algorithm

Encrypts and decrypts data in fixed size, multiple octet blocks. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.

Key encryption method algorithm

Represents public key encryption algorithms that are specified for encrypting and decrypting keys. The algorithm selected for the server response sender configuration must match the algorithm selected in the client response receiver configuration.

Encryption key name

Represents a Subject from a public key certificate typically distinguished name (DN) that is found by the encryption key locator and used by the key encryption method algorithm to encrypt the private key. The private key is used to encrypt the data.

The key name chosen in the server response sender encryption information must be the public key of the key configured in the client response receiver encryption information. Encryption by the response sender must be done using the public key and decryption must be done by the response receiver using the associated private key (the personal certificate of the response receiver).

Encryption key locator

The encryption key locator represents a reference to a key locator implementation class that finds the correct key store where the alias and the certificate exist. For more information on configuring key locators, see “Configuring key locators using an assembly tool” on page 1306 and “Configuring key locators using the administrative console” on page 1307.

8. Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Data Encryption method algorithm and Key Encryption method algorithm drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

The encryption key name chosen must refer to a public key of the response receiver. For the encryption key name, use the Subject of the public key certificate, typically a Distinguished Name (DN). The name chosen is used by the default key locator to find the key. If you write a custom key locator, the encryption key name might be anything used by the key locator to find the correct encryption key (a public key). The encryption key locator references the implementation class that finds the correct key store where the alias and certificate exist. For more information, see “Configuring key locators using an assembly tool” on page 1306 and “Configuring key locators using the administrative console” on page 1307.

You must specify which parts of the response message to encrypt. See “Configuring the server for response encryption: encrypting the message parts” on page 1359 if you have not previously specified this information.

Response receiver

The response receiver defines the security requirements of the response received from a request to a Web service. The security constraints for response sender must match the security requirements of the response receiver. If the constraints do not match, the response is not accepted by the caller or the sender.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

The security handler enforces the security constraints based on the security requirements defined in the IBM extension deployment descriptor, located in the `ibm-webservicesclient-ext.xmi` file and in the bindings, located in the `ibm-webservicesclient-bnd.xmi` file.

For example, the security requirement might have the response SOAP body encrypted. If the SOAP body of the SOAP message is not encrypted, the response is rejected and the appropriate fault code is communicated back to the caller of the Web services.

You can specify the following security requirements for a response receiver:

Required integrity (digital signature)

You can select which parts of a message are digitally signed. The following list contains the integrity options:

- Body
- Time stamp

Required confidentiality (encryption)

You can encrypt the body content of the message.

Received time stamp

You can have a time stamp for checking the timeliness of the message.

Response receiver binding collection:

Use this page to specify the binding configuration for receiver response messages for Web services security.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

To view this administrative console page, complete the following steps:

1. Click **Applications > Enterprise applications > *application_name***.
2. Click **Manage modules > *URI_file_name* > Web Services: Client security bindings**.
3. Under Response receiver binding, click **Edit**.

Signing information:

Specifies the configuration for the signing parameters. Signing information is used to sign and to validate parts of the message including the body and the timestamp.

You can also use these parameters for X.509 validation when the authentication method is `IDAssertion` and the ID type is `X509Certificate`, in the server-level configuration. In such cases, you must fill in the certificate path fields only.

Encryption information:

Specifies the configuration for the encryption and decryption parameters.

Encryption information is used for encrypting and decrypting various parts of a message, including the body and the user name token.

Trust anchors:

Specifies a list of keystore objects that contain the trusted root certificates that are self-signed or issued by a certificate authority.

The certificate authority authenticates a user and issues a certificate. After the certificate is issued, the keystore objects, which contain these certificates, use the certificate for certificate path or certificate chain validation of incoming X.509-formatted security tokens.

Collection certificate store:

Specifies a list of the untrusted, intermediate certificate files.

The collection certificate store contains a chain of untrusted, intermediate certificates. The `CertPath` API attempts to validate these certificates, which are based on the trust anchor.

Key locators:

Specifies a list of key locator objects that retrieve the keys for a digital signature and encryption from a keystore file or a repository.

The key locator maps a name or a logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

Configuring the client for response decryption: decrypting the message parts

To configure the client for response decryption, specify which response message parts to decrypt when configuring the client. The server response encryption and client response decryption configurations must match.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Binding** tab in the Client Deployment Descriptor Editor within an assembly tool:

- “Configuring the client security bindings using an assembly tool” on page 1335
- “Configuring the security bindings on a server acting as a client using the administrative console” on page 1338

These two tabs are used to configure the Web services security extensions and the Web services security bindings, respectively.

Complete the following steps to specify which response message parts to decrypt when configuring the client for response decryption. The server response encryption and client response decryption configurations must match.

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > *application_name* > appClientModule > META-INF**.
4. Right-click the `application-client.xml` file, select **Open with > Deployment descriptor editor**.
5. Click the **WS Extensions** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Response receiver configuration > Required confidentiality** section.
7. Select the parts of the message that you must decrypt by clicking **Add** and selecting either **Bodycontent** or **Username token**. The following information describes these message parts:

Bodycontent

The user data portion of the message.

Username token

The basic authentication information, if selected.

The information selected in this step is encrypted by the server in the response sender.

Important: A username token is typically not sent in the response. Thus, you usually do not need to select username token.

After you specify which message parts to decrypt, you must specify which method to use when decrypting the response message. See “Configuring the client for response decryption: choosing a decryption method” for more information.

Configuring the client for response decryption: choosing a decryption method

To configure the client for response decryption, specify which decryption method to use when the client decrypts the response message. The server response encryption and client response decryption configurations must match.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, read either of the following topics to become familiar with the **WS Extensions** tab and the **WS Bindings** tab in the Client Deployment Descriptor Editor within an assembly tool such as the Application Server Toolkit or Rational Web Developer:

- “Configuring the client security bindings using an assembly tool” on page 1335
- “Configuring the security bindings on a server acting as a client using the administrative console” on page 1338

These two tabs are used to configure the Web services security extensions and Web services security bindings, respectively.

Complete the following steps to specify which decryption method to use when the client decrypts the response message. The server response encryption and client response decryption configurations must match.

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > application_name > appClientModule > META-INF**.
4. Right-click the `application-client.xml` file, select **Open with > Deployment descriptor editor**.
5. Click the **WS Binding** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Security response receiver binding configuration > Encryption information** section. For more information on encrypting and decrypting SOAP messages, see “XML encryption” on page 1343.
7. Click **Edit** to view the encryption information. The following table describes the purpose for this information. Some of these definitions are based on the XML-Encryption specification, which is located at the following Web address: <http://www.w3.org/TR/xmlenc-core>

Encryption name

Refers to the alias that is used for the encryption information entry.

Data encryption method algorithm

Encrypts and decrypts data in fixed size, multiple octet blocks.

Key encryption method algorithm

Represents public key encryption algorithms specified for encrypting and decrypting keys.

Encryption key name

Represents a Subject from a personal certificate, which is typically a distinguished name (DN) that is found by the encryption key locator. The Subject is used by the key encryption method algorithm to decrypt the secret key. The secret key is used to decrypt the data.

Important: The key chosen must be a private key of the client. Encryption must be done using the public key and decryption must be done by the private key (personal certificate). For example, the personal certificate of the client is: CN=Alice, O=IBM, C=US. Therefore, the client contains the public and private key pair. The target server that sends the response encrypts the secret key by using the public key for CN=Alice, O=IBM, C=US. The client decrypts the secret key by using the private key for CN=Alice, O=IBM, C=US.

Encryption key locator

Represents a reference to a key locator implementation class that finds the correct key store where the alias and the certificate exist. For more information on configuring key locators, see “Configuring key locators using an assembly tool” on page 1306 and “Configuring key locators using the administrative console” on page 1307.

8. **Optional:** Select **Show only FIPS Compliant Algorithms** if you only want the FIPS compliant algorithms to be shown in the Data Encryption method algorithm and Key Encryption method algorithm

drop-down lists. Use this option if you expect this application to be run on a WebSphere Application Server that has set the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option in the SSL certificate and key management panel of the administrative console for WebSphere Application Server.

For decryption, the encryption key name chosen must refer to a personal certificate that can be located by the client key locator. The Subject (**owner** field of the certificate) of the personal certificate should be entered in the Encryption key name, this is typically a Distinguished Name (DN). The default key locator uses the Encryption key name to find the key within the keystore. If you write a custom key locator, the encryption key name can be anything used by the key locator to find the correct encryption key. The encryption key locator references the implementation class that locates the correct key store where this alias and certificate exists. For more information, see “Configuring key locators using an assembly tool” on page 1306 and “Configuring key locators using the administrative console” on page 1307.

You must specify which parts of the request message to decrypt. See the topic “Configuring the client for response decryption: decrypting the message parts” on page 1362 if you have not previously specified this information.

Securing Web services for Version 5.x applications using basicauth authentication

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

WebSphere Application Server provides several different methods to secure your Web services. XML digital signature is one of these methods. You might also secure your Web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

With the basicauth authentication method, the request sender generates a basicauth security token using a callback handler. The request receiver retrieves the basicauth security token from the SOAP message and validates it using a Java Authentication and Authorization Service (JAAS) login module. Trust is established using user name and password validation. To use basicauth authentication to secure Web services, complete the following tasks:

1. Secure the client for basicauth authentication.
 - a. Configure the client for basicauth authentication: Specifying the method
 - b. Configure the client for basicauth authentication: Collecting the authentication information
2. Secure the server for basicauth authentication.
 - a. Configure the server to handle basicauth authentication
 - b. Configure the server to validate basicauth authentication information

After completing these steps, you have secured your Web services using basicauth authentication.

Configuring the client for basic authentication: specifying the method

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

BasicAuth refers to the user ID and password of a valid user in the registry of the target server. BasicAuth information can be collected in many ways including through an administrative console prompt, a standard in (Stdin) prompt, or specified in the bindings, which prevents user interaction. For more information on BasicAuth authentication, see: "BasicAuth authentication method."

Attention: WebSphere Application Server supports nonce (randomly generated token) with BasicAuth authentication. For more information, see Nonce.

Complete the following steps to specify BasicAuth as the authentication method:

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > application_name > appClientModule > META-INF**.
4. Right-click the application-client.xml file, select **Open with > Deployment descriptor editor**.
5. Click the WS Extensions tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration > Login configuration** section. The only valid login configuration choices for a pure client are BasicAuth and Signature.
7. Select **BasicAuth** to authenticate the client using a user ID and a password. This user ID and password must be specified in the target user registry. The other choice, Signature, attempts to authenticate the client using the certificate used to digitally sign the message.

For more information on getting started with the Web services client editor within the assembly tool, see either of the following topics:

- "Configuring the client security bindings using an assembly tool" on page 1335
- "Configuring the security bindings on a server acting as a client using the administrative console" on page 1338

After you specify the BasicAuth authentication method, you must specify how to collect the authentication information. See "Configuring the client for basic authentication: collecting the authentication information" on page 1367.

BasicAuth authentication method:

When you use the BasicAuth authentication method, the security token that is generated is a <wsse:UsernameToken> element with <wsse:Username> and <wsse:Password> elements.

WebSphere Application Server supports text passwords but not password digest because passwords are not stored and cannot be retrieved from the server. On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, a Java Authentication and Authorization Service (JAAS) login module is used to validate the security token. These two operations, token generation and token validation, are described in the following sections.

BasicAuth token generation

The request sender generates a BasicAuth security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The callback handler that is used is specified in the <LoginBinding> element of the bindings file, ibm-

webservicesclient-bnd.xmi . The following callback handler implementations are provided with WebSphere Application Server and can be used with the BasicAuth authentication method:

- com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler
- com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler
- com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

You can add your own callback handlers that implement the `javax.security.auth.callback.CallbackHandler` method.

BasicAuth token validation

The request receiver retrieves the BasicAuth security token from the SOAP message and validates it using a JAAS login module. The `<wsse:Username>` and `<wsse>Password>` elements in the security token are used to perform the validation. If the validation is successful, the login module returns a JAAS Subject. This Subject is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the `<LoginMapping>` element of the bindings file. Default bindings are specified in the `ws-security.xml` file. However, you can override these bindings using the application-specific `ibm-webservices-bnd.xmi` file. The configuration information consists of a `CallbackHandlerFactory` and a `ConfigName` value. The `CallbackHandlerFactory` option specifies the name of a class that is used for creating the JAAS `CallbackHandler` object. WebSphere Application Server provides the `com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl` `CallbackHandlerFactory` implementation. The `ConfigName` value specifies a JAAS configuration name entry. WebSphere Application Server searches the `security.xml` file for a matching configuration name entry. If a match is not found, it searches the `wsjaas.conf` file for a match. WebSphere Application Server provides the `WSLogin` default configuration entry, which is suitable for the BasicAuth authentication method.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Configuring the client for basic authentication: collecting the authentication information

The BasicAuth authentication method refers to the user ID and the password of a valid user in the registry of the target server. Collection of BasicAuth information can occur in many ways including through a user interface prompt, a standard in (Stdin) prompt, or specified in the bindings, which prevents user interaction.

Note: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

For more information on BasicAuth authentication, see “BasicAuth authentication method” on page 1366.

Complete this task to specify the authentication information needed for BasicAuth authentication:

1. Launch an assembly tool. For more information on the assembly tools, see [Assembly tools](#).
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > application_name > appClientModule > META-INF**.
4. Right-click the `application-client.xml` file, select **Open with > Deployment descriptor editor**.
5. Click the WS Binding tab, which is located at the bottom of deployment descriptor editor within the assembly tool such as the Application Server Toolkit or Rational Web Developer.

6. Expand the **Security request sender binding configuration > Login binding** section.
7. Click **Edit** or **Enable** to view the login binding information. The login binding information displays and enter the following information:

Authentication method

Specifies the type of authentication. Select **BasicAuth** to use basic authentication.

Token value type URI and Token value type local name

When you select **BasicAuth**, you cannot edit the token value type URI and the local name values. Specifies values for custom authentication types. For BasicAuth authentication, leave these values blank.

Callback handler

Specifies the Java Authentication and Authorization Server (JAAS) callback handler implementation for collecting the BasicAuth information. You can use the following default implementations for the callback handler:

com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler

This implementation is used for non-user interface console prompts.

com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler

This implementation is used for user interface panel prompts.

com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

This implementation is used when you plan to always enter the user ID and password in the BasicAuth user ID and password section that follows.

Basic Authentication user ID and Basic Authentication password

Specifies values for the BasicAuth user ID and password, regardless of the default callback handler indicated previously, these user ID and password values are used to authenticate to the server for the Web services security authentication. If you leave these values blank, use either the GUIPromptCallbackHandler or the StdinPromptCallbackHandler implementation, but only on a pure client. Always fill-in these values for any Web service that acts as a client to another Web service that you want to specify for BasicAuth for authentication downstream. If you want the client identity of the originator to flow downstream, configure the Web service client to use either ID assertion or Lightweight Third Party Authentication (LTPA).

Property

Specifies properties with name and value pairs for custom callback handlers to use. For BasicAuth authentication, you do not need to enter any information. To enter a new property, click **Add** and enter the new property and value.

Other basic authentication entries: There is a basic authentication entry in the Port Qualified Name Binding Details section. This entry is used for HTTP transport authentication, which might be required if the router servlet is protected.

Information specified in the Web services security basic authentication section overrides the basic authentication information specified in the Port Qualified Name Binding Details section for authorizing the Web service.

For a server that acts as a client, do not specify a user interface or non-user interface prompt callback handler. To configure BasicAuth authentication from one Web service to a downstream Web service, select the `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler` implementation and explicitly specify the BasicAuth user ID and password. If you want the client identity of the originator to flow downstream, configure the Web service client to use ID assertion.

To use the BasicAuth authentication method, you must specify the method in the Login configuration section of the assembly tool . See “Configuring the client for basic authentication: specifying the method” on page 1366 if you have not previously specified this information.

Identity assertion authentication method:

When using the identity assertion (IDAssertion) authentication method, the security token generated is a <wsse:UsernameToken> element that contains a <wsse:Username> element.

On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, the security token is validated. These two operations, token generation and token validation operations, are described in the following sections.

Identity assertion token validation:

The request receiver retrieves the IDAssertion security token from the SOAP message and validates it using a Java Authentication and Authorization Service (JAAS) login module. With identity assertion, special processing is required to establish trust before asserting the identity as the established identity of the running thread. This special processing is defined by the <IDAssertion> element in the deployment descriptor file, `ibm-webservices-ext.xmi`. If all the validation checks are successful, the asserted identity is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the <LoginMapping> element of the bindings file. Default bindings are specified in the `ws-security.xml` file. However, you can override these bindings using the application specific `ibm-webservices-bnd.xmi` file. The configuration information consists of `CallbackHandlerFactory` and a `ConfigName`. `CallbackHandlerFactory` specifies the name of a class that is used for creating the JAAS `CallbackHandler` object. WebSphere Application Server provides the `com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl` `CallbackHandlerFactory` implementation. `ConfigName` specifies a JAAS configuration name entry.

WebSphere Application Server searches the `security.xml` file for a matching configuration name entry. If a match is not found it searches the `wsjaas.conf` file. WebSphere Application Server provides the `system.wssecurity.IDAssertion` default configuration entry, which is suitable for the identity assertion authentication method.

The <IDAssertion> element in the `ibm-webservices-ext.xmi` deployment descriptor file specifies the special processing required when using the identity assertion authentication method. The <IDAssertion> element is composed of two sub-elements: <IDType> and <TrustMode>.

The <IDType> element specifies the method for asserting the identity. The supported values for asserting the identity are:

- Username
- Distinguished name (DN)
- X.509 certificate

When <IDType> is *username*, a username token (for example, Bob) is provided. This user name is mapped to a user in the user registry and is the asserted identity after successful trust validation. When the <IDType> value is *DN*, a user name token containing a distinguished name is provided (for example, `cn=Bob Smith, o=ibm, c=us`). This DN is mapped to a user in the user registry and this user is the asserted identity after successful trust validation. When the <IDType> is *X509Certificate*, a binary security token containing an X509 certificate is provided and the SubjectDN value from the certificate (for example, `cn=Bob Smith, o=ibm, c=us`) is extracted. This SubjectDN value is mapped to a user in the user registry and this user is the asserted identity after successful trust validation.

The <TrustMode> element specifies how the trust authority, or asserting authority, provides trust information. The supported values are:

- Signature
- BasicAuth

- No value specified

When the <TrustMode> value is `Signature` the signature is validated. Then, the signer (for example, `cn=IBM Authority, o=ibm, c=us`) is mapped to an identity in the user registry (for example, `IBMAuthority`). To ensure that the asserting authority is trusted, the mapped identity (for example, `IBMAuthority`) is validated against a list of trusted identities. When the <TrustMode> element is `BasicAuth`, there is a user name token with a user name and password, which is the user name and password of the asserting authority.

The user name and password are validated. If they are successfully validated, that user name (for example, `IBMAuthority`) is validated against a list of trusted identities. If a value is not specified for <TrustMode>, trust is presumed and additional trust validation is not performed. This type of identity assertion is called *presumed trust mode*. Use the presumed trust mode only in an environment where the trust is established using some other mechanism.

If all the validations described previously succeed, the asserted identity (for example, `Bob`) is set as the identity of the running thread. If any of the validations fail, the request is rejected with a SOAP fault exception.

Important: There is an important distinction between Version 5.x and Version 6.0.x applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x applications.

Configuring the server to handle BasicAuth authentication information

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

BasicAuth refers to the user ID and the password of a valid user in the registry of the target server. After a request is received that contains basic authentication information, the server needs to log in to form a credential. The credential is used for authorization. If the user ID and the password supplied are not valid, an exception is thrown and the request ends without invoking the resource. For more information on BasicAuth authentication, see “BasicAuth authentication method” on page 1366.

Complete the following steps to configure the server to handle BasicAuth authentication information:

1. Launch an assembly tool. For more information on the assembly tools, see [Assembly tools](#).
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects > application_name > ejbModule > META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Extensions tab, which is located at the bottom of the Web services editor within an assembly tool such as the Application Server Toolkit or Rational Web Developer.
6. Expand the **Request receiver service configuration details > Login configuration** section. You can select the following options:
 - BasicAuth
 - Signature
 - ID assertion
 - Lightweight Third Party Authentication (LTPA)

7. Select **BasicAuth** to authenticate the client with a user ID and a password. The client must specify a valid user ID and password in the server user registry.

You can select multiple login configurations, which means that different types of security information might be received at the server. The order in which the login configurations are added decides the order in which they are processed when a request is received. Problems can occur if you have multiple login configurations added that have security tokens in common. For example, ID assertion contains a BasicAuth token. For ID assertion to work properly, list ID assertion ahead of BasicAuth in the processing list or the BasicAuth processing overrides the IDAssertion processing.

After you specify how the server handles BasicAuth authentication information, you must specify how the server validates the authentication information. See “Configuring the server to validate BasicAuth authentication information” for more information.

Configuring the server to validate BasicAuth authentication information

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

BasicAuth refers to the user ID and the password of a valid user in the registry of the target server. Once a request is received that contains basic authentication information, the server needs to log in to form a credential. The credential is used for authorization. If the user ID and the password supplied is invalid, an exception is thrown and the request ends without invoking the resource. For more information on BasicAuth authentication, see “BasicAuth authentication method” on page 1366.

Complete the following steps to specify how the server validates the BasicAuth authentication information:

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects > application_name > ejbModule > META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Binding Configurations tab, which is located at the bottom of the Web services editor within an assembly tool such as the Application Server Toolkit or Rational Web Developer.
6. Expand the **Request receiver binding configuration details > Login mapping** section.
7. Click **Edit** to view the login mapping information or click **Add** to add new login mapping information. The login mapping dialog is displayed. Select or enter the following information:

Authentication method

Specifies the type of authentication that occurs. Select **BasicAuth** to use basic authentication.

Configuration name

Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the BasicAuth authentication method, enter `WSLogin` for the JAAS login Configuration name.

Use token valid type

Determines if you want to specify a custom token type. For the default authentication method selections, you do not need to specify this option.

Token value type URI and Token value type URI local name

When you select BasicAuth, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For BasicAuth authentication leave these fields blank.

Callback handler factory class name

Creates a JAAS CallbackHandler implementation that understands the following callbacks:

- javax.security.auth.callback.NameCallback
- javax.security.auth.callback.PasswordCallback
- com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback
- com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback
- com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback

Callback handler factory property name and Callback handler factory property value

Specifies callback handler properties for custom callback handler factory implementations. You do not need to specify any properties for the default callback handler factory implementation. For BasicAuth, you do not need to enter any property values.

Login mapping property name and Login mapping property value

Specifies properties for a custom login mapping. For the default implementations including BasicAuth, leave these fields blank.

You must specify how the server handles the BasicAuth authentication method. See “Configuring the server to handle BasicAuth authentication information” on page 1370 if you have not previously specified this information.

Identity assertion

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Identity assertion is a method for expressing the identity of the sender (for example, user name) in a SOAP message. When identity assertion is used as an authentication method, the authentication decision is performed based only on the name of the identity and not on other information such as passwords and certificates.

ID type

The Web Services Security implementation in WebSphere Application Server can handle these identity types:

User name

Denotes the user name, such as the one in the local operating system (for example, *alice*). This name is embedded in the <Username> element within the <UsernameToken> element.

DN

Denotes the distinguished name (DN) for the user, such as “CN=*alice*, O=*IBM*, C=*US*”. This name is embedded in the <Username> element within the <UsernameToken> element.

X.509 certificate

Represents the identity of the user as an X.509 certificate instead of a string name. This certificate is embedded in the <BinarySecurityToken> element.

Managing trust

The intermediary host in the SOAP message itinerary can assert claimed identity of the initial sender. Two methods (called *trust mode*) are supported for this assertion:

Basic authentication

The intermediary adds its user name and password pair to the message.

Signature

The intermediary digitally signs the <UsernameToken> element of the initial sender.

Note: This trust mode does not support the X.509 certificate ID type.

Typical scenario

ID assertion is typically used in the multihop environment where the SOAP message passes through one or more intermediary hosts. The intermediary host authenticates the initial sender. The following scenario describes the process:

1. The initial sender sends a SOAP message to the intermediary host with some embedded authentication information. This authentication information might be a user name and a password pair with an Lightweight Third Party Authentication (LTPA) token.
2. The intermediary host authenticates the initial sender according to the embedded authentication information.
3. The intermediary host removes the authentication information from the SOAP message and replaces it with the <UsernameToken> element, which contains a user name.
4. The intermediary host asserts the trust according to the trust mode.
5. The intermediary host sends the updated SOAP message to the ultimate receiver.
6. The ultimate receiver checks the trust against the intermediary host information according to the configured trust mode. Also, the trusted ID evaluator is invoked.
7. If trust is established by the final receiver, the receiver invokes the Web service under the authorization of the user name (that is, the initial sender) in the SOAP message.

Securing Web services for Version 5.x applications using identity assertion authentication

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

WebSphere Application Server provides several different methods to secure your Web services. XML digital signature is one of these methods. You might also secure your Web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

With the identity assertion authentication method, the security token generates a <wsee:Username Token> element that contains a <wsse:Username> element. On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, the security token is validated. Unlike basicauth authentication, trust is established through the use of a security token rather than through user name and password validation. To use identity assertion authentication to secure Web services, complete the following tasks:

1. Secure the client for identity assertion authentication.
 - a. “Configuring the client for identity assertion: specifying the method” on page 1374
 - b. “Configuring the client for identity assertion: collecting the authentication method” on page 1375
2. Secure the server for identity assertion authentication.
 - a. “Configuring the server to handle identity assertion authentication” on page 1376
 - b. “Configuring the server to validate identity assertion authentication information” on page 1377

After completing these steps, you have secured your Web services using identity assertion authentication.

Configuring the client for identity assertion: specifying the method

You can configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a Web service to a downstream Web service.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

This task is used to configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a Web service to a downstream Web service. Do not attempt to configure identity assertion from a pure client. Identity assertion works only when you configure on the client-side of a Web service acting as a client to a downstream Web service.

In order for the downstream Web service to accept the identity of the originating client (just the user name), you must supply a special trusted BasicAuth credential that the downstream Web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream Web service configuration. For more information on trusted ID evaluators, see “Trusted ID evaluator” on page 1310.

Complete the following steps to specify identity assertion as the authentication method:

1. Launch an assembly tool. For more information on the assembly tools, see [Assembly tools](#).
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > application_name > appClientModule > META-INF**.
4. Right-click the `application-client.xml` file, select **Open with > Deployment descriptor editor**.
5. Click the **WS Extension** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration > Login configuration** section.
7. Select **IDAssertion** as the authentication method. For more conceptual information on identity assertion authentication, see “Identity assertion” on page 1372.
8. Expand the IDAssertion section.
9. For the ID type, select **Username**. This value works with all registry types and originating authentication methods.
10. For the trust mode, select either **BasicAuth** or **Signature**.
 - By selecting **BasicAuth**, you must include basic authentication information (user ID and password), which the downstream Web service has specified in the trusted ID evaluator as a trusted user ID. See “Configuring the client for signature authentication: collecting the authentication information” on page 1381 to specify the user ID and password information.
 - By selecting **Signature** the certificate configured in the signature information section used to sign the data also is that is used as the trusted subject. The Signature is used to create a credential and user ID, which the certificate mapped to the downstream registry, is used in the trusted ID evaluator as a trusted user ID.

See “Configuring the client security bindings using an assembly tool” on page 1335 for more information on the Web services client editor within the assembly tool.

After you specify identity assertion as the authentication method used by the client, you must specify how to collect the authentication information. See “Configuring the client for identity assertion: collecting the authentication method” on page 1375 for more information.

Configuring the client for identity assertion: collecting the authentication method

You can configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a Web service to a downstream Web service.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

This task is used to configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a Web service to a downstream Web service. Do not attempt to configure identity assertion from a pure client. Identity assertion works only when you configure on the client-side of a Web service acting as a client to a downstream Web service.

In order for the downstream Web service to accept the identity of the originating client (just the user name), you must supply a special trusted BasicAuth credential that the downstream Web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream Web service configuration. For more information on trusted ID evaluators, see “Trusted ID evaluator” on page 1310.

Complete the following steps to specify how the client collects the authentication information:

1. Launch an assembly tool. For more information on the assembly tools, see [Assembly tools](#).
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > *application_name* > appClientModule > META-INF**.
4. Right-click the `application-client.xml` file, select **Open with > Deployment descriptor editor**.
5. Click the WS Binding tab, which is located at the bottom of the Deployment Descriptor Editor within an assembly tool.
6. Expand the **Security request sender binding configuration > Login binding** section.
7. Click **Edit** to view the login binding information and select **IDAssertion**. The login binding dialog is displayed. Select or enter the following information:

Authentication method

The authentication method specifies the type of authentication that occurs. Select **IDAssertion** to use identity assertion.

Token value type URI and Token value type Local name

When you select IDAssertion, you cannot edit the token value type Universal Resource Identifier (URI) and the local name. Specifies custom authentication types. For IDAssertion authentication, leave these values blank.

Callback handler

Specifies the Java Authentication and Authorization Service (JAAS) callback handler implementation for collecting the BasicAuth information. Specify the `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler` implementation for IDAssertion.

Basic authentication User ID and Basic authentication Password

In this field, the trust mode entered in the extensions is BasicAuth. Specifies the trusted user ID and password in these fields. The user ID specified must be an ID that is trusted by the downstream Web service. The Web service trusts the user ID if it is entered as a trusted ID in a trusted ID evaluator in the downstream Web service bindings. If the trust mode entered in the extensions is Signature, you do not need to specify any information in this field.

Property name and Property value

Specifies properties with name and value pairs, for use by custom callback handlers. For IDAssertion, you do not need to specify any information in this field.

To use the identity assertion authentication method, you must specify the method in the Security extensions section of an assembly tool. See “Configuring the client for identity assertion: specifying the method” on page 1374 if you have not previously specified this information.

Configuring the server to handle identity assertion authentication

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Use this task to configure identity assertion authentication. The purpose of identity assertion is to assert the authenticated identity of the originating client from a Web service to a downstream Web service. Do not attempt to configure identity assertion from a pure client.

For the downstream Web service to accept the identity of the originating client (user name only), you must supply a special trusted BasicAuth credential that the downstream Web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream Web service configuration. For more information on trusted ID evaluators, see “Trusted ID evaluator” on page 1310. The server side passes the special BasicAuth credential into the trusted ID evaluator, which returns `true` or `false` that this ID is trusted. Once it is trusted, the user name of the client is mapped to the credential, which is used for authorization.

Complete the following steps to configure the server to handle identity assertion authentication information:

1. Launch an assembly tool. For more information on the assembly tools, see [Assembly tools](#).
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects > *application_name* > ejbModule > META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Extensions tab, which is located at the bottom of the Web services editor within the assembly tool.
6. Expand the **Request receiver service configuration details > Login configuration** section. The options you can select are:
 - **BasicAuth**
 - **Signature**
 - **ID assertion**
 - **Lightweight Third Party Authentication (LTPA)**
7. Select **IDAssertion** to authenticate the client using the identity assertion data provided.

The user ID of the client must be in the target user registry or repository, which is configured on the **Security > Secure administration, applications, and infrastructure** panel in the administrative console for WebSphere Application Server. You can select multiple login configurations, which means that different types of security information can be received at the server. The order in which the login configurations are added determines the processing order when a request is received. Problems can occur if you have multiple login configurations added that have common security tokens. For example, ID assertion contains a BasicAuth token, which is the trusted token. For ID assertion to work properly, you must list ID assertion ahead of BasicAuth in the list or BasicAuth processing overrides ID assertion processing.
8. Expand the **IDAssertion** section and select both the **ID Type** and the **Trust Mode**.
 - a. For ID Type, the options are:
 - Username
 - Distinguished name (DN)
 - X509certificate

These choices are just preferences and are not guaranteed. Most of the time the Username option is used. You must choose the same ID Type as the client.

b. For Trust Mode, the options are:

- BasicAuth
- Signature

The Trust Mode refers to the information sent by the client as the trusted ID.

- 1) If you select **BasicAuth**, the client sends basic authentication data (user ID and password). This basicauth data is authenticated to the configured user registry. When the authentication occurs successfully, the user ID must be part of the trusted ID evaluator trust list.
- 2) If you select **Signature**, the client signing certificate is sent. This certificate must be mappable to the configured user registry. For **Local OS**, the common name (CN) of the distinguished name (DN) is mapped to a user ID in the registry. For **Lightweight Directory Access Protocol (LDAP)**, the DN is mapped to the registry for the ExactDN mode. If it is in the CertificateFilter mode, attributes are mapped accordingly. In addition, the user name from the credential generated must be in the Trusted ID Evaluator trust list.

For more information on getting started with the Web Services Editor within an assembly tool, see “Configuring the server security bindings using an assembly tool” on page 1339.

After you specify how the server handles identity assertion authentication information, you must specify how the server validates the authentication information. See “Configuring the server to validate identity assertion authentication information” for more information.

Configuring the server to validate identity assertion authentication information

The purpose of identity assertion is to assert the authenticated identity of the originating client from a Web service to a downstream Web service.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Use this task to configure identity assertion authentication. Do not attempt to configure identity assertion from a pure client.

For the downstream Web service to accept the identity of the originating client (user name only), you must supply a special trusted BasicAuth credential that the downstream Web service trusts and can authenticate successfully. You must specify the user ID of the special BasicAuth credential in a trusted ID evaluator on the downstream Web service configuration. For more information on trusted ID evaluators, see “Trusted ID evaluator” on page 1310. The server side passes the special BasicAuth credential into the trusted ID evaluator, which returns a true or false response that this ID is trusted. After it is trusted, the user name of the client is mapped to the credential, which is used for authorization.

Complete the following steps to validate the identity assertion authentication information:

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects > application_name > ejbModule > META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Binding Configurations tab, which is located at the bottom of the Web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details > Login mapping** section.

- Click **Edit** to view the login mapping information. Click **Add** to add new login mapping information. The login mapping dialog is displayed. Select or enter the following information:

Authentication method

Specifies the type of authentication that occurs. Select **IDAssertion** to use basic authentication.

Configuration name

Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the IDAssertion authentication method, enter `system.wssecurity.IDAssertion` for the Java Authentication and Authorization Service (JAAS) login configuration name.

Use token value type

Determines if you want to specify a custom token type. For the default authentication method selections, you do not need to specify this option.

Token value type URI and Token value type local name

When you select ID assertion, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For the ID assertion authentication method, leave these values blank.

Callback handler factory class name

Creates a JAAS CallbackHandler implementation that understands the following callbacks:

- `javax.security.auth.callback.NameCallback`
- `javax.security.auth.callback.PasswordCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback`

For any of the default authentication methods (BasicAuth, IDAssertion, and Signature), use the callback handler factory default implementation. Enter the following class name for any of the default Authentication methods including IDAssertion:

`com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl`

This implementation creates the correct callback handler for the default implementations.

Callback handler factory property name and Callback handler factory property value

Specifies callback handler properties for custom callback handler factory implementations. The default callback handler factory implementation does not need any specified properties. For ID assertion, leave these values blank.

Login mapping property name and Login mapping property value

Specifies properties for a custom login mapping. For the default implementations including IDAssertion, leave these values blank.

- Expand the **Trusted ID evaluator** section.
- Click **Edit** to see a dialog that displays all the trusted ID evaluator information. The following table describes the purpose of this information.

Class name

Refers to the implementation of the trusted ID evaluator that you want to use. Enter the default implementation as `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`. If you want to implement your own trusted ID evaluator, you must implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface.

Property name

Represents the name of this configuration. Enter `BasicIDEvaluator`.

Property value

Defines the name and value pairs that can be used by the trusted ID evaluator implementation. For the default implementation, the trusted list is defined here. When a

request comes in and the trusted ID is verified, the user ID, as it appears in the user registry, must be listed in this property. Specify the property as a name and value pair where the name is *trustedId_n*. *n* is an integer starting from 0 and the value is the user ID associated with that name. An example list with the trusted names include two properties.

For example: `trustedId_0 = user1`, `trustedId_1 = user2`. The previous example means that both `user1` and `user2` are trusted. `user1` and `user2` must be listed in the configured user registry

10. Expand the **Trusted ID evaluator reference** section.
11. Click **Enable** to add a new entry. The text you enter for the **Trusted ID evaluator reference** must be the same as the name entered previously in the **Trusted ID evaluator**. Make sure that the name matches exactly because the information is case sensitive. If an entry is already specified, you can change it by clicking **Edit**.

You must specify how the server handles the identity assertion authentication method. See “Configuring the server to handle identity assertion authentication” on page 1376 if you have not previously specified this information.

Securing Web services for version 5.x applications using signature authentication

WebSphere Application Server provides several different methods to secure your Web services. XML digital signature is one of these methods.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

You can secure your Web services by using any of the following methods:

- XML digital signature
- XML encryption
- BasicAuth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

With the signature authentication method, the request sender generates a signature security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The request receiver retrieves the Signature security token from the SOAP message and validates it using a Java Authentication and Authorization Service (JAAS) login module. To use signature authentication to secure Web services, complete the following tasks:

1. Secure the client for signature authentication.
 - a. “Configuring the client for signature authentication: specifying the method” on page 1380.
 - b. “Configuring the client for signature authentication: collecting the authentication information” on page 1381.
2. Secure the server for signature authentication.
 - a. “Configuring the server to support signature authentication” on page 1383.
 - b. “Configuring the server to validate signature authentication information” on page 1384.

After completing these steps, you have secured your Web services using signature authentication.

Configuring the client for signature authentication: specifying the method

Signature authentication, the use of an X.509 certificate to login on the target server, can be configured.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

This task is used to configure signature authentication. A signature refers to the use of an X.509 certificate to login on the target server. For more information on signature authentication, see “Signature authentication method.”

Complete the following steps to specify signature as the authentication method:

1. Launch an assembly tool. For more information on the assembly tools, see [Assembly tools](#).
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > application_name > appClientModule > META-INF**.
4. Right-click the `application-client.xml` file, select **Open with > Deployment descriptor editor**.
5. Click the WS Extension tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration > Login configuration** section. The following login configuration options are valid for a managed client and Web services acting as a client are:

BasicAuth

Use this option for a managed client.

Signature

Use this option for a managed client.

IDAssertion

Use this option for Web services acting as a client.

7. Select **Signature** to authenticate the client using the certificate used to digitally sign the request.

For more information on getting started with the Web services client editor within the assembly tool, see “Configuring the client security bindings using an assembly tool” on page 1335.

After you specify signature as the authentication method, you must specify how to collect the authentication information. See “Configuring the client for signature authentication: collecting the authentication information” on page 1381 for more information.

Signature authentication method:

When using the signature authentication method, the security token is generated with a `<ds:Signature>` and a `<wsse:BinarySecurityToken>` element.

On the request sender side, a callback handler is invoked to generate the security token. On the request receiver side, a Java Authentication and Authorization Service (JAAS) login module is used to validate the security token. These two operations, token generation and token validation, are described in the following sections.

Signature token generation

The request sender generates a Signature security token using a callback handler. The security token returned by the callback handler is inserted in the SOAP message. The callback handler is specified in the `<LoginBinding>` element of the bindings file, `ibm-webservicesclient-bnd.xml`. WebSphere Application Server provides the following callback handler implementation that can be

used with the Signature authentication method:
com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler

You can add your own callback handlers that implement the
javax.security.auth.callback.CallbackHandler implementation.

Security token validation

The request receiver retrieves the Signature security token from the SOAP message and validates it using a JAAS login module. The <ds:Signature> and <wsse:BinarySecurityToken> elements in the security token are used to perform the validation. If the validation is successful, the login module returns a Java Authentication and Authorization Service (JAAS) Subject. This Subject then is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault exception.

The JAAS login configuration is specified in the <LoginMapping> element of the bindings file. Default bindings are specified in the ws-security.xml file. However, you can override these bindings using the application-specific ibm-webservices-bnd.xmi file. The configuration information consists of a CallbackHandlerFactory and a ConfigName. The CallbackHandlerFactory specifies the name of a class that is used for creating the JAAS CallbackHandler object. WebSphere Application Server provides the com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImp CallbackHandlerFactory implementation. The ConfigName specifies a JAAS configuration name entry. WebSphere Application Server searches in the security.xml file for a matching configuration name entry. If a match is not found, it searches the wsjaas.conf file. WebSphere Application Server provides the system.wssecurity.Signature default configuration entry, which is suitable for the signature authentication method.

Remember: The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Configuring the client for signature authentication: collecting the authentication information

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

This task is used to configure signature authentication. A signature refers to the use of an X.509 certificate to login on the target server. For more information on signature authentication, see “Signature authentication method” on page 1380.

Complete the following steps to specify how the client collects the authentication information for signature authentication:

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > application_name > appClientModule > META-INF**.
4. Right-click the application-client.xml file, select **Open with > Deployment descriptor editor**.
5. Click the WS Binding tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Security request sender binding configuration > Signing information** and click **Edit** to modify the signing key name and signing key locator. To create new signing information, click **Enable**.

The certificate that is sent to log in at the server is the one configured in the Signing Information section. Review the section on “Key locator” on page 1303 to understand how the signing key name maps to a key within the key locator entry.

The following list describes the purpose of this information. Some of these definitions are based on the XML-Signature specification, which is located at the following Web address: <http://www.w3.org/TR/xmlsig-core>

Canonicalization method algorithm

Canonicalizes the SignedInfo element before it is digested as part of the signature operation.

Digest method algorithm

Represents the algorithm that is applied to the data after transforms are applied, if specified, to yield the <DigestValue> element. The signing of the DigestValue element binds the resource content to the signer key. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.

Signature method algorithm

Represents the algorithm that is used to convert the canonicalized <SignedInfo> value into the <SignatureValue> value. The algorithm selected for the client request sender configuration must match the algorithm selected in the server request receiver configuration.

Signing key name

Represents the key entry associated with the signing key locator. The key entry refers to an alias of the key, which is used to sign the request.

Signing key locator

Represents a reference to a key locator implementation. For more information on configuring key locators, see “Key locator” on page 1303.

7. Expand the **Security request sender binding configuration > Login binding** section.
8. Click **Edit** to view the login binding information. Then, select or enter the following information:

Authentication method

Specifies the type of authentication that occurs. Select **Signature** to use signature authentication.

Token value type URI and Token value type URI local name

When you select **Signature**, you cannot edit token value type Uniform Resource Identifier (URI) and local name values. Specifies custom authentication types. For signature authentication, leave these fields blank.

Callback handler

Specifies the Java Authentication and Authorization Server (JAAS) callback handler implementation for collecting signature information. Enter the following callback handler for signature authentication:

```
com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler
```

This callback handler is used because the signature method does not require user interaction.

Basic authentication user ID and Basic authentication password

Leave the BasicAuth fields blank when Signature authentication is used.

Property name and property value

This field enables you to enter properties and name and value pairs for use by custom callback handlers. For signature authentication, you do not need to enter any information.

Other customization entries: There is a basic authentication entry in the Port Qualified Name Binding Details section. This entry is used for HTTP transport authentication, which might be required if the router servlet is protected.

Information specified in the Web services security signature authentication section overrides the basic authentication information specified in the Port Qualified Name Binding Details section for authorizing the Web service.

To use the signature authentication method, you must specify the authentication method in the Login config section of an assembly tool. See “Configuring the client for signature authentication: specifying the method” on page 1380 if you have not previously specified this information.

Configuring the server to support signature authentication

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Use this task to configure signature authentication at the server. Signature authentication refers to an X.509 certificate sent by the client to the server. The certificate is used to authenticate to the user registry configured at the server. After a request is received by the server that contains the certificate, the server needs to log in to form a credential. The credential is used for authorization. If the certificate supplied cannot be mapped to an entry in the user registry, an exception is thrown and the request ends without invoking the resource. For more information on signature authentication, see “Signature authentication method” on page 1380.

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective by clicking **Window > Open perspective > Other > J2EE**.
3. Click **EJB Projects > application_name > ejbModule > META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Extensions tab, which is located at the bottom of the Web Services Editor within the assembly tool.
6. Expand the **Request receiver service configuration details > Login configuration** section. You can select from the following options:
 - BasicAuth
 - Signature
 - ID assertion
 - Lightweight Third Party Authentication (LTPA)
7. Select **Signature** to authenticate the client using an X509 certificate. The certificate that is sent from the client is the certificate that issued for signing the message. You must be able to map this certificate to the configured user registry. For Local operating system (OS) registries, the common name (cn) of the distinguished name (DN) is mapped to a user ID in the registry. For Lightweight Directory Access Protocol (LDAP), you can configure multiple mapping modes:
 - EXACT_DN is the default mode that directly maps the DN of the certificate to an entry in the LDAP server.
 - CERTIFICATE_FILTER is the mode that provides the LDAP advanced configuration with a place to specify a filter that maps specific attributes of the certificate to specific attributes of the LDAP server.

For more information on getting started with the Web services editor within the assembly tool, see “Configuring the server security bindings using an assembly tool” on page 1339.

After you specify how the server handles signature authentication information, you must specify how the server validates the authentication information. See “Configuring the server to validate signature authentication information” on page 1384 for more information.

Configuring the server to validate signature authentication information

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Use this task to configure signature authentication at the server. Signature authentication refers to an X.509 certificate sent by the client to the server. The certificate is used to authenticate to the user registry configured at the server. After a request is received by the server that contains the certificate, the server needs to log in to form a credential. The credential is used for authorization. If the certificate supplied cannot be mapped to an entry in the user registry, an exception is thrown and the request ends without invoking the resource. For more information on signature authentication, see “Signature authentication method” on page 1380.

Complete the following steps to configure the server to validate signature authentication:

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective by clicking **Window > Open perspective > Other > J2EE**.
3. Click **EJB Projects > application_name > ejbModule > META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Binding Configurations tab, which is located at the bottom of the Web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details > Login mapping** section.
7. Click **Edit** to view the login mapping information or click **Add** to add new login mapping information. The login mapping dialog is displayed and you select (or enter) the following information:

Authentication method

Specifies the type of authentication. Select **Signature** to use signature authentication.

Configuration name

Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the signature authentication method, enter `system.wssecurity.Signature` for the JAAS login configuration name. This specification logs in with the `com.ibm.wsspi.wssecurity.auth.module.SignatureLoginModule` JAAS login module.

Use token value type

Determines if you want to specify a custom token type. For the default authentication method selections, you can leave this field blank.

URI and local name

When you select Signature method, you cannot edit the token value type URI and local name values. Specifies custom authentication types. For signature authentication, you can leave this field blank.

Callback handler factory class name

Creates a JAAS CallbackHandler implementation that understands the following callback handlers:

- `javax.security.auth.callback.NameCallback`
- `javax.security.auth.callback.PasswordCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback`

For any of the default authentication methods (BasicAuth, IDAssertion, and Signature), use the callback handler factory default implementation. Enter the following class name for any of the default authentication methods including signature:

```
com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl
```

This implementation creates the correct callback handler for the default implementations.

Callback handler factory property name and callback handler factory property value

Specifies callback handler properties for custom callback handler factory implementations. You do not need to specify any properties for the default callback handler factory implementation. For signature, you can leave this field blank.

Login mapping property name and login mapping property value

Specifies properties for a custom login mapping to use. For the default implementations including signature, you can leave this field blank.

Specify how the server handles the signature authentication method. See “Configuring the server to support signature authentication” on page 1383 if you have not previously specified this information.

Overview of token types

Web services security defines two types of security tokens. The deployment descriptor extension file defines the types of tokens that the message can accept.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.1x and later applications.

The two types of security tokens that are defined by Web services security are:

- User name token
- Binary security token

A user name token consists of a user name and, optionally, password information. You can include a user name token directly in the <Security> header within the message. Binary tokens, such as X.509 certificates, Kerberos tickets, Lightweight Third Party Authentication (LTPA) tokens, or other non-XML formats, require a special encoding for inclusion. The Web services security specification describes how to encode binary security tokens such as X.509 certificates and Kerberos tickets, and it also describes how to include opaque encrypted keys. The specification also includes extensibility mechanisms that you can use to further describe the characteristics of the credentials that are included with a message.

WebSphere Application Server Version 5.0.2 supports user name tokens, which include both user name and password for basic authentication and user name, which is used for identity assertion. The WebSphere Application Server Version 5.0.2 binary security token implementation supports both X.509 certificates and LTPA binary security. You extend the implementation to generate other types of tokens. However, Kerberos tickets are not supported in WebSphere Application Server Version 5.0.2. Each type of token is processed by a corresponding token generation and validation module. The binary token generation and validation modules are pluggable that is based on the Java Authentication and Authorization Service (JAAS) framework. For example, an arbitrary XML-based token format is supported using the JAAS pluggable framework. WebSphere Application Server Version 5.0.2 does not support an XML-based token that is used in the SecurityTokenReference.

You can define the types of tokens that the message can accept in the deployment descriptor extension file, `ibm.webservices-ext.xml`. A message receiver might support one or more types of security tokens. The following example shows that the receiver supports four types of security tokens:

Important: In the following code sample, several lines were split into multiple lines due to the width of the printed page. See the close bracket for an indication of where each line of code ends.

```
?xml version="1.0" encoding="UTF-8"?>
<com.ibm.etools.webservice.wsext:WsExtension xmi:version="2.0"
xmlns:xmi="http://www.omg.org/XMI"
xmlns:com.ibm.etools.webservice.wsext=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsext.xmi"
xmi:id="WsExtension_1052760331306" routerModuleName="StockQuote.war">
  <wsDescExt xmi:id="WsDescExt_1052760331306" wsDescNameLink="StockQuoteFetcher">
    <pcBinding xmi:id="PcBinding_1052760331326" pcNameLink="urn:xmltoday-delayed-quotes"
scope="Session">
      <serverServiceConfig
xmi:id="ServerServiceConfig_1052760331326" actorURI="myActorURI">
        <securityRequestReceiverServiceConfig
xmi:id="SecurityRequestReceiverServiceConfig_1052760331326">
          <loginConfig xmi:id="LoginConfig_1052760331326">
            <authMethods xmi:id="AuthMethod_1052760331326" text="BasicAuth"/>
            <authMethods xmi:id="AuthMethod_1052760331327" text="IDAssertion"/>
            <authMethods xmi:id="AuthMethod_1052760331336" text="Signature"/>
            <authMethods xmi:id="AuthMethod_1052760331337" text="LTPA"/>
          </loginConfig>
        </idAssertion xmi:id="IDAssertion_1052760331336" idType="Username" trustMode="Signature"/>
      </serverServiceConfig>
    </pcBinding>
  </wsDescExt>
</com.ibm.etools.webservice.wsext:WsExtension>
```

The message sender might choose one of the token types that are supported by the receiver when sending a message. You can define the type of token to be used by the sending side in the client descriptor extension file, `ibm-webservicesclient-ext.xmi`. The following example shows that the sender chooses to send a `UsernameToken` to the receiver:

Important: In the following code sample, several lines were split into multiple lines due to the width of the printed page. See the close bracket for an indication of where each line of code ends.

```
<?xml version="1.0" encoding="UTF-8"?>
<com.ibm.etools.webservice.wsext:WsClientExtension xmi:version="2.0"
xmlns:xmi="http://www.omg.org/XMI"
xmlns:com.ibm.etools.webservice.wsext=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsext.xmi"
xmi:id="WsClientExtension_1052760331496">
  <ServiceRefs xmi:id="ServiceRef_1052760331506" serviceRefLink="service/StockQuoteService">
    <portQnameBindings xmi:id="PortQnameBinding_1052760331506"
portQnameLocalNameLink="StockQuote">
      <clientServiceConfig xmi:id="ClientServiceConfig_1052760331506"
actorURI="myActorURI">
        <securityRequestSenderServiceConfig
xmi:id="SecurityRequestSenderServiceConfig_1052760331506" actor="myActorURI">
          <loginConfig xmi:id="LoginConfig_1052760331506" authMethod="BasicAuth"/>
        </securityRequestSenderServiceConfig>
      </clientServiceConfig>
    </portQnameBindings>
  </ServiceRefs>
</com.ibm.etools.webservice.wsext:WsClientExtension>
```

User name token element

You can use the `UsernameToken` element to propagate a user name and, optionally, password information. Also, you can use this token type to carry basic authentication information. Both a user name and a password are used to authenticate the message. A `UsernameToken` element that contains the user name is used in identity assertion. Identity assertion establishes the identity of the user based on the trust relationship.

The following example shows the syntax of the `UsernameToken` element:

```
<UsernameToken Id="...">
  <Username>...</Username>
  <Password Type="...">...</Password>
</UsernameToken>
```

The Web services security specification defines the following password types:

wsse:PasswordText (default)

This type is the actual password for the user name.

wsse:PasswordDigest

The type is the digest of the password for the user name. The value is a base64-encoded SHA1 hash value of the UTF8-encoded password.

WebSphere Application Server supports the default PasswordText type. However, it does not support password digest because most user registry security policies do not expose the password to the application software.

The following example illustrates the use of the UsernameToken element:

```
<S:Envelope xmlns:S="http://www.w3.org/2001/12/soap-envelope"
  xmlns:wsse="http://schemas.xmlsoap.org/ws/2002/04/secext">
  <S:Header>
    ...
    <wsse:Security>
      <wsse:UsernameToken>
        <wsse:Username>Joe</wsse:Username>
        <wsse:Password>ILoveJava</wsse:Password>
      </wsse:UsernameToken>
    </wsse:Security>
  </S:Header>
</S:Envelope>
```

Remember: The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Nonce, a randomly generated token:

Nonce is a randomly generated, cryptographic token used to prevent the theft of user name tokens used with SOAP messages. Nonce is used with the basicauth authentication method.

Without nonce, when a user name token is passed from one machine to another machine using a non-secure transport, such as HTTP, the token might be intercepted and used in a replay attack. The same key might be reused when the username token is transmitted between the client and the server, which leaves it vulnerable to attack. The user name token can be stolen even if you use XML digital signature and XML encryption.

To help eliminate these replay attacks, the <wsse:Nonce> and <wsu:Created> elements are generated within the <wsse: usernameToken> element and used to validate the message. The request receiver or response receiver checks the freshness of the message to verify the difference between when the message is created and the current time falls within a specified time period. Also, WebSphere Application Server verifies that the receiver has not processed the token within the specified time period. These two features are used to lessen the chance that a user name token is used for a replay attack.

Configuring nonce for the application level:

You can configure nonce for the application level using the WebSphere Application Server administrative console.

Important: The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Nonce is a randomly generated, cryptographic token used to thwart the hijacking of username tokens used with SOAP messages. Nonce is used in conjunction with the BasicAuth authentication method.

However, you must consider the order of precedence:

1. Application level
2. Server level

If you configure nonce on the application level and the server level, the values specified for the application level take precedence over the values specified for the server level.

1. Connect to the administrative console.
Type `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.
2. Click **Applications > Enterprise applications > application_name**.
3. Under Manage modules, click *URI_name*.
4. Under Web Services Security Properties, click **Web services: Server security bindings**.
5. Click **Edit** under Request receiver binding
6. Under Additional properties, click **Login mappings > New**.
7. Specify (optional) a value, in seconds, for the **Nonce maximum age** field. This panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt to specify values for this field, the following error message displays and you must remove the specified value:

Nonce is not supported for authentication methods other than BasicAuth.

If you specify BasicAuth, but do not specify values for the Nonce maximum age field, the Web services security run time searches for a Nonce Maximum Age value on the server level. If a value is not found on the server level, the run time searches the cell level. If a value is not found on either the server level or the cell level, the default is 300 seconds.

The value specified for the Nonce Maximum Age field indicates how long the nonce is valid. You must specify a minimum of 300 seconds, but the value cannot exceed the number of seconds specified for the Nonce Cache Timeout field for the server level.

You can specify the Nonce Cache Timeout value for the server level by completing the following steps:

- a. Click **Servers > Application servers > server_name**.
- b. Under Security, click **Web Services: Default bindings for Web services security**.

You can specify the Nonce Cache Timeout value for the cell level by clicking **Security > Web services**.

8. Specify (optional) a value, in seconds, for the Nonce clock skew field. The value specified for the Nonce Clock Skew field specifies the amount of time, in seconds, to consider when the message receiver checks the timeliness of the value. This panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt to specify values for this field, the following error message displays and you must remove the specified value:

Nonce is not supported for authentication methods other than BasicAuth.

If you specify BasicAuth, but do not specify values for the Nonce clock skew field, the Web services security run time searches for a Nonce clock skew value on the server level. If a value is not found on the server level, the run time searches the cell level. If a value is not found on either the server level or the cell level, the default is 0 seconds.

Consider the following information when you set this value:

- Difference in time between the message sender and the message receiver if the clocks are not synchronized.
- Time needed to encrypt and transmit the message.

- Time needed to get through network congestion.
9. Restart the server.

Configuring nonce for the server level:

Important: The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Nonce is a randomly generated, cryptographic token used to prevent the theft of username tokens used with Simple Object Access Protocol (SOAP) messages. Nonce is used in conjunction with the BasicAuth authentication method.

This task provides instructions on how to configure nonce for the server level using the WebSphere Application Server administrative console.

However, you must consider the order of precedence:

1. Application level
2. Server level

If you configure nonce on the application level and the server level, the values specified for the application level take precedence over the values specified for the server level.

In a WebSphere Application Server or WebSphere Application Server Express environment, you must specify values for the Nonce cache timeout, Nonce maximum age, and Nonce clock skew fields on the server level to use nonce effectively.

Complete the following steps to configure nonce on the server level:

1. Click **Servers > Application servers > *server_level***.
2. Under Security, click **Web Services: Default bindings for Web services security**.
3. Specify a value, in seconds, for the Nonce cache timeout field. The value specified for the Nonce cache timeout field indicates how long the nonce remains cached before it is expunged. You must specify a minimum of 300 seconds. However, if you do not specify a value, the default is 600 seconds. This field is required for the server level.
4. Specify (optional) a value, in seconds, for the Nonce maximum age field.
The value specified for the Nonce Maximum Age field indicates how long the nonce is valid. You must specify a minimum of 300 seconds, but the value cannot exceed the number of seconds specified for the Nonce cache timeout field on the server level.
5. Specify a value, in seconds, for the Nonce clock skew field. The value specified for the Nonce clock skew field specifies the amount of time, in seconds, to consider when the message receiver checks the timeliness of the value. Consider the following information when you set this value:
 - Difference in time between the message sender and the message receiver if the clocks are not synchronized.
 - Time needed to encrypt and transmit the message.
 - Time needed to get through network congestion.

You must specify at least 0 seconds for the Nonce clock skew field. However, the maximum value cannot exceed the number of seconds specified in the Nonce maximum age field on the server level. If you do not specify a value, the default is 0 seconds.

6. Restart the server. If you change the Nonce cache timeout value and do not restart the server, the change is not recognized by the server.

Configuring nonce for the cell level:

You can configure nonce for the cell level using the WebSphere Application Server administrative console.

Important: The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Nonce is a randomly generated, cryptographic token used to thwart the highjacking of username tokens used with SOAP messages. Nonce is used in conjunction with the BasicAuth authentication method.

You can configure nonce at the application level, the server level, and cell level. However, you must consider the order of precedence. The following list shows the order of precedence:

1. Application level
2. Server level

If you configure nonce on the application level and the server level, the values specified for the application level take precedence over the values specified for the server level. Likewise, the values specified for the application level take precedence over the values specified for the server level and the cell level. In WebSphere Application Server Network Deployment, the Nonce cache timeout, Nonce maximum age, and Nonce clock skew fields are required to use nonce effectively. However, these fields are optional on the server level. Complete the following steps to configure nonce on the cell level:

1. Connect to the administrative console.
Type `http://server_name:port_number/ibm/console` in your Web browser unless you have changed the port number.
2. Click **Servers > Application servers > server_name**.
3. Under Security, click **Web Services: Default bindings for Web services security**.
4. Specify a value, in seconds, for the Nonce cache timeout field. The value specified for the Nonce cache timeout field indicates how long the nonce remains cached before it is expunged. You must specify a minimum of 300 seconds. However, if you do not specify a value, the default is 600 seconds. This field is optional on the server level, but required on the cell level.
5. Specify a value, in seconds, for the Nonce maximum age field. The value specified for the Nonce maximum age field indicates how long the nonce is valid. You must specify a minimum of 300 seconds, but the value cannot exceed the number of seconds specified for the Nonce cache timeout field in the previous step. If you do not specify a value, the default is 600 seconds. In a Network Deployment environment or on the z/OS platform, if you specify a value on the server level for the Nonce cache timeout field, the value cannot exceed the value specified for on the cell level for the Nonce cache timeout field. This field is optional on the server level, but required on the cell level.
6. Specify a value, in seconds, for the Nonce clock skew field. The value specified for the Nonce clock skew field specifies the amount of time, in seconds, to consider when the message receiver checks the freshness of the value. Consider the following information when you set this value:
 - Difference in time between the message sender and the message receiver if the clocks are not synchronized.
 - Time needed to encrypt and transmit the message.
 - Time needed to get through network congestion.

At a minimum, you must specify 0 seconds in this field. However, the maximum value cannot exceed the number of seconds indicated in the Nonce maximum age field. If you do not specify a value, the default is 0 seconds. This field is optional on the server level, but required on the cell level.

7. Restart the server. If you change the Nonce cache timeout value and do not restart the server, the change is not recognized by the server.

Binary security token

The Value Type attribute identifies the type of the security token, for example, a Lightweight Third Party Authentication (LTPA) token. The Encoding Type indicates how the security token is encoded, for example,

Base64Binary. The BinarySecurityToken element defines a security token that is binary encoded. The encoding is specified using the EncodingType attribute. The value type and space are specified using the ValueType attribute. The Web services security implementation for WebSphere Application Server, Version 5.0.2 supports both LTPA and X.509 certificate binary security tokens.

A binary security token has the following attributes that are used for interpretation:

- Value type
- Encoding type

The following example depicts an LTPA binary security token in a Web services security message header:

```
<wsse:BinarySecurityToken xmlns:ns7902342339871340177="
    "http://www.ibm.com/websphere/appserver/tokentype/5.0.2"
    EncodingType="wsse:Base64Binary"
    ValueType="ns7902342339871340177:LTPA">
    MIZ6LGPt2CzXBQfio9wZTo1VotWov0NW3Za6lU5K7Li78DSnIK6iHj3hxXgrUn6p4wZI
    8Xg26havepvmSJ8XxiACMihTJuh1t3ufsrjbfFQJ0qh5VcRvI+AKEaNmnEgEV65jUYAC9
    C/iwBBWk5U/6DIk7LfXcTT0ZPAD+3D3nCS0f+6tnqMou8EG9mtMeTKccz/pJVTZjaRSo
    msu0sewsOKf1/WPsjW0bR/2g3NaVvBy18V1TFBpUbGFVGgZHRjBKAGo+ctk180n1VLIk
    TUjt/XdYvEp0r6QoddGi4okjDGPpyoDxcvKZnReXww5Usoq1pfXwN4KG9as=
</wsse:BinarySecurityToken></wsse:Security></soapenv:Header>
```

As shown in the example, the token is Base64Binary encoded.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

XML token

XML tokens are offered in two formats, Security Assertion Markup Language (SAML) and Extensible rights Markup Language (XrML).

XML-based security tokens are growing in popularity. Two well-known formats are:

- Security Assertion Markup Language (SAML)
- Extensible rights Markup Language (XrML)

Using textensibility of the <wsse:Security> header in XML-based security tokens, you can directly insert these security tokens into the header.

SAML assertions are attached to Web services security messages using Web services by placing assertion elements inside the <wsse:Security> header. The following example illustrates a Web services security message with a SAML assertion token.

```
<S:Envelope xmlns:S="...">&
  <wsse:Security xmlns:wsse="...">
    <saml:Assertion
      MajorVersion="1"
      MinorVersion="0"
      AssertionID="SecurityToken-ef375268"
      Issuer="elliottw1"
      IssueInstant="2002-07-23T11:32:05.6228146-07:00"
      xmlns:saml="urn:oasis:names:tc:SAML:1.0:assertion">
      ...
    </saml:Assertion>
  </wsse:Security>
</S:Header>
<S:Body>
  ...
</S:Body>
</S:Envelope>
```

For more information on SAML and XrML, see [Web services: Resources for learning](#).

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Security token

A security token represents a set of claims made by a client that might include a name, password, identity, key, certificate, group, privilege, and so on.

Web services security provides a general-purpose mechanism to associate security tokens with messages for single message authentication. A specific type of security token is not required by Web services security. Web services security is designed to be extensible and support multiple security token formats to accommodate a variety of authentication mechanisms. For example, a client might provide proof of identity and proof of a particular business certification.

A security token is embedded in the SOAP message within the SOAP header. The security token within the SOAP header is propagated from the message sender to the intended message receiver. On the receiving side, the WebSphere Application Server security handler authenticates the security token and sets up the caller identity on the running thread.

Remember: The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Securing Web services for version 5.x applications using a pluggable token

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

WebSphere Application Server provides several different methods to secure your Web services; a pluggable token is one of these methods. You might secure your Web services using any of the following methods:

- XML digital signature
- XML encryption
- Basicauth authentication
- Identity assertion authentication
- Signature authentication
- Pluggable token

Complete the following steps to secure your Web services using a pluggable token:

1. Generate a security token using the Java Authentication and Authorization Service (JAAS) CallbackHandler interface. The Web services security run time uses the JAAS CallbackHandler interface as a plug-in to generate security tokens on the client side or when Web services is acting as a client.
2. Configure your pluggable token. To use pluggable tokens to secure your Web services, you must configure both the client request sender and the server request receiver. You can configure your pluggable tokens using either the WebSphere Application Server administrative console or the Application Server Toolkit. For more information, see the following topics:

- “Configuring pluggable tokens using an assembly tool”
- “Configuring pluggable tokens using the administrative console” on page 1395

Configuring pluggable tokens using an assembly tool

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

This document describes how to configure a pluggable token in the request sender (`ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` file) and request receiver (`ibm-webservices-ext.xmi` and `ibm-webservices-bnd.xmi` file).

The pluggable token is required for the request sender and request receiver because they are a pair. The request sender and the request receiver must match for the receiver to accept a request.

Prior to completing these steps, it is assumed that you have already created a Web service that is based on the Java 2 Platform, Enterprise Edition (J2EE) specification. If not, see *Developing Web services applications* to create a Web service that is based on the J2EE specification. See either of the following topics for an introduction of how to manage Web services security binding information for the server:

- “Configuring the server security bindings using an assembly tool” on page 1339
- “Configuring the server security bindings using the administrative console” on page 1342

You must specify the security constraints in the `ibm-webservicesclient-ext.xmi` and the `ibm-webservices-ext.xmi` files for the required tokens using an assembly tool such as the Application Server Toolkit or Rational Web Developer.

Complete the following steps to configure the request sender using the `ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` files:

1. Launch an assembly tool. For more information on the assembly tools, see *Assembly tools*.
2. Switch to the J2EE perspective. Click **Window > Open Perspective > J2EE**.
3. Click **Application Client Projects > *application_name* > appClientModule > META-INF**.
4. Right-click the `application-client.xml` file, select **Open with > Deployment descriptor editor**.
5. Click the WS Extension tab. The Web service client security extensions editor is displayed.
 - a. Under Service References, select an existing service reference or click **Add** to create a new reference.
 - b. Under Port QName Bindings, select an existing port qualified name for the selected service reference or click **Add** to create a new port name binding.
 - c. Under Request Sender Configuration: Login Configuration, select an exiting authentication method or type in a new one in the editable list box (Lightweight Third Party Authorization (LTPA) is a supported token generation when Web services is acting as client).
 - d. Click **File > Save** to save the changes.
6. Click the Web services client binding tab. The Web services client binding editor is displayed.
 - a. Under Port qualified name binding, select an existing entry or click **Add** to add a new port name binding. The Web services client binding editor displays for the selected port.
 - b. Under Login binding, click **Edit** or **Enable**. The Login Binding dialog box is displayed.
 - 1) In the Authentication Method field, enter the authentication method. The authentication method that you enter in this field must match the authentication method defined on the Security Extension tab for the same Web service port. This field is mandatory.
 - 2) (Optional) Enter the token value type information in the URI and Local name fields. These fields are ignored for the BasicAuth, Signature, and IDAssertion authentication methods, but

required for other authentication methods. The token value type information is inserted into the <wsse:BinarySecurityToken>@ValueType element for binary security token and is used as the namespace for the XML-based token.

- 3) Enter an implementation of the Java Authentication and Authorization Service (JAAS) javax.security.auth.callback.CallbackHandler interface. This field is mandatory.
- 4) Enter the basic authentication information in the User ID and Password fields. The basic authentication information is passed to the construct of the CallbackHandler implementation. The use of the basic authentication information depends on the implementation of CallbackHandler.
- 5) In the Property field, add name and value pairs. These pairs are passed to the construct of the CallbackHandler implementation as java.util.Map values.
- 6) Click **OK**.

Click **Disable** under Login binding on the Web services client port binding tab to remove the authentication method login binding.

- c. Click **File > Save** to save the changes.
7. In the Package Explorer window, right-click the webservices.xml file and click **Open with > Web services editor**. The Web Services window displays.
 - a. Click the Security extensions tab. The Web service security extensions editor is displayed.
 - 1) Under Web Service Description Extension, select an existing service reference or click **Add** to create a new extension.
 - 2) Under Port Component Binding, select an existing port qualified name for the selected service reference or click **Add** to create a new one.
 - 3) Under Request Receiver Service Configuration Details: Login Configuration, select an exiting authentication method or click **Add** and enter a new method in the Add AuthMethod field that displays. You can select multiple authentication methods for the request receiver. The security token of the incoming message is authenticated against the authentication methods in the order that they are specified in the list. Click **Remove** to remove the selected authentication method or methods.
 - b. Click **File > Save** to save the changes.
 - c. Click the Bindings tab. The Web services bindings editor is displayed.
 - 1) Under Web service description bindings, select an existing entry or click **Add** to add a new Web services descriptor.
 - 2) Click the Binding configurations tab. The Web services binding configurations editor is displayed for the selected Web services descriptor.
 - 3) Under Request receiver binding configuration details: login mapping, click **Add** to create a new login mapping or click **Edit** to edit the selected login mapping. The Login mapping dialog is displayed.
 - a) In the Authentication method field, enter the authentication method. The information entered in this field must match the authentication method defined on the Security Extensions tab for the same Web service port. This field is mandatory.
 - b) In the Configuration name field, enter a JAAS login configuration name. This is a mandatory field. You must define the JAAS login configuration name in the WebSphere Application Server administrative console under **Security > Secure administration, applications, and infrastructure**. Under Authentication, click **Java Authentication and Authorization Service > Application logins**. For more information, see “Configuring programmatic logins for Java Authentication and Authorization Service” on page 567.
 - c) (Optional) Select **Use Token value type** and enter the token value type information in the URI and Local name fields. This information is optional for BasicAuth, Signature and IDAssertion authentication methods, but required for any other authentication method. The token value type is used to validate the <wsse:BinarySecurityToken>@ValueType element for binary security tokens and to validate the namespace of the XML-based token.

- d) Under Callback Handler Factory, enter an implementation of the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` interface in the Class name field. This field is mandatory.
 - e) Under Callback Handler Factory property, click **Add** and enter the name and value pairs for the Callback Handler Factory Property. These name and value pairs are passed as `java.util.Map` to the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory.init()` method. The use of these name and value pairs is determined by the `CallbackHandlerFactory` implementation.
 - f) Under Login Mapping Property, click **Add** and enter the name and value pairs for the Login mapping property. These name and value pairs are available to the JAAS Login Modules through the `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback` JAAS Callback interface. Click **Remove** to delete the selected login mapping.
 - g) Click **OK**.
- d. Click **File > Save** to save the changes.

The previous steps define how to configure the request sender to create security tokens in the Simple Object Access Protocol (SOAP) message and to configure the request receiver to validate the security tokens found in the incoming SOAP message. WebSphere Application Server supports pluggable security tokens.

You can use the authentication method defined in the login bindings and login mappings to generate security tokens in the request sender and validate security tokens in the request receiver.

After you configure pluggable tokens, you must configure both the client and the server to support pluggable tokens. See the following topics to configure the client and the server:

- Configuring the client for LTPA token authentication: Specifying LTPA token authentication
- Configuring the client for LTPA token authentication: Collecting the authentication information
- Configuring the server to handle LTPA token authentication
- Configuring the server to validate LTPA token authentication information

Configuring pluggable tokens using the administrative console

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Prior to completing these steps, it is assumed that you have already created a Web service that is based on the Java 2 Platform, Enterprise Edition (J2EE) specification. If not, see *Developing Web services applications to create Web services that is based on the J2EE specification*. See either of the following topics for an introduction of how to manage Web services security binding information for the server:

- “Configuring the server security bindings using an assembly tool” on page 1339
- “Configuring the server security bindings using the administrative console” on page 1342

This document describes how to configure a pluggable token in the request sender (`ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` file) and request receiver (`ibm-webservices-ext.xmi` and `ibm-webservices-bnd.xmi` file).

Important: The pluggable token is required for the request sender and request receiver as they are a pair. The request sender and the request receiver must match for a request to be accepted by the receiver.

Prior to completing these steps, it is assumed that you deployed a Web services-enabled enterprise application to the WebSphere Application Server.

Use the following steps to configure the client-side request sender (`ibm-webservicesclient-bnd.xmi` file) or server-side request receiver (`ibm-webservices-bnd.xmi` file) using the WebSphere Application Server administrative console.

1. Click **Applications > Enterprise applications > *enterprise_application***.
2. Under Manage modules, click *URI_name*. The *URI* is the Web services-enabled module.
 - a. Under Web Services Security Properties, click **Web services: client security bindings** to edit the response sender binding information, if Web services is acting as client.
 - 1) Under Response sender binding, click **Edit**.
 - 2) Under Additional Properties, click **Login binding**.
 - 3) Select **Dedicated login binding** to define a new login binding.
 - a) Enter the authentication method, this must match the authentication method defined in IBM extension deployment descriptor. The authentication method must be unique in the binding file.
 - b) Enter an implementation of the JAAS `javax.security.auth.callback.CallbackHandler` interface.
 - c) Enter the basic authentication information (User ID and Password) and the basic authentication information is passed to the construct of the `CallbackHandler` implementation. The usage of the basic authentication information is up to the implementation of the `CallbackHandler`.
 - d) Enter the token value type, it is optional for `BasicAuth`, `Signature` and `IDAssertion` authentication methods but required for any other authentication method. The token value type is inserted into the `<wsse:BinarySecurityToken>@ValueType` for binary security token and used as the namespace of the XML based token.
 - e) Click **Properties**. Define the property with name and value pairs. These pairs are passed to the construct of the `CallbackHandler` implementation as `java.util.Map`.

Select **None** to deselect the login binding.

- b. Under Web Services Security Properties, click **Web services: server security bindings** to edit the request receiver binding information.
 - 1) Under Request Receiver Binding, click **Edit**.
 - 2) Under Additional Properties, click **Login mappings**.
 - 3) Click **New** to create new login mapping.
 - a) Enter the authentication method, this must match the authentication method defined in the IBM extension deployment descriptor. The authentication method must be unique in the login mapping collection of the binding file.
 - b) Enter a JAAS Login Configuration name. The JAAS Login Configuration must be defined under **Security > Global security**. Under Authentication, click **JAAS Configuration > Application Logins**. For more information, see “Configuring programmatic logins for Java Authentication and Authorization Service” on page 567.
 - c) Enter an implementation of the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` interface. This is a mandatory field.
 - d) Enter the token value type, it is optional for `BasicAuth`, `Signature` and `IDAssertion` authentication methods but required for any other authentication method. The token value type is used to validate against the `<wsse:BinarySecurityToken>@ValueType` for binary security token and against the namespace of the XML based token.
 - e) Enter the name and value pairs for the “Login Mapping Property” by clicking **Properties**. These name and value pairs are available to the JAAS Login Module or Modules by `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback` JAAS Callback. **Note:** This is true when editing existing login mappings but not when creating new login mappings.

- f) Enter the name and value pairs for the "Callback Handler Factory Property", these name and value pairs is passed as `java.util.Map` to the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory.init()` method. The usage of these name and value pairs is up to the `CallbackHandlerFactory` implementation.
 - c. Click authentication method link to edit the selected login mapping.
 - d. Click **Remove** to remove the selected login mapping or mappings.
3. Click **Save** .

The previous steps define how to configure the request sender to create security tokens in the Simple Object Access Protocol (SOAP) message and the request receiver to validate the security tokens found in the incoming SOAP message. WebSphere Application Server supports pluggable security tokens.

You can use the authentication method defined in the login bindings and login mappings to generate security tokens in the request sender and validate security tokens in the request receiver.

Once you have configured pluggable tokens, you must configure both the client and the server to support pluggable tokens. See the following topics to configure the client and the server:

- "Configuring the client for LTPA token authentication: specifying LTPA token authentication" on page 1398
- "Configuring the client for LTPA token authentication: collecting the authentication method information" on page 1399
- "Configuring the server to handle LTPA token authentication information" on page 1400
- "Configuring the server to validate LTPA token authentication information" on page 1401

Pluggable token support

Important: There is an important distinction between Version 5.x and Version 6.0.x applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x applications.

You can extend the WebSphere Application Server login mapping mechanism to handle new types of authentication tokens. WebSphere Application Server provides a pluggable framework to generate security tokens on the sender-side of the message and to validate the security token on the receiver-side of the message. The framework is based on the Java Authentication and Authorization Service (JAAS) Application Programming Interfaces (APIs). Pluggable security token support provides plug-in points to support customer security token types including token generation, token validation, and client identity mapping to a WebSphere Application Server identity that is used by the Java 2 Platform, Enterprise Edition (J2EE) authorization engine. Moreover, the pluggable token generation and validation framework supports XML-based tokens to be inserted into the Web service message header and validated on the receiver-side validation.

Use the `javax.security.auth.callback.CallbackHandler` implementation to create a new type of security token following these guidelines:

- Use a constructor that takes a user name (a string or null, if not defined), a password (a `char[]` or null, if not defined) and `java.util.Map` (empty, if properties are not defined).
- Use `handle()` methods that can process the following implementations:
 - `javax.security.auth.callback.NameCallback`
 - `javax.security.auth.callback.PasswordCallback`
 - `com.ibm.wsspi.wssecurity.auth.callback.XMLTokenCallback`
 - `com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl`

If:

1. Either the `javax.security.auth.callback.NameCallback` or the `javax.security.auth.callback.PasswordCallback` implementation is populated with data, then a `<wsse:UsernameToken>` element is created.
2. `com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl` is populated, the `<wsse:BinarySecurityToken>` element is created from the `com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl` implementation.
3. `com.ibm.wsspi.wssecurity.auth.callback.XMLTokenCallback` is populated, a XML-based token is created based on the Document Object Model (DOM) element that is returned from the `XMLTokenCallback`.

Encode the token byte by using the security handler and not by using the `javax.security.auth.callback.CallbackHandler` implementation.

You can implement the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` interface, which is a factory for instantiating the `javax.security.auth.callback.CallbackHandler` implementation. For your own implementation, you must provide the `javax.security.auth.callback.CallbackHandler` interface. The Web service security run time instantiates the factory implementation class and passes the authentication information from the Web services message header to the factory class through the setter methods. The Web services security run time then invokes the `newCallbackHandler()` method of the factory implementation class to obtain an instance of the `javax.security.auth.CallbackHandler` object. The object is passed to the JAAS login configuration.

The following is an example the definition of the `CallbackHandlerFactory` interface:

```
public interface com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory {
    public void setUsername(String username);
    public void setRealm(String realm);
    public void setPassword(String password);
    public void setHashMap(Map properties);
    public void setTokenByte(byte[] token);
    public void setXMLToken(Element xmlToken);
    public CallbackHandler newCallbackHandler();
}
```

Configuring the client for LTPA token authentication: specifying LTPA token authentication

To configure Lightweight Third-Party Authentication (LTPA) token authentication, specify LTPA token authentication. Only configure the client for LTPA token authentication if the authentication mechanism configured in WebSphere Application Server is LTPA.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Use this task to configure Lightweight Third-Party Authentication (LTPA) token authentication. Only configure the client for LTPA token authentication if the authentication mechanism configured in WebSphere Application Server is LTPA. When a client authenticates to a WebSphere Application Server, the credential created contains an LTPA token. When a Web service calls a downstream Web service, you can configure the first Web service to send the LTPA token from the originating client. Do not attempt to configure LTPA from a pure client. LTPA works only when you configure the client-side of a Web service acting as a client to a downstream Web service. For the downstream Web service to validate the LTPA token, the LTPA keys on both servers must be the same.

Complete the following steps to specify LTPA token as the authentication method:

1. Launch an assembly tool. For more information on the assembly tools, see [Assembly tools](#).
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.

3. Click **Application Client Projects** > *application_name* > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **Extensions** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Request sender configuration** > **Login configuration** section.
7. Select **LTPA** as the authentication method. For more conceptual information on LTPA authentication, see “Lightweight Third Party Authentication” on page 1402.

After you specify LTPA token as the authentication method, you must specify how to collect the LTPA token information. See “Configuring the client for LTPA token authentication: collecting the authentication method information” for more information.

Configuring the client for LTPA token authentication: collecting the authentication method information

To configure Lightweight Third-Party Authentication (LTPA) token authentication, collect the LTPA token authentication information. Do not configure the client for LTPA token authentication unless the authentication mechanism configured in WebSphere Application Server is LTPA.

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

Use this task to configure Lightweight Third-Party Authentication (LTPA) token authentication. Do not configure the client for LTPA token authentication unless the authentication mechanism configured in WebSphere Application Server is LTPA. When a client authenticates to a WebSphere Application Server, the credential created contains an LTPA token. When a Web service calls a downstream Web service, you can configure the first Web service to send the LTPA token from the originating client. Do not attempt to configure LTPA from a pure client. LTPA works only when you configure the client-side of a Web service acting as a client to a downstream Web service. In order for the downstream Web service to validate the LTPA token, the LTPA keys on both servers must be the same.

Complete the following steps to specify how to collect the LTPA token authentication information:

1. Launch an assembly tool. For more information on the assembly tools, see Assembly tools.
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window** > **Open Perspective** > **J2EE**.
3. Click **Application Client Projects** > *application_name* > **appClientModule** > **META-INF**.
4. Right-click the `application-client.xml` file, select **Open with** > **Deployment descriptor editor**.
5. Click the **WS Bindings** tab, which is located at the bottom of the deployment descriptor editor within the assembly tool.
6. Expand the **Security request sender binding configuration** > **Login binding** section.
7. Click **Edit** to view the login binding information and select **LTPA**. If LTPA is not already there, enter it as an option. The login binding dialog is displayed. Select or enter the following information:

Authentication method

Specifies the type of authentication that occurs. Select **LTPA** to use identity assertion.

Token value type URI and token value type local name

When you select **LTPA**, you must edit the token value type **URI** (Uniform Resource Identifier) and the **local name** fields. Specifies values for custom authentication types, which are authentication methods not mentioned in the specification. For the token value type **URI** field, enter the following string: `http://www.ibm.com/websphere/appserver/tokentype/5.0.2`. For the **local name** field, enter the following string: `LTPA`.

Callback handler

Specifies the Java Authentication and Authorization Service (JAAS) callback handler implementation for collecting the LTPA information. Specify the `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler` implementation for LTPA.

Basic authentication user ID and basic authentication password

For LTPA, you can leave these fields empty. However, when you omit this information, the LTPA CallbackHandler implementation attempts to obtain the LTPA token from the invocation (RunAs) credential. If an invocation (RunAs) credential does not exist, then the LTPA token is not propagated.

Property name and property value

For LTPA, you can leave these fields blank.

See “Configuring the client for LTPA token authentication: specifying LTPA token authentication” on page 1398 if you have not previously specified this information.

Configuring the server to handle LTPA token authentication information

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

This task is used to configure Lightweight Third-Party Authentication (LTPA). LTPA is a type of authentication mechanism in WebSphere Application Server security that defines a particular token format. The purpose of the LTPA token authentication is to flow the LTPA token from the first Web service, which authenticated the originating client, to the downstream Web service. Do not attempt to configure LTPA from a pure client. Once the downstream Web service receives the LTPA token, it validates the token to verify that the token has not been modified and has not expired. For validation to be successful, the LTPA keys used by both the sending and receiving servers must be the same.

Complete the following steps to specify that LTPA is authentication method. The authentication method indicated in these steps must match the authentication method specified for the client.

1. Launch an assembly tool. For more information on the assembly tools, see [Assembly tools](#).
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects > *application_name* > ejbModule > META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Extensions tab, which is located at the bottom of the Web services editor within the assembly tool.
6. Expand the **Request receiver service configuration details > Login configuration** section. You can select from the following options:
 - BasicAuth
 - Signature
 - ID assertion
 - LTPA
7. Select **LTPA** to authenticate the client using the LTPA token received from the request.

After you specify the authentication method, you must specify the information that the server must validate. See “Configuring the server to validate LTPA token authentication information” on page 1401 for more information.

Configuring the server to validate LTPA token authentication information

Important: There is an important distinction between Version 5.x and Version 6 and later applications. The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6.0.x and later applications.

This task is used to configure Lightweight Third-Party Authentication (LTPA). LTPA is a type of authentication mechanism in WebSphere Application Server security that defines a particular token format. The purpose of the LTPA token authentication is to flow the LTPA token from the first Web service, which authenticated the originating client, to the downstream Web service. Do not attempt to configure LTPA from a pure client. Once the downstream Web service receives the LTPA token, it validates the token to verify that the token has not been modified and has not expired. For validation to be successful, the LTPA keys used by both the sending and receiving servers must be the same.

Complete the following steps to specify how the server must validate the LTPA token authentication information:

1. Launch an assembly tool. For more information on the assembly tools, see [Assembly tools](#).
2. Switch to the Java 2 Platform, Enterprise Edition (J2EE) perspective. Click **Window > Open Perspective > J2EE**.
3. Click **EJB Projects > *application_name* > ejbModule > META-INF**.
4. Right-click the `webservices.xml` file, and click **Open with > Web services editor**.
5. Click the Binding Configurations tab, which is located at the bottom of the Web services editor within the assembly tool.
6. Expand the **Request receiver binding configuration details > Login mapping** section.
7. Click **Edit** to view the login mapping information. The login mapping information is displayed. Select or enter the following information:

Authentication method

Specifies the type of authentication that occurs. Select **LTPA** to use LTPA token authentication.

Configuration name

Specifies the Java Authentication and Authorization Service (JAAS) login configuration name. For the LTPA authentication method, enter `WSLogin` for the JAAS login configuration name. This configuration understands how to validate an LTPA token.

Use token value type

Determines if you want to specify a custom token type. For LTPA authentication, you must select this option because LTPA is considered a custom type. LTPA is not in the Web Services Security Specification.

Token value type URI and local name

Specifies custom authentication types. If you select **Use Token value type** you must enter data into the Token value Type URI (Uniform Resource Identifier) and local name fields. For the token value type URI field, enter the following string: `http://www.ibm.com/websphere/appserver/tokentype/5.0.2`. For the local name, enter the following string: `LTPA`

Callback handler factory class name

Creates a JAAS CallbackHandler implementation that understands the following callback handlers:

- `javax.security.auth.callback.NameCallback`
- `javax.security.auth.callback.PasswordCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.XMLTokenReceiverCallback`
- `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback`

For any of the default authentication methods (BasicAuth, IDAssertion, Signature, and LTPA), use the callback handler factory default implementation. Enter the following class name for any of the default authentication methods including LTPA:

```
com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl
```

This implementation creates the correct callback handler for the default implementations.

Callback handler factory property

Specifies callback handler properties for custom callback handler factory implementations. Default callback handler factory implementation does not any property specifications. For LTPA, you can leave this field blank.

Login mapping property

Specifies properties for a custom login mapping. For default implementations including LTPA, you can leave this field blank.

See “Configuring the server to handle LTPA token authentication information” on page 1400 if you have not previously specified this information.

Lightweight Third Party Authentication:

When you use the lightweight third party authentication (LTPA) method, the <wsse:BinarySecurityToken> security token is generated. On the request sender side, the security token is generated by invoking a callback handler. On the request receiver side, the security token is validated by a Java Authentication and Authorization Service (JAAS) login module.

The following information describes token generation and token validation operations.

LTPA token generation

The request sender uses a callback handler to generate an LTPA security token. The callback handler returns a security token that is inserted in the SOAP message. Specify the appropriate callback handler in the <LoginBinding> element of the bindings file (`ibm-webservicesclient-bnd.xmi`). The following callback handler implementation can be used with the LTPA authentication method:

- `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`

You can add your own callback handlers that implement the `javax.security.auth.callback.CallbackHandler` property.

When using the LTPA authentication method (or any authentication method other than BasicAuth, Signature or IDAssertion), the `TokenType` attribute of the <LoginBinding> element in the bindings file (`ibm-webservicesclient-bnd.xmi`) must be specified. The values to use for the LTPA `TokenType` attribute are:

- `uri="http://www.ibm.com/websphere/appserver/tokentype/5.0.2"`
- `localName="LTPA"`

LTPA token validation

The request receiver retrieves the LTPA security token from the SOAP message and validates the message using a JAAS login module. The <wsse:BinarySecurityToken> security token is used to perform the validation. If the validation is successful, the login module returns a JAAS Subject. Subsequently, this Subject is set as the identity of the running thread. If the validation fails, the request is rejected with a SOAP fault.

The appropriate JAAS login configuration to use is specified in the bindings file <LoginMapping> element. Default bindings specified in the `ws-security.xml` file, but these can be overridden using the application-specific `ibm-webservices-bnd.xmi` file. The configuration information consists of a `CallbackHandlerFactory`, a `ConfigName` and a `TokenType` attribute. The `CallbackHandlerFactory` specifies the name of a class to use to create the JAAS `CallbackHandler` object. A `CallbackHandlerFactory` implementation is provided

(com.ibm.wsspi.wssecurity.auth.callback.WSCallbackHandlerFactoryImpl). The ConfigName attribute specifies a JAAS configuration name entry. The Web services security run time first searches the security.xml file for a matching entry and if a matching entry is not found, the run time searches the wsjaas.conf file. A default configuration entry suitable for the LTPA authentication method is provided (WSLogin). An appropriate TokenValueType element is located in the LTPA LoginMapping section of the default ws-security.xml file.

Remember: The information in this article supports Version 5.x applications only that are used with WebSphere Application Server Version 6.0.x and later. The information does not apply to Version 6 and later applications.

Tuning Web services security for Version 5.x applications

The Java Cryptography Extension (JCE) policy is integrated into the software development kit (SDK) Version 1.4.x and is no longer an optional package. However, due to export and import regulations, the default JCE jurisdiction policy file shipped with the SDK enables you to use strong, but limited, cryptography only. To enforce this default policy, WebSphere Application Server uses a JCE jurisdiction policy file that might introduce a performance impact. The default JCE jurisdiction policy might have a performance impact on the cryptographic functions that are supported by Web services security. If you have Web services applications that use transport level security for XML encryption or digital signatures, you might encounter performance degradation over previous releases of WebSphere Application Server. However, IBM and Sun Microsystems provide versions of these jurisdiction policy files that do not have restrictions on cryptographic strengths. If you are permitted by your governmental import and export regulations, download one of these jurisdiction policy files. After downloading one of these files, the performance of JCE and Web Services security might improve.

For WebSphere Application Server platforms using IBM Developer Kit, Java Technology Edition Version 1.4.2, including the AIX, Linux, and Windows platforms, you can obtain unlimited jurisdiction policy files by completing the following steps:

1. Go to the following Web site: <http://www.ibm.com/developerworks/java/jdk/security/index.html>
2. Click **Java 1.4.2**
3. Click **IBM SDK Policy files**.
The Unrestricted JCE Policy files for SDK 1.4 Web site is displayed.
4. Enter your user ID and password or register with IBM to download the policy files. The policy files are downloaded onto your machine.

For WebSphere Application Server platforms using the Sun-based Java Development Kit (JDK) Version 1.4.2, including the Solaris environments and the HP-UX platform, you can obtain unlimited jurisdiction policy files by completing the following steps:

1. Go to the following Web site: <http://java.sun.com/j2se/1.4.2/download.html>
2. Click **Other Downloads**.
3. Locate the JCE Unlimited Strength Jurisdiction Policy Files 1.4.2 information and click **Download**. The policy files are downloaded onto your machine.

After following either of these sets of steps, two Java Archive (JAR) files are placed in the JVM `jre/lib/security/` directory.

Enabling security for WSIF

Here are the steps to be taken to enable the Web Services Invocation Framework (WSIF) to interact with a security manager.

WSIF interacts with a security manager in the following ways:

- WSIF runs in the Java 2 platform, Enterprise Edition (J2EE) security context without modification.

- When WSIF is run under a J2EE container, port implementations can use the security context to pass on security tokens or credentials as necessary.
- WSIF implementations can automatically convert J2EE security context into appropriate context for onward services.

For WSIF to interact effectively with the WebSphere Application Server security manager, complete the following step:

To load the WSDL file, enable the **FilePermission** attribute in the `was.policy` file. This permission is required when a WSDL file is referred to using the `file://` protocol.

Security API for the UDDI Version 3 registry

In UDDI Version 1 and Version 2 the security API was part of the Publish API. In UDDI Version 3 the security API is independent.

Use the UDDI Version 3 Client for Java (see UDDI Version 3 Client) to access programmatically all API calls and arguments supported by the UDDI Version 3 registry. You can also access the API functions graphically by using the UDDI user interface, however not all of the functions are available with this method.

The UDDI Version 3 registry supports the following Security API calls:

discard_authToken

Used to inform a node that a previously obtained authentication token is no longer required and should be considered invalid if used after this message is received. The token is to be discarded and the session is effectively ended.

get_authToken

Used to request an authentication token in the form of an `authInfo` element from a UDDI node.

For full details of the syntax of the above queries, refer to the UDDI Version 3 API specification at http://www.uddi.org/pubs/uddi_v3.htm.

Chapter 17. Data access resources

Security of lookups with component managed authentication

External Java clients (stand alone clients or servers from other cells) with Java Naming and Directory Interface (JNDI) access can look up a Java 2 Connector (J2C) resource such as a data source or Java Message Service (JMS) queue. However, they are not permitted to take advantage of the component managed *authentication alias* defined on the resource. This alias is a default value used when the *user* and *password* are not supplied on the `getConnection()` call. Therefore, if an external client needs to get a connection, it must assume responsibility for the authentication by passing it through arguments on the `getConnection()` call.

Any client running in the WebSphere Application Server process (such as a Servlet or an enterprise bean) within the same cell that can look up a resource in the JNDI namespace can obtain connections without explicitly providing authentication data on the `getConnection()` call. In this case, if the component's `res-auth` setting is **Application**, authentication is taken from the component-managed authentication alias defined on the connection factory. With `res-auth` set to **Container**, authentication is taken from the login configuration defined on the component's resource-reference. It is important to note that J2C authentication alias is per **cell**. An enterprise bean or Servlet in one application server cannot look up a resource in another server process which is in a different cell, because the alias would not be resolved.

Chapter 18. Messaging resources

Configuring authorization security for a Version 5 default messaging provider

Use this task to configure authorization security for the default messaging provider on a WebSphere Application Server version 5 node in a deployment manager cell.

To configure authorization security for the version 5 default messaging provider complete the following steps.

Note: Security for the version 5 default messaging provider is enabled when you enable global security for WebSphere Application Server on the version 5 node. For more information about enabling global security, see [Enabling security for all application servers](#).

1. Configure authorization settings to access JMS resources owned by the embedded WebSphere JMS provider.

Authorization to access JMS resources owned by the embedded messaging subsystem is controlled by settings in the `app_server_root\config\cells\your_cell_name\integral-jms-authorizations.xml` file. The settings grant or deny authenticated users access to messaging resources (queues or topics). As supplied, the `integral-jms-authorisations.xml` file grants the following permissions:

- Read and write permissions to all queues.
- Pub, sub, and persist to all topics.

To configure authorization settings, edit the `integral-jms-authorisations.xml` file according to the information in this topic and in that file. Please note the file is in Unicode, which requires a binary FTP to the host from a workstation.

2. Edit the `queue-admin-userids` element to create a list of userids with administrative access to all queues. Administrative access is needed to create queues and perform other administrative activities on queues. For example, consider the following `queue-admin-userids` section:

```
<queue-admin-userids>
  <userid>adminid1</userid>
  <userid>adminid2</userid>
</queue-admin-userids>
```

In this example the userids `adminid1` and `adminid2` are defined to have administrative access to all queues.

3. Edit the `queue-default-permissions` element to define the default queue access permissions. These permissions are used for queues for which you do not define specific permissions (in queue sections). If this section is not specified, then access permissions exist only for those queues for which you have specifically created queue elements.

For example, consider the following `queue-default-permissions` element:

```
<queue-default-permissions>
  <permission>write</permission>
</queue-default-permissions>
```

In this example the default access permission for all queues is **write**. This can be overridden for a specific queue by creating a queue element that sets its access permission to **read**.

4. If you want to define specific access permissions for a queue, create a queue element, then define the following elements:

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
  </public>
  <authorize>
    <userid>useridr</userid>
```

```

    <permission>read</permission>
  </authorize>
</authorize>
  <userid>useridw</userid>
  <permission>write</permission>
</authorize>
</authorize>
  <userid>useridrw</userid>
  <permission>read</permission>
  <permission>write</permission>
</authorize>
</queue>

```

In this example for the queue q1, the userid useridr has read permission, the userid useridw has write permission, the userid useridrw has both read and write permissions, and all other userids have no access permissions (<public></public>).

5. Edit topic elements to define the access permissions for publish/subscribe topic destinations.

For topics, you can grant and deny access permissions. Full permission inheritance is supported on topics. If you do not define specific access permissions for a userid on a specific topic then permissions are inherited first from the public permissions on that topic then from the parent topic. The inheritance of access permissions continues until the root topic from which the root permissions are assumed.

- a. If you want to define default access permissions for the root topic, edit a topic element with an empty name element. If you omit such a topic section, topics have no default topic permissions other than those defined by specific topic elements. For example, consider the following topic element for the root topic:

```

<topic>
  <name></name>
  <public>
    <permission>+pub</permission>
  </public>
</topic>

```

In this example, the default access permission for all topics is set to publish. This can be overridden by other topic elements for specific topic names.

- b. If you want to define access permissions for a specific topic, create a topic element with the name for the topic then define the access permissions in the public and authorize elements of the topic element. For example, consider the following topic section:

```

<topic>
  <name>a/b/c</name>
  <public>
    <permission>+sub</permission>
  </public>
  <authorize>
    <userid>useridpub</userid>
    <permission>+pub</permission>
  </authorize>
</topic>

```

In this example, the subscribe permission is granted to anyone accessing any topic whose name starts with a/b/c. Also, the userid useridpub is granted publish permission for any topic whose name starts with a/b/c.

6. Save the integral-jms-authorizations.xml file.

If the dynamic update setting is selected, changes to the integral-jms-authorizations.xml file become active when the changed file is saved, so there is no need to stop and restarted the JMS server. If the dynamic update setting is not selected, you need to stop and restart the JMS server to make changes active.

Authorization settings for Version 5 default JMS resources

Use the `integral-jms-authorisations.xml` file to view or change the authorization settings for Java Message Service (JMS) resources owned by the default messaging provider on WebSphere Application Server version 5 nodes.

Authorization to access default JMS resources owned by the default messaging provider on WebSphere Application Server nodes is controlled by the following settings in the `was_install\config\cells\your_cell_name\integral-jms-authorisations.xml` file.

This structure of the settings in `integral-jms-authorisations.xml` is shown in the following example. Descriptions of these settings are provided after the example. To configure authorization settings, follow the instructions provided in [Configuring authorization security for the Version 5 JMS providers](#)

```
<integral-jms-authorizations>

  <dynamic-update>true</dynamic-update>

  <queue-admin-userids>
    <userid>adminid1</userid>
    <userid>adminid2</userid>
  </queue-admin-userids>

  <queue-default-permissions>
    <permission>write</permission>
  </queue-default-permissions>

  <queue>
    <name>q1</name>
    <public>
    </public>
    <authorize>
      <userid>useridr</userid>
      <permission>read</permission>
    </authorize>
    <authorize>
      <userid>useridw</userid>
      <permission>write</permission>
    </authorize>
  </queue>

  <queue>
    <name>q2</name>
    <public>
      <permission>write</permission>
    </public>
    <authorize>
      <userid>useridr</userid>
      <permission>read</permission>
    </authorize>
  </queue>

  <topic>
    <name></name>
    <public>
      <permission>+pub</permission>
    </public>
  </topic>

  <topic>
    <name>a/b/c</name>
    <public>
      <permission>+sub</permission>
    </public>
    <authorize>
      <userid>useridpub</userid>
```

```
    <permission>+pub</permission>
  </authorize>
</topic>
```

```
</integral-jms-authorizations>
```

dynamic-update

Controls whether or not the JMS Server checks dynamically for updates to this file.

true (Default) Enables dynamic update support.

false Disables dynamic update checking and improves authorization performance.

queue-admin-userids

This element lists those userids with administrative access to all Version 5 default queue destinations. Administrative access is needed to create queues and perform other administrative activities on queues. You define each userid within a separate userid sub element:

```
<userid>adminid</userid>
```

Where *adminid* is a user ID that can be authenticated by IBM WebSphere Application Server.

queue-default-permissions

This element defines the default queue access permissions that are assumed if no permissions are specified for a specific queue name. These permissions are used for queues for which you do not define specific permissions (in queue elements). If this element is not specified, then no access permissions exist unless explicitly authorized for individual queues.

You define the default permission within a separate permission sub element:

```
<permission>read-write</permission>
```

Where *read-write* is one of the following keywords:

read By default, userids have read access to Version 5 default queue destinations.

write By default, userids have write access to Version 5 default queue destinations.

queue

This element contains the following authorization settings for a single queue destination:

name The name of the queue.

public The default public access permissions for the queue. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the queue.

You define each default permission within a separate permission element.

authorize

The access permissions for a specific userid. Within each authorize element, you define the following elements:

userid The userid that you want to assign a specific access permission.

permission

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain the keyword read or write to define the access permission.

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
</public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
```

```

</authorize>
<authorize>
  <userid>useridrw</userid>
  <permission>read</permission>
  <permission>write</permission>
</authorize>
</queue>

```

topic

This element contains the following authorization settings for a single topic destination:

Each topic element has the following sub elements:

name The name of the topic, without wildcards or other substitution characters.

public The default public access permissions for the topic. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the topic.

You define each default permission within a separate permission element.

authorize

The access permissions for a specific userid. Within each authorize element, you define the following elements:

userid The userid that you want to assign a specific access permission.

permission

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain one of the following keywords to define the access permission:

+pub Grant publish permission

+sub Grant subscribe permission

+persist

Grant persist permission

-pub Deny publish permission

-sub Deny subscribe permission

-persist

Deny persist permission

Securing WebSphere MQ messaging directories and log files

Use this task to restrict access to the /var/mqm directories and log files needed for WebSphere MQ as a JMS provider.

Note: The /var file system is used to store all the security logging information for the system, and is used to store the temporary files for email and printing. Therefore, it is critical that you maintain free space in /var for these operations and prevent unauthorized access to the file system. If you do not create a separate file system for messaging data, and /var fills up, all security logging will be stopped on the system until some free space is available in /var. Also, email and printing will no longer be possible until some free space is available in /var.

This procedure involves steps that you complete at different stages of installing and using IBM WebSphere Application Server, as described below. The steps are also described at appropriate points in other tasks, but are collected here for completeness.

1. Before installing WebSphere MQ, create and mount a file system called /var/mqm. This means that other system activity is not affected if a large amount of messaging work builds up in /var/mqm.
2. Install WebSphere MQ as a messaging provider.

As part of this stage, the installation program creates the /var/mqm/errors directory used to hold messaging logging files as well as the directories used to hold the messaging data. During the installation process these directories are secured with a default set of security attributes to prevent

unauthorised access. If you change these permissions you should ensure that the permissions specified give WebSphere MQ messaging the required access.

Configuring security for EJB 2.1 message-driven beans

Use this task to configure resource security and security permissions for Enterprise JavaBeans (EJB) Version 2.1 message-driven beans.

The association between connection factories, destinations, and message-driven beans is provided by listener ports. A listener port allows a deployed message-driven bean associated with the port to retrieve messages from the associated destination. You create listener ports by specifying their administrative name, the connection factory JNDI name, and the destination name (other optional properties are also configurable). Listener ports provide simplified administration of the associations between connection factories, destinations and message-driven beans, and are managed by a listener manager. The listener manager is provided by the message listener service to control and monitor the JMS listeners that are monitoring JMS destinations on behalf of deployed message-driven beans. For more information about listener ports, see [Message-driven beans - listener port components](#)

Messages handled by message-driven beans have no client credentials associated with them. The messages are anonymous.

To call secure enterprise beans from a message-driven bean, the message-driven bean needs to be configured with a RunAs Identity deployment descriptor. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component.

For more information about EJB security, see [EJB component security](#). For more information about configuring security for your application, see [Assembling secured applications](#).

Connections used by message-driven beans can benefit from the added security of using J2C container-managed authentication. To enable the use of J2C container authentication aliases and mapping, define an authentication alias on the J2C activation specification that the message-driven bean is configured with. If defined, the message-driven bean uses the authentication alias for its JMSConnection security credentials instead of any application-managed alias.

To set the authentication alias, you can use the administrative console to complete the following steps. This task description assumes that you have already created an activation specification. If you want to create a new activation specification, see the related tasks.

- For a message-driven bean listening on a JMS destination of the default messaging provider, set the authentication alias on a JMS activation specification.
 1. To display the JMS activation specification settings, click **Resources** → **JMS Providers** → **Default messaging** → **[Activation Specifications] JMS activation specification**
 2. If you have already created a JMS activation specification, click its name in the list displayed. Otherwise, click **New** to create a new JMS activation specification.
 3. Set the **Authentication alias** property.
 4. Click **OK**
 5. Save your changes to the master configuration.
- For a message-driven bean listening on a destination (or endpoint) of another JCA provider, set the authentication alias on a J2C activation specification.
 1. To display the J2C activation specification settings, click **Resources** → **Resource Adapters** → **adapter_name** → **J2C Activation specifications** → **activation_specification_name**
 2. Set the **Authentication alias** property.
 3. Click **OK**
 4. Save your changes to the master configuration.

Chapter 19. Mail, URLs, and other J2EE resources

JavaMail security permissions best practices

In many of its activities, the JavaMail API needs to access certain configuration files. The JavaMail and JavaBeans Activation Framework binary packages themselves already contain the necessary configuration files. However, the JavaMail API allows the user to define user-specific and installation-specific configuration files to meet special requirements.

The two locations where such configuration files can exist are `<user.home>` and `<java.home>/lib`. For example, if the JavaMail API needs to access a file named `mailcap` when sending a message, it first tries to access `<user.home>/mailcap`. If that attempt fails, either due to lack of security permission or a nonexistent file, the API continues to try `<java.home>/lib/mailcap`. If that attempts also fails, it tries `META-INF/mailcap` in the class path, which actually leads to the configuration files contained in the `mail-impl.jar` and `activation-impl.jar` files. WebSphere Application Server uses the general-purpose JavaMail configuration files contained in the `mail-impl.jar` and `activation-impl.jar` files and does not put any mail configuration files in `<user.home>` and `<java.home>/lib`. File read permission for both the `mail-impl.jar` and `activation-impl.jar` files is granted to all applications to ensure proper functioning of the JavaMail API, as shown in the following segment of the `app.policy` file:

```
grant codeBase "file:${application}" {
    // The following are required by Java mail
    permission java.io.FilePermission "${was.install.root}${/}lib${/}mail-impl.jar", "read";
    permission java.io.FilePermission "${was.install.root}${/}lib${/}activation-impl.jar", "read";
};
```

JavaMail code attempts to access configuration files at `<user.home>` and `<java.home>/lib` causing `AccessControlExceptions` to be thrown, since there is no file read permission granted for those two locations by default. This activity does not affect the proper functioning of the JavaMail API, but you might see a large amount of JavaMail-related security exceptions reported in the system log, which might swamp harmful errors that you are looking for. If this situation is a problem, consider adding two more permission lines to the permission block above. This should eliminate most, if not all, JavaMail-related harmless security exceptions from the log file. The application permission block in the `app.policy` file now looks like:

```
grant codeBase "file:${application}" {
    // The following are required by Java mail
    permission java.io.FilePermission "${was.install.root}${/}lib${/}mail-impl.jar", "read";
    permission java.io.FilePermission "${was.install.root}${/}lib${/}activation-impl.jar", "read";
    java.io.FilePermission "${java.home}${/}lib${/}mailcap", "read";
    permission java.io.FilePermission "${user.home}${/}lib${/}mailcap", "read";
};
```

Chapter 20. Learn about WebSphere programming extensions

Use this section as a starting point to investigate the WebSphere programming model extensions for enhancing your application development and deployment.

See *Learn about WebSphere applications: Overview and new features* for a brief description of each WebSphere extension.

See the *Developing and deploying applications* PDF book for a brief description of each WebSphere extension.

In addition, now your applications can use the Eclipse extension framework. Your applications are extensible as soon as you define an extension point and provide the extension processing code for the extensible area of the application. You can also plug an application into another extensible application by defining an extension that adheres to the target extension point requirements. The extension point can find the newly added extension dynamically and the new function is seamlessly integrated in the existing application. It works on a cross Java 2 Platform, Enterprise Edition (J2EE) module basis.

The application extension registry uses the Eclipse plug-in descriptor format and application programming interfaces (APIs) as the standard extensibility mechanism for WebSphere applications. Developers that build WebSphere application modules can use WebSphere Application Server extensions to implement Eclipse tools and to provide plug-in modules to contribute functionality such as actions, tasks, menu items, and links at predefined extension points in the WebSphere application. Read the information about Application extension registry in the *Developing and deploying applications* PDF book.

Scheduler

Securing scheduler tasks

Scheduled tasks are protected using application isolation and administrative roles. This topic describes how to secure scheduler tasks.

If a task is created using a Java 2 Platform, Enterprise Edition (J2EE) server application, only applications with the same name can access those tasks. Tasks created with a WASScheduler MBean using the AdminClient interface or scripting are not part of a J2EE application and have access to all tasks regardless of the application with which they were created. Tasks created with a WASScheduler MBean are only accessible from the WASScheduler MBean API and are not accessible from the Scheduler API.

If the Use Administration Roles attribute is enabled on a scheduler and administrative security is enabled on the Application Server, all Scheduler API methods and WASScheduler MBean API operations enforce access based on the WebSphere Administration Roles. If either of these attributes are disabled, then all API methods are fully accessible by all users.

1. Enable security for all application servers.
2. Manage schedulers.

Chapter 21. Tuning, hardening, and maintaining

After you have installed WebSphere Application Server, there are several considerations for tuning, strengthening, and maintaining your security configuration.

The following topics are covered in this section:

- Tuning security configurations
- Hardening security configurations
- Changing keys and passwords
- Securing passwords in files

Tuning security configurations

Performance issues typically involve trade-offs between function and speed. Usually, the more function and the more processing that are involved, the slower the performance. Consider what type of security is necessary and what you can disable in your environment. For example, if your application servers are running in a Virtual Private Network (VPN), consider whether you can disable Secure Sockets Layer (SSL). If you have a lot of users, can they be mapped to groups and then associated to your Java 2 Platform, Enterprise Edition (J2EE) roles? These questions are things to consider when designing your security infrastructure.

- Consider the following recommendations for tuning general security.
 - Consider disabling Java 2 security manager if you know exactly what code is put onto your server and you do not need to protect process resources. Remember that in doing so, you put your local resources at some risk.
 - Consider propagating new security settings to all nodes before restarting the deployment manager and node agents, to change the new security policy.

If your security configurations are not consistent across all servers, you get access denied errors. Therefore, you must propagate new security settings when enabling or disabling administrative security.

Configuration changes are generally propagated using configuration synchronization. If auto-synchronization is enabled, you can wait for the automatic synchronization interval to pass, or you can force synchronization before the synchronization interval expires. If you are using manual synchronization, you must synchronize all the nodes.

If the cell is in a configuration state and the security policy is mixed with nodes that have security enabled and disabled, you can use the `syncNode` utility to synchronize the nodes where the new settings are not propagated.

For more detailed information about enabling security in a distributed environment, see “Enabling security for the realm” on page 72.

- Consider increasing the cache and token timeout if you feel your environment is secure enough. By increasing these values, you have to re-authenticate less often. This action supports subsequent requests to reuse the credentials that already are created. The downside of increasing the token timeout is the exposure of having a token hacked and providing the hacker more time to hack into the system before the token expires. You can use security cache properties to determine the initial size of the primary and secondary hashtable caches, which affect the frequency of rehashing and the distribution of the hash algorithms.
See the article “Security cache properties” on page 282 for a list of these properties.
- Consider changing your administrative connector from Simple Object Access Protocol (SOAP) to Remote Method Invocation (RMI) because RMI uses stateful connections while SOAP is completely stateless. Run a benchmark to determine if the performance is improved in your environment.
- Use the `wsadmin` script to complete the access IDs for all the users and groups to speed up the application startup. Complete this action if applications contain many users or groups, or if

applications are stopped and started frequently. WebSphere Application Server maps user and group names to unique access IDs in the authorization table. The exact format of the access ID depends on the repository. The access ID can only be determined during and after application deployment. Authorization tables created during assembly time do not have the proper access IDs. See Commands for the AdminApp object for more information about how to update access IDs.

- Consider tuning the Object Request Broker (ORB) because it is a factor in enterprise bean performance with or without security enabled. Refer to the ORB tuning guidelines topic.
- If using SSL, enable the SSL session tracking mechanism option as described in the article, Session management settings.
- In some cases, using the unrestricted Java Cryptography Extension (JCE) policy file can improve performance. Refer to the article, Tuning Web services security.
- Consider the following steps to tune Common Secure Interoperability version 2 (CSIv2).
 - Consider using Secure Sockets Layer (SSL) client certificates instead of a user ID and password to authenticate Java clients. Because you are already making the SSL connection, using mutual authentication adds little overhead while it removes the service context that contains the user ID and password completely.
 - If you send a large amount of data that is not very security sensitive, reduce the strength of your ciphers. The more data you have to bulk encrypt and the stronger the cipher, the longer this action takes. If the data is not sensitive, do not waste your processing with 128-bit ciphers.
 - Consider putting only an asterisk (*) in the trusted server ID list (meaning trust all servers) when you use identity assertion for downstream delegation. Use SSL mutual authentication between servers to provide this trust. Adding this extra step in the SSL handshake performs better than having to fully authenticate the upstream server and check the trusted list. When an asterisk (*) is used, the identity token is trusted. The SSL connection trusts the server through client certificate authentication.
 - Ensure that stateful sessions are enabled for CSIv2. This is the default, but requires authentication only on the first request and on any subsequent token expirations.
- **V6.0.x** If you are communicating only with WebSphere Application Server Version 5 or higher servers, make the Active Authentication Protocol CSI, instead of CSI and SAS. This action removes an interceptor invocation for every request on both the client and server sides.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

- Consider the following steps to tune Lightweight Directory Access Protocol (LDAP) authentication.
 1. In the administration console, click **Security > Secure administration, applications, and infrastructure**.
 2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry** and click **Configure**.
 3. Select the **Ignore case for authorization** option in the standalone LDAP registry configuration, when case-sensitivity is not important.
 4. Select the **Reuse connection** option.
 5. Use the cache features that your LDAP server supports.
 6. Choose either the IBM Tivoli Directory Server or SecureWay directory type, if you are using an IBM Tivoli Directory Server. The IBM Tivoli Directory Server yields improved performance because it is programmed to use the new group membership attributes to improve group membership searches. However, authorization must be case insensitive to use IBM Tivoli Directory Server.
 7. Choose either iPlanet Directory Server (also known as Sun ONE) or Netscape as the directory if you are an iPlanet Directory user. Using the iPlanet Directory Server directory can increase performance in group membership lookup. However, use **Role** only for group mechanisms.
- Consider the following steps to tune Web authentication.

- Increase the cache and token timeout values if you feel your environment is secure enough. The Web authentication information is stored in these caches and as long as the authentication information is in the cache, the login module is not invoked to authenticate the user. This supports subsequent requests to reuse the credentials that are already created. A disadvantage of increasing the token timeout is the exposure of having a token stolen and providing the thief more time to hack into the system before the token expires.
See the article “Security cache properties” on page 282 for a list of these properties.
- Enable single sign-on (SSO). To configure SSO, click **Security > Secure administration, applications, and infrastructure**. Under Web security, click **Single sign-on (SSO)**.
SSO is only available when you configure **LTPA** as the authentication mechanism in the Authentication mechanisms and expiration panel. Although you can select Simple WebSphere Authentication Mechanism (SWAM) as the authentication mechanism on the Authentication mechanisms and expiration panel, SWAM is deprecated in Version 6.1 and does not support SSO. When you select SSO, a single authentication to one application server is enough to make requests to multiple application servers in the same SSO domain. Some situations exist where SSO is not a desirable and you do not want to use it in those situations.
- Disable or enabling the **Web Inbound Security Attribute Propagation** option on the Single sign-on (SSO) panel if the function is not required. In some cases, having the function enabled can improve performance. This improvement is most likely for higher volume cases where a considerable number of user registry calls reduces performance. In other cases, having the feature disabled can improve performance. This improvement is most likely when the user registry calls do not take considerable resources.
- Consider the following steps to tune authorization.
 - Map your users to groups in the user registry. Associate the groups with your Java 2 Platform, Enterprise Edition (J2EE) roles. This association greatly improves performance when the number of users increases.
 - Judiciously assign method-permissions for enterprise beans. For example, you can use an asterisk (*) to indicate all the methods in the method-name element. When all the methods in enterprise beans require the same permission, use an asterisk (*) for the method-name to indicate all methods. This indication reduces the size of deployment descriptors and reduces the memory that is required to load the deployment descriptor. It also reduces the search time during method-permission match for the enterprise beans method.
 - Judiciously assign security-constraints for servlets. For example, you can use the *.jsp URL pattern to apply the same authentication data constraints to indicate all JavaServer Pages (JSP) files. For a given URL, the exact match in the deployment descriptor takes precedence over the longest path match. Use the *.jsp, *.do, *.html extension match if no exact matches exist and longest path matches exist for a given URL in the security constraints.

You always have a trade off between performance, feature, and security. Security typically adds more processing time to your requests, but for a good reason. Not all security features are required in your environment. When you decide to tune security, create a benchmark before making any change to ensure that the change is improving performance.

In a large scale deployment, performance is very important. Running benchmark measurements with different combinations of features can help you to determine the best performance versus the benefit of configuration for your environment. Continue to run benchmarks if anything changes in your environment, to help determine the impact of these changes.

Secure Sockets Layer performance tips

Use this page to learn about Secure Sockets Layer (SSL) performance tips. Be sure to consider that performance issues typically involve trade-offs between function and speed. Usually, the more function and the more processing that are involved, the slower the performance.

The following are two types of Secure Sockets Layer (SSL) performance:

- Handshake
- Bulk encryption and decryption

When an SSL connection is established, an SSL handshake occurs. After a connection is made, SSL performs bulk encryption and decryption for each read-write. The performance cost of an SSL handshake is much larger than that of bulk encryption and decryption.

To enhance SSL performance, decrease the number of individual SSL connections and handshakes.

Decreasing the number of connections increases performance for secure communication through SSL connections, as well as non-secure communication through simple Transmission Control Protocol/Internet Protocol (TCP/IP) connections. One way to decrease individual SSL connections is to use a browser that supports HTTP 1.1. Decreasing individual SSL connections can be impossible if you cannot upgrade to HTTP 1.1.

Another common approach is to decrease the number of connections (both TCP/IP and SSL) between two WebSphere Application Server components. The following guidelines help to verify the HTTP transport of the application server is configured so that the Web server plug-in does not repeatedly reopen new connections to the application server:

- Verify that the maximum number of keep alives are, at minimum, as large as the maximum number of requests per thread of the Web server (or maximum number of processes for IBM HTTP Server on UNIX). Make sure that the Web server plug-in is capable of obtaining a keep alive connection for every possible concurrent connection to the application server. Otherwise, the application server closes the connection after a single request is processed. Also, the maximum number of threads in the Web container thread pool should be larger than the maximum number of keep alives, to prevent the keep alive connections from consuming the Web container threads.

Note: HTTP Transports have been deprecated. For instructions on how to set a maximum keep alive value for channel based configurations, see HTTP transport channel settings.

- Increase the maximum number of requests per keep alive connection. The default value is 100, which means the application server closes the connection from the plug-in after 100 requests. The plug-in then has to open a new connection. The purpose of this parameter is to prevent denial of service attacks when connecting to the application server and preventing continuous send requests to tie up threads in the application server.
- Use a hardware accelerator if the system performs several SSL handshakes.

Hardware accelerators currently supported by WebSphere Application Server only increase the SSL handshake performance, not the bulk encryption and decryption. An accelerator typically only benefits the Web server because Web server connections are short-lived. All other SSL connections in WebSphere Application Server are long-lived.

The IBM Cryptographic Coprocessor is not supported for use with WebSphere Application Server. However, you can use the IBM Cryptographic Coprocessor to improve SSL performance for other products, such as IBM HTTP Server for iSeries, which is powered by Apache.

- Use an alternative cipher suite with better performance.

The performance of a cipher suite is different with software and hardware. Just because a cipher suite performs better in software does not mean a cipher suite will perform better with hardware. Some algorithms are typically inefficient in hardware, for example, Data Encryption Standard (DES) and triple-strength DES (3DES); however, specialized hardware can provide efficient implementations of these same algorithms.

The performance of bulk encryption and decryption is affected by the cipher suite used for an individual SSL connection. The following chart displays the performance of each cipher suite. The test software calculating the data was Java Secure Socket Extension (JSSE) for both the client and server software, which used no cryptographic hardware support. The test did not include the time to establish a connection, but only the time to transmit data through an established connection. Therefore, the data reveals the relative SSL performance of various cipher suites for long running connections.

Before establishing a connection, the client enables a single cipher suite for each test case. After the connection is established, the client times how long it takes to write an integer to the server and for the server to write the specified number of bytes back to the client. Varying the amount of data had negligible effects on the relative performance of the cipher suites.

An analysis of the above data reveals the following:

- Bulk encryption performance is only affected by what follows the WITH in the cipher suite name. This is expected since the portion before the WITH identifies the algorithm used only during the SSL handshake.
- MD5 and Secure Hash Algorithm (SHA) are the two hash algorithms used to provide data integrity. MD5 is generally faster than SHA, however, SHA is more secure than MD5.
- DES and RC2 are slower than RC4. Triple DES is the most secure, but the performance cost is high when using only software.
- The cipher suite providing the best performance while still providing privacy is SSL_RSA_WITH_RC4_128_MD5. Even though SSL_RSA_EXPORT_WITH_RC4_40_MD5 is cryptographically weaker than RSA_WITH_RC4_128_MD5, the performance for bulk encryption is the same. Therefore, as long as the SSL connection is a long-running connection, the difference in the performance of high and medium security levels is negligible. It is recommended that a security level of high be used, instead of medium, for all components participating in communication only among WebSphere Application Server products. Make sure that the connections are long running connections.

Tuning security

Use the following procedures to tune the performance, without compromising your security settings.

Enabling security decreases performance. The following tuning parameters provide ways to minimize this performance impact.

- Disable security on any application servers that do not need security. You can disable security in the administrative console by clicking **Security > Secure administration, applications, and infrastructure** and deselecting the **Enable administrative security** option.
- Fine-tune the **Authentication cache timeout** value on the Authentication mechanisms and expiration panel in the administrative console. For more information, see the “Secure administration, applications, and infrastructure settings” on page 73 topic.
- Configure the security cache properties. For more information, see the “Security cache properties” on page 282 topic.

- Enable the **Enable SSL ID tracking** option on the Session management panel in the administrative console. For more information, see the Session management settings topic.
- Improve the performance of Web services security by downloading a Java Cryptography Extension (JCE) unlimited jurisdiction policy file that does not have restrictions on cryptography strength. For more information, see the “Tuning Web services security for Version 6.1 applications” on page 1259 topic.
- Read the Secure Sockets Layer performance tips and “Tuning security configurations” on page 1417 topics for more information.

Hardening security configurations

There are several methods that you can use to protect the WebSphere Application Server infrastructure and applications from different forms of attack. Several different techniques can help with multiple forms of attack. Sometimes a single attack can leverage multiple forms of intrusion to achieve the end goal.

For example, in the simplest case, network sniffing can be used to obtain passwords and those passwords can then be used to mount an application-level attack. The following issues are discussed in IBM WebSphere Developer Technical Journal: WebSphere Application Server V5 advanced security and system hardening:

- Take preventative measures to protect the infrastructure.
- Make applications less vulnerable to attack.

Securing passwords in files

Password encoding and encryption deters the casual observation of passwords in server configuration and property files.

The following topics are covered in this section:

- Password encoding and encryption
- Encoding passwords in files
- Enabling custom password encryption

Password encoding and encryption

Password encoding deters the casual observation of passwords in server configuration and property files.

By default, passwords are automatically encoded with a simple masking algorithm in various WebSphere Application Server ASCII configuration files. Additionally, you can manually encode passwords in properties files that are used by Java clients and by administrative commands for WebSphere Application Server.

The default encoding algorithm is referred to as XOR. An alternate OS400 encoding algorithm can be used with WebSphere Application Server for i5/OS that exploits native validation list (*VLDL) objects only. With the OS400 algorithm, passwords are stored in an encrypted form within a validation list. The configuration files contain indexes to the stored passwords instead of the masked passwords, as is done with the XOR algorithm.

Encoded passwords use the following syntax:

```
{algorithm}encoded_password
```

where {algorithm} is a tag that specifies the algorithm that is used to encode the password, which is either XOR or OS400. The *encoded_password* variable is the encoded value of the password. When a server or client needs to decode a password, it uses the tag to determine what algorithm to use and then uses that algorithm to decode the encoded password.

Java clients use passwords from the `sas.client.props` file, which is in the `profile_root/properties` directory.

To use password encoding with Java clients, the passwords must be manually encoded in the `sas.client.props` file using the **PropFilePasswordEncoder** tool.

The administrative commands for WebSphere Application Server use passwords from the `soap.client.props` file, which is also located in the `/properties` subdirectory, for SOAP connections. Some administrative commands optionally use passwords from the `sas.client.props` file in the `/properties` subdirectory for Remote Method Invocation (RMI) connections. To use password encoding with administrative commands, you must manually encode the passwords in the `soap.client.props` and `sas.client.props` files using the **PropFilePasswordEncoder** tool.

Attention: Whether you select to use the OS400 encoding algorithm or the default encoding algorithm, encoding is not sufficient to fully protect passwords. Native security is the primary mechanism for protecting passwords that are used in the configuration and property files for WebSphere Application Server.

Issues to consider when you use the OS400 password encoding algorithm

The following issues are important for you to consider before deciding to use the OS400 password encoding algorithm:

- You must set the QRETSVRSEC operating system value to 1 to use on the system that hosts the Java client application or WebSphere Application Server. With this setting, WebSphere Application Server to retrieve the encrypted passwords from the validation list.
 - Attention:** The QRETSVRSEC system value affects access to the encrypted data in all of the validation lists on your operating system. Do not use the OS400 password encoding algorithm if this setting is not consistent with your security policy for your operating system.
- You can use the OS400 algorithm with server instances only when all of the server instances within the administrative domain for WebSphere Application Server reside on the same i5/OS system. Consider the following related issues:
 - Administrative domains for WebSphere Application Server can extend across multiple i5/OS systems. You can use the OS400 password algorithm only when all of the servers within an administrative domain reside on the same i5/OS system.
 - Server configuration XML files contain encoded passwords. If the passwords that are contained in the XML files are encoded using the OS400 encoding algorithm, those encodings are valid only for the Application Server instances on the same i5/OS system on which the passwords were originally encoded. Copies of configuration files that contain passwords that are encoded using the OS400 encoding algorithm cannot be used to configure servers on other i5/OS systems.
 - All server instances within an administrative domain must be configured to use the same native validation list (*VLDL) object.
- For Java clients, you can use the OS400 password algorithm on any i5/OS system. However, option 1 must be installed on the system that hosts the Java client.
- If an error occurs while a password is encoded using the OS400 encoding algorithm, the XOR encoding algorithm is used to encode the password. An error might occur if an administrator manually creates the validation list object and grants insufficient authority to the validation list object for the i5/OS QEJB user profile.

Object and file security

This topic discusses the various objects and files that contain sensitive information and need to be protected.

Secure integrated file system files

In addition to enterprise beans and servlets, WebSphere Application Server accesses integrated file system stream files. The following files might contain sensitive information. It is recommended that you give these files close consideration to ensure that unauthorized access is not granted.

- In the `/properties` subdirectory of your profile, the following files can contain user IDs and passwords:
 - `sas.client.props`
 - `soap.client.props`
 - `sas.stdclient.properties`
 - `sas.tools.properties`
 - `wssserver.key`

By default, the `/properties` subdirectory is located in the `profile_root` directory. Each of the previous files is shipped with `*PUBLIC` authority set to `*EXCLUDE`. The `QEJBSVR` user profile is granted `*RW` authority to these files. Additional protection is available through password encoding. For more information, see “Password encoding and encryption” on page 1422.

- In the `/etc` subdirectory of your profile, protect all of the key (KDB) files and trust (JKS) files that you create for your WebSphere Application Server profile.

For the JKS files, the `QEJBSVR` user profiles should have `*R` authority and `*PUBLIC` should have `*EXCLUDE` authority.

For the KDB files, the user profile that the Web server is running under should have `*RX` authority and `*PUBLIC` should have `*EXCLUDE` authority.

Secure database resources for WebSphere Application Server

WebSphere Application Server uses tables to persist data for user applications such as enterprise beans persistence and servlet session data. You have several options for controlling which user profiles are allowed access to this user data. For more information, see Database access security.

Secure WebSphere Application Server files

When you enable WebSphere Application Server security, the server user profile and password are placed into server configuration files, which should be maintained in a secure way using operating system security. Additionally, you can password protect some WebSphere Application Server resources. These passwords are also placed in server configuration files. The server automatically encodes passwords to deter casual observation, but password encoding alone is not sufficient protection.

The following files are located in the `/config` subdirectory of your profile and they can contain user identifiers and passwords:

- `cells/cell_name/security.xml`
- `cells/cell_name/nodes/node_name/resources.xml`
- `cells/cell_name/nodes/node_name/servers/server_name/server.xml`

For example, for the default profile, the `server_name` is `server1`.

The server user profile and password are used for authenticating the server when it initializes. This authentication is required for the following reasons:

- The user ID and password are used as the system identity for the server when an enterprise bean security is deployed to use `SYSTEM_IDENTITY` for method delegation. In this case, the user ID and password are used when method calls are made from one enterprise bean to another.
- The user ID and password are used to authenticate servers for inter-server communication. Because security for these files can be compromised, use a non-default user profile for the server identity and

password. The default user profile is QEJBSVR. If you use the local OS user registry, you might choose to create and use a user profile that has no special authorities. For more information, see Running application servers under specific user profiles.

Secure user profiles for WebSphere Application Server

When WebSphere Application Server is first installed, by default, it uses the following user profiles:

QEJB This profile provides access to some administrative data, including passwords.

QEJBSVR

This profile provides the context in which your WebSphere Application Server runs. For security or administrative purposes, you might want to create other user profiles under which to run various parts of WebSphere Application Server. For more information, see Running application servers under specific user profiles.

Encoding password in files

Use the **PropFilePasswordEncoder** utility to encode your passwords in the files. WebSphere Application Server does not provide a utility for decoding the passwords.

WebSphere Application Server contains several encoded passwords that are not encrypted. WebSphere Application Server provides the **PropFilePasswordEncoder** utility, which you can use to encode these passwords. However, the utility does not encode passwords that are contained within XML or XMI files. Instead, WebSphere Application Server automatically encodes the passwords in the following XML or XMI files.

Table 56. XML and XMI files that contain encoded passwords

File name	Additional information
<code>profile_root/config/cells/cell_name/security.xml</code>	The following fields contain encoded passwords: <ul style="list-style-type: none"> • LTPA password • JAAS authentication data • User registry server password • LDAP user registry bind password • Keystore password • Truststore password • Cryptographic token device password
<code>war/WEB-INF/ibm_web_bnd.xml</code>	Specifies the passwords for the default basic authentication for the resource-ref bindings within all the descriptors, except in the Java cryptography architecture
<code>ejb jar/META-INF/ibm_ejbjar_bnd.xml</code>	Specifies the passwords for the default basic authentication for the resource-ref bindings within all the descriptors, except in the Java cryptography architecture
<code>client jar/META-INF/ibm_appclient_bnd.xml</code>	Specifies the passwords for the default basic authentication for the resource-ref bindings within all the descriptors, except in the Java cryptography architecture
<code>ear/META-INF/ibm_application_bnd.xml</code>	Specifies the passwords for the default basic authentication for the run as bindings within all the descriptors

Table 56. XML and XMI files that contain encoded passwords (continued)

File name	Additional information
<code>profile_root/config/cells/cell_name/nodes/node_name/servers/security.xml</code>	The following fields contain encoded passwords: <ul style="list-style-type: none"> • Keystore password • Truststore password • Cryptographic token device password • Session persistence password • DRS client data replication password
<code>profile_root/config/cells/cell_name/nodes/node_name/servers/server1/resources.xml</code>	The following fields contain encoded passwords: <ul style="list-style-type: none"> • WAS40Datasource password • mailTransport password • mailStore password • MQQueue queue mgr password
<code>profile_root/config/cells/cell_name/ws-security.xml</code>	
<code>ibm-webservices-bnd.xmi</code>	
<code>ibm-webservicesclient-bnd.xmi</code>	

You can use the **PropFilePasswordEncoder** utility to encode the passwords that are located in the following files.

Table 57. Files that you can encode using the PropFilePasswordEncoder utility

File name	Additional information
<code>profile_root/properties/sas.client.props</code>	Specifies the passwords for the following files: <ul style="list-style-type: none"> • com.ibm.ssl.keyStorePassword • com.ibm.ssl.trustStorePassword • com.ibm.CORBA.loginPassword
<code>profile_root/properties/soap.client.props</code>	Specifies passwords for: <ul style="list-style-type: none"> • com.ibm.ssl.keyStorePassword • com.ibm.ssl.trustStorePassword • com.ibm.SOAP.loginPassword
<code>profile_root/properties/sas.tools.properties</code>	Specifies passwords for: <ul style="list-style-type: none"> • com.ibm.ssl.keyStorePassword • com.ibm.ssl.trustStorePassword • com.ibm.CORBA.loginPassword
<code>profile_root/properties/sas.stdclient.properties</code>	Specifies passwords for: <ul style="list-style-type: none"> • com.ibm.ssl.keyStorePassword • com.ibm.ssl.trustStorePassword • com.ibm.CORBA.loginPassword
<code>profile_root/properties/wssserver.key</code>	

To encode a password again in one of the previous files, complete the following steps:

1. Access the file using a text editor and type over the encoded password. The new password is shown is no longer encoded and must be re-encoded.
2. Use the **PropFilePasswordEncode** script in the `app_server_root/bin/` directory to encode the password again.

V6.0.x

If you are encoding the SAS properties files again, type: `PropFilePasswordEncoder "file_name" -sas` and the `PropFilePasswordEncoder` file encodes the known SAS properties.

If you are encoding files that are not SAS properties files, type `PropFilePasswordEncoder "file_name" password_properties_list`
"file_name" is the name of the SAS properties file and `password_properties_list` is the name of the properties to encode within the file.

Note: Only the password should be encoded in this file by using the **PropFilePasswordEncoder** tool. Use the **PropFilePasswordEncoder** tool to encode WebSphere Application Server password files only. The utility cannot encode passwords that are contained in XML files or other files that contain open and close tags.

If you reopen the affected files, the passwords are encoded. WebSphere Application Server does not provide a utility for decoding the passwords.

Manually encoding passwords in properties files

To use password encoding with WebSphere Application Server administrative commands and Java clients, passwords must be manually encoded in the `soap.client.props` and `sas.client.props` files using the **PropFilePasswordEncoder** tool.

To run the script, your user profile must have `*ALLOBJ` authority.

Use the **PropFilePasswordEncoder** utility to encode the passwords in properties files. The **PropFilePasswordEncoder** utility is a Qshell script. Complete the following steps to manually encode the passwords:

1. Sign on the server with a user profile that has all object (`*ALLOBJ`) special authority.
2. Run the Start Qshell (STRQSH) command on a command line to start the Qshell environment.
3. Use the **PropFilePasswordEncoder** utility to encode the passwords.

For example, to encode the passwords for properties in the `sas.client.props` file for the default WebSphere Application Server profile (in a default installation), enter the following command:

```
profile_root/bin/PropFilePasswordEncoder
-profileName server1
profile_root/properties/sas.client.props -SAS
```

For example, to encode the passwords for properties in the `soap.client.props` file for the default standalone application server profile, enter the following command:

```
profile_root/bin/PropFilePasswordEncoder
-profileName server1
profile_root/properties/soap.client.props
com.ibm.SOAP.loginPassword,com.ibm.ssl.keyStorePassword,
com.ibm.ssl.trustStorePassword
```

For more information on the `sas.client.props` utility, see the "PropFilePasswordEncoder command reference."

The passwords are encoded in the `soap.client.props` and `sas.client.props` files.

See "Restoring or replacing damaged validation list objects" on page 1430 for information on how to restore or replace a damaged validation list object.

PropFilePasswordEncoder command reference

The **PropFilePasswordEncoder** command encodes passwords that are located in plain text property files. This command encodes both Secure Authentication Server (SAS) property files and non-SAS property files. After you encode the passwords, a decoding command does not exist.

To encode passwords, you must run this command from the directory:

- **V6.0.x** `app_server_root/bin`

To run this script, your user profile must have *ALLOBJ authority.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Syntax

V6.0.x The command syntax is as follows:

```
PropFilePasswordEncoder "fileName" { passwordPropertiesList  
  | -SAS } [ -profileName profile ] [ -help | -? ]
```

Important: You must specify either the passwordPropertiesList parameter or the -SAS parameter.

Parameters

The following option is available for the **PropFilePasswordEncoder** command:

fileName

This required parameter specifies the name of the file in which passwords are encoded.

passwordPropertiesList

This parameter is required if you are encoding passwords in the soap.client.props file. Specify one or more password properties that you want to encode.

V6.0.x **-SAS**

This parameter is required if you are encoding passwords in the sas.client.props file.

-profileName

This parameter is optional. The profile value specifies an application server profile name. The script uses the password encoding algorithm that it retrieves from the specified profile. If you do not specify this parameter, the script uses the default profile.

-help or -?

If you specify this parameter, the script ignores all other parameters and displays usage text.

V6.0.x The following command encodes the passwords in the sas.client.props file for the default stand-alone application server profile:

```
app_server_root/bin/PropFilePasswordEncoder  
profile_root/default/properties/sas.client.props -SAS
```

The following command encodes the passwords in the soap.client.props file for the default stand-alone application server profile:

```
app_server_root/bin/PropFilePasswordEncoder  
profile_root/default/properties/soap.client.props  
com.ibm.SOAP.loginPassword,com.ibm.ssl.keyStorePassword,com.ibm.ssl.trustStorePassword
```

Attention: These commands are displayed on multiple lines for illustrative purposes only.

Enabling the non-default OS/400 password encoding algorithm

The purpose of password encoding is to deter casual observation of passwords in server configuration and property files.

Make sure all server instances within the administration console reside on the same i5/OS system.

By default, passwords are automatically encoded with a simple masking algorithm in various ASCII configuration files for WebSphere Application Server. You can manually encode passwords in properties files that are used by Java clients and by Application Server administrative commands.

For a description of the OS400 encoding algorithm, see “Password encoding and encryption” on page 1422. To enable the OS400 password encoding algorithm for a WebSphere Application Server profile, complete these steps:

1. Set the `os400.security.password` properties to turn on the OS400 password encoding algorithm and to specify which the validation list object to use.

Use the same validation list object for all WebSphere Application Server profiles. However, it is not recommended if you do not back up the objects and data for all profiles simultaneously. Consider your backup and restore policy when you decide what validation list object to use for each WebSphere Application Server profile.

To set the properties, complete one of these steps:

- Use the **-os400passwords** and **-validationlist** options for the `manageprofiles -create` utility, which is located in the `app_server_root/bin` directory, to set the properties when creating the profile. To create a WebSphere Application Server profile named `prod`, and to enable that profile for the OS400 encoding algorithm using the `/QSYS.LIB/QUSRSYS.LIB/WAS.VLDL` validation list object, you can complete the following steps:

- a. Run the Start Qshell (STRQSH) command on the i5/OS command line.
- b. In Qshell, run the following command:

```
app_server_root/bin/manageprofiles
-create -profileName prod -startingPort 10150
-templatePath default -os400passwords
-validationlist /QSYS.LIB/QUSRSYS.LIB/WAS.VLDL
```

The previous command is on multiple lines for illustration purposes only.

- Set the Java system properties in the **setupCmdLine** Qshell script of the WebSphere Application Server profile. To enable the OS400 password encoding algorithm, edit the `profile_root/bin/setupCmdLine` script using the following steps:
 - a. Set the `os400.security.password.encoding.algorithm` property to `OS400`. The default setting is `XOR`.
 - b. Set the `os400.security.password.validation.list.object` property to the absolute name of the validation list that you need to use. The default setting is `/QSYS.LIB/QUSRSYS.LIB/EJSADMIN.VLDL`.
 - c. Save the file.
2. Grant the QEJB user profile run authority (*X) to the library that contains the validation list. If QEJB already has the minimum required authority (*X) to access the library, then proceed to the next step.
 - a. Use the Display Authority (DSPAUT) to check for the minimum required authority if the validation list is created in the `/QSYS.LIB/WSADMIN.LIB` file.

For example:

```
DSPAUT OBJ('/QSYS.LIB/WSADMIN.LIB')
```
 - b. Use the Change Authority (CHGAUT) command to grant run authority to the QEJB profile only if the QEJB profile does not already have this authority.

For example:

```
CHGAUT OBJ('/QSYS.LIB/WSADMIN.LIB') USER(QEJB) DTAUT(*X)
```
3. Create a native validation list object (*VLDL). This step is optional for server profiles. The validation list object is created when the server is started. For remote profiles, create the validation list if the validation list does not already exist on the system that hosts the remote profile. Also, consider your backup and restore policy when you decide what validation list object to use with each remote profile.

Attention: When you use the OS400 password encoding algorithm, the Java client is not required to reside on the same i5/OS system as the WebSphere Application Server profile that the client accesses.

To create a validation list object, perform the following steps with an i5/OS user profile that has *ALLOBJ special authority:

- a. Sign on the server with a user profile that has the *ALLOBJ special authority.
- b. Use the Create Validation List (**CRTVLDL**) command to create the validation list object.
For example, to create the WSVLIST validation list object in the WSADMIN.LIB library, use the following command:

```
CRTVLDL VLDL(WADMIN/WSVLIST)
```
- c. Grant the QEJB user profile *RWX authority to the validation list object. For example, to grant *RWX authority to the WSVLIST validation list object in the WSADMIN library, use the following command:

```
CHGAUT OBJ('/QSYS.LIB/WSADMIN.LIB/WSVLIST.VLDL') USER(QEJB) DTAUT(*RWX)
```

4. Use the Change System Value (**CHGSYSVAL**) command to set the QRETSVRSEC system value to 1. For example:

```
CHGSYSVAL SYSVAL(QRETSVRSEC) VALUE('1')
```
5. For server profile, start or restart the server and wait until the server is ready for service before attempting to manually encode passwords in properties files that belong to the profile.

You have enabled the OS400 password encoding algorithm.

After completing the previous steps and restarting the server, you can manually encode passwords in properties files. See “Manually encoding passwords in properties files” on page 1427 for more information.

Using the non-default OS/400 password encoding algorithm

Use these steps to change your encoding algorithm from OS400 to XOR.

WebSphere Application Server supports both the OS400 and the XOR encoding algorithms. The default encoding algorithm is XOR. For more conceptual information on these algorithms, see “Password encoding and encryption” on page 1422.

There might be instances where you need to use the OS400 encoding algorithm. See “Enabling the non-default OS/400 password encoding algorithm” on page 1428.

If you use the OS400 encoding algorithm, but change the `os400.security.password.encoding.algorithm` property value to XOR as described in the first step, then all of the passwords remain encoded with the OS400 algorithm. However, after you restart the server, when you make changes to the passwords through the administrative console, the passwords are encoded using the XOR algorithm.

The following steps describe how to change your encoding algorithm from OS400 to XOR:

1. Set the `os400.security.password.encoding.algorithm` property to XOR for each WebSphere Application Server profile that uses the Validation list object.
2. Stop all of the servers.
3. Edit the configuration files and change all of the encoded passwords to their unencoded values.
4. Edit the properties files and change all of the encoded passwords to their clear text values.

You have changed your encoding algorithm from OS400 to XOR.

After you completing these steps, you can encode the passwords in the properties files. See “Manually encoding passwords in properties files” on page 1427 for more information.

Restoring or replacing damaged validation list objects

Periodically, you should save your validation list objects with the other configuration data objects that are used by WebSphere Application Server. Use this task if you need to restore or replace a damaged validation list object.

You can share validation lists between multiple WebSphere Application Server profiles. For example, if you have two profiles of WebSphere Application Server, default and prod, both profiles can use the /QSYS.LIB/QUSRSYS.LIB/EJSADMIN.VLDL validation list.

To restore or replace a damaged validation list object, complete the following steps:

1. Replace the encoded passwords with the unencoded value of the password for all of the WebSphere Application Server profiles that use the validation list object. To replace the password values, complete the following steps:
 - a. Stop each of the servers.
 - b. Set the `os400.security.password.validation.list.object` property for all of the servers to the absolute name of the new validation list that you want to use. You can use an existing validation list object or specify a new object. For new validation list objects, create them manually or use the objects that are created automatically when the server is restarted. For more information on manually creating validation list objects, see “Manually encoding passwords in properties files” on page 1427.
 - c. Edit the configuration files and set each encoded password to the appropriate clear text value.
2. Edit the `sas.client.props` and `soap.client.props` files and set each encoded password to the appropriate unencoded value before manually encoding the passwords.
3. Restart the servers for all of the WebSphere Application Server profiles whose validation list objects that are replaced.

After restarting the server, you have successfully replaced a damaged validation list object.

For additional information on backing up your data objects, see “Backing up security configuration files” on page 1433.

Enabling custom password encryption

After creating the server profile, perform this task to better protect passwords contained in configuration.

Create your custom class for encrypting passwords. For more information, see “Plug point for custom password encryption” on page 658.

Complete the following steps to enable custom password encryption.

1. Add the following system properties for every server and client process. For server processes, update the `server.xml` file for each process. Add these properties as a `genericJvmArgument` argument preceded by a **-D** prefix.

```
com.ibm.wsspi.security.crypto.customPasswordEncryptionClass=  
    com.acme.myPasswordEncryptionClass  
com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=true
```

- Tip:** If the custom encryption class name is `com.ibm.wsspi.security.crypto.CustomPasswordEncryptionImpl`, it is automatically enabled when this class is present in the classpath. Do not define the system properties that are listed previously when the custom implementation has this package and class name. To disable encryption for this class, you must specify `com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=false` as a system property.
2. Add the Java archive (JAR) file containing the implementation class to the `app_server_root/classes` directory so that the WebSphere Application Server runtime can load the file.
 3. Restart all server processes.
 4. Edit each configuration document that contains a password and save the configuration. All password fields are then run through the **WSEncoderDecoder** utility, which calls the plug point when it is

enabled. The `{custom:alias}` tags are displayed in the configuration documents. The passwords, even though they are encrypted, are still Base64-encoded. They seem similar to encoded passwords, except for the tags difference.

5. Encrypt any passwords that are in client-side property files using the **PropsFilePasswordEncoder** (.bat or .sh) utility. This utility requires that the properties listed previously are defined as system properties in the script to encrypt new passwords instead of encoding them.
6. To decrypt passwords from client Java virtual machines (JVMs), add the properties listed previously as system properties for each client utility.
7. Ensure that all nodes have the custom encryption classes in their class paths prior to enabling this function. The order in which enablement occurs is important. When adding a new node to a cell that contains password encryption, the new node must contain the custom encryption classes prior to using the **addNode** command. Consider the following Network Deployment enablement scenarios:
 - a. The StandAloneProfile profile is encrypting passwords with a different key prior to federation to a deployment manager cell. For this scenario, you must uninstall custom password encryption to ensure that the configuration has `{xor}` tags preceding the passwords prior to running the **addNode** command. The same implementation of the plug point must be in the `/classes` directory prior to running the **addNode** command, and the proper configuration properties are set so that the new node can recognize the encrypted password format of the `security.xml` file after federation completes.
 - b. The StandAloneProfile profile does not have password encryption configured prior to federation to a deployment manager cell. The same implementation of the plug point must be in the `/classes` directory prior to running the **addNode** command, and the proper configuration properties are set so that the new node can recognize the encrypted password format of the `security.xml` file after federation completes.
 - c. If enabling custom password encryption in a cell with multiple nodes present, update the correct configuration properties and have the custom password encryption implementation class located on all nodes. Stop all processes in the cell, and then start the deployment manager. Use the administrative console to edit the security configuration and then save it. Verify that the passwords are encrypted by looking at the `security.xml` file to see if the passwords are preceded by `{custom:alias}` tags.
 - d. Run the **syncNode** command on each node, and start each one individually. If any nodes fail to start, make sure that they have custom password encryption enabled properly in each `security.xml` file and that the implementation class is in the appropriate `/classes` directory for the platform.

Custom password encryption is enabled.

If custom password encryption fails or is no longer required, see “Disabling custom password encryption.”

Disabling custom password encryption

If custom password encryption fails or is no longer required, perform this task to disable custom password encryption.

Enable custom password encryption.

Complete the following steps to disable custom password encryption.

1. Change the `com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled` property to be `false` in the `security.xml` file, but leave the `com.ibm.wsspi.security.crypto.customPasswordEncryptionClass` property configured. Any passwords in the model that still have the `{custom:alias}` tag are decrypted by using the customer password encryption class.
2. If an encryption key is lost, any passwords that are encrypted with that key cannot be retrieved. To recover a password, retype the password in the password field in plaintext and save the document. The new password must be written out using encoding with the `{xor}` tag with scripting or from the administrative console.

```
com.ibm.wsspi.security.crypto.customPasswordEncryptionClass=  
    com.acme.myPasswordEncryptionClass  
com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=false
```

3. Restart all processes to make the changes effective.
4. Edit each configuration document that contains an encrypted password and save the configuration. All password fields are then run through the **WSEncoderDecoder** utility, which calls the plug point in the presence of the {custom:alias} tag. The {xor} tags display in the configuration documents again after the documents are saved.
5. Decrypt and encode any passwords that are in client-side property files using the **PropsFilePasswordEncoder** (.bat or .sh) utility. If the encryption class is specified, but custom encryption is disabled, running this utility converts the encryption to encoding and causes the {xor} tags to display again.
6. Disable custom password encryption from the client Java virtual machines (JVMs) by adding the system properties listed previously to all client scripts. This action enables the code to decrypt passwords, but this action is not used to encrypt them again. The {xor} algorithm becomes the default for encoding. Leave the custom password encryption class defined for a time in case any encrypted passwords still exist in the configuration.

Custom password encryption is disabled.

Backing up security configuration files

Back up your security configuration files to prevent the loss of information due to a potential system failure.

Consider backing up the following security information:

- Back up your user profiles.

When you use local OS security, back up your user profiles, using the normal save procedures for user profiles. For more information, see the Backup and Recovery Guide by searching for "Saving group and user profiles" in the iSeries information center.

For information about the Directory Services Product (LDAP server), see the iSeries information center.

For information about Lotus Domino, see the Lotus Domino reference library.

- Back up your security property files.

Security settings are saved in several properties files. By default, these properties are located in the *profile_root/properties* directory. The default standalone profile name is default. If you define additional WebSphere Application Server profiles, there are additional properties files located in the directories for those profiles.

The following command saves all of the properties in the /SAS subdirectory:

```
SAV DEV('/QSYS.lib/wsplib.lib/wsasavf.file')  
OBJ(('profile/properties/sas*'))
```

This previous command is on two lines for illustrative purposes only. Enter it as one continuous line

You can save security property files while WebSphere Application Server is running.

- Back up your HTTP configuration.

The following information applies to IBM HTTP Server. If you are using Lotus Domino HTTP Server, see the Notes.net Documentation Library.

Changes to the HTTP configuration are often made to enable WebSphere Application Server to serve servlets and JavaServer Pages (JSP) file requests and to enable WebSphere Application Server security. Consider saving your HTTP configuration as a part of your WebSphere Application Server backup and recovery. The IBM HTTP Server configurations are stored as members of the QATMHTTTPC file in the QUSRSYS library. HTTP server instances are members of the QATMHINSTC file in the QUSRSYS library. The following example commands back up these files:

SAVOBJ OBJ(QUSRSYS/QATMHTTPC)

SAVOBJ OBJ(QUSRSYS/QATMHINSTC)

- Back up your key files.

The key files contain certificates that are used by the security infrastructure for WebSphere Application Server. These certificates are also used for HTTPS transport between servers. Save all of the files in the WAS_INSTANCE_ROOT/etc directory. Key files are contained in the WAS_INSTANCE_ROOT/etc directory, but administrators might create and store these files in other directories.

- Back up your validation lists.

Passwords are stored as encrypted data in validation list objects when you use the OS/400 password encoding algorithm. The default validation list is /QSYS.LIB/QUSRSYS.LIB/EJSADMIN.VLDL, but you can change it in the administrative console by specifying it as a system property for the application server. For more information, see Administering application servers.

For more information on backup and recovery strategies, see the following references:

- iSeries Information Center
- iSeries Backup and Recovery Version 5
- Security: Resources for learning

Chapter 22. Troubleshooting security configurations

The following topics help to troubleshoot specific problems that are related to configuring and enabling security configurations.

Refer to Security components troubleshooting tips for instructions on how to troubleshoot errors that are related to security.

Refer to SPNEGO TAI troubleshooting tips for instructions on how to troubleshoot errors that are related to diagnosing Simple and Protected GSS-API Negotiation (SPNEGO) trust association interceptor (TAI) problems and exceptions.

- Errors when configuring or enabling security
- Errors after enabling security
- Access problems after enabling security
- Errors after configuring or enabling Secure Sockets Layer
- Single sign-on configuration troubleshooting tips
- Enterprise Identity Mapping troubleshooting tips
- Authorization provider troubleshooting tips
- Password decoding troubleshooting tips

Security components troubleshooting tips

This document explains basic resources and steps for diagnosing security-related issues in WebSphere Application Server.

Basic resources and steps for diagnosing security-related issues in WebSphere Application Server include:

- What “Log files” on page 1436 to look at and what to look for in them.
- What to look at and what to look for “Using SDSF” on page 1437.
- “General approach for troubleshooting security-related issues” on page 1438 to isolating and resolving security problems.
- When and how to “Trace security” on page 1442.
- An overview and table of “CSIv2 CORBA minor codes” on page 1443.

The following security-related problems are addressed elsewhere in the information center:

- Errors and access problems after enabling security

After enabling security, a degradation in performance is realized. For more information about using unrestricted policy files, see the Enabling security for the realm section of the *Securing applications and their environment* PDF book.

- Errors after enabling SSL, or SSL-related error messages
- Errors trying to configure and enable security

If none of these steps solves the problem, check to see if the problem is identified and documented using the links in Diagnosing and fixing problems: Resources for learning.

If you do not see a problem that resembles yours, or if the information provided does not solve your problem, contact IBM support for further assistance.

V6.0.x

For an overview of WebSphere Application Server security components such as Secure Authentication Services (SAS) and how they work in a distributed or an iSeries environment, refer to the *Securing applications and their environment* PDF book.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Log files

When troubleshooting the security component, browse the Java Virtual Machine (JVM) logs for the server that hosts the resource you are trying to access. The following is a sample of messages you would expect to see from a server in which the security service has started successfully:

```
SASRas      A CWWSA0001I: Security configuration initialized.
SASRas      A CWWSA0002I: Authentication protocol: CSIV2/IBM
SASRas      A CWWSA0003I: Authentication mechanism: SWAM
SASRas      A CWWSA0004I: Principal name: MYHOSTNAME/aServerID
SASRas      A CWWSA0005I: SecurityCurrent registered.
SASRas      A CWWSA0006I: Security connection interceptor initialized.
SASRas      A CWWSA0007I: Client request interceptor registered.
SASRas      A CWWSA0008I: Server request interceptor registered.
SASRas      A CWWSA0009I: IOR interceptor registered.
NameServerImp I CWNMS0720I: Do Security service listener registration.
SecurityCompo A CWSCJ0242A: Security service is starting
UserRegistryI A CWSCJ0136I: Custom Registry:com.ibm.ws.security.registry.nt.
NTLocalDomainRegistryImpl has been initialized
SecurityCompo A CWSCJ0202A: Admin application initialized successfully
SecurityCompo A CWSCJ0203A: Naming application initialized successfully
SecurityCompo A CWSCJ0204A: Rolebased authorizer initialized successfully
SecurityCompo A CWSCJ0205A: Security Admin mBean registered successfully
SecurityCompo A CWSCJ0243A: Security service started successfully
SecurityCompo A CWSCJ0210A: Security enabled true
```

The following is an example of messages from a server which cannot start the security service, in this case because the administrative user ID and password given to communicate with the user registry is wrong, or the user registry itself is down or misconfigured:

```
SASRas      A CWWSA0001I: Security configuration initialized.
SASRas      A CWWSA0002I: Authentication protocol: CSIV2/IBM
SASRas      A CWWSA0003I: Authentication mechanism: SWAM
SASRas      A CWWSA0004I: Principal name: MYHOSTNAME/aServerID
SASRas      A CWWSA0005I: SecurityCurrent registered.
SASRas      A CWWSA0006I: Security connection interceptor initialized.
SASRas      A CWWSA0007I: Client request interceptor registered.
SASRas      A CWWSA0008I: Server request interceptor registered.
SASRas      A CWWSA0009I: IOR interceptor registered.
NameServerImp I CWNMS0720I: Do Security service listener registration.

SecurityCompo A CWSCJ0242A: Security service is starting
UserRegistryI A CWSCJ0136I: Custom Registry:com.ibm.ws.security.
registry.nt.NTLocalDomainRegistryImpl has been initialized
Authenticatio E CWSCJ4001E: Login failed for badID/<null>
javax.security.auth.login.LoginException: authentication failed: bad user/password
```

The following is an example of messages from a server for which Lightweight Directory Access Protocol (LDAP) has been specified as the security mechanism, but the LDAP keys have not been properly configured:

```
SASRas      A CWWSA0001I: Security configuration initialized.
SASRas      A CWWSA0002I: Authentication protocol: CSIV2/IBM
SASRas      A CWWSA0003I: Authentication mechanism: LTPA
SASRas      A CWWSA0004I: Principal name: MYHOSTNAME/anID
SASRas      A CWWSA0005I: SecurityCurrent registered.
SASRas      A CWWSA0006I: Security connection interceptor initialized.
SASRas      A CWWSA0007I: Client request interceptor registered.
SASRas      A CWWSA0008I: Server request interceptor registered.
SASRas      A CWWSA0009I: IOR interceptor registered.
```

```
NameServerImp I CWNMS0720I: Do Security service listener registration.
SecurityCompo A CWSCJ0242A: Security service is starting
UserRegistryI A CWSCJ0136I: Custom Registry:com.ibm.ws.security.registry.nt.
NTLocalDomainRegistryImpl has been initialized
SecurityServe E CWSCJ0237E: One or more vital LTPAServerObject configuration
attributes are null or not available. The attributes and values are password :
LTPA password does exist, expiration time 30, private key <null>, public key <null>,
and shared key <null>.
```

A problem with the Secure Sockets Layer (SSL) configuration might lead to the following message. Ensure that the keystore location and keystore passwords are valid. Also, ensure the keystore has a valid personal certificate and that the personal certificate public key or certificate authority (CA) root has been extracted on put into the truststore.

```
SASRas      A CWWSA0001I: Security configuration initialized.
SASRas      A CWWSA0002I: Authentication protocol: CSIV2/IBM
SASRas      A CWWSA0003I: Authentication mechanism: SWAM

General approach for troubleshooting security-related issues

When troubleshooting security-related problems, the following questions are very helpful:

Does the problem occur when security is disabled?

This question is a good litmus test to determine that a problem is security related. However, just because a problem only occurs when security is enabled does not always make it a security problem. More troubleshooting is necessary to ensure the problem is really security-related.

Did security seem to initialize properly?

A lot of security code is visited during initialization. So you can see problems there first if the problem is configuration related.

The following sequence of messages that are generated in the SystemOut.log indicate normal code initialization of an application server. This sequence varies based on the configuration, but the messages are similar:

```

SASRas      A CWWSA0001I: Security configuration initialized.
SASRas      A CWWSA0002I: Authentication protocol: CSIV2/IBM
SASRas      A CWWSA0003I: Authentication mechanism: SWAM
SASRas      A CWWSA0004I: Principal name: BIRKT20/pbirk
SASRas      A CWWSA0005I: SecurityCurrent registered.
SASRas      A CWWSA0006I: Security connection interceptor initialized.
SASRas      A CWWSA0007I: Client request interceptor registered.
SASRas      A CWWSA0008I: Server request interceptor registered.
SASRas      A CWWSA0009I: IOR interceptor registered.
NameServerImp I CWNMS0720I: Do Security service listener registration.
SecurityCompo A CWSCJ0242A: Security service is starting
UserRegistryI A CWSCJ0136I: Custom Registry:com.ibm.ws.security.registry.nt.
NTLocalDomainRegistryImpl has been initialized
SecurityCompo A CWSCJ0202A: Admin application initialized successfully
SecurityCompo A CWSCJ0203A: Naming application initialized successfully
SecurityCompo A CWSCJ0204A: Rolebased authorizer initialized successfully
SecurityCompo A CWSCJ0205A: Security Admin mBean registered successfully
SecurityCompo A CWSCJ0243A: Security service started successfully

SecurityCompo A CWSCJ0210A: Security enabled true

```

The following sequence of messages generated in the SDSF active log indicate normal code initialization of an application server. Non-security messages have been removed from the sequence that follows. This sequence will vary based on the configuration, but the messages are similar:

```

Is there a stack trace or exception printed in the system log file?

A single stack trace tells a lot about the problem. What code initiated the code that failed? What is the failing component? Which class did the failure actually come from? Sometimes the stack trace is all that is needed to solve the problem and it can pinpoint the root cause. Other times, it can only give us a clue, and can actually be misleading. When support analyzes a stack trace, they can request additional trace if it is not clear what the problem is. If it seems to be security-related and the solution cannot be determined from the stack trace or problem description, you are asked to gather the following trace specification: SASRas=all=enabled:com.ibm.ws.security.*=all=enabled from all processes involved.

Is this a distributed security problem or a local security problem?

- If the problem is local, that is the code involved does not make a remote method invocation, then troubleshooting is isolated to a single process. It is important to know when a problem is local versus distributed because the behavior of the object request broker (ORB), among other components, is different between the two. When a remote method invocation takes place, an entirely different security code path is entered.
- **V6.0.x** When you know that the problem involves two or more servers, the techniques of troubleshooting change. You need to trace all the servers involved simultaneously so that the trace shows the client and server sides of the problem. Make sure the timestamps on all machines match as closely as possible so that you can find the request and reply pair from two different processes. Enable both Secure Authentication Services (SAS) or z/SAS and Security trace using the trace specification: SASRas=all=enabled:com.ibm.ws.security.*=all=enabled.

For more information on enabling trace, see Enabling trace.

For more information on enabling trace, see Working with Trace.

Is the problem related to authentication or authorization?

Most security problems fall under one of these two categories. Authentication is the process of determining who the caller is. Authorization is the process of validating that the caller has the proper authority to invoke the requested method. When authentication fails, typically this failure is related to either the authentication protocol, authentication mechanism or user registry. When authorization fails, this is usually related to the application bindings from assembly and deployment and to the caller's identity who is accessing the method and the roles that are required by the method.

Is this a Web or EJB request?

Web requests have a completely different code path than Enterprise JavaBeans (EJB) requests. Different security features exist for Web requests than for EJB requests, requiring a completely

different body of knowledge to resolve. For example, when using the Lightweight Third-Party Authentication (LTPA) authentication mechanism, the single sign-on feature (SSO) is available for Web requests but not for EJB requests. Web requests involve HTTP header information that is not required by EJB requests due to the protocol differences. Also, the Web container or servlet engine is involved in the entire process. Any of these components can be involved in the problem and all require consideration during troubleshooting, based on the type of request and where the failure occurs.

Secure EJB requests heavily involve the ORB and Naming components since they flow over the RMI/IIOP protocol. In addition, when Workload Manager (WLM) is enabled, other behavior changes in the code can be observed. All of these components interact closely for security to work properly in this environment. At times, trace in any or all of these components might be necessary to troubleshoot problems in this area.

V6.0.x

The trace specification to begin with is

SASRas=all=enabled:com.ibm.ws.security.*=all=enabled. ORB trace is also very beneficial when the SAS/Security trace does not seem to pinpoint the problem.

Does the problem seem to be related to the Secure Sockets Layer (SSL)?

SSL is a totally distinct separate layer of security. Troubleshooting SSL problems is usually separate from troubleshooting authentication and authorization problems, and you have many considerations. Usually, SSL problems are first-time setup problems because the configuration can be difficult. Each client must contain the signer certificate of the server. During mutual authentication, each server must contain the client's signer certificate. Also, there can be protocol differences (SSLv3 vs. Transport Layer Security (TLS)), and listener port problems related to stale Interoperable Object References (IORs), that is IORs from a server, that reflect the port prior to the server restarting.

For SSL problems, sometimes you get a request for an SSL trace to determine what is happening with the SSL handshake. The SSL handshake is the process that occurs when a client opens a socket to a server. If anything goes wrong with the key exchange, cipher exchange, and so on, the handshake fails and the socket is not valid. Tracing JSSE (the SSL implementation that is used in WebSphere Application Server) involves the following steps:

- Set the following system property on the client and server processes: `-Djavax.net.debug=true`. For the server, add the system property to the generic JVM arguments property of the JVM settings page. For more information on this task, refer to Java virtual machine settings section of the *Administering applications and their environment* PDF book.
- Turn on ORB trace as well.
- Recreate the problem.

The `SystemOut.log` of both processes contain the JSSE trace. You can find trace similar to the following example:

```
SSLConnection: install <com.ibm.sslite.e@3ae78375>
>> handleHandshakeV2 <com.ibm.sslite.e@3ae78375>
>> handshakeV2 type = 1
>> clientHello: SSLv2.
SSL client version: 3.0
...
...
...
JSSEContext: handleSession[Socket[addr=null,port=0,localport=0]]

<< sendServerHello.
SSL version: 3.0
SSL_RSA_WITH_RC4_128_MD5
HelloRandom
...
...
...
<< sendCertificate.
<< sendServerHelloDone.
>> handleData <com.ibm.sslite.e@3ae78375>
>> handleHandshake <com.ibm.sslite.e@3ae78375>
>> handshakeV3 type = 16
```

```

>> clientKeyExchange.
>> handleData <com.ibm.sslite.e@3ae78375>
>> handleChangeCipherSpec <com.ibm.sslite.e@3ae78375>
>> handleData <com.ibm.sslite.e@3ae78375>
>> handleHandshake <com.ibm.sslite.e@3ae78375>
>> handshakeV3 type = 20
>> finished.
<< sendChangeCipherSpec.
<< sendFinished.

```

Trace security

The classes that implement WebSphere Application Server security are:

- com.ibm.ws.security.*
- com.ibm.websphere.security.*
- com.ibm.WebSphereSecurityImpl.*
- SASRas
- com.ibm.ws.wim.* for tracing with a Virtual Member Manager (VMM) repository

To view detailed information on the run time behavior of security, enable trace on the following components and review the output:

- com.ibm.ws.security.*=all=enabled:com.ibm.WebSphereSecurityImpl.*=all=enabled:com.ibm.websphere.security.*=all=enabled. This trace statement collects the trace for the security runtime.
- com.ibm.ws.console.security.*=all=enabled. This trace statement collects the trace for the security center administrative console.
- **V6.0.x** SASRas=all=enabled. This trace statement collects the trace for SAS (low-level authentication logic).
- com.ibm.ws.wim.*=all=enabled:com.ibm.websphere.wim.*=all=enabled. This trace statement collects the trace for VMM.

V6.0.x

Fine tuning Security traces:

If a subset of packages need to be traced, specify a trace specification more detailed than com.ibm.ws.security.*=all=enabled. For example, to trace just dynamic policy code, you can specify com.ibm.ws.security.policy.*=all=enabled. To disable dynamic policy trace, you can specify com.ibm.ws.security.policy.*=all=disabled.

Configuring CSiv2, or SAS Trace Settings

Situations arise where reviewing trace for the CSiv2 or SAS authentication protocols can assist in troubleshooting difficult problems. This section describes how to enable to CSiv2 and SAS trace.

Enabling Client-Side CSiv2 and SAS Trace

To enable CSiv2 and SAS trace on a pure client, the following steps need to be taken:

- Edit the file TraceSettings.properties in the /WebSphere/AppServer/properties directory. For example, edit *profile_root/properties/TraceSettings.properties*.
- In this file, change traceFileName= to point to the path in which you want the output file created. For example, traceFileName=*profile_root/logs/sas_client*.
- In this file, add the trace specification string: SASRas=all=enabled. Any additional trace strings can be added on separate lines.
- Point to this file from within your client application. On the Java command line where you launch the client, add the following system property:
-DtraceSettingsFile=TraceSettings.properties.

Note: Do not give the fully qualified path to the TraceSettings.properties file. Make sure that the TraceSettings.properties file is in your class path.

Enabling Server-Side CSiv2 and SAS Trace

To enable SAS trace in an application server, complete the following:

- Add the trace specification, SASRas=all=enabled, to the server.xml file or add it to the Trace settings within the WebConsole GUI.
- Typically it is best to also trace the authorization security runtime in addition to the authentication protocol runtime. To do this, use the following two trace specifications in combination: SASRas=all=enabled:com.ibm.ws.security.*=all=enabled.
- When troubleshooting a connection type problem, it is beneficial to trace both CSiv2 and SAS or CSiv2 and z/SAS and the ORB. To do this, use the following three trace specifications:
SASRas=all=enabled:com.ibm.ws.security.*=all=enabled:ORBRas=all=enabled.
- In addition to adding these trace specifications, for ORB trace there are a couple of system properties that also need to be set. Go to the ORB settings in the GUI and add the following two properties: com.ibm.CORBA.Debug=true and com.ibm.CORBA.CommTrace=true.

CSiv2 CORBA minor codes

Whenever exceptions occur within the security code on either the client or server, the eventual exception becomes a Common Object Request Broker Architecture (CORBA) exception. Any exception that occurs gets embedded in a CORBA exception because the CORBA architecture is used by the security service for its own inter-process communication. CORBA exceptions are generic and indicate a problem in communication between two components. CORBA minor codes are more specific and indicate the underlying reason that a component could not complete a request.

The following shows the CORBA minor codes that a client can expect to receive after running a security-related request such as authentication. It also includes the CORBA exception type that the minor code appears in.

The following exception shows an example of a CORBA exception where the minor code is 49424300 and indicates Authentication Failure. Typically, a descriptive message is also included in the exception to assist in troubleshooting the problem. Here, the detailed message is: "Exception caught invoking authenticateBasicAuthData from SecurityServer for user jdoe. Reason: com.ibm.WebSphereSecurity.AuthenticationFailedException" which indicates that the authentication failed for user jdoe.

The completed field in the exception indicates whether the method was completed or not. In the case of a NO_PERMISSION, never invoke the message; therefore it is always completed:No. Other exceptions that are caught on the server side can have a completed status of "Maybe" or "Yes".

```
org.omg.CORBA.NO_PERMISSION: Caught WSSecurityContextException in
WSSecurityContext.acceptSecContext(),
reason: Major Code[0] Minor Code[0] Message[Exception caught invoking
authenticateBasicAuthData from SecurityServer for user jdoe. Reason:
com.ibm.WebSphereSecurity.AuthenticationFailedException] minor code: 49424300
completed: No
```

```

```

The following table shows the CORBA minor codes which a client can expect to receive after running a security-related request such as authentication. It also includes the CORBA exception type that the minor code would appear in.

Table 58.

Minor code name	Minor code value (in hex)	Exception type (all in the package of org.omg.CORBA .*)	Minor code description	Retry performed (when authenticationRetryEnabled = true)
AuthenticationFailed	49424300	NO_PERMISSION	This code is a generic authentication failed error. It does not give any details about whether or not the user ID or password is valid. Some user registries can choose to use this type of error code, others can choose to use the next three types that are more specific.	Yes
InvalidUserId	49424301	NO_PERMISSION	This code occurs when the registry returns bad user ID.	Yes
InvalidPassword	49424302	NO_PERMISSION	This code occurs when the registry returns a bad password.	Yes
InvalidSecurityCredentials	49424303	NO_PERMISSION	This is a generic error indicating that the credentials are bad for some reason. It might be that the right attributes are not set.	Yes, if client has BasicAuth credential (token based credential was rejected in the first place).
InvalidRealm	49424304	NO_PERMISSION	This code occurs when the REALM in the token received from the client does not match the server's current realm.	No
ValidationFailed	49424305	NO_PERMISSION	A validation failure occurs when a token is sent from the client or server to a target server but the token format or the expiration is not valid.	Yes, if client has BasicAuth credential (token based credential was rejected in the first place).
CredentialTokenExpired	49424306	NO_PERMISSION	This code is more specific about why the validation failed. In this case, the token has an absolute lifetime and the lifetime has expired. Therefore, it is no longer a valid token and cannot be used.	Yes, if client has BasicAuth credential (token based credential was rejected in the first place).
InvalidCredentialToken	49424307	NO_PERMISSION	This is more specific about why the validation failed. In this case, the token cannot be decrypted or the data within the token is not readable.	Yes, if client has BasicAuth credential (token based credential was rejected in the first place).
SessionDoesNotExist	49424308	NO_PERMISSION	This indicates that the CSv2 session does not exist on the server. Typically, a retry occurs automatically and successfully creates a new session.	Yes
SessionConflictingEvidence	49424309	NO_PERMISSION	This indicates that a session already exists on the server that matches the context_id sent over by the client. However, the information provided by the client for this EstablishContext message is different from the information originally provided to establish the session.	Yes
SessionRejected	4942430A	NO_PERMISSION	This indicates that the session referenced by the client has been previously rejected by the server.	Yes

Table 58. (continued)

Minor code name	Minor code value (in hex)	Exception type (all in the package of org.omg.CORBA.*)	Minor code description	Retry performed (when authenticationRetryEnabled = true)
SecurityServerNotAvailable	4942430B	NO_PERMISSION	This error occurs when the server cannot contact the local or remote security server in order to authenticate or validate.	No
InvalidIdentityToken	4942430C	NO_PERMISSION	This error indicates that identity cannot be obtained from the identity token when Identity Assertion is enabled.	No
IdentityServerNotTrusted	4942430D	NO_PERMISSION	This indicates that the server ID of the sending server is not on the target server's trusted principal list.	No
InvalidMessage	4942430E	NO_PERMISSION	This indicates that the CSIV2 message format is not valid for the receiving server.	No
AuthenticationNotSupported	49421090	NO_PERMISSION	This error occurs when a mechanism does not support authentication (very rare).	No
InvalidSecurityMechanism	49421091	NO_PERMISSION	This is used to indicate that the specified security mechanism is not known.	No
CredentialNotAvailable	49421092	NO_PERMISSION	This indicates a credential is not available when it is required.	No
SecurityMechanismNotSupported	49421093	NO_PERMISSION	This error occurs when a security mechanism that is specified in the CSIV2 token is not implemented on the server.	No
ValidationNotSupported	49421094	NO_PERMISSION	This error occurs when a mechanism does not support validation, such as LocalOS. This error does not occur since the LocalOS credential is not a forwardable credential, therefore, validation never needs to be called on this credential.	No
CredentialTokenNotSet	49421095	NO_PERMISSION	This is used to indicate that the token inside the credential is null.	No
ServerConnectionFailed	494210A0	COMM_FAILURE	This error is used when a connection attempt fails.	Yes (via ORB retry)
CorbaSystemException	494210B0	INTERNAL	This code is a generic CORBA specific exception in system code.	No
JavaException	494210B1	INTERNAL	This is a generic error that indicated that an unexpected Java exception occurred.	No
ValuelsNull	494210B2	INTERNAL	This code is used to indicate that a value or parameter that passed in is null.	No
EffectivePolicyNotPresent	494210B3	INTERNAL	This indicates that an effective policy object for CSIV2 is not present. This object is used to determine what security configuration features are specified.	No
NullPointerException	494210B4	INTERNAL	This code is used to indicate that a NullPointerException is caught in the runtime.	No
ErrorGettingClassInstance	494210B5	INTERNAL	This indicates a problem loading a class dynamically.	No

Table 58. (continued)

Minor code name	Minor code value (in hex)	Exception type (all in the package of org.omg.CORBA.*)	Minor code description	Retry performed (when authenticationRetryEnabled = true)
MalFormedParameters	494210B6	INTERNAL	This indicates parameters are not valid.	No
DuplicateSecurityAttributeType	494210B7	INTERNAL	This indicates a duplicate credential attribute that is specified during the set_attributes operation.	No
MethodNotImplemented	494210C0	NO_IMPLEMENT	This indicates that a method invoked is not implemented.	No
GSSFormatError	494210C5	BAD_PARAM	This code indicates that a Generic Security Services (GSS) encoding or decoding routine has created an exception.	No
TagComponentFormatError	494210C6	BAD_PARAM	This code indicates that a tag component cannot be read properly.	No
InvalidSecurityAttributeType	494210C7	BAD_PARAM	This code indicates an attribute type specified during the set_attributes operation is not a valid type.	No
SecurityConfigError	494210CA	INITIALIZE	This code indicates a problem exists between the client and server configuration.	No

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Errors when trying to configure or enable security

Use this information to troubleshoot problems with configuring or enabling security.

What kind of error are you seeing?

- ““LTPA password not set. validation failed” message displayed as error in the administrative console after saving administrative or application security settings ” on page 1447
- “Errors when trying to configure or enable security”
- “WebSphere Application Server Version 6 is not working correctly with Enterprise Workload Manager (EWLM)” on page 1447
- If you successfully configured security, but are now having problems accessing Web resources or the administrative console, refer to Errors or access problems after enabling security.
- “NMSV0610I: A NamingException is being thrown from a javax.naming.Context implementation” on page 1447

For general tips on diagnosing and resolving security-related problems, see the topic Troubleshooting the security component.

IBM Support has documents and tools that can save you time gathering information needed to resolve problems as described in Troubleshooting help from IBM. Before opening a problem report, see the Support page:

- <http://www.ibm.com/servers/eserver/support/series/software/v5r3/index.html>

"LTPA password not set. validation failed" message displayed as error in the administrative console after saving administrative or application security settings

This error can be caused if, when configuring WebSphere Application Server security, LTPA is selected as the authentication mechanism and the LTPA password field is not set. To resolve this problem:

- Select **Security > Secure administration, applications and infrastructure > Authentication mechanisms and expiration** .
- Complete the password and confirm password fields.
- Click **OK**.
- Try setting administrative or application security again.

WebSphere Application Server Version 6 is not working correctly with Enterprise Workload Manager (EWLM)

To use WebSphere Application Server Version 6 with EWLM, you must manually update the WebSphere Application Server server.policy files. For example:

```
grant codeBase "file:<EWLM_Install_Home>/classes/ARM/arm4.jar" {
    permission java.security.AllPermission;
};
```

Otherwise, you might encounter a Java 2 security exception for violating the Java 2 security permission.

For more information on configuring server.policy files, refer to the server.policy file permissions section in the *Developing and deploying applications* PDF book.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

NMSV0610I: A NamingException is being thrown from a javax.naming.Context implementation

If you use CSiv2 inbound authentication, basic authentication is required, and Java clients running with `com.ibm.CORBA.validateBasicAuth=true` might fail with the following exception:

If you use CSiv2 inbound authentication, basic authentication is required, and Java™ clients running with `com.ibm.CORBA.validateBasicAuth=true` might fail with the following exception:

```
NMSV0610I: A NamingException is being thrown from a javax.naming.Context
implementation. Details follow:
```

```
Context implementation: com.ibm.ws.naming.jndicos.CNContextImpl
Context method: lookupExt
Context name: TestaburgerNode01Cell/nodes/TestaburgerNode01/servers/server1
Target name: SecurityServer
Other data: ""
Exception stack trace: javax.naming.NoPermissionException: NO_PERMISSION
exception caught. Root exception is org.omg.CORBA.NO_PERMISSION:
vmcid: 0x49421000 minor code: 92 completed: No
...
SECJ0395E: Could not locate the SecurityServer at host/port:9.42.72.27/9100
to validate the userid and password entered. You may need to specify valid
securityServerHost/Port in (WAS_INSTALL_ROOT)/properties/sas.client.props file.
```

To fix this problem, modify the `com.ibm.CORBA.validateBasicAuth=false` property in the `clients.sas.clients.props` file and then run the client.

Errors after enabling security

Use this information if you are experiencing errors after security is enabled.

What kind of error are you seeing?

- Authentication error accessing a Web page
- Authorization error accessing a Web page
- Error Message: CWSCJ0314E: Current Java 2 security policy reported a potential violation
- CWMSG0508E: The JMS Server security service was unable to authenticate user ID: error displayed in SystemOut.log when starting an application server
- Error Message: CWSCJ0237E: One or more vital LTPAServerObject configuration attributes are null or not available after enabling security and starting the application server
- An AccessControlException is reported in the SystemOut.log
- Error Message: CWSCJ0336E: Authentication failed for user {0} because of the following exception {1}

For general tips on diagnosing and resolving security-related problems, see the topic [Troubleshooting the security component](#).

IBM Support has documents and tools that can save you time gathering information needed to resolve problems as described in [Troubleshooting help from IBM](#). Before opening a problem report, see the [Support page](#):

- <http://www.ibm.com/servers/eserver/support/series/software/v5r3/index.html>

Authentication error accessing a Web page

Possible causes for authentication errors include:

- **Incorrect user name or passwords.** Check the user name and password and make sure that they are correct.
- **Security configuration error : User registry type is not set correctly.** Check the user registry property in administrative security settings in the administrative console. Verify that the user registry property is the intended user registry.
- **Internal program error.** If the client application is a Java standalone program, this program might not gather or send credential information correctly.

If the user registry configuration, user ID, and password appear correct, use the WebSphere Application Server trace to determine the cause of the problem. To enable security trace, use the `com.ibm.ws.security.*=all=enabled` trace specification.

Authorization error accessing a Web page

If a user who is supposed to have access to a resource does not, a configuration step is probably missing. For more information on configuring access to resources, review the chapter [Authorizing access to administrative roles](#) in the *Securing applications and their environment* PDF book.

Specifically:

- Check the required roles for the accessed Web resource.
- Check the authorization table to make sure that the user, or the groups to which the user belongs, is assigned to one of the required roles.
- View required roles for the Web resource in the deployment descriptor of the Web resource.
- View the authorization table for the application that contains the Web resource, using the administrative console.
- Test with a user who is granted the required roles, to see if the user can access the problem resources.
- If the user is required to have one or more of the required roles, use the administrative console to assign that user to required roles, stop, and restart the application.

If the user is granted required roles, but still fails to access the secured resources, enable security trace, using `com.ibm.ws.security.*=all=enabled` as the trace specification. Collect trace information for further resolution.

Error Message: CWSCJ0314E: Current Java 2 security policy reported a potential violation on server

If you find errors on your server similar to:

```
Error Message: CWSCJ0314E: Current Java 2 Security policy reported a potential violation of
Java 2 Security Permission. Please refer to Problem Determination Guide for further information.
{0}Permission/:{1}Code/:{2}{3}Stack Trace/:{4}Code Base Location/:{5}
```

The Java security manager `checkPermission` method has reported a `SecurityException` exception .

The reported exception might be critical to the secure system. Turn on security trace to determine the potential code that might have violated the security policy. Once the violating code is determined, verify if the attempted operation is permitted with respect to Java 2 Security, by examining all applicable Java 2 security policy files and the application code.

A more detailed report is enabled by either configuring RAS trace into debug mode, or specifying a Java property.

- Check the trace enabling section for instructions on how to configure Reliability Availability Serviceability (RAS) trace into debug mode, or
- Specify the following property in the **Application Servers > server_name > ProcessDefinition > Java Virtual Machine** panel from the administrative console in the **Generic JVM arguments** panel:
 - Add the **java.security.debug** run-time flag
 - Valid values:
 - access** Print all debug information including required permission, code, stack, and code base location.
 - stack** Print debug information including required permission, code, and stack.
 - failure** Print debug information including required permission, and code.

For a review of Java security policies, see the Java 2 Security documentation at <http://java.sun.com/j2se/1.3/docs/guide/security/index.html>.

Tip: If the application is running with a Java Mail application programming interface (API), this message might be benign. You can update the `installed Enterprise Application root/META-INF/was.policy` file to grant the following permissions to the application:

- `permission java.io.FilePermission "${user.home}${}/.mailcap", "read";`
- `permission java.io.FilePermission "${user.home}${}/.mime.types", "read";`
- `permission java.io.FilePermission "${java.home}${}/lib${}/mailcap", "read";`
- `permission java.io.FilePermission "${java.home}${}/lib${}/mime.types", "read";`

Error message: CWMSG0508E: The JMS Server security service was unable to authenticate user ID:" error displayed in SystemOut.log when starting an application server

This error can result from installing the Java Message Service (JMS) API sample and then enabling security. You can follow the instructions in the `Configure and Run` page of the corresponding JMS sample documentation to configure the sample to work with WebSphere Application Server security.

You can verify the installation of the message-driven bean sample by launching the installation program, selecting **Custom**, and browsing the components which are already installed in the `Select the features you like to install` panel. The JMS sample is shown as **Message-Driven Bean Sample**, under `Embedded Messaging`.

You can also verify this installation by using the administrative console to open the properties of the application server that contains the samples. Select **MDBSamples** and click **uninstall**.

Error message: CWSCJ0237E: One or more vital LTPAServerObject configuration attributes are null or not available after enabling security and starting the application server.

This error message can result from selecting Lightweight Third Party Authentication (LTPA) as the authentication mechanism, but not generating the LTPA keys. The LTPA keys encrypt the LTPA token.

To resolve this problem:

1. Click **Security > Secure administration, applications and infrastructure> Authentication > Authentication mechanisms and expiration> LTPA**
2. Enter a password, which can be anything.
3. Enter the same password in **Confirm Password**.
4. Click **Apply**.
5. Click **Generate Keys**.
6. Click **Save**.

The AccessControlException exception, is reported in the SystemOut.log

The problem is related to the Java 2 security feature of WebSphere Application Server, the API-level security framework that is implemented in WebSphere Application Server. An exception similar to the following example displays. The error message and number can vary.

```
CWSRV0020E: [Servlet Error]-[validator]: Failed to load servlet:  
java.security.AccessControlException: access denied  
(java.io.FilePermission  
app_server_root/systemApps/isclite.ear/isclite.war/WEB-INF/validation.xml read)
```

For an explanation of Java 2 security, how and why to enable or disable it, how it relates to policy files, and how to edit policy files, see the Java 2 security topic in the *Securing applications and their environment* PDF book. The topic explains that Java 2 security is not only used by this product, but developers can also implement it for their business applications. Administrators might need to involve developers, if this exception is created when a client tries to access a resource that is hosted by WebSphere Application Server.

Possible causes of these errors include:

- Syntax errors in a policy file.
- Syntax errors in permission specifications in the ra.xml file that is bundled in a .rar file. This case applies to resource adapters that support connector access to CICS or other resources.
- An application is missing the specified permission in a policy file, or in permission specifications in ra.xml file bundled in a .rar file.
- The class path is not set correctly, preventing the permissions for the resource.xml file for Service Provider Programming Interface (SPI) from being correctly created.
- A library called by an application, or the application, is missing a doPrivileged block to support access to a resource.
- Permission is specified in the wrong policy file.

To resolve these problems:

- Check all of the related policy files to verify that the permission shown in the exception, for example java.io.FilePermission, is specified.
- Look for a related ParserException exception in the SystemOut.log file which reports the details of the syntax error. For example:

```
CWSCJ0189E: Caught ParserException while creating template for application policy  
  
profile_root/config/cells/cell_name/nodes/node_name/app.policy
```

Where:

- *cell_name* represents the name of your cell.
- *profile_name* represents the name of your profile.
- *node_name* represents the name of your node.

The exception is `com.ibm.ws.security.util.ParserException: line 18: expected ';', found 'grant'`

- Look for a message similar to: `CWSCJ0325W: The permission permission specified in the policy file is unresolved.`
- Check the call stack to determine which method does not have the permission. Identify the class path of this method. If it is hard to identify the method, enable the Java2 security Report.
 - Configuring RAS trace by specifying `com.ibm.ws.security.core.*=all=enabled`, or specifying a Java **property.java.security.debug** property. Valid values for the **java.security.debug** property are:
 - access**
Print all debug information including: required permission, code, stack, and code base location.
 - stack** Print debug information including: required permission, code, and stack.
 - failure** Print debug information including: required permission and code.
 - The report shows:
 - Permission**
The missing permission.
 - Code** Which method has the problem.
 - Stack Trace**
Where the access violation occurred.
 - CodeBaseLocation**
The detail of each stack frame.

Usually, permission and code are enough to identify the problem. The following example illustrates a report:

Permission:

```
profile_root/logs/server1/SystemOut_02.08.20_11.19.53.log :
access denied (java.io.FilePermission
profile_root/logs/server1/SystemOut_02.08.20_11.19.53.log delete)
```

Code:

```
com.ibm.ejs.ras.RasTestHelper$7 in
{file:profile_root/installedApps/app1/JrasFVTApp.ear/RasLib.jar
}
```

Stack Trace:

```

```

Where:

- *app1* represents the name of your application.
- *app_server_root* represents the installation root directory for WebSphere Application Server Network Deployment.
- *profile_root* represents the location and name of a particular profile in your system.
- *profile1* or *profile_name* represents the name of your profile.
- *server1* or *server_name* represents the name of your application server.
- If the method is SPI, check the resources.xml file to ensure that the class path is correct.
- To confirm that all of the policy files are loaded correctly, or what permission each class path is granted, enable the trace with **com.ibm.ws.security.policy.*=all=enabled**. All loaded permissions are listed in the trace.log file. Search for the app.policy, was.policy and ra.xml files. To check the permission list for a class path, search for **Effective Policy for classpath**.
- If there are any syntax errors in the policy file or the ra.xml file, correct them with the policy tool. Avoid editing the policy manually, because syntax errors can result. For additional information about using this tool, refer to the section Using PolicyTool to edit policy files in the *Developing and deploying applications* PDF book.
- If a permission is listed as Unresolved, it does not take effect. Verify that the specified permission name is correct.
- If the class path that is specified in the resource.xml file is not correct, correct it.
- If a required permission does not exist in either the policy files or the ra.xml file, examine the application code to see if you need to add this permission. If so, add it to the proper policy file or the ra.xml file.
- If the permission is not granted outside of the specific method that is accessing this resource, modify the code needs to use a doPrivileged block.
- If this permission does exist in a policy file or a ra.xml file and the permission was loaded correctly, but the class path still does not have the permission in its list, the location of the permission might not be correct. Read the Java 2 security chapter in the *Securing applications and their environment* PDF book carefully to determine in which policy file or ra.xml file to specify that permission.

Tip: If the application is running with the Java Mail API, you can update the *installed Enterprise Application root/META-INF/was.policy* file to grant the following permissions to the application:

- permission java.io.FilePermission "\${user.home}\${}/.mailcap", "read";
- permission java.io.FilePermission "\${user.home}\${}/.mime.types", "read";
- permission java.io.FilePermission "\${java.home}\${}/lib\${}/mailcap", "read";
- permission java.io.FilePermission "\${java.home}\${}/lib\${}/mime.types", "read";

Error Message: CWSCJ0336E: Authentication failed for user {0} because of the following exception {1}

This error message results if the user ID that is indicated is not found in the Lightweight Directory Access Protocol (LDAP) user registry. To resolve this problem:

1. Verify that your user ID and password are correct.
2. Verify that the user ID exists in the registry.
3. Verify that the base distinguished name (DN) is correct.
4. Verify that the user filter is correct.
5. Verify that the bind DN and the password for the bind DN are correct. If the bind DN and password are not specified, add the missing information and retry.
6. Verify that the host name and LDAP type are correct.

Consult with the administrator of the user registry if the problem persists.

Access problems after enabling security

Use this information if you are experiencing access problems after enabling security.

What kind of error are you seeing?

- I cannot access all or part of the administrative console or use the wsadmin tool after enabling security
- I cannot access a Web page after enabling security
- Authentication error accessing a Web page
- Authorization error accessing a Web page
- The client cannot access an enterprise bean after enabling security
- The client never gets prompted when accessing a secured enterprise bean
- I cannot stop an application server, node manager, or node after enabling security
- AccessControlException is reported in SystemOut.log
- After enabling single sign-on, I cannot log on to the administrative console
- The following exception displays in the SystemOut.log file after I start the server and enable security:
"SECJ0306E: No received or invocation credential exists on the thread."

For general tips on diagnosing and resolving security-related problems, see the topic Troubleshooting the security component.

If you do not see a problem that resembles yours, or if the information provided does not solve your problem, see Troubleshooting help from IBM.

I cannot access all or part of the administrative console or use the wsadmin tool after enabling security

- If you cannot access the administrative console, or view and update certain objects, look in the SystemOut log of the application server which hosts the administrative console page for a related error message.
- You might not have authorized your ID for administrative tasks. This problem is indicated by errors such as:
 - [8/2/02 10:36:49:722 CDT] 4365c0d9 RoleBasedAuth A CWSCJ0305A: Role based authorization check failed for security name MyServer/myUserId, accessId MyServer/S-1-5-21-882015564-4266526380-2569651501-1005 while invoking method getProcessType on resource Server and module Server.
 - Exception message: "CWMN0022E: Access denied for the getProcessType operation on Server MBean"
 - When running the command: wsadmin -username j2ee -password j2ee: CWWAX7246E: Cannot establish "SOAP" connection to host "BIRKT20" because of an authentication failure. Ensure that user and password are correct on the command line or in a properties file.

To grant an ID administrative authority, from the administrative console, click **System Administration > Console Users** and validate that the ID is a member. If the ID is not a member, add the ID with at least monitor access privileges, for read-only access.

- Verify that the `enable_trusted_application` flag is set to `true`. To check the `enable_trusted_application` flag value using the administrative console, click **Security > Secure administration, applications and infrastructure**. Under Additional properties, click **Custom properties > EnableTrustedApplications**.

I cannot access a Web page after enabling security

When secured resources are not accessible, probable causes include:

- Authentication errors - WebSphere Application Server security cannot identify the ID of the person or process. Symptoms of authentication errors include:
 - On a Netscape browser:
 - Authorization failed. Retry? message is displayed after an attempt to log in.
 - Accepts any number of attempts to retry login and displays Error 401 message when Cancel is clicked to stop retry.
 - A typical browser message displays: Error 401: Basic realm='Default Realm'.
 - On an Internet Explorer browser:
 - Login prompt displays again after an attempt to log in.
 - Allows three attempts to retry login.
 - Displays Error 401 message after three unsuccessful retries.
- Authorization errors - The security function has identified the requesting person or process as not authorized to access the secured resource. Symptoms of authorization errors include:
 - Netscape browser: "Error 403: AuthorizationFailed" message is displayed.
 - Internet Explorer:
 - "You are not authorized to view this page" message is displayed.
 - "HTTP 403 Forbidden" error is also displayed.
- SSL errors - WebSphere Application Server security uses Secure Sockets Layer (SSL) technology internally to secure and encrypt its own communication, and incorrect configuration of the internal SSL settings can cause problems. Also you might have enabled SSL encryption for your own Web application or enterprise bean client traffic which, if configured incorrectly, can cause problems regardless of whether WebSphere Application Server security is enabled.
 - SSL-related problems are often indicated by error messages that contain a statement such as:
ERROR: Could not get the initial context or unable to look up the starting context.Exiting. followed by `javax.net.ssl.SSLHandshakeException`

The client cannot access an enterprise bean after enabling security

If the client access to an enterprise bean fails after security is enabled:

- Review the steps for securing and granting access to resources.
- Browse the server JVM logs for errors relating to enterprise bean access and security. Look up any errors in the message table.

Errors similar to Authorization failed for /UNAUTHENTICATED while invoking *resource* `securityName:/UNAUTHENTICATED;accessId:UNAUTHENTICATED` not granted any of the required roles *roles* indicate that:

- An unprotected servlet or JavaServer Pages (JSP) file accessed a protected enterprise bean. When an unprotected servlet is accessed, the user is not prompted to log in and the servlet runs as UNAUTHENTICATED. When the servlet makes a call to an enterprise bean that is protected, the servlet fails.

To resolve this problem, secure the servlet that is accessing the protected enterprise bean. Make sure that the `runAs` property for the servlet is set to an ID that can access the enterprise bean.

- An unauthenticated Java client program is accessing an enterprise bean resource that is protected. This situation can happen if the file that is read by the `sas.client.props` properties file that is used by the client program does not have the `securityEnabled` flag set to `true`.

To resolve this problem, make sure that the `sas.client.props` file on the client side has its `securityEnabled` flag set to `true`.

Errors similar to Authorization failed for `valid_user` while invoking `resource` `securityName:/username;accessId:xxxxxx` not granted any of the required roles `roles` indicate that a client attempted to access a secured enterprise bean resource, and the supplied user ID is not assigned the required roles for that enterprise bean.

- Check that the required roles for the enterprise bean resource are accessed. View the required roles for the enterprise bean resource in the deployment descriptor of the Web resource.
- Check the authorization table and make sure that the user or the group that the user belongs to is assigned one of the required roles. You can view the authorization table for the application that contains the enterprise bean resource using the administrative console.

If `org.omg.CORBA.NO_PERMISSION` exceptions occur when programmatically logging on to access a secured enterprise bean, an authentication exception has occurred on the server. Typically the CORBA exception is triggered by an underlying `com.ibm.WebSphereSecurity.AuthenticationFailedException`. To determine the actual cause of the authentication exception, examine the full trace stack:

1. Begin by viewing the text following `WSSecurityContext.acceptSecContext()`, `reason:` in the exception. Typically, this text describes the failure without further analysis.
2. If this action does not describe the problem, look up the Common Object Request Broker Architecture (CORBA) minor code. The codes are listed in the article titled [Troubleshooting the security components reference](#).

For example, the following exception indicates a CORBA minor code of 49424300. The explanation of this error in the CORBA minor code table reads:

```
authentication failed error
```

In this case the user ID or password supplied by the client program is probably not valid:

```
org.omg.CORBA.NO_PERMISSION: Caught WSSecurityContextException in
WSSecurityContext.acceptSecContext(), reason: Major Code[0] Minor Code[0]
Message[ Exception caught invoking authenticateBasicAuthData from SecurityServer
for user jdoe. Reason: com.ibm.WebSphereSecurity.AuthenticationFailedException]
minor code: 49424300 completed:
No at com.ibm.ISecurityLocalObjectBaseL13Impl.PrincipalAuthFailReason.map_auth_fail_to_minor_code
(PrincipalAuthFailReason.java:83)
```

A CORBA INITIALIZE exception with `CWSA1477W: SECURITY CLIENT/SERVER CONFIGURATION MISMATCH` error embedded, is received by client program from the server.

This error indicates that the security configuration for the server differs from the client in some fundamental way. The full exception message lists the specific mismatches. For example, the following exception lists three errors:

```
Exception received: org.omg.CORBA.INITIALIZE:
CWSA1477W: SECURITY CLIENT/SERVER CONFIG MISMATCH:
The client security configuration (sas.client.props or outbound settings in
administrative console) does not support the server security configuration for
the following reasons:
ERROR 1: CWSA0607E: The client requires SSL Confidentiality but the server does not
support it.
ERROR 2: CWSA0610E: The server requires SSL Integrity but the client does not
support it.
ERROR 3: CWSA0612E: The client requires client (e.g., userid/password or token),
but the server does not support it.
minor code: 0
completed: No at
com.ibm.ISecurityLocalObjectBaseL13Impl.SecurityConnectionInterceptor.getConnectionKey
(SecurityConnectionInterceptor.java:1770)
```

In general, resolving the problem requires a change to the security configuration of either the client or the server. To determine which configuration setting is involved, look at the text following the CWSA error

message. For more detailed explanations and instructions, look in the message reference, by selecting the **Reference** view of the information center navigation and expanding **Messages** in the navigation tree.

In these particular cases:

- In ERROR 1, the client is requiring SSL confidentiality but the server does not support SSL confidentiality. Resolve this mismatch in one of two ways. Either update the server to support SSL confidentiality or update the client so that it no longer requires it.
- In ERROR 2, the server requires SSL integrity but the client does not support SSL integrity. Resolve this mismatch in one of two ways. Either update the server to support SSL integrity or update the client so that it no longer requires it.
- In ERROR 3, the client requires client authentication through a user id and password, but the server does not support this type of client authentication. Either the client or the server needs to change the configuration. To change the client configuration, modify the `SAS.CLIENT.PROPS` file for a pure client or change the outbound configuration for the server in the Security administrative console. To change the configuration for the target server, modify the inbound configuration in the Security administrative console.

Similarly, an exception like `org.omg.CORBA.INITIALIZE: JSAS0477W: SECURITY CLIENT/SERVER CONFIG MISMATCH`: appearing on the server trying to service a client request indicates a security configuration mismatch between client and server. The steps for resolving the problem are the same as for the `JSAS1477W` exceptions previously described.

Client program never gets prompted when accessing secured enterprise bean

Even though it seems that security is enabled and an enterprise bean is secured, occasions can occur when the client runs the remote method without prompting. If the remote method is protected, an authorization failure results. Otherwise, run the method as an unauthenticated user.

Possible reasons for this problem include:

- The server with which you are communicating might not have security enabled. Check with the WebSphere Application Server administrator to ensure that the server security is enabled. Access the security settings from within the **Security** section of the administrative console.
- The client does not have security enabled in the `sas.client.props` file. Edit the `sas.client.props` file to ensure the property `com.ibm.CORBA.securityEnabled` is set to `true`.
- The client does not have a `ConfigURL` specified. Verify that the property `com.ibm.CORBA.ConfigURL` is specified on the command line of the Java client, using the `-D` parameter.
- The specified `ConfigURL` does not have a valid URL syntax, or the `sas.client.props` that is pointed to cannot be found. Verify that the `com.ibm.CORBA.ConfigURL` property is valid. Check the Java documentation for a description of URL formatting rules. Also, validate that the file exists at the specified path.
- The client configuration does not support message layer client authentication (user ID and password). Verify that the `sas.client.props` file has one of the following properties set to `true`:
 - `com.ibm.CSI.performClientAuthenticationSupported=true`
 - `com.ibm.CSI.performClientAuthenticationRequired=true`
- The server configuration does not support message layer client authentication, which consists of a user ID and password. Check with the WebSphere Application Server administrator to verify that user ID and password authentication is specified for the inbound configuration of the server within the System Administration section of the administrative console administration tool.

Cannot stop an application server, node manager, or node after enabling security

If you use command-line utilities to stop WebSphere Application Server processes, apply additional parameters after enabling security to provide authentication and authorization information.

Use the `./stopServer -help` command to display the parameters to use.

Use the following command options after enabling security:

- `./stopServer serverName -username name -password password`
- `./stopNode -username name -password password`
- `./stopManager -username name -password password`

After enabling single sign-on, I cannot logon to the administrative console

This problem occurs when single sign-on (SSO) is enabled, and you attempt to access the administrative console using the short name of the server, for example `http://myserver:port_number/ibm/console`. The server accepts your user ID and password, but returns you to the logon page instead of the administrative console.

To correct this problem, use the fully qualified host name of the server, for example `http://myserver.mycompany.com:9060/ibm/console`.

The following exception displays in the SystemOut.log file after I start the server and enable security: "SECJ0306E: No received or invocation credential exists on the thread."

The following message displays when one or more nodes within the cell was not synchronized during configuration:

```
SECJ0306E: No received or invocation credential exists on the thread. The Role based authorization check will not have an accessId of the caller to check. The parameters are: access check method getServerConfig on resource FileTransferServer and module FileTransferServer. The stack trace is java.lang.Exception: Invocation and received credentials are both null.
```

Make sure that each of the nodes are synchronized and then restart the deployment manager.

Errors after configuring or enabling Secure Sockets Layer

This topic explains various problems you might encounter after configuring or enabling Secure Sockets Layer (SSL).

Stopping the deployment manager after configuring Secure Sockets Layer

After configuring the Secure Sockets Layer repertoires, if you stop the deployment manager without also stopping the node agents, you might receive the following error message when you restart the deployment manager:

```
CWWMU0509I: The server "nodeagent" cannot be reached. It appears to be stopped.  
CWWMU0211I: Error details may be seen in the file:  
    /opt/WebSphere/AppServer/logs/nodeagent/stopServer.log
```

The error occurs because the deployment manager did not propagate the new SSL certificate to the node agents. The node agents are using an older certificate file than the deployment manager and the certificate files are incompatible. To work around this problem, you must manually stop the node agent and deployment manager processes.

You need to consider certain items when identifying the specific process to stop. For each process that is stopped, WebSphere Application Server stores the process ID in a pid file and you need to find these *.pid files. For example, the server1.pid for a stand-alone install action might be found at: `app_server_root/logs/server1.pid`

javax.net.ssl.SSLHandshakeException - The client and server could not negotiate the desired level of security. Reason: handshake failure

If you see a Java exception stack similar to the following example:

```
[Root exception is org.omg.CORBA.TRANSIENT: CAUGHT_EXCEPTION_WHILE_CONFIGURING_SSL_CLIENT_SOCKET: CWWJE0080E: javax.net.ssl.SSLHandshakeException - The client and server could not negotiate the desired level of security. Reason: handshake failure:host=MYSERVER,port=1079 minor code: 4942F303 completed: No] at com.ibm.CORBA.transport.TransportConnectionBase.connect (TransportConnectionBase.java:NNN)
```

Some possible causes are:

- Not having common ciphers between the client and server.
- Not specifying the correct protocol.

To correct these problems:

1. Review the SSL settings. In the administrative console, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > endpoint_configuration_name**. Under Related items, click **SSL configurations > SSL_configuration_name**. You can also browse the file manually by viewing the *app_server_root/properties/sas.client.props* file.
2. Check the property that is specified by the *com.ibm.ssl.protocol* file to determine which protocol is specified.
3. Check the cipher types that are specified by the *com.ibm.ssl.enabledCipherSuites* interface. You might want to add more cipher types to the list. To see which cipher suites are currently enabled, click **Quality of protection settings (QoP)**, and look for the **Cipher Suites** property.
4. Correct the protocol or cipher problem by using a different client or server protocol and cipher selection. Typical protocols are SSL or SSLv3.
5. Make the cipher selection 40-bit instead of 128-bit. For Common Secure Interoperability Version 2 (CSlv2), set both of the following properties to false in the *sas.client.props* file, or set *security level=medium* in the administrative console settings:
 - *com.ibm.CSI.performMessageConfidentialityRequired=false*
 - *com.ibm.CSI.performMessageConfidentialitySupported=false*

javax.net.ssl.SSLHandshakeException: unknown certificate

If you see a Java exception stack similar to the following example, it might be caused by not having the personal certificate for the server in the client truststore file:

```
ERROR: Could not get the initial context or unable to look up the starting context. Exiting. Exception received: javax.naming.ServiceUnavailableException: A communication failure occurred while attempting to obtain an initial context using the provider url: "corbaloc:iiop:localhost:2809". Make sure that the host and port information is correct and that the server identified by the provider url is a running name server. If no port number is specified, the default port number 2809 is used. Other possible causes include the network environment or workstation network configuration. [Root exception is org.omg.CORBA.TRANSIENT: CAUGHT_EXCEPTION_WHILE_CONFIGURING_SSL_CLIENT_SOCKET: CWWJE0080E: javax.net.ssl.SSLHandshakeException - The client and server could not negotiate the desired level of security. Reason: unknown certificate:host=MYSERVER,port=1940 minor code: 4942F303 completed: No]
```

To correct this problem:

1. Check the client truststore file to determine if the signer certificate from the server personal certificate is there. For a self-signed server personal certificate, the signer certificate is the public key of the personal certificate. For a certificate authority (CA)-signed server personal certificate, the signer certificate is the root CA certificate of the CA that signed the personal certificate.
2. Add the server signer certificate to the client truststore file.

javax.net.ssl.SSLHandshakeException: bad certificate

A Java exception stack error might display if the following situations occur:

- A personal certificate exists in the client keystore that is used for SSL mutual authentication.

- The signer certificate is not extracted into the server truststore file, and thus the server cannot trust the certificate whenever the SSL handshake is made.

The following message is an example of the Java exception stack error:

```
ERROR: Could not get the initial context or unable to look
up the starting context. Exiting.
Exception received: javax.naming.ServiceUnavailableException:
A communication failure occurred while attempting to obtain an
initial context using the provider url: "corbaloc:iiop:localhost:2809".
Make sure that the host and port information is correct and that the
server identified by the provider url is a running name
server. If no port number is specified, the default port number 2809
is used. Other possible causes include the network environment or
workstation network configuration.
[Root exception is org.omg.CORBA.TRANSIENT: CAUGHT_EXCEPTION_WHILE_CONFIGURING_SSL_
CLIENT_SOCKET: CWWJE0080E: javax.net.ssl.SSLHandshakeException - The client and
server could not negotiate the desired level of security. Reason:
bad certificate: host=MYSERVER,port=1940 minor code: 4942F303 completed: No]
```

To verify this problem, check the server truststore file to determine if the signer certificate from the client personal certificate is there. For a self-signed client personal certificate, the signer certificate is the public key of the personal certificate. For a certificate authority-signed client personal certificate, the signer certificate is the root CA certificate of the CA that signed the personal certificate.

To correct this problem, add the client signer certificate to the server truststore file.

org.omg.CORBA.INTERNAL: EntryNotFoundException or NTRegistryImp E CWSCJ0070E: No privilege id configured for: error when programmatically creating a credential

If you encounter the following exception in a client application attempting to request a credential from a WebSphere Application Server using SSL mutual authentication:

```
ERROR: Could not get the initial context or unable to look up the starting context.
Exiting. Exception received: org.omg.CORBA.INTERNAL: Trace from server: 1198777258
at host MYHOST on port 0 >>org.omg.CORBA.INTERNAL: EntryNotFoundException minor
code: 494210B0 completed:
No at com.ibm.ISecurityLocalObjectBaseL13Impl.PrincipalAuthFailReason.
map_auth_fail_to_minor_code(PrincipalAuthFailReason.java:99)
```

or a simultaneous error from the WebSphere Application Server that resembles:

```
[7/31/02 15:38:48:452 CDT] 27318f5 NTRegistryImp E CWSCJ0070E: No privilege id
configured for: testuser
```

The cause might be that the user ID sent by the client to the server is not in the user registry for that server.

To confirm this problem, check that an entry exists for the personal certificate that is sent to the server. Depending on the user registry mechanism, look at the native operating system user ID or Lightweight Directory Access Protocol (LDAP) server entries.

To correct this problem, add the user ID to the user registry entry (for example, operating system, LDAP directory, or other custom registry) for the personal certificate identity.

Single sign-on configuration troubleshooting tips

This topic describes common problems in configuring single sign-on (SSO) between a WebSphere Application Server and a Domino server and suggests possible solutions.

- Failure to save the Domino Web SSO configuration document

The client must find Domino server documents for the participating SSO Domino servers. The Web SSO configuration document is encrypted for the servers that you specify. The home server that is indicated by the client location record must point to a server in the Domino domain where the participating servers reside. This pointer ensures that lookups can find the public keys of the servers. If you receive a message stating that one or more of the participating Domino servers cannot be found, then those servers cannot decrypt the Web SSO configuration document or perform SSO.

When the Web SSO configuration document is saved, the status bar indicates how many public keys are used to encrypt the document by finding the listed servers, authors, and administrators in the document.

- Failure of the Domino server console to load the Web SSO configuration document at Domino HTTP server startup

During configuration of SSO, the server document is configured for Multi-Server in the **Session Authentication** field. The Domino HTTP server tries to find and load a Web SSO configuration document during startup. The Domino server console reports the following information if a valid document is found and decrypted: HTTP: Successfully Loaded Web SSO Configuration.

If a server cannot load the Web SSO configuration document, SSO does not work. In this case, a server reports the following message: HTTP: Error Loading Web SSO configuration. Reverting to single-server session authentication.

Verify that only one Web SSO configuration document is in the Web configurations view of the Domino directory and in the \$WebSSOConfigs hidden view. You cannot create more than one document, but you can insert additional documents during replication.

If you can verify only one Web SSO configuration document, consider another condition. When the public key of the server document does not match the public key in the ID file, this same error message can display. In this case, attempts to decrypt the Web SSO configuration document fail and the error message is generated.

This situation can occur when the ID file is created multiple times, but the Server document is not updated correctly. Usually, an error message is displayed on the Domino server console stating that the public key does not match the server ID. If this situation occurs, SSO does not work because the document is encrypted with a public key for which the server does not possess the corresponding private key.

To correct a key-mismatch problem:

1. Copy the public key from the server ID file and paste it into the Server document.
2. Create the Web SSO configuration document again.

- Authentication fails when accessing a protected resource.

If a Web user is repeatedly prompted for a user ID and password, SSO is not working because either the Domino or the WebSphere Application Server security server cannot authenticate the user with the Lightweight Directory Access Protocol (LDAP) server. Check the following possibilities:

- Verify that the LDAP server is accessible from the Domino server machine. Use the TCP/IP ping utility to check TCP/IP connectivity and to verify that the host machine is running.
- Verify that the LDAP user is defined in the LDAP directory. Use the **idsldapsearch** utility to confirm that the user ID exists and that the password is correct. For example, you can run the following command, entered as a single line:

You can use the OS/400 Qshell, a UNIX shell, or a Windows DOS prompt

```
% ldapsearch -D "cn=John Doe, ou=Rochester, o=IBM, c=US" -w mypassword  
-h myhost.mycompany.com -p 389 -b "ou=Rochester, o=IBM, c=US" (objectclass=*)
```

The percent character (%) indicates the prompt and is not part of the command. A list of directory entries is expected. Possible error conditions and causes are contained in the following list:

- No such object: This error indicates that the directory entry referenced by either the user's distinguished name (DN) value, which is specified after the **-D** option, or the base DN value, which is specified after the **-b** option, does not exist.
- Credentials that are not valid: This error indicates that the password is not valid.

- Cannot contact the LDAP server: This error indicates that the host name or the port specified for the server is not valid or that the LDAP server is not running.
- An empty list means that the base directory that is specified by the **-b** option does not contain any directory entries.
- If you are using the user's short name or user ID instead of the distinguished name, verify that the directory entry is configured with the short name. For a Domino directory, verify the **Short name/UserID** field of the Person document. For other LDAP directories, verify the `userid` property of the directory entry.
- If Domino authentication fails when using an LDAP directory other than a Domino directory, verify the configuration settings of the LDAP server in the Directory assistance document in the Directory assistance database. Also verify that the Server document refers to the correct Directory assistance document. The following LDAP values that are specified in the Directory Assistance document must match the values specified for the user registry in the WebSphere Application Server administrative domain:
 - Domain name
 - LDAP host name
 - LDAP port
 - Base DN

Additionally, the rules that are defined in the Directory assistance document must refer to the base distinguished name (DN) of the directory that contains the directory entries of the users.

You can trace Domino server requests to the LDAP server by adding the following line to the server `notes.ini` file:

```
webauth_verbose_trace=1
```

After restarting the Domino server, trace messages are displayed in the Domino server console as Web users attempt to authenticate to the Domino server.

- Authorization failure when accessing a protected resource.

After authenticating successfully, if an authorization error message is displayed, security is not configured correctly. Check the following possibilities:

- For Domino databases, verify that the user is defined in the access-control settings for the database. Refer to the Domino administrative documentation for the correct way to specify the user's DN. For example, for the DN `cn=John Doe, ou=Rochester, o=IBM, c=US`, the value on the access-control list must be set as `John Doe/Rochester/IBM/US`.
- For resources that are protected by WebSphere Application Server, verify that the security permissions are set correctly.
 - If granting permissions to selected groups, make sure that the user attempting to access the resource is a member of the group. For example, you can verify the members of the groups by using the following Web site to display the directory contents: `Ldap://myhost.mycompany.com:389/ou=Rochester, o=IBM, c=US??sub`
 - If you changed the LDAP configuration information (host, port, and base DN) in a WebSphere Application Server administrative domain since the permissions were set, the existing permissions are probably not valid and need to be recreated.

- SSO failure when accessing protected resources.

If a Web user is prompted to authenticate with each resource, SSO is not configured correctly. Check the following possibilities:

1. Configure both WebSphere Application Server and the Domino server to use the same LDAP directory. The HTTP cookie that is used for SSO stores the full DN of the user, for example, `cn=John Doe, ou=Rochester, o=IBM, c=US`, and the domain name service (DNS) domain.
2. Define Web users by hierarchical names if the Domino directory is used. For example, update the **User name** field in the Person document to include names of this format as the first value: `John Doe/Rochester/IBM/US`.
3. Specify the full DNS server name, not just the host name or TCP/IP address for Web sites issued to Domino servers and WebSphere Application Servers that are configured for SSO. For browsers to

send cookies to a group of servers, the DNS domain must be included in the cookie, and the DNS domain in the cookie must match the Web address. This requirement is why you cannot use cookies across TCP/IP domains.

4. Configure both Domino and the WebSphere Application Server to use the same DNS domain. Verify that the DNS domain value is exactly the same, including capitalization. You need the name of the DNS domain in which WebSphere Application Server is configured. For additional information about configuring DNS domains for SSO, refer to the Single sign-on topic in the *Securing applications and their environment* PDF book.
5. Verify that the clustered Domino servers have the host name populated with the full DNS server name in the server document. By using the full DNS server name, Domino Internet Cluster Manager (ICM) can redirect to cluster members using SSO. If this field is not populated, by default, ICM redirects Web addresses to clustered Web servers by using the host name of the server only. ICM cannot send the SSO cookie because the DNS domain is not included in the Web address. To correct the problem:
 - a. Edit the Server document.
 - b. Click **Internet Protocols > HTTP** tab.
 - c. Enter the full DNS name of the server in the **Host names** field.
6. If a port value for an LDAP server is specified for a WebSphere Application Server administrative domain, edit the Domino Web SSO configuration document and insert a backslash character (\) into the value of the **LDAP Realm** field before the colon character (:). For example, replace `myhost.mycompany.com:389` with `myhost.mycompany.com\:389`.

Enterprise Identity Mapping troubleshooting tips

The following information provides troubleshooting information for Enterprise Identity Mapping (EIM) configuration or connection factory configuration.

AdminControl service is not available

Symptom

The following message is displayed:

Message: WASX7017E: Exception received while running file "/QIBM/ProdData/OS400/Java400/cfgldToken.jacl"; exception information: com.ibm.ws.scripting.ScriptingException: AdminControl service not available.

Explanation

The application server or deployment manager of the WebSphere Application Server profile is not started, or the wsadmin option `-conntype NONE` is specified.

Configuration-related messages returned by the sample application to your Web browser session

Symptom

The following message is displayed:

Message: com.ibm.as400.access.AS400SecurityException: User ID is not known.

Explanation

The EIM does not contain a mapping for the user ID that is used to log in to the sample application.

Symptom

The following message is displayed:

Message: com.ibm.as400.access.ServerStartupException: Password encryption indicator is not valid.

Explanation

The target iSeries server is not configured for Enterprise Identity Mapping (EIM).

Symptom	The following message is displayed:
Explanation	Message: java.net.ConnectException: A remote host refused an attempted connect operation.
Symptom	The target server is not an iSeries server. The following message is displayed:
Explanation	Message: The lookup for the connection factory failed. Either the connector is not configured, or the servlet resource reference (JNDI name) is not set correctly in the web.xml file. The servlet expects the resource reference in the web.xml file to be eis/IdentityToken_Shared_Reference.
Symptom	Either the connector is not configured, or the servlet resource reference (JNDI name) is not set correctly in the web.xml file. The servlet expects the resource reference in the web.xml file to be eis/IdentityToken_Shared_Reference.
Explanation	The following message is displayed:
Symptom	Message: The JAAS Subject object was not passed to the Java 2 Connector (J2C) connector because WebSphere Application Server security is not correctly configured for the servlet.
Explanation	WebSphere Application Server administrative security is not enabled.
Symptom	The following message is displayed:
Explanation	Message: javax.resource.ResourceException: com.ibm.eim.jndi.DomainJNDI:method_name: failed to connect to initial directory context. This message is caused by one of the following issues: <ul style="list-style-type: none"> • The authentication data entry that is configured for the connection factory contains an incorrect Lightweight Directory Access Protocol (LDAP) distinguished name. • The authentication data entry that is configured for the connection factory contains an incorrect LDAP password. • The LDAP host name that is configured for the connection factory is incorrect. • The LDAP port that is configured for the connection factory is incorrect. • The LDAP server is not started. • The Enterprise Identity Mapping (EIM) domain name that is configured for the connection factory is incorrect. • The EIM parent name that is configured for the connection factory is incorrect.
Symptom	The following message is displayed:
Explanation	Message: javax.resource.ResourceException: Input URL is null or not valid. An LDAP host name is not configured for the connection factory.
Symptom	The following message is displayed:
Explanation	Message: com.ibm.as400.access.AS400SecurityException: An unknown problem occurred.

Explanation

The target iSeries server is not joined to the EIM domain that is configured for the connection factory, or the EIM source registry name is incorrect.

Perform the following steps to enable trace for EIM:

Note: This trace is only available for idTokenRA.JCA15.rar.

1. From the administrative console, select **Servers > Application Servers > server_name > Change Log Details Levels**.
2. Click the **Runtime** tab.
3. Select **Save runtime changes to configuration as well**.
4. Remove any previous entries in the text field, and type the following:
`com.ibm.jca.idtoken.*=all: com.ibm.eim.token.*=all`
5. Click **Apply** and save the changes.

Authorization provider troubleshooting tips

This article describes the issues you might encounter using a Java Authorization Contract for Containers (JACC) authorization provider. Tivoli Access Manager is bundled with WebSphere Application Server as an authorization provider. However, you also can plug in your own authorization provider.

Tivoli Access Manager as a Java Authorization Contract for Containers authorization provider

You might encounter the following issues when using Tivoli Access Manager as a JACC authorization provider:

- The configuration of JACC might fail.
- The server might fail to start after configuring JACC.
- The application might not deploy properly.
- The startServer command might fail after you have configured Tivoli Access Manager or a clean uninstall did not take place after unconfiguring JACC.
- An "HPDIA0202w An unknown user name was presented to Access Manager" error might occur.
- An "HPDAC0778E The specified user's account is set to invalid" error might occur.
- An WASX7017E: Exception received while running file "InsuranceServicesSingle.jacl" error might occur.
- "Access denied exceptions accessing applications when using JACC" on page 1468
- "An "HPDBA0219E: An error occurred reading data from an SSL connection" might occur" on page 1469

External providers for Java Authorization Contract for Containers authorization provider

You might encounter the following issues when you use an external provider for JACC authorization:

- An "HPDJA0506E Invalid argument: Null or zero-length user name field for the ACL entry" error might occur.

The configuration of JACC might fail

If you have problems configuring JACC, check the following items:

- Ensure that the parameters are correct. For example, you do not want a number after TAM_Policy_server_hostname:7135, but you do want be a number after TAM_Authorization_server_hostname:7136 (for example, TAM_Authorization_server_hostname:7136:1).

- If a message such as “server can’t be contacted” is displayed, it is possible that the host names or port numbers of the Tivoli Access Manager servers are incorrect, or that the Tivoli Access Manager servers have not started.
- Ensure that the password for the sec_master user is correct.
- Check the SystemOut.log file and search for the AMAS string to see if any error messages are present.

The server might fail to start after configuring JACC

If the server does not start after JACC is configured, check the following items:

- Ensure that WebSphere Application Server and Tivoli Access Manager use the same Lightweight Directory Access Protocol (LDAP) server.
- If the message “Policy Director Authentication failed” is displayed, ensure that the:
 - WebSphere Application Server LDAP server ID is the same as the “Administrator user” in the Tivoli Access Manager JACC configuration panel.
 - Verify that the Tivoli Access Manager Administrator distinguished name (DN) is correct.
 - Verify that the password of the Tivoli Access Manager administrator has not expired and is valid.
 - Ensure that the account is valid for the Tivoli Access Manager administrator.
- If a message such as socket can't be opened for xxxx (where xxxx is a number) is displayed, take the following actions:
 1. Go to the *profile_root/etc/tam* directory.
 2. Change xxxx to an available port number in the *amwas.commomconfig.properties* file, and the *amwas*cellName_dmgr.properties* file if the deployment manager failed to start. If the node failed to start, change xxx to an available port number in the *amwas*cellName_nodeName_.properties* file. If the Application Server failed to start, change xxxx in the *amwas*cellname_nodeName_serverName.properties* file.

The application might not deploy properly

When you click **Save**, the policy and role information is propagated to the Tivoli Access Manager policy. This process might take some time to finish. If the save fails, you must uninstall the application and then reinstall it.

To access an application after it is installed, you must wait 30 seconds, by default, to start the application after you save.

The startServer command might fail after you configure Tivoli Access Manager or a clean uninstall did not take place after unconfiguring JACC.

If the cleanup for JACC unconfiguration or start server fails after JACC is configured, take the following actions:

- Remove Tivoli Access Manager properties files from WebSphere Application Server. For each application server in a Network Deployment (ND) environment with N servers defined (for example, server1, server2).

The following files must be removed.

```
profile_root/etc/pd/PolicyDirector/PDPerm.properties
profile_root/etc/pd/PolicyDirector/PdPerm.ks
profile_root/etc/tam/*
```

- Use a utility to clear the security configuration and return the system to the state it was in before you configure the JACC provider for Tivoli Access Manager. The utility removes all of the PDLoginModuleWrapper entries as well as the Tivoli Access Manager authorization table entry from the security.xml file, effectively removing the JACC provider for Tivoli Access Manager. Backup the security.xml file before running this utility.

Enter the following commands:

```
java -Djava.version=1.5 -classpath  
"app_server_root/lib/AMJACCProvider.jar:CLASSPATH"  
com.tivoli.pd.as.jacc.cfg.CleanSecXML fully_qualified_path/security.xml
```

An "HPDIA0202W An unknown user name was presented to Access Manager" error might occur

You might encounter the following error message if you try to use an existing user in a Local Directory Access Protocol (LDAP) user registry with Tivoli Access Manager:

```
AWXJR0008E Failed to create a PDPrincipal for principal mgr1.:  
AWXJR0007E A Tivoli Access Manager exception was caught. Details are:  
"HPDIA0202W An unknown user name was presented to Access Manager."
```

This problem might be caused by the host name exceeding predefined limits with Tivoli Access Manager when it is configured against MS Active Directory. In WebSphere Application Server, the maximum length of the host name can not exceed 46 characters.

Check that the host name is not fully qualified. Configure the machine so that the host name does not include the host domain.

To correct this error, complete the following steps:

1. On the command line, type the following information to get a Tivoli Access Manager command prompt:

```
pdadmin -a administrator_name -p administrator_password
```

The pdadmin *administrator_name* prompt is displayed. For example:

```
pdadmin -a administrator1 -p password
```

2. At the pdadmin command prompt, import the user from the LDAP user registry to Tivoli Access Manager by typing the following information:

```
user import user_name cn=user_name,o=organization_name,c=country
```

For example:

```
user import jstar cn=jstar,o=ibm,c=us
```

After importing the user to Tivoli Access Manager, you must use the **user modify** command to set the user account to valid. The following syntax shows how to use this command:

```
user modify user_name account-valid yes
```

For example:

```
user modify jstar account-valid yes
```

For information on how to import a group from LDAP to Tivoli Access Manager, see the Tivoli Access Manager documentation.

An "HPDAC0778E The specified user's account is set to invalid" error might occur

You might encounter the following error message after you import a user to Tivoli Access Manager and restart the client:

```
AWXJR0008E Failed to create a PDPrincipal for principal mgr1.:  
AWXJR0007E A Tivoli Access Manager exception was caught.  
Details are: "HPDAC0778E The specified user's account is set to invalid."
```

To correct this error, use the user modify command to set the user account to valid. The following syntax shows how to use this command:

```
user modify user_name account-valid yes
```

For example:

```
user modify jstar account-valid yes
```

An "HPDJA0506E Invalid argument: Null or zero-length user name field for the ACL entry" error might occur

You might encounter an error similar to the following message when you propagate the security policy information from the application to the provider using the wsadmin **propagatePolicyToJACCProvider** command:

```
AWXJR0035E An error occurred while attempting to add member,
           cn=agent3,o=ibm,c=us, to role AgentRole
HPDJA0506E Invalid argument: Null or zero-length user name field for
           the ACL entry
```

To correct this error, create or import the user, that is mapped to the security role to the Tivoli Access Manager. For more information on propagating the security policy information, see the documentation for your authorization provider.

An WASX7017E: Exception received while running file "InsuranceServicesSingle.jacl" error might occur

After the JACC provider and Tivoli Access Manager are enabled, when attempting to install the application, which is configured with security roles using the wsadmin command, the following error might occur:

```
WASX7017E: Exception received while running file "InsuranceServicesSingle.jacl";
exception information: com.ibm.ws.scripting.ScriptingException: WASX7111E:
Cannot find a match for supplied option:
"[RuleManager, , , cn=mgr3,o=ibm,c=us|cn=agent3,o=ibm,c=us, cn=ManagerGro
up,o=ibm,c=us|cn=AgentGroup,o=ibm,c=us]" for task "MapRolesToUsers
```

The \$AdminApp MapRolesToUsers task option is no longer valid when Tivoli Access Manager is used as the authorization server. To correct the error, change MapRolesToUsers to TAMMapRolesToUsers.

Access denied exceptions accessing applications when using JACC

In the case of Tivoli Access Manager, you might see the following error message.

```
AWXJR0044E: The access decision for Permission, {0}, was denied because either the
PolicyConfiguration or RoleConfiguration objects did not get created successfully at
application installation time. RoleConfiguration exists = {false}, PolicyConfiguration
exists = {false}."
```

If the access denied exceptions are not expected for the application, check the SystemOut.log files to see if the security policy information was correctly propagated to the provider.

If the security policy information for the application is successfully propagated to the provider, the audit statements with the message key SECJ0415I appear. However, if there was a problem propagating the security policy information to the provider (for example: network problems, JACC provider is not available), the SystemOut.log files contain the error message with the message keys SECJ0396E (during install) or SECJ0398E (during modification). The installation of the application is not stopped due to a failure to propagate the security policy to the JACC provider. Also, in the case of failure, no exception or error messages appear during the save operation. When the problem causing this failure is fixed, run the propagatePolicyToJaccProvider tool to propagate the security policy information to the provider without reinstalling the application. For more information about this task, see the Propagating security policy of installed applications to a JACC provider using wsadmin scripting topic in the *Securing applications and their environment* PDF book.

An "HPDBA0219E: An error occurred reading data from an SSL connection" might occur

An error message (HPDBA0219E) might appear in dmgr SystemOut.log when you install an application on WebSphere Application Server for Network Deployment (ND) and a managed node with Tivoli Access Manager is enabled.

If the error occurs, then the security policy data of recently deployed applications might not be immediately available. The policy data is available based on the server replicate time of the Tivoli Access Manager. This is defaulted to 30 seconds after all updates have been completed. To ensure that the latest policy data is available, log on to the pdadmin console and type: server replicate.

Password decoding troubleshooting tips

If the password encoding is corrupted and you cannot decode a password, you can complete one of the following tasks.

- If the password is contained in a server configuration file, edit the file and set the password to the clear text value. After changing the value, restart the server.
- If the password is contained in the sas.client.props file or the soap.client.props file, edit the file and set the password to the appropriate clear text value. After changing the value, use the PropFilePasswordEncoder utility to encode the password. For more information on the PropFilePasswordEncoder utility, see the "PropFilePasswordEncoder command reference" on page 1427.

The profile-specific setupCmdLine QShell script contains a property that you can use to obtain trace information when using the OS400 algorithm with Java clients and administrative commands for WebSphere Application Server. To obtain the trace, set the os400.security.password.debug property to true. The trace is printed to standard output.

SPNEGO trust association interceptor (TAI) troubleshooting tips

Presented here is a list of trouble shooting tips useful in diagnosing Simple and Protected GSS-API Negotiation (SPNEGO) TAI problems and exceptions.

The IBM Java Generic Security Service (JGSS) and IBM SPNEGO providers use a Java virtual machine (JVM) custom property to control trace information. The SPNEGO TAI uses the JRas facility to allow an administrator to trace only specific classes. To debug the TAI using tracing, the following important trace specifications or JVM customer should be used:

Table 59. SPNEGO TAI trace specifications

Trace	Use
<code>com.ibm.security.jgss.debug</code>	Set this JVM Custom Property to all to trace through JGSS code. Messages appear in the trace.log file, and SystemOut.log .
<code>com.ibm.security.krb5.Krb5Debug</code>	Set this JVM Custom Property to all to trace through the Kerberos5-specific JGSS code. Messages appear in the trace.log file, and SystemOut.log .
<code>com.ibm.ws.security.spnego.*</code>	Set this trace on using the administrative console > troubleshooting > Logging and Tracing > server1 > Change Log Detail Levels > com.ibm.ws.security.spnego.* . Messages appear in the trace.log file.

Problem: WebSphere Application Server and the Active Directory (AD) Domain Controller's time are not synchronized within 5 minutes

The time is not synchronized between WebSphere Application Server and AD Domain Controller.

```

Solution: You can fix this in one of two ways. The preferred way is to synchronize the WebSphere Application Server system time to within 5 minutes of the AD server's time. A best practice is to use a time server to keep all systems synchronized. Or you can add or adjust the clockskew parameter in the Kerberos configuration file.

Note: The default for the clockskew parameter is 300 seconds (or 5 minutes).

Problem: Getting exception: No factory available to create a name for mechanism 1.3.6.1.5.5.2

There apparently is no factory available to process the creation of a name for the specific mechanism.

The systemout.log file displays something like this:

```
[4/8/05 22:51:24:542 EDT] 5003e481 SystemOut      0 [JGSS_DBG_PROV] Provider
IBMJGSSProvider version 1.01 does not support mech 1.3.6.1.5.5.2
[4/8/05 22:51:24:582 EDT] 5003e481 ServerCredent >
com.ibm.ws.security.spnego.ServerCredential initialize ENTRY
SPNEG0014: Kerberos initialization Failure: org.ietf.jgss.GSSEException, major code: 2,
minor code: 0
major string: Unsupported mechanism
minor string: No factory available to create name for mechanism 1.3.6.1.5.5.2
at com.ibm.security.jgss.i18n.I18NException.throwGSSEException
(I18NException.java:30)
```

```
at com.ibm.security.jgss.GSSManagerImpl.a(GSSManagerImpl.java:36)
at com.ibm.security.jgss.GSSCredentialImpl.add(GSSCredentialImpl.java:217)
at com.ibm.security.jgss.GSSCredentialImpl.<init>(GSSCredentialImpl.java:264)
```

Solution: Check the `java.security` file to ensure it contains the IBMSPNego security provider and that the provider is defined correctly. The `java.security` file should contain a line similar to:

```
security.provider.6=com.ibm.security.jgss.mech.spnego.IBMSPNego
```

Problem: Getting an exception

An exception has occurred when reporting to the client.

You get the following display.

```
Error authenticating request. Reporting to client
Major code = 11, Minor code = 31
org.ietf.jgss.GSSEException, major code: 11, minor code: 31
  major string: General failure, unspecified at GSSAPI level
  minor string: Kerberos error while decoding and verifying token:
                com.ibm.security.krb5.internal.KrbException, status code: 31
message: Integrity check on decrypted field failed
```

as the JGSS library is trying to process the SPNEGO token.

Cause: This exception is the result of encoding the ticket using one key and attempting to decode it using a different key. There are number of possible reasons for this condition:

1. The Kerberos keytab file has not been copied to the server machine after it has been regenerated.
2. The Kerberos configuration points to the wrong Kerberos keytab file.
3. The Kerberos service principal name (SPN) has been defined to the Active Directory more than once; this can occur because you have another userid with a similarly defined SPN (either exactly the same name, or one having a different name but with a port defined part of the SPN).

Solution: If the problem is with the Kerberos keytab file, then fix it. If the problem is with multiple SPN definitions, then remove the extra or conflicting SPN, confirm that the SPN is no longer registered with the Active Directory, and then add the SPN. The Active Directory may need to be searched for other entries with SPNs defined that clash with the SPN.

To confirm that the SPN is not registered, the command:

```
setspn -l userid
```

should return with the following response:

```
Cannot find account userid
```

Problem: Single sign-on is not occurring.

When trace is turned on, the following message appears:

```
[2/27/06 14:28:04:191 CST] 00000059 SpnegoHandler <
  com.ibm.ws.security.spnego.SpnegoHandler handleRequest: Received a
  non-SPNEGO Authorization Header RETURN
```

Cause: The client is returning an NT LAN manager (NTLM) response to the authorize challenge, not a SPNEGO token. This condition can be occur due to any of the following reasons:

- The client has not been configured properly.
- The client is not using a supported browser. For example, when using Microsoft Internet Explorer 5.5, SP1 responds with a non-SPNEGO authentication header.

- The user has not logged into the Active Directory domain, or into a trusted domain, or the client used does not support integrated authentication with Windows – in this case, the SPNEGO TAI is working properly.
- The user is accessing a service defined on the same machine upon which the client is running (local host). Microsoft Internet Explorer resolves the host name of the URL to `http://localhostsomeURL` instead of a fully qualified name.
- The SPN is not found in the Active Directory. The SPN must be of the format `HTTP/server.realm.com`. The command to add the SPN is

```
setspn -a HTTP/server.realm.com userid
```

If the SPN is defined incorrectly as `HTTP/server.realm.com@REALM.COM` with the addition of `@REALM.COM`, then delete the user, redefine the user, and redefine the SPN.

Problem: Credential Delegation is not working

An invalid option is detected. When trace is turned on, the following message is displayed:

```
com.ibm.security.krb5.KrbException, status code: 101 message: Invalid option in
ticket request
```

Cause: The Kerberos configuration file is not properly configured.

Solution: Ensure that neither `renewable`, nor `proxiable` are set to `true`.

Problem: Unable to get SSO working using RC4-HMAC encryption.

When trace is turned on, you get the following message in the trace:

```
com.ibm.security.krb5.internal.crypto.KrbCryptoException, status code: 0
message: Checksum error; received checksum does not match computed checksum
```

Cause: RC4-HMAC encryption is not supported with a Microsoft Windows 2000 Kerberos key distribution center (KDC). To confirm this condition, examine the trace and identify where the exception is thrown. The content of the incoming ticket should be visible in the trace. Although the incoming ticket is encrypted, the SPN for the service is readable. If a Microsoft Windows 2000 KDC is used and the system is configured to use RC4-HMAC, the string representing the ticket for `userid@REALM` (instead of the expected `HTTP/hostname.realm@REALM`) is displayed. For example, this is beginning of the ticket received from a Microsoft Windows 2000 KDC:

```
0000: 01 00 6e 82 04 7f 30 82 04 7b a0 03 02 01 05 a1 ..n...0.....
0010: 03 02 01 0e a2 07 03 05 00 20 00 00 00 a3 82 03 .....
0020: a5 61 82 03 a1 30 82 03 9d a0 03 02 01 05 a1 0a .a...0.....
0030: 1b 08 45 50 46 44 2e 4e 45 54 a2 18 30 16 a0 03 ...REALM.COM.0..
0040: 02 01 01 a1 0f 30 0d 1b 0b 65 70 66 64 77 61 73 ....0...userid
0050: 75 6e 69 74 a3 82 03 6e 30 82 03 6a a0 03 02 01 .a.f...n0..j....
```

The realm is `REALM.COM`. The service name is `userid`. A correctly formed ticket for the same SPN is:

```
0000: 01 00 6e 82 04 56 30 82 04 52 a0 03 02 01 05 a1 ..n..V0..R.....
0010: 03 02 01 0e a2 07 03 05 00 20 00 00 00 a3 82 03 .....
0020: 82 61 82 03 7e 30 82 03 7a a0 03 02 01 05 a1 0a .a...0..z.....
0030: 1b 08 45 50 46 44 2e 4e 45 54 a2 2a 30 28 a0 03 ..REALM.COM.0...
0040: 02 01 02 a1 21 30 1f 1b 04 48 54 54 50 1b 17 75 ....0...HTTP..u
0050: 73 31 30 6b 65 70 66 77 61 73 73 30 31 2e 65 70 serid.realm.com.
0060: 66 64 2e 6e 65 74 a3 82 03 39 30 82 03 35 a0 03 ...n.....90..5..
```

Solution: To correct the problem, either use the Single data encryption standard (DES) or use a Microsoft Windows 2003 Server for a KDC. Remember to regenerate the SPN, and the Kerberos keytab file.

Problem: User receives the following message when accessing a protected URL through the SPNEGO SSO

Bad Request

Your browser sent a request that this server could not understand.
Size of request header field exceeds server limit.

Authorization: Negotiate YII.....

Cause: This message is generated by the Apache/IBM HTTP Server. This server is indicating that the authorization header returned by the user's browser is too large. The long string that follows the word Negotiate (in the error message above) is the SPNEGO token. This SPNEGO token is a wrapper of the Microsoft Windows Kerberos token. Microsoft Windows includes the user's PAC information in the Kerberos token. The more security groups that the user belongs to, the more PAC information is inserted in the Kerberos token, and the larger the SPNEGO becomes. IBM HTTP Server 2.0 (also Apache 2.0 and IBM HTTP Server 6.0) limit the size of any acceptable HTTP header to be 8K. In Microsoft Windows domains having many groups, and with user membership in many groups, the size of the user's SPNEGO token may exceed the 8K limit.

Solution: If possible, reduce the number of security groups the user is a member of. IBM HTTP Server 2.0.47 cumulative fix PK01070 allows for HTTP header sizes up to and beyond the Microsoft limit of 12K. WebSphere Application Server Version 6.0 users can obtain this fix in fixpack 6.0.0.2.

Note: Non-Apache based Web servers may require differing solutions.

Problem: Even with JGSS tracing disabled, some KRB_DBG_KDC messages appear in the SystemOut.log

Cause: While most of the JGSS tracing is controlled by the `com.ibm.security.jgss.debug` property, a small set of messages are controlled by the `com.ibm.security.krb5.Krb5Debug` property. The `com.ibm.security.krb5.Krb5Debug` property has a default value to put some messages to the **SystemOut.log**.

Solution: To remove all KRB_DBG_KDC messages from the **SystemOut.log**, set the JVM property as follows:

```
-Dcom.ibm.security.krb5.Krb5Debug=none
```

Problem: HTTP Post parameters are lost during interaction with the SPNEGO TAI, when stepping down to userid/password login.

Cause: The Microsoft Internet Explorer maintains state during a user's request. If a request was given the response of an "HTTP 401 Authenticate Negotiate", and the browser responds with a NTLM token obtained through a userid/password challenge, the browser resubmits the request. If this second request is given a response of an HTML page containing a redirection to the same URL but with new arguments (via Javascript) then the browser does not resubmit the POST parameters. To avoid this problem, it is critical to NOT perform the automatic redirection. If the user clicks on a link, the problem does not occur. See section 5.2 Client Returns NTLM Token to SPNEGO Challenge for a resolution to the problem,

Solution: The browser responds to the Authenticate/Negotiate challenge with an NTLM token, not an SPNEGO token. The SPNEGO TAI sees the NTLM, and returns back a HTTP 403 response, along with the HTML page. When the browser runs the Javascript `redirTimer` function, any POST or GET parameters that were present on the original request are lost.

By leveraging the SPN<id>.NTLMTokenReceivedPage property, an appropriate message page can be returned to the user. The default message that is returned (in the absence of a user defined property) is:

```
"<html><head><title>An NTLM Token was Received.</title></head>"
+ "<body>Your browser configuration is correct, but you have not logged into
  a supported Windows Domain."
+ "<p>Please login to the application using the normal login page.</html>";
```

Using the SPN<id>.NTLMTokenReceivedPage property, you can customize the exact response. It is critical that the returned HTML not perform a redirection.

When the SPNEGO TAI has been configured to use the shipped default HTTPHeaderFilter class as the SPN<id>.filterClass, then the SPN<id>.filter can be used to allow the second request to flow directly to the normal WebSphere Application Server security mechanism. In this way, the user experiences the normal authentication mechanism.

An example of such a configuration follows. The required SPNEGO TAI properties necessary and the HTML file content are presented.

Table 60. SPNEGO TAI properties and HTML

SPNEGO TAI Property Name	HTML File Content
com.ibm.ws.security.spnego.SPN1.hostName	server.wasteched30.torolab.ibm.com
com.ibm.ws.security.spnego.SPN1.filterClass	com.ibm.ws.security.spnego.HTTPHeaderFilter
com.ibm.ws.security.spnego.SPN1.filter	request-ur!=noSPNEGO
com.ibm.ws.security.spnego.SPN1.NTLMTokenReceivedPage	File:///C:/temp/NTLM.html

Note: Observe that the filter property instructs the SPNEGO TAI to NOT intercept any HTTP request that contains the string “noSPNEGO”.

Here is an example of a generating a helpful response.

```
<html>
<head>
<title>NTLM Authentication Received </title>
<script language="javascript">
  var purl="" + document.location;
  if (purl.indexOf("noSPNEGO") < 0) {
    if (purl.indexOf('?') >= 0) purl += "&noSPNEGO";
    else purl += "?noSPNEGO";
  }
</script>
</head>
<body>
<p>An NTLM token was retrieved in response to the SPNEGO challenge. It is likely that
you are not logged into a Windows domain.<br>
Click on the following link to get the requested website.
<script language="javascript">
  document.write("<a href='"+purl+"'>");
  document.write("Open the same page using the normal authentication
  mechanism.");
  document.write("</a><br>");
</script>
You will not automatically be redirected.
</body>
</html>
```

Appendix. Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories infer specific default directory locations. This topic describes the conventions in use for WebSphere Application Server Network Deployment.

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server Network Deployment products or components, of course, require multiple locations.

app_server_root - the install_root for WebSphere Application Server

The default installation root directory for WebSphere Application Server Network Deployment is the /QIBM/ProdData/WebSphere/AppServer/V61/ND directory.

profile_root

The default directory for a profile named *profile_name* for WebSphere Application Server Network Deployment is the /QIBM/UserData/WebSphere/AppServer/V61/ND/profiles/*profile_name* directory.

app_server_user_data_root - the user_data_root for WebSphere Application Server

The default user data directory for WebSphere Application Server Network Deployment is the /QIBM/UserData/WebSphere/AppServer/V61/ND directory.

plugins_root

The default installation root directory for Web server plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V61/webserver directory.

plugins_user_data_root

The default Web server plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V61/webserver directory.

plugins_profile_root

The default Web server plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V61/webserver/profiles/*profile_name* directory.

app_client_root

The default installation root directory for the J2EE WebSphere Application Client is the /QIBM/ProdData/WebSphere/AppClient/V61/client directory.

app_client_user_data_root

The default J2EE WebSphere Application Client user data root is the /QIBM/UserData/WebSphere/AppClient/V61/client directory.

app_client_profile_root

The default J2EE WebSphere Application Client profile root is the /QIBM/UserData/WebSphere/AppClient/V61/client/profiles/*profile_name* directory.

web_server_root

The default web server path is /www/*web_server_name*.

shared_product_library

The shared product library, which contains all of the objects shared by all Version 6.1 installations on the system, is QWAS61. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

product_library

The product library, which contains program and service program objects (similar to .exe, .dll, .so objects for Windows, Linux, and UNIX operating system platforms), is: QWAS61*x* where *x* is A, B, C, ... For the default installation, the value is QWAS61A.

product_lib

The product library that contains the service program objects for the web server plugins. For the default Web Server Plugins install, this is QWAS61A. If you install the Web Server Plugins multiple times, the product_lib is QWAS61c, where *c* is B, C, D, ... The plugins_install_root/properties/product.properties contains the value for the product library..

cip_app_server_root

The default installation root directory is the /QIBM/ProdData/WebSphere/AppServer/V61/ND/cip/cip_uid directory for a customized installation package (CIP) produced by the Installation Factory.

A CIP is a WebSphere Application Server Network Deployment product bundled with optional maintenance packages, an optional configuration archive, one or more optional enterprise archive files, and other optional files and scripts.

cip_user_data_root

The default user data root directory is the /QIBM/UserData/WebSphere/AppServer/V61/ND/cip/cip_uid directory for a customized installation package (CIP) produced by the Installation Factory.

cip_profile_root

The default profile root directory is the /QIBM/UserData/WebSphere/AppServer/V61/ND/cip/cip_uid/profiles/profile_name directory for a customized installation package (CIP) produced by the Installation Factory.
