For durable subscriptions created by message-driven beans, the subscription name value is set on the JMS activation specification. For other durable subscriptions, the value is set by the administrator on the JMS connection factory and by the JMS application on the `createDurableSubscriber` operation.

**Note:** The *server\_name*-durableSubscriptions.ser file in the *WAS\_HOME*/temp directory is used by the messaging service to keep track of durable subscriptions for message-driven beans. If you uninstall an application that contains a message-driven bean, this file is used to unsubscribe the durable subscription. If you have to delete the *WAS\_HOME*/temp directory or other files in it, ensure that you preserve this file.

## Procedure

- List durable subscriptions.
- Stop active subscribers for durable subscriptions.
- Enable providers to stream messages to cloned durable subscriptions.
- Delete durable subscriptions.

## Listing subscriptions

Use this task to list the subscriptions that exist at runtime for a topic space.

## About this task

The runtime state of a subscription is linked to the publication point for the messaging engine that is used to store messages delivered to the subscription. You can list subscriptions by first displaying the publication point, either from the messaging engine panel or the list of all publication points for a service integration bus.

To display a list of subscriptions for a publication point, use the administrative console to complete the following steps:

### Procedure

1. Click **Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations**. This displays any existing destinations in the content pane.
2. Click the name of the topic space.
3. Under Message Points, click **Publication points**. This displays the publication points for the topic space.
4. Click the name of the publication point.
5. Click the Runtime tab.
6. Under Additional Properties, click **Subscriptions**

### Results

The list of subscriptions for the selected topic space is displayed in the content pane. For more information about the list of subscriptions, see “Subscriptions [Collection]” on page 2310.

Each subscription has a unique subscription identifier that has the form, *clientID##subName* where:

#### *clientID*

The client identifier used to associate a connection and its objects with the messages maintained for applications (as clients of the JMS provider). You should use a naming convention that helps you identify the applications, in case you have to relate subscriptions to the associated applications for runtime administration. For more information about client identifiers, see section 4.3.2 of the JMS 1.1 specification.

#### *subName*

The JMS subscription name used to uniquely identify a durable subscription within a given client identifier. For more information about JMS subscription names, see section 6.11.1 of the JMS 1.1 specification.

## What to do next

To display details of a subscription, click the name of the subscription in the list. To delete one or more subscriptions, select the check box next to the subscription names then click **Delete**.

## Stopping active subscribers for durable subscriptions

Use this task to enable applications to change a cloned durable subscription. This task enables applications to connect to an existing cloned durable subscription, and to specify parameters that differ from those that were used to create the existing subscription.

## About this task

When an application connects to an existing durable subscription, but specifies parameters that differ from those that were used to create the existing subscription, **the subscription is deleted then recreated with the new parameters**. A durable subscription can be changed in this way only when it has no active consumers.

**Note:** The *server\_name-durableSubscriptions.ser* file in the *WAS\_HOME/temp* directory is used by the messaging service to keep track of durable subscriptions for message-driven beans. If you uninstall an application that contains a message-driven bean, this file is used to unsubscribe the durable subscription. If you have to delete the *WAS\_HOME/temp* directory or other files in it, ensure that you preserve this file.

To stop active subscribers for one or more durable subscriptions, complete the following steps:

### Procedure

1. Use the administrative console to list the durable subscriptions
2. From the list, identify the client identifier of the durable subscription. The name column lists the unique subscription name for each durable subscription, in the form *clientID##subName* where:

*clientID*

The client identifier used to associate a connection and its objects with the messages maintained for the client by the JMS provider.

*subName*

The name used to uniquely identify a durable subscription within a given client identifier.

3. Use your client identifier naming convention to identify the application assigned to the client identifier.
4. List the applications that have active consumers for the durable subscription. In the navigation pane of the administrative console, click **Applications -> Application Types -> WebSphere enterprise applications**.
5. In the console pane, select the check box next to the name of each application that you want to stop.
6. Click **Stop**

### Results

This stops the active consumers created by the applications, so applications can reconnect to the durable subscriptions with different parameters from those that were used to create the previous subscriptions.

### Deleting durable subscriptions

Use this task to delete a durable subscription.

### About this task

To delete one or more durable subscriptions, complete the following steps:

### Procedure

1. Display the durable subscriptions
2. Select the check box for each subscription you want to delete.
3. Click **Delete**

### Results

The selected durable subscriptions are deleted.

---

## Administering mediations

These topics provide information about mediations, which are used to change how messages are handled at destinations on a service integration bus.

## Procedure

- `../ae/cjp_learning.dita`
- Mediation programming
- Programming mediations
- “Securing mediations”
- “Configuring mediations” on page 2149
- “Configuring mediation points” on page 2159
- “Managing mediations with administrative commands” on page 2161
- “Operating mediations at mediation points” on page 2162
- “Administering messages on mediation points” on page 2164
- “Message properties support for mediations” on page 2580
- “Error handling in mediations” on page 2585
- “Mediation thread pool properties” on page 2586

## Securing mediations

Use the following tasks to secure mediations at an operations level. For example, a mediation inherits its identity from a the messaging engine, but you might want to specify an alternative identity for the mediation to use.

### Configuring an alternative mediation identity for a mediation handler

Use this task to configure an alternative mediation identity for a mediation handler

#### About this task

By default, a mediation inherits the identity used by the messaging engine. In some cases, you might want to specify an alternative identity for a mediation handler to use. For example, for a single mediation that sends messages to a destination. To do this, you specify a "run-as" identity for the mediation handler at deployment, and map the mediation handler to an identity other than the default mediation identity by using a role name. Follow the steps below to specify an alternative mediation identity:

#### Procedure

1. Package your mediation handler as an EAR file.
2. Edit the deployment descriptor file to define the roles. For more information, see [Configuring programmatic logins for Java Authentication and Authorization Service](#).
3. Assign users to the role. For more information, see [Mapping users to RunAs roles using an assembly tool](#) and [Securing applications during assembly and deployment](#).
4. Deploy the mediation handler in WebSphere Application Server, and assign users to the RunAs role. For more information, see [Assigning users to RunAs roles](#). You can confirm the mappings of users to roles, add new users and groups, and modify existing information during this step. For more information, see [Deploying secured applications](#).

#### Example

#### What to do next

Next, you are ready to authorize mediations to access destinations. For more information, see [Administering authorization permissions](#).

### Configuring the bus to access secured mediations

Use this task to ensure that the service integration bus is authorized to access secured mediations.

## Before you begin

The mediation is secured by using a Java Platform, Enterprise Edition (Java EE) Connector Architecture authentication alias. For information about creating a Java EE authentication alias, see `../ae/tsec_j2cauthdata.dita`.

## About this task

To configure the bus to access a secured mediation, you must add the mediation authentication alias for the secured mediation to the properties for the bus:

- If the bus has a Version 6 bus member, you must provide the principal and its associated password.
- If the bus has WebSphere Application Server Version 7.0 or later bus members only, you need only provide the principal.

## Procedure

1. Log into the navigation pane.
2. Click **Service integration -> Buses -> security\_value**. The bus security configuration panel is displayed.
3. In the **Mediations authentication alias** field, select the principal for the mediation, and its associated password if required.
4. Click **OK**.
5. Save your changes to the master configuration.

## Results

The selected bus is configured to access secured mediations.

## What to do next

You can assign security roles to your mediation handlers to protect them from use by unauthorized users. For more information, see [Deploying secured applications](#).

## Configuring a bus to run mediations in a multiple security domain environment

Use this task to configure a secured bus so that it can run mediations successfully on bus members in different security domains.

## Before you begin

The secured bus must be configured to use a non-global security domain. For more information about securing buses by using multiple security domains, refer to [Securing buses](#).

## About this task

If your bus topology has bus members in different security domains, you can configure the bus to allow mediations to run under the server identity. This means that a mediation can run on any server in any domain. You do not have to add a dedicated user ID for each mediation to the user repository, or maintain a mediation authentication alias.

Use the administrative console to configure a secured bus to run mediations successfully as follows:

## Procedure

1. In the navigation pane, click **Service integration -> Buses -> security\_value**. The security settings for the selected bus are displayed.
2. Check the option **Use the Server ID when running mediations**.

3. Click **Apply**.
4. Save your changes to the master configuration.

## Results

You have configured the bus to run mediations successfully across servers in multiple security domains.

## What to do next

You can use the administrative console to control access to the bus by administering users and groups in the bus connector role.

## Configuring mediations

Use the following tasks if you want to modify the behavior of a mediation, control which messages are mediated, or influence how messages are processed.

### Installing a mediation

You can install an enterprise application (EAR file) containing a mediation on a server or a cluster.

#### Before you begin

- You have an EAR file that you can deploy into WebSphere Application Server (base). The EAR file contains a mediation handler enterprise bean. You can use the tooling provided with IBM Rational Application Developer to assemble EAR files.
- For guidance on selecting the target application server or a cluster for your mediation, see Mediation application installation.

#### About this task

In this task, you use the administrative console to install a mediation application into WebSphere Application Server (base). For additional information about installing enterprise applications, see Installing enterprise application files with the console. For information about installing a secure mediation handler, see Deploying secured applications.

#### Procedure

1. Click **Applications -> New Application -> New Enterprise Application**.
2. On the first Preparing for application install page, specify the full path name of your EAR file, and click **Next**.
3. On the second Preparing for application install page, choose to generate default bindings.
  - a. Expand **Choose to generate default bindings and mappings**.
  - b. Select **Generate default bindings**. Using the default bindings causes any incomplete bindings in the application to be completed with default values. The product does not change existing bindings.
  - c. Click **Next**. The Select Installation options page is displayed.
4. Type the name of your EAR file in the **Application name** field, if it not already specified, and click **Next**. The Map modules to servers page is displayed.
5. Select the target application server or a cluster where you want to install the modules that are contained in your application, and click **Next**.
6. Optional: If the panel **Deploy enterprise beans** is displayed, click **Apply**, and click **Next**.
7. Review the summary of the installation options you have chosen:
  - a. If you want to make changes, click **Previous** to return to the appropriate page.
  - b. When you are ready, click **Finish** to confirm your installation options.
8. Save your changes to the master configuration.

## Results

Your mediation application is installed on your chosen server or cluster.

## What to do next

You can configure the properties for the mediation in the administrative console. For more information, see “Configuring a new mediation.”

## Configuring a new mediation

Use this task to configure a mediation in the administrative console.

## Before you begin

This task assumes that you have installed a mediation application on the server or cluster where you want to run the mediation. For more information, see “Installing a mediation” on page 2149.

## About this task

Configuring a new mediation makes it available for use in mediating one or more destinations.

In this task, you use the administrative console to configure a mediation:

## Procedure

1. Click **Service integration -> Buses -> bus\_name -> [Destination resources] Mediations**.
2. In the content pane, click **New**.
3. Specify the following properties for the mediation:

### Mediation name

Type a name for the mediation that is unique to the service integration bus. This name is used to identify the mediation for administrative purposes.

### Description

Optionally, type a description for the mediation.

### Handler list name

Type the handler list name. This is the name that was used when the mediation handler was deployed. Handler list names are unique within the WebSphere Application Server administrative cell.

### Global transaction

Optionally, select this option (setting it to `true`) if you want to start a global transaction for each message mediated by the mediation. By default, Global transaction is set to `false`, and a global transaction is not started when a message is mediated.

### Allow concurrent mediation

Optionally, select this option (setting it to `true`) if you want to mediate multiple messages at the mediated destination.

By default, Allow concurrent mediation is set to `false`, and concurrent mediations are not allowed.

**Note:** Do not allow concurrent mediation if message ordering is important.

### Selector

Optionally, type a message selector to control which messages are mediated by the mediation. The selector operates on the content of the message header. The syntax of the message selector is defined by the JMS specification.

If the message content meets the conditions of the selector, the message is mediated. Otherwise, the message is not mediated.

### **Discriminator**

Optionally, type a message discriminator to control which messages are mediated by the mediation. Message discriminators conform to the publish/subscribe topicspace syntax.

If the message meets the conditions of the discriminator, the message is mediated. Otherwise, the message is not mediated.

4. Click **OK**.
5. Save your changes to the master configuration.

## **Results**

You have configured a new mediation.

## **What to do next**

You can use the mediation to mediate a destination. For more information, see “Mediating a destination” on page 2158.

## **Deleting a mediation**

Use this task to delete a selected mediation in the administrative console.

### **Before you begin**

Before deleting a mediation, you must ensure that it is not in use at a bus destination. You cannot delete a mediation that is in use at a destination; you must first unmediate the destination. For more information, see “Unmediating a destination” on page 2159.

### **About this task**

Deleting a mediation removes it from the administrative console. To delete a mediation, use the administrative console to complete the following steps

### **Procedure**

1. Click **Service integration -> Buses -> *bus\_name* -> [Destination resources] Mediations**.
2. Select the mediations that you want to delete.
3. Click **Delete**.
4. Save your changes to the master configuration.

## **Results**

The mediations are deleted.

## **Modifying the properties of a mediation**

Use this task to set properties to control some aspects of the runtime behavior of an existing mediation.

### **Before you begin**

You should ensure that the mediation exists. If you want to configure a new mediation, see “Configuring a new mediation” on page 2150.

## About this task

Using the administrative console, you can specify the following options for a selected mediation:

- Each message processed by the mediation runs within a global transaction.
- The mediation processes messages concurrently.
- The mediation processes only those messages that meet some selection criteria.

## Procedure

1. Click **Service integration** -> **Buses** -> *bus\_name* -> **[Destination resources] Mediations** -> *mediation\_name*.
2. Select any of the following properties for the mediation:

### Description

Optionally, type a description of the behavior of the mediation, taking into account any properties specified for the mediation.

### Handler list name

Type the name of the handler list that was defined when the mediation was deployed. Handler list names start with an uppercase letter, and are unique within the service integration bus.

### Global transaction

Optionally, select this option (setting it to true) if you want to start a global transaction for each message mediated by the mediation.

By default, Global transaction is set to false, and a global transaction is not started when a message is mediated.

### Allow concurrent mediation

Optionally, select this option (setting it to true) if you want to mediate multiple messages at the mediated destination.

By default, Allow concurrent mediation is set to false, and concurrent mediations are not allowed.

**Note:** Do not allow concurrent mediation if message ordering is important.

### Selector

Optionally, type a message selector to control which messages are mediated by the mediation. The selector operates on the content of the message header. The syntax of the message selector is defined by the JMS specification.

If the message meets the conditions of the selector, the message is mediated. Otherwise, the message is not mediated.

For information about the properties that can be used in selectors, see “Message properties support for mediations” on page 2580.

### Discriminator

Optionally, type a message discriminator to control which messages are mediated by the mediation. Message discriminators conform to the publish/subscribe topic space syntax.

If the message meets the conditions of the discriminator, the message is mediated. Otherwise, the message is not mediated.

3. Specify any additional properties.
4. Click **OK**.
5. Save your changes to the master configuration.

## Results

You have changed the properties for the selected mediation.

### What to do next

- If you want to configure the mediation context information, see “Configuring mediation context properties” on page 2155.
- To use the mediation to mediate a destination, see “Mediating a destination” on page 2158.

## Adding mediation context information

Use this task to add a mediation context property for a selected mediation.

### Before you begin

The mediation for which you want to add context information must exist in the administrative console. To create a mediation, see “Configuring a new mediation” on page 2150.

### About this task

Mediation context information is used, in addition to the message header information, to determine how a message is processed at run time. New context information is defined by adding a mediation context property. A destination can also have context properties. If you add a context property for a mediation that has the same name as a destination context property, the property on the destination takes precedence.

You can add the following mediation context properties:

Property name	Description	Value	Additional information
<b>sib:SkipWellFormedCheck</b>	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.
<b>sib:GlobalTransactionLPSEnabled</b>	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one-phase commit resource to participate in a global transaction that has two-phase commit resources.	True or false	

To add new mediation context information for a selected mediation, use the administrative console to complete the following steps:

### Procedure

1. Display the Context Properties panel for a selected mediation: click **Service integration -> Buses -> bus\_name -> [Destination resources] Mediations -> mediation\_name -> [Additional Properties] Context properties**. Any mediation context properties that have already been defined for the selected mediation are displayed.
2. Click **New** in the content pane.
3. Specify the following information for the mediation context property:

**Name** Type a name for the mediation context property. You must type the name exactly as it appears in the table above.

### Context type

Select the type Boolean for the mediation context property.

### Context value

Type True to set the property. The value is not case sensitive.

4. Click **OK**.
5. Save your changes to the master configuration.

## Results

You have added new mediation context information for the selected mediation.

## What to do next

You can repeat this task to add another mediation context property.

## Listing mediation context properties

Use this task to list context properties for a selected mediation.

### About this task

Mediation context information is used, in addition to the message header information, to determine how a message is processed at run time. The context information is provided by one or more of the following mediation context properties:

Property name	Description	Value	Additional information
<b>sib:SkipWellFormedCheck</b>	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.
<b>sib:GlobalTransactionLPSEnabled</b>	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one-phase commit resource to participate in a global transaction that has two-phase commit resources.	True or false	

In this task, you use the administrative console to list the mediation context properties for a selected mediation, as follows:

### Procedure

1. Log in to the administrative console.
2. Click **Service integration -> Buses -> bus\_name -> [Destination resources] Mediations -> mediation\_name -> [Additional Properties] Context properties**.

## Results

The mediation context properties for the selected mediation are displayed.

## What to do next

You can configure or delete the context information, or add a new context property for the selected mediation.

## Configuring mediation context properties

Use this task to configure context properties for a selected mediation.

### Before you begin

The mediation context property you want to configure must exist in the administrative console. To add a new mediation context property, see “Configuring a new mediation” on page 2150.

### About this task

Mediation context information is used, in addition to the message header information, to determine how a message is processed at run time. By configuring the mediation context properties, you ensure that messages are processed correctly. A destination can also have context properties. If a context property is configured for both a destination and a mediation, with the same name for the property, the property on the destination takes precedence.

You can configure the following mediation context properties:

Property name	Description	Value	Additional information
<b>sib:SkipWellFormedCheck</b>	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.
<b>sib:GlobalTransactionLPSEnabled</b>	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one-phase commit resource to participate in a global transaction that has two-phase commit resources.	True or false	

To configure an existing mediation context property, use the administrative console to complete the following steps:

### Procedure

1. Display the mediation context property for a selected mediation: click **Service integration -> Buses -> bus\_name -> [Destination resources] Mediations -> mediation\_name -> [Additional Properties] Context properties**. The mediation context properties for the selected mediation are displayed.
2. Select the mediation context property you want to configure.
3. Specify the following information for the mediation context property:
  - Name** Type a name for the mediation context property. You must type the name exactly as it appears in the table above.
  - Context type**  
Select the type Boolean for the mediation context property.
  - Context value**  
Type a value for the mediation context property: either True to set the property, or False to unset it. The value is not case sensitive.
4. Click **OK**.
5. Save your changes to the master configuration.

## Results

The context property is configured for the selected mediation.

## What to do next

You can repeat this task to configure additional mediation context properties.

## Deleting mediation context information

Use this task to delete a mediation context property for a selected mediation.

## About this task

In this task, you delete a mediation context property. The mediation context information provided by the property is no longer used at runtime to process messages.

You can delete the following mediation context properties:

Property name	Description	Value	Additional information
<b>sib:SkipWellFormedCheck</b>	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.
<b>sib:GlobalTransactionLPSEnabled</b>	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one-phase commit resource to participate in a global transaction that has two-phase commit resources.	True or false	

To delete mediation context information for a selected mediation, use the administrative console to complete the following steps:

## Procedure

1. Display the Context Properties panel for a selected mediation: click **Service integration -> Buses -> bus\_name -> [Destination resources] Mediations -> mediation\_name -> [Additional Properties] Context properties**. The mediation context properties for the selected mediation are displayed.
2. Select the property you want to delete, and click **Delete**.
3. Click **OK**.
4. Save your changes to the master configuration.

## Results

Your chosen mediation context property is deleted for the selected mediation.

## What to do next

You can repeat this task to delete another mediation context property.

## Configuring the mediation thread pool

Use this task to configure the mediation thread pool.

## Before you begin

The wsadmin tool must be running. For more information, see Starting the wsadmin scripting client using wsadmin scripting.

## About this task

You configure the mediation thread pool if you want to change the number of threads used when running mediations concurrently. The maximum size of the thread pool determines the maximum number of messages that can be mediated concurrently for a messaging engine.

The mediations thread pool, attribute name `mediationsThreadPool`, is an attribute of the messaging engine. By default, `mediationsThreadPool` does not exist, and a default thread pool is created and used at run time. In this task, use the wsadmin tool to create a thread pool object, and then modify its properties using JACL, as shown in the examples below:

## Procedure

1. Use this example to create a `mediationThreadPool` object:

```
AdminConfig.create("ThreadPool" , messagingEngine,
 [["name" , "stitch.server1-bus2-mediationThreadPool"]] ,
 "mediationThreadPool")
```

**Tip:** In this case, the thread pool name is based on the name of the messaging engine. Although it is not required to do this, it makes it easier to find the thread pool name when using Performance Monitoring Infrastructure (PMI).

2. Use this example to modify a `mediationThreadPool` object:

```
AdminConfig.modify(AdminConfig.showAttribute(messagingEngine,
 "mediationThreadPool"), [["maximumSize" , "10"]])
```

`maximumSize` can contain any of the `mediationsThreadPool` properties. To add additional parameters, insert `[attribute_name attribute_value]` within the outer brackets ([]).

**Tip:** There is a space between `attribute_name` and `attribute_value`.

## Setting tuning properties for a mediation

Use this task to tune a mediation for performance by using the administrative console.

## Before you begin

Review the guidance on when it is appropriate to tune a mediation for performance in the topic Performance tuning for mediations.

## About this task

You can set the following tuning property in the administrative console to improve the performance of a mediation:

### **sib:SkipWellFormedCheck**

Whether you want to omit the well formed check that is performed on messages after they have been processed by the mediation. Either true or false.

**Note:** This property is overridden for messages that have the delivery option assured persistent, and a well formed check is always performed.

To set, or unset, one or more tuning properties for a mediation, use the administrative console to complete the following steps:

## Procedure

1. Display the mediation context information:
  - a. Click **Service integration -> Buses -> bus\_name -> [Destination resources] Mediations**.
  - b. In the content pane, select the name of the mediation for which you want to configure tuning information.
  - c. Click **[Additional Properties] Context information**.
2. In the content pane, click **New**.
3. Type the name of the property in the **Name** field.
4. Select the type `Boolean` from the drop-down list.
5. Type **true** in the **Context Value** field to set the property, or type **false** to unset the property.
6. Click **OK**.
7. Save your changes to the master configuration.

## Mediating a destination

Use the administrative console to mediate a service integration destination with a mediation hosted by service integration. A mediation point is created for the mediated destination on the bus member where you want the mediation to run, and is used to process messages at runtime.

### Before you begin

Ensure that the following resources exist:

- The mediation you want to apply to the destination. For more information, see “Configuring a new mediation” on page 2150.
- The bus member where the mediation point is to be created.

### About this task

You can mediate a destination with a single mediation only, but you can associate the same mediation with more than one destination. This scenario mediates a destination with a service integration mediation point, and a service integration mediation. If you want to mediate a destination by using an WebSphere MQ program, or assign it to an WebSphere MQ queue point, see “Mediating a destination by using a WebSphere MQ queue as the mediation point” on page 663.

## Procedure

1. Click **Service integration -> Buses -> bus\_name -> [Destination resources] Destinations**. The bus destinations for the selected bus are displayed.
2. Select the destination you want to mediate, and click **Mediate**. A list of available mediations is displayed.
3. Select the mediation to associate with the destination, and click **Next**.
4. Select the bus member where you want the mediation to run, and click **Next**.
5. Click **Finish** to mediate the destination, or **Previous** to make any changes to your selections.
6. Save your changes to the master configuration.

## Results

Your chosen destination is mediated with your chosen mediation, and a mediation point is created for the destination on the bus member.

### What to do next

You can control some aspects of how the mediation processes messages at the mediation point. For example, whether the mediation run within a global transaction, or processes multiple messages

concurrently. For more information, see “Modifying the properties of a mediation” on page 2151.

## Unmediating a destination

Use this task to unmediate a selected bus destination.

### Before you begin

Before you start this task, you should consider whether you want to preserve message ordering at the bus destination you intend to unmediate.

### About this task

Unmediating a selected bus destination breaks the association between the bus destination and the mediation, and the mediation stops processing messages at the bus destination at run time. This task unmediates a bus destination, and optionally preserves message ordering at the bus destination.

To unmediate a bus destination use the administrative console to complete the following steps:

**Tip:** If you want to preserve message ordering, complete all the following steps. If message ordering is not important, you can omit steps 2 and 4:

### Procedure

1. Display the bus destination you want to unmediate. Click **Service integration -> Buses -> bus\_name -> [Destination resources] Destinations -> destination\_name**.
2. Optional: If you want to preserve message ordering at the destination, take the following steps:
  - a. Clear the **Send Allowed** check box (setting it to false) to stop sending messages to the message points for this destination.
  - b. Wait until there are no messages listed for the mediation points.
  - c. Stop all the mediation points, and wait for all the mediation points to enter the stopped state.
  - d. Optional: If it is not already selected, select the bus destination you want to unmediate.
3. Click **Unmediate** to unmediate the destination.
4. Optional: Select the **Send Allowed** check box (setting it to true) to resume sending messages to the mediation points for this destination.
5. Save your changes to the master configuration.

### Results

The destination is unmediated, and the mediation point is deleted from the destination.

If you did not preserve message ordering, any messages that remain on the mediation point after you have unmediated the destination are processed as for a non-mediated destination. Messages with an empty forward routing path are placed on the next appropriate message point for the destination. Messages with a non-empty forward routing path are sent to the destination specified in the forward routing path.

The unmediated destination now operates as a non-mediated destination, and new messages are sent to a message point on the destination.

## Configuring mediation points

In service integration technologies, messages are held at specialized message points called mediation points before they are processed by a mediation. Use the following tasks to set properties at mediation points to route messages and start and stop mediations:

## Configuring a mediation point

You can use the administrative console to browse or change the configuration properties for a selected mediation point for a selected bus destination.

### Before you begin

You must first create a mediation point on a bus destination. For more information, see “Mediating a destination” on page 2158.

### About this task

A mediation point is a specialized message point on a bus location where messages are stored and mediated. Configuring the properties of a mediation point enables you to control some aspects of how messages are sent to and received from a bus destination. In this task you use the administrative console to configure the properties for a selected mediation point for a selected bus destination.

**Note:** You should be aware that the mediation point properties Send allowed and Initial state override the general properties defined for the bus destination.

To browse or change the properties for a selected mediation point, use the administrative console to complete the following steps:

### Procedure

1. Start the administrative console, and click **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Message points] Mediation points -> *mediation\_point\_name***. The properties for the selected mediation point are displayed.
2. Optional: Browse or change the following properties for the mediation point:

#### Identifier

The identifier by which this message point is known for administrative purposes. This field is for display purposes only.

**UUID** The universal unique identifier assigned to this mediation point for administrative purposes. This field is for display purposes only.

#### High message threshold

The maximum total number of messages that can be placed on this mediation point. This field is for display purposes only.

#### Send allowed

This property specifies whether messages are sent to this mediation point. By default, True is selected, and messages are sent to this mediation point. Select False to prevent messages from being sent to this mediation point.

#### Initial state

This property specifies the state of the mediation point when the host messaging engine is started for the first time. Permitted values are Started or Stopped. The default state is Started. The mediation does not start mediating messages until Initial state is Started.

#### Target UUID

The UUID of the bus destination where this mediation point is created. This field is for display purposes only.

3. Click **OK**.
4. Save your changes to the master configuration.

### Results

You have browsed or changed the configuration properties for the selected mediation point.

## Listing mediation points for a bus destination

Use this task to list mediation points for a selected bus destination.

### About this task

This task lists the mediation points for a selected bus destination. You might want to do this, for example, to check that a destination is mediated.

To display a list of mediation points for a bus destination, use the administrative console to complete the following steps:

### Procedure

1. Click **Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *destination\_name***.
2. Click **[Message Points] Mediation Points**.

### Results

All the mediation points for the selected bus destination are displayed.

## Listing mediation points for a messaging engine

You can use the administrative console to list all the known mediation points for a selected messaging engine. You can then view the properties for a mediation point, administer messages for a mediation point, or operate mediations at a mediation point.

### About this task

To list the mediation points for a selected messaging engine, use the administrative console to complete the following steps:

### Procedure

Start the administrative console, and click **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Message points] Mediation points**.

### Results

The Mediation points panel displays a list of all the mediation points for the selected messaging engine.

### What to do next

You can click the name of a mediation point in the list to work with its properties, administer its messages or operate mediations.

## Managing mediations with administrative commands

You can use wsadmin commands to administer service integration technologies mediations. For example you can create, delete and view mediations, configure mediation properties and mediate destinations.

### About this task

These commands provide an alternative to using the administrative console.

## Procedure

1. Open a wsadmin command session in local mode For example:  
wsadmin -conntype none -lang jython
2. Type `AdminTask.command` where *command* is the command format as indicated in the related reference topics. For example:

```
wsadmin>AdminTask.listSIBMediations("-bus abus")
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098217858584)
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098220051588)
```

## Operating mediations at mediation points

Use these tasks to start, stop and restart mediations at runtime at specialized message points called mediation points.

### Before you begin

These tasks assume that mediations are configured in the administrative console. For more information, see “Configuring mediations” on page 2149.

### Starting a mediation

Use this task when you want a mediation to apply its message processing to messages at a selected specialized message point on a destination, at runtime.

### Before you begin

The mediation you want to start must be associated with a destination. For more information, see “Mediating a destination” on page 2158.

### About this task

Starting (and stopping) a mediation is a runtime operation. All mediation runtime operations are performed on specialized destination message points called mediation points. When you start a mediation, the mediation begins operating on messages at a selected mediation point. You can start a mediation after the server has started. A mediation cannot operate on new messages at a mediation point after server shutdown begins.

**Tip:** To ensure that a mediation operates on a specific message at a mediation point, remove all existing messages from the mediation point before you start the mediation. For more information, see “Deleting messages on a mediation point” on page 2165.

To start a mediation, complete the following steps in the administrative console:

## Procedure

1. List the mediation points by using the administrative console:
  - To list the mediation points for a bus destination, click **Service integration -> Buses -> bus\_name -> [Destination resources] Destinations -> destination\_name -> [Message Points] Mediation points**.
  - To list the mediation points for a messaging engine, click **Service integration -> Buses -> bus\_name -> [Topology] Messaging engines -> engine\_name -> [Message points] Mediation points**.
2. Select the mediation name.
3. Click **Start**.

## Results

The mediation starts operating on messages at the selected mediation point.

## What to do next

To list or delete messages at selected mediation points, see “Administering messages on mediation points” on page 2164. To restart a mediation, refer to “Restarting a mediation that has stopped on error.”

## Stopping a mediation

Use this task to stop a selected mediation at a mediation point.

## Before you begin

Before you can operate a mediation, it must be associated with a destination. For more information, see “Mediating a destination” on page 2158.

## About this task

Stopping a mediation, as with all runtime operations on mediations, is carried out at a specialized message point on the destination, called a mediation point. By stopping a mediation, you stop any further messages from being delivered to the mediation point. Messages sent to the destination are held at the pre-mediated part of the destination. The messages are not mediated and are not made available to message consumers until the mediation is restarted. Note that mediations starts operating on messages after the server has started and no new messages are mediated after server shutdown begins.

To stop a selected mediation, use the administrative console to complete the following steps:

## Procedure

1. List the mediation points.
  - To list the mediation points for a bus destination, click **Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *destination\_name* -> [Message Points] Mediation points.**
  - To list the mediation points for a messaging engine, click **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Message points] Mediation points.**
2. Select the mediation name.
3. Click **Stop**.

## Results

The mediation is stopped at the mediation point. Messages arriving at the mediation point are not processed by the mediation. The messages are stored at the mediation point until the mediation is restarted.

## Restarting a mediation that has stopped on error

You must restart a mediation that has stopped on error so that the mediation can continue processing messages. When the mediation is restarted, the mediation resumes mediating messages on the pre-mediated part of the destination.

## About this task

Changes in the state of a mediation usually occur as the result of operations performed by the administrator. If the state of a mediation moves from Started to Stopped on error, and you have not stopped it intentionally, you should investigate the cause of the problem, and resolve it before attempting to restart the mediation.

To restart a mediation that has stopped on error, use the administrative console to complete the following steps:

### Procedure

1. List the mediation points.
  - To list the mediation points for a bus destination, click **Service integration -> Buses -> bus\_name -> [Destination resources] Destinations -> destination\_name -> [Message Points] Mediation points**.
  - To list the mediation points for a messaging engine, click **Service integration -> Buses -> bus\_name -> [Topology] Messaging engines -> engine\_name -> [Message points] Mediation points**.
2. In the content pane, select the mediation name.
3. Click the **Runtime** tab.
4. Under **General Properties**, view the information in the **Reason** field.
5. Resolve the problem.
6. Restart the mediation so that it can continue processing messages.

## Administering messages on mediation points

Use these tasks to list and delete runtime messages held at mediation points in a service integration bus.

### Listing messages at a mediation point

Use this topic to list messages at a mediation point.

## About this task

The mediation point is a specialized message point that defines the association between a mediation and a destination. You can browse and delete messages on a mediation point for a selected bus destination or messaging engine.

To display a list of messages on a selected mediation point, use the administrative console to complete the following steps:

### Procedure

1. List the mediation points.
  - To list the mediation points for a bus destination, click **Service integration -> Buses -> bus\_name -> [Destination resources] Destinations -> destination\_name -> [Message Points] Mediation points**.
  - To list the mediation points for a messaging engine, click **Service integration -> Buses -> bus\_name -> [Topology] Messaging engines -> engine\_name -> [Message points] Mediation points**.
2. Click the mediation point name. This displays the properties of the mediation point.
3. Click the **Runtime** tab.
4. Click **[Additional Properties] Messages**.

## Results

A list of messages on the selected mediation point is displayed in the content pane.

## Deleting messages on a mediation point

Use this topic to delete messages that exist on a mediation point for a selected bus destination.

### About this task

The mediation point is a specialized message point that defines the association between a mediation and a destination. As with other message points, you can delete messages on a mediation point for a selected bus destination or messaging engine. For example, if you want to preserve message ordering at a destination before it is unmediated, you can delete all the messages at that destination.

### Procedure

1. List the messages at the mediation point. For more information, see “Listing messages at a mediation point” on page 2164.
2. In the content pane, select the check box next to each message you want to delete. Alternatively, select all the messages in the list by clicking **Select All Items**.
3. Click **Delete**.

## Results

The selected messages are removed from the destination.

## Example: Using mediations to trace, monitor and log messages

The most straightforward use of a mediation is for tracing, monitoring or logging messages that pass through a destination or topics spaces. This type of mediation does not modify the message; it only extracts information from the message and saves or displays the information elsewhere.

For example, the following mediation handler displays the API message and correlation IDs for each message it is sent:

```
public boolean(MessageContext context)
{
 SIFMessageContext msgCtx = (SIFMessageContext)context;
 SIFMediationSession session = msgCtx.getSession();
 SIFMessage msg = msgCtx.getMessage();
 String msgId = msg.getApiMessageId();
 String corrId = msg.getCorrelationId();
 String dest = session.getDestinationName();

 System.out.println(msgId+" (correlation id="+corrId) is passing through "+dest+".");

 return true;
}
```

---

## SIB service [Settings]

The service that provides service integration functions.

To view this page in the console, click the following path:

**Servers -> Server Types -> WebSphere application servers -> *server\_name* -> [Server messaging] SIB service.**

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### ***Enable service at server startup:***

Specifies whether or not the server attempts to start the specified service when the server starts.

If you want applications to use service integration technologies provided by this application server, including JMS resources of the default messaging provider of this application server, this option must be selected. The SIB Service is enabled automatically when you add a server to a service integration bus. You can choose to disable the SIB service, for example if you have removed the only bus member for a server.

Enabling or disabling the SIB Service has the same effect as enabling or disabling the Control Region Adjunct (CRA).

For information about using service integration technologies, see [Administering service integration](#).

<b>Required</b>	No
<b>Data type</b>	Boolean

#### ***Configuration reload enabled:***

Select this option to enable the dynamic reloading of the SIB configuration files for this server.

The information that defines the configuration of service integration buses and their resources is saved in a set of configuration files. When a server starts up, it uses the current information about service integration read from those configuration files. When a messaging engine is started, it uses the information in the server that it is running in.

If the information in the configuration files is changed while the server is running, the server must either be dynamically updated or restarted to use the updated information.

With dynamic reloading of configuration files, any updates to the configuration information are dynamically passed to the server, and therefore made available to messaging engines whether or not they are started. You can enable dynamic reloading of configuration files for servers and for service integration buses.

If you choose not to enable dynamic reloading of configuration files, you must restart the server to pick up any changes to the configuration files.

In a cluster deployment with failover, the configuration information is likely to be updated between the initialization and start up of a messaging engine (A messaging engine is initialized when the server starts, but might not get started for a long time after that). Therefore you should enable dynamic reloading of configuration files in a cluster deployment with failover, because restarting a server to pick up configuration changes causes a failover. To get predictable behavior on failover, you must ensure that the standby (inactive) servers had been updated and recycled before the active server.

<b>Required</b>	No
<b>Data type</b>	Boolean

---

## Add a transport to the list of permitted transports [Settings]

Add a transport to the list of permitted transports.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Additional Properties] Permitted transports -> *member\_name*.**

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### *Transport chain name:*

Select the transport name from the list of chain names.

You can manage inbound chains through the administrative console by selecting either **Servers -> Server Types -> WebSphere application servers -> *server\_name* -> [Server messaging] Messaging engine inbound transports** or **Servers -> Server Types -> WebSphere application servers -> *server\_name* -> [Server messaging] WebSphere MQ link inbound transports**. You can also use these administrative console panels to define new transport chains from a set of templates.

The outbound chains that an application server uses for bootstrap operations are defined when the server is defined. They can be altered, or new bootstrap chains can be defined, by using the wsadmin tool.

<b>Required</b>	No
<b>Data type</b>	drop-down list

## Range

### **InboundBasicMessaging**

This transport chain allows communication through the TCP protocol. The default port used by this chain for the first server on the node is 7276. You should verify that the selected port is not already used, for example if you are configuring a second server with the same name as the first server. Messaging engines hosted in other application servers and JMS applications running in a client container can communicate with the messaging engines of the server by using this transport chain.

### **InboundSecureMessaging**

This transport chain provides secure communication by using the secure sockets layer (SSL) based encryption protocol over a TCP network. The default port used by this chain for the first server on the node is 7286. You should verify that the selected port is not already used, for example if you are configuring a second server with the same name as the first server. The SSL configuration information for this chain is based on the default SSL repertoire for the application server. Messaging engines hosted in other application servers and JMS applications running in the client container can communicate using this transport chain.

### **InboundBasicMQLink**

This transport chain supports WebSphere MQ queue manager sender channels and applications by using the WebSphere MQ JMS provider connecting over a TCP network. The default port used by this chain is 5558, although this can be automatically adjusted to avoid conflicts.

### **InboundSecureMQLink**

This transport chain enables WebSphere MQ queue manager sender channels and applications by using the WebSphere MQ JMS provider to establish SSL based encrypted connections over a TCP network. The default port used by this chain is 5578, although this is automatically adjusted to avoid conflicts.

### **BootstrapBasicMessaging**

This transport chain is used to establish bootstrap connections to inbound chains configured for TCP-only connections to an application server, such as the InboundBasicMessaging chain.

### **BootstrapSecureMessaging**

This transport chain is used to establish secure connections by using secure sockets layer (SSL) based encryption. The SSL configuration used is taken from the default SSL repertoire when used in an application server environment or from a configuration file when used by the client container. This chain can be used for establishing bootstrap connections to inbound chains that are configured to use SSL, for example, the InboundSecureMessaging chain. Success in establishing such a connection depends on a compatible set of SSL credentials being associated with both this bootstrap outbound

---

## Alias destination [Settings]

An alias destination makes a destination available by another name and, optionally, overrides the parameters of the destination.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *destination\_name*.**

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

#### General Properties

##### ***Identifier:***

The identifier by which this destination is known for administrative purposes.

The identifier and bus are used to identify this destination to applications.

<b>Required</b>	No
<b>Data type</b>	String

##### ***Bus:***

The name of the bus on which this destination is known to applications.

The identifier and bus are used to identify this destination to applications.

<b>Required</b>	No
<b>Data type</b>	String

##### ***UUID:***

The universal unique identifier assigned by the system to this destination for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

##### ***Type:***

Whether this bus destination is for a queue, topic space, or some other type of destination.

<b>Required</b>	No
<b>Data type</b>	String

##### ***Description:***

An optional description for the bus destination, for administrative purposes.

**Required** No  
**Data type** Text area

***Target identifier:***

The name of the destination for which this is an alias.

**Note:** The targetIdentifier field is read-only and cannot be modified; if you want to change the target of an alias, you must delete the alias destination then re-create it.

**Required** No  
**Data type** String

***Target bus:***

The name of the bus on which the destination for which this is an alias exists.

If you do not specify a bus name, the target destination is assumed to be on the same bus as the alias destination.

**Note:** The targetBus field is read-only and cannot be modified; if you want to change the target of an alias, you must delete the alias destination then re-create it.

**Required** No  
**Data type** String

***Enable producers to override default reliability:***

Select this option to enable producers to override the default reliability that is set on the destination.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the Enable producers to override default reliability property is set to True. Otherwise, the Default reliability setting is used.

**Required** No  
**Data type** drop-down list  
**Range**

**Inherit** The alias destination uses (inherits) the value of the corresponding property on the target destination.

**True** The alias destination uses the delivery option value specified by producers.

**False** The alias destination uses the delivery option value specified by the Reliability property of the destination.

***Default reliability:***

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

This reliability setting is used if a message has not set a reliability or if the “Enable producers to override default reliability” on page 2170 is set to False.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the Enable producers to override default reliability property is set to True. Otherwise, the Default reliability setting is used.

**Required**  
**Data type**  
**Range**

No  
drop-down list

**Inherit** The alias destination uses (inherits) the value of the corresponding property on the target destination.

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

***Maximum reliability:***

The maximum reliability of messages accepted by this destination.

Producers cannot send messages to this destination with a reliability higher than the value specified for this property.

**Required**  
**Data type**

No  
drop-down list

## Range

**Inherit** The alias destination uses (inherits) the value of the corresponding property on the target destination.

### **Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

### **Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

### **Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

### **Reliable persistent**

Messages might be discarded when a messaging engine fails.

### **Assured persistent**

Messages are not discarded.

## **Default priority:**

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	-1 through 9

## **Send allowed:**

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	
<b>Inherit</b>	The alias destination uses (inherits) the value of the corresponding property on the target destination.
<b>True</b>	The alias destination uses the delivery option value specified by producers.
<b>False</b>	The alias destination uses the delivery option value specified by the Reliability property of the destination.

### ***Receive allowed:***

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	
<b>Inherit</b>	The alias destination uses (inherits) the value of the corresponding property on the target destination.
<b>True</b>	The alias destination uses the delivery option value specified by producers.
<b>False</b>	The alias destination uses the delivery option value specified by the Reliability property of the destination.

### ***Reply destination:***

The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination.

This property is intended for use with mediations on reply messages.

For more information about the use of this property, see “Configuring a destination reverse routing path” on page 2131.

<b>Required</b>	No
<b>Data type</b>	String

### ***Reply destination bus:***

The bus on which the reply destination exists.

This property is intended for use with mediations on reply messages.

For more information about the use of this property, see “Configuring a destination reverse routing path” on page 2131.

<b>Required</b>	No
<b>Data type</b>	String

### ***Default forward routing path:***

The value to which a message's forward routing path will be set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of line-delimited bus destinations specified as *bus:name*.

If you want to forward messages to one or more bus destinations, type a list of bus destinations. Type each destination entry on a separate line, and in the form *bus\_name:destination\_name* or *:destination\_name*

Where

*bus\_name*

Is the name of the service integration bus on which the destination is configured. If you do not specify a bus name, the destination is assumed to be on the same bus as the destination for which you are setting this property.

*destination\_name*

is the name of a bus destination.

<b>Required</b>	No
<b>Data type</b>	Text area

***Delegate authorization check to target destination:***

Indicates whether the authorization check is performed on the alias or the target destination.

Indicates which destination access role is checked when a user accesses the alias destination. When this option is selected, the destination access role of the target destination is checked. When this option is not selected, the destination access role of the alias destination is checked. If you do not want to override the security of the target destination, select this option.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Include an RFH2 message header when sending messages to WebSphere MQ:***

If selected, messages sent to WebSphere MQ include an RFH2 header. The RFH2 header stores additional information to that which is stored in the WebSphere MQ message header.

This property applies when the target bus is a WebSphere MQ queue manager or queue-sharing group. When service integration converts a message from the service integration format to WebSphere MQ format, by default it includes an MQRHF2 header in the WebSphere MQ message. This header contains message attributes, such as JMS message attributes, that are not WebSphere MQ message attributes and therefore do not appear in the WebSphere MQ message descriptor (MQMD). Some WebSphere MQ applications cannot process messages that include an MQRHF2 header. If messages sent to this destination will be processed by WebSphere MQ applications that cannot tolerate an MQRHF2, clear this option.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Use all target queue points:***

Whether to use all target queue points

**Note:** This option is only visible when an alias destination is defined to point at a destination with multiple queue points.

Indicates whether all the queue points of the target queue can be used, including any queue points created after the alias is configured. When selected, the **Target queue points** menu is disabled.

<b>Required</b>	Yes
<b>Data type</b>	Boolean

### ***Unselected queue points:***

This is a list of the queue points that are not addressable by the alias definition. The list is generated from the complete list of queue points for this queue.

**Note:** This option is only visible when an alias destination is defined to point at a destination with multiple queue points.

This list is enabled only when **Use all target queue points** is unchecked.

<b>Required</b>	No
<b>Data type</b>	drop-down list

### ***Selected queue points:***

This is a list of the queue points that are addressable by the alias definition. Messages produced to or consumed from this alias apply to only these queue points.

**Note:** This option is only visible when an alias destination is defined to point at a destination with multiple queue points.

This list is enabled only when **Use all target queue points** is unchecked.

<b>Required</b>	No
<b>Data type</b>	drop-down list

## **Additional Properties**

### **Context properties**

Context information passed to the mediation.

## **Related Items**

### **Application resources topology**

A expandable tree view of all applications and messaging resources that reference the current destination.

---

## **Application resources for this destination**

This pane provides an expandable tree view of all the applications and messaging resources that reference the current destination, both directly and indirectly. As many of the references as possible are resolved to links to the associated configuration panel for the referenced object.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *queue\_name* -> [Related Items] Application resources topology**
- **Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *topic\_space\_name* -> [Related Items] Application resources topology**

Use this panel to inspect the configuration from the queue or topic space (destination) to the application or other JMS resources to ensure that the configuration is correct.

Using the default messaging provider, a JMS activation specification refers to a JMS destination (either a JMS Queue or JMS Topic) that in turn points to a service integration bus destination (either a queue destination or a topic space destination). JMS resources are referenced through Java Naming and Directory Interface (JNDI) names and service integration resources are referenced through bus and resource identifiers. This panel enables you to review the dependencies within your configuration, making it easier to detect inconsistencies, for example as a result of references being entered incorrectly, or JNDI or resource names being changed or deleted without the associated configuration having been updated.

Problems with the configuration are usually detected in one of two ways:

- An application can no longer send or receive messages.
- A destination becomes full and can no longer receive messages because the existing messages are not being consumed.

This panel can help you find the cause of the problem by giving you a high level view of many relevant resources.

**Note:** For a related view of the JMS resources for a given application, see the following panel:  
“Messaging resources for this application” on page 2271.

- “Local Topology tab”

## Local Topology tab

Topology properties for this object. These properties detail how this object relates to other objects in the system topology.

---

## Bootstrap members [Collection]

Bus members, servers and clusters that client applications can target to bootstrap into the given bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Bootstrap members.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This panel displays the bootstrap members for the selected bus. A bootstrap member is an application server or cluster that has been configured to accept bootstrap requests into the bus. The bootstrap member authenticates a connection request, and directs the request to a bus member. Select a bootstrap member policy to restrict which of the following types of server can service requests to bootstrap into the bus:

### All members of the cell with the Service Integration Bus Service enabled

This the default policy. Use any server in the cell that has the Service Integration Bus Service enabled to service bootstrap requests.

### Bus members and nominated bootstrap members

Use bus members and nominated cell members to service bootstrap requests.

### Bus members only

Use bus members only to service bootstrap requests.

Click **Apply** for the policy to take effect.

**Name** The server or cluster name for the bootstrap member.

**Type** The type of bootstrap member. Values are Bus member, Nominated member or SIB Service enabled.

### SIB Service

Whether SIB Service is enabled on this member. Values are Enabled or Disabled.

**Host** The host name for the node on which the bootstrap member is located.

**Ports** The ports from which the server can accept bootstrap requests.

### Buttons

New	This button is only displayed if you have applied the bootstrap member policy option "Bus members and nominated bootstrap members". Click to start the Add bootstrap member wizard.
Delete	Click to remove the selected bootstrap member. This button is only displayed if you have applied the bootstrap member policy option "Bus members and nominated bootstrap members". You cannot remove bus members, or members for which SIB Service is enabled.

---

## Bus members [Settings]

Bus members are the servers, WebSphere MQ servers and clusters that have been added to the bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Bus members -> *bus\_member\_name*.**

Use this pane to view or change messaging engine settings for a cluster when you are using messaging engine policy assistance.

You can change the currently selected messaging engine policy assistance, view the configuration diagram for the cluster, undertake further messaging engine configuration steps by using the links available in Additional Properties, or disable messaging engine policy assistance.

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Name:**

The name of the bus member.

This field is read-only.

**Required**

No

**Data type** String

**Type:**

The resource type of the bus member (Server, Server Cluster, or WebSphere MQ Server).

This field is read-only.

**Required** No  
**Data type** String

**Enable messaging engine policy assistance:**

A value that shows whether messaging engine policy assistance is set for the server cluster. This option is always selected when you first view this pane. To disable messaging engine policy assistance, deselect this option. The list of messaging engine policy assistance types and the configuration diagram are no longer displayed.

**Policy name:**

A value that shows the currently selected messaging engine policy assistance type for the server cluster. To change the selection, click the required radio button in the Select column, then click **Apply** or **OK**. For each messaging engine policy assistance type, except Custom, the **Is further configuration required?** column shows No if the number of messaging engines and their behavior are correctly configured. Otherwise, this column shows one or more messages with suggested actions to achieve the number of messaging engines and the required messaging engine behavior for each messaging engine policy assistance type. A diagram shows the servers, the currently configured messaging engines, and an indication of messaging engine behavior in the cluster. It also shows any changes required to support the currently selected messaging engine policy assistance type.

## Additional Properties

### Messaging engines

Use the **Messaging engines** option to view or change the messaging engines in this cluster. For example, you can add, remove, start or stop a messaging engine.

### Messaging engine policy maintenance

Use the **Messaging engine policy maintenance** option to view or correct the policy settings for the messaging engines in this cluster, that is, the settings that affect messaging engine behavior.

### Redundant core group policies

Use the **Redundant core group policies** option to view or delete any core group policies that are associated with this cluster, but that are not associated with any messaging engine in this cluster. When you use messaging engine policy assistance, you do not have to create or manage core group policies directly. A redundant core group policy might occur if messaging engine policy assistance is not enabled and you remove a messaging engine without deleting its associated core group policy, or create a core group policy that is not associated with a messaging engine.

---

## Bus members [Collection]

Bus members are the servers, WebSphere MQ servers and clusters that have been added to the bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Bus members.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Name** The name of the bus member.

**Type** The resource type of the bus member (Server, Server Cluster, or WebSphere MQ Server)

### Messaging engine policy assistance

A value that shows whether messaging engine policy assistance is set for the bus member when the bus member is a server cluster. If the **Type** is Server or WebSphere MQ Server, the value is Not applicable. For a **Type** of Cluster, the value can be Disabled, Enabled (High availability), Enabled (Scalability), Enabled (Scalability with high availability), or Enabled (Custom). The words in parentheses show the type of messaging engine policy assistance that is set. If the current configuration of the cluster is either not suitable or not complete for the type of messaging engine policy assistance that is set, a warning icon is also displayed.

## Buttons

Add	Add a server, a cluster, or a WebSphere MQ server to a bus.
Remove	Remove the selected bus members from the bus.

---

## Buses [Collection]

A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

To view this page in the console, click the following path:

**Service integration -> Buses.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A messaging engine manages messaging resources and, through destinations assigned to the messaging engine, provides a connection point to which both local and remote applications connect to access messaging resources on the bus. If you add an application server or a server cluster as a bus member, a

messaging engine is automatically created for this new member. If you add the same server as a member of multiple buses, the server is associated with multiple messaging engines (one messaging engine for each bus). You can create additional messaging engines for use with server clusters that are bus members, for availability and scalability reasons. However, in its simplest form a bus can be realized by a single engine.

The functions of service integration buses comprise the *SIB service*, which is available on each application server in the WebSphere Application Server environment. By default, the SIB service is disabled, so when a server starts it cannot undertake any messaging. If you add the server to a service integration bus, the SIB service is automatically enabled. If required, you can disable the service again by configuring the server.

The bus appears to its applications as if it were a single logical entity, which means applications only have to connect to the bus and do not have to be aware of the bus topology. In many cases the knowledge of how to connect to the bus and of which bus resources are defined are handled by a suitable API abstraction, such as the administered JMS connection factory and JMS destination objects

**Name** The name of the service integration bus. Choose a unique name.

**Note:** The system is unable to differentiate between upper and lowercase characters in bus names. For example, you will not be able to create two buses named BUS1 and bus1 because they will not be recognized as different to each other.

#### Description

An optional description for the bus, for administrative purposes.

#### Security

Security of your service integration bus can be managed from here.

#### Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

---

## Buses [Settings]

A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name*.**

- "Configuration tab"
- "Local Topology tab" on page 2184

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Name:**

The name of the service integration bus. Choose a unique name.

**Note:** The system is unable to differentiate between upper and lowercase characters in bus names. For example, you will not be able to create two buses named BUS1 and bus1 because the names will not be recognized as different to each other.

<b>Required</b>	No
<b>Data type</b>	String

***UUID:***

The universal unique identifier assigned by the system to this bus for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

***Description:***

An optional description for the bus, for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	Text area

***Inter-engine transport chain:***

The transport chain used for communication between messaging engines in this bus.

The transport chain must correspond to one of the transport chains defined in the Messaging engine inbound transports settings for the server. All servers automatically have a number of transport chains defined to them, and it is also possible to create new transport chains.

The default transport chain is InboundBasicMessaging.

For more information see ../ae/cjr0490\_.dita.

<b>Required</b>	No
<b>Data type</b>	String

***Discard messages:***

Whether messages on a deleted message point should be retained at a system exception destination or can be discarded.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Configuration reload enabled:***

Select this option to enable certain changes to the bus configuration to be applied without requiring the messaging engines to be restarted.

Select this option to enable automatic update of configuration information about all the messaging engines on the bus.

Changes to bus destinations or mediations are applied when destinations or mediations are added to or removed from the bus.

Changes to the modifiable configuration information for any foreign bus connections are also updated automatically. The time when these changes take effect varies:

**Foreign Bus Connection properties**

Immediately

**WebSphere MQ link properties**

On channel restart, except Description (immediately), and Initial State (on messaging engine restart)

**MQ sender channel properties**

On channel restart, except Initial State (on messaging engine restart or sender channel creation)

**MQ receiver channel properties**

On channel restart, except Initial State (on messaging engine restart or receiver channel creation)

**Publish/subscribe broker profile (0 to n) properties**

Immediately

**Service integration bus link properties**

On link restart, except Description (immediately), and Initial State (on messaging engine restart or link creation)

The **Configuration reload enabled** property also needs to be set on the SIB Service of the application server. To ensure that dynamic configuration updates are made on an application server, click **Servers -> Server Types -> WebSphere application servers -> server\_name -> [Server messaging] SIB service** to display the Application Servers window, then select **Configuration reload enabled**.

To ensure that dynamic configuration updates are made to each node, click **System administration -> Console Preferences** to display the Console Preferences window then select **Synchronize changes with Nodes**.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Default messaging engine high message threshold:***

A threshold above which the messaging system will take action to limit the addition of more messages to a message point.

When a messaging engine is created on this bus, the value of this property is used to set the default high message threshold for the messaging engine.

<b>Required</b>	No
<b>Data type</b>	Long
<b>Range</b>	1 through 9223372036854775807

***Bootstrap members:***

Bus members, servers and clusters that client applications can target to bootstrap into the given bus.

Select one of the following bootstrap member policies to limit the range of available bootstrap members:

### **All members of the cell with the Service Integration Bus Service enabled**

This the default policy. Use any server in the cell that has the Service Integration Bus Service enabled to service bootstrap requests.

### **Bus members and nominated bootstrap members**

Use bus members and nominated cell members to service bootstrap requests.

### **Bus members only**

Use bus members only to service bootstrap requests.

**Required**

No

**Data type**

Radio button

## **Topology**

### **Bus members**

New bus member link

### **Messaging engines**

A messaging engine manages bus resources and provides a connection point for applications.

### **Foreign bus connections**

A foreign bus is another bus with which this bus can exchange messages.

### **Bootstrap members**

Bus members, servers and clusters that client applications can target to bootstrap into the given bus.

## **Destination resources**

### **Destinations**

A bus destination is a logical address within a service integration bus.

### **Mediations**

Mediations define the information needed by a messaging engine to perform the mediation processing for associated destinations.

## **Services**

### **Inbound services**

An inbound service describes the web service enablement of a service destination. It provides the configuration of endpoint listeners within a port.

### **Outbound services**

An outbound service represents a WSDL-described service.

### **WS-Notification services**

A WS-Notification service provides access to service integration bus resources for web services publish and subscribe clients.

### **Reliable messaging state**

Use this page to view and manage the WS-ReliableMessaging runtime state.

## **Additional Properties**

### **Custom properties**

Arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

### **Web service gateway instances**

A web services gateway allows you to configure specific endpoint listeners and deploy gateway and proxy services to those listeners.

## Security

Security of your service integration bus can be managed from here.

## Local Topology tab

Topology properties for this object. These properties detail how this object relates to other objects in the system topology.

---

### Context properties [Collection]

Context information used to enable correct processing of messages. This information adds to the context information derived from processing the message header.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Additional Properties] Destination defaults -> [Additional Properties] Context information**
- **Service integration -> Buses -> *bus\_name* -> [Destination resources] Mediations -> *mediation\_name* -> [Additional Properties] Context properties**
- **Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *destination\_name* -> [Additional Properties] Context information**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Dynamic updates to this list are effective immediately.

**Name** The name of this context property. The mediation will retrieve the context property using this name.

#### Context type

The type of the context property, for example, Boolean, Byte, or Character.

#### Context value

The value of the context property.

## Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

---

### Context properties [Settings]

Context information used to enable correct processing of messages. This information adds to the context information derived from processing the message header.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Additional Properties] Destination defaults -> [Additional Properties] Context information -> *context\_information\_item\_name***

- Service integration -> Buses -> *bus\_name* -> [Destination resources] Mediations -> *mediation\_name* -> [Additional Properties] Context properties -> *context\_information\_item\_name*
- Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *destination\_name* -> [Additional Properties] Context information -> *context\_information\_item\_name*

You can use this panel to view or change context information settings. This panel is useful for configuring extra context information, because it is not possible to anticipate in advance all of the context information that might be required to allow correct processing of messages.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Name:**

The name of this context property. The mediation will retrieve the context property using this name.

<b>Required</b>	Yes
<b>Data type</b>	String

#### **Context type:**

The type of the context property, for example, Boolean, Byte, or Character.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	

#### **Boolean**

This context has a Boolean information type.

#### **Byte**

This context has a byte information type.

#### **Character**

This context has a character information type.

#### **Double**

This context has a double information type.

#### **Float**

This context has a floating point information type.

#### **Integer**

This context has an integer information type.

#### **Long**

This context has a long information type.

#### **Short**

This context has a short information type.

#### **String**

This context has a string information type.

#### **Context value:**

The value of the context property.

<b>Required</b>	Yes
<b>Data type</b>	String

---

## Custom properties [Collection]

Use this page to specify an arbitrary name and value pair. The value that is specified for the name and value pair is a string that can set internal system configuration properties.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Additional Properties] Custom properties.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

---

## Custom properties [Collection]

Use this page to specify an arbitrary name and value pair. The value that is specified for the name and value pair is a string that can set internal system configuration properties.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] Custom properties.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

---

## Custom properties [Settings]

Arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] Custom properties -> *property\_name*.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Name:**

Specifies the name of the property.

<b>Required</b>	Yes
<b>Data type</b>	String

#### **Value:**

Specifies the value that is paired with the specified name.

<b>Required</b>	Yes
<b>Data type</b>	String

#### **Description:**

Specifies a description of the name and value pair. The description should help to differentiate this pair for other defined pairs.

<b>Required</b>	No
<b>Data type</b>	Text area

#### **Optional:**

Specifies an optional attribute that determines whether this property must have a value.

<b>Required</b>	No
<b>Data type</b>	Boolean

#### **Validation Expression:**

Specifies a value that the administrative console and some host tools use to validate the contents of the value of this property.

<b>Required</b>	No
<b>Data type</b>	String

---

## Data store [Settings]

The persistent store for messages and other state managed by the messaging engine.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] Message store.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **UUID:**

The universal unique identifier assigned by the system to this data store for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

#### **Data source JNDI name:**

The JNDI name of the data source that the messaging engine uses to access the relational database management system (RDBMS) for the data store.

<b>Required</b>	Yes
<b>Data type</b>	Text

#### **Schema name:**

The name of the database schema used to contain the tables for the data store.

Each messaging engine stores its resources, such as tables, in a single schema. Each database schema is used by one messaging engine only. Although every messaging engine uses the same table names, its relationship with the schema gives each messaging engine exclusive use of its own tables.

<b>Required</b>	No
<b>Data type</b>	String

#### **Authentication alias:**

The name of the authentication alias used by the messaging engine to access the data source.

<b>Required</b>	No
<b>Data type</b>	drop-down list

#### **Create tables:**

If this option is selected, the messaging engine creates the database tables for the data store automatically. Otherwise, the database administrator must create the database tables manually.

<b>Required</b>	No
<b>Data type</b>	Boolean

#### **Number of tables for permanent objects:**

Number of database tables to use for storage of permanent objects.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	1 through 2147483647

***Number of tables for temporary objects:***

Number of database tables to use for storage of temporary objects.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	1 through 2147483647

## Related Items

### JAAS - J2C authentication data

Specifies a list of user identities and passwords for Java 2 connector security to use.

---

## Default access roles [Settings]

This pane shows the role type assignments for the default access.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Manage default access roles.**

*security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane displays users and groups that have been assigned access roles for the default resource. Use this pane to add users and groups to the appropriate default role or roles, and to manage users and groups that have already been assigned role types for the default resource. Adding a user or group to any of the default roles grants the user or group the authorization permissions for that role for all the local destinations that are allowed to inherit defaults.

The information for each user and group is contained within a section that you can expand and collapse.

### Expand/Collapse

Click to expand the section and display users and groups that have been assigned role types for the default resource.

## General Properties

**Select** A check box that you can use to select the users and groups for which you want to manage access roles.

**Name** The name of the user or group that has an access role for the selected resource. If the user is a group member, the user ID and the group name is displayed.

**Type** The type of the user or group. There are three types of user or group: “user”, “group” and “member”. A user that inherits its access roles from a group has the type “member”.

**Sender**

Whether a user, group or member is in the sender role for a selected resource.

**Receiver**

Whether a user, group or member is in the receiver role for a selected resource.

**Browser**

Whether a user, group or member is in the browser role for a selected resource.

**Creator**

Whether a user, group or member is in the creator role for a selected resource.

**Security access roles**

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 221. Interacting with access role icons

Access role icon	Access role assignment state	User action
	Role type not set.	Click to change to role type set  .
	Role type set.	Click to change to role type not set. The icon changes to role type not set  if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set  .
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

**Buttons**

Add	Click to add users and groups to this resource.
Remove	Click to remove selected users and groups from all the role types for this resource.

---

## Destinations access roles [Collection]

This pane displays a list of all destinations known by the bus: aliases, foreign destinations, ports, queues, temporary destination prefixes, topic spaces and web services.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Manage destination access roles.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane displays the name and type of all the bus destination defined for the selected service integration bus. Use this pane to view and change the access roles defined for selected destinations:

- To act on a single destination, click its name in the list.
- To act on more than one destination, first select the check box next to the name of each destination you want to act on, and then click **Manage Access Roles**.

### Destination

The name of each destination defined for the selected bus.

**Type** The type of destination defined for the selected bus.

### Buttons

Manage Access Roles	Click to view and manage users and groups assigned to the access role types for the selected resources.
---------------------	---------------------------------------------------------------------------------------------------------

---

## Destinations access roles [Settings]

This pane displays the role type assignments for the selected destinations.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Manage destination access roles -> *destination\_name* > Manage access roles.**

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane lists users and groups that have been assigned role types for the destinations selected in the **Manage destination access roles** panel. You can use this pane to add and remove users and groups, and manage role type assignments and inheritance for a destination.

The information for each destination is contained within a section that you can expand and collapse. For each destination, a section header displays the type of destination, for example whether it is a queue, topic space, or some other type of destination and the destination name.

## Expand/Collapse

Click the icon to expand the section and display the collection of users and groups that have been assigned role types for the selected destination.

## Inherit from default

Select the check box to have the selected destination inherit access roles for users and groups from the default resource. Only access roles that apply to the selected destination can be inherited.

## General Properties

**Select** A check box that you can use to select the users and groups for which you want to manage access roles.

**Name** The name of the user or group that has an access role for the selected resource. If the user is a group member, the user ID and the group name is displayed.

**Type** The type of the user or group. There are three types of user or group: “user”, “group” and “member”. A user that inherits its access roles from a group has the type “member”.

### Sender

Whether a user, group or member is in the sender role for a selected resource.

### Receiver

Whether a user, group or member is in the receiver role for a selected resource.

### Browser

Whether a user, group or member is in the browser role for a selected resource.

### Creator

Whether a user, group or member is in the creator role for a selected resource.

## Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 222. Interacting with access role icons

Access role icon	Access role assignment state	User action
<input type="checkbox"/>	Role type not set.	Click to change to role type set <input checked="" type="checkbox"/> .
<input checked="" type="checkbox"/>	Role type set.	Click to change to role type not set. The icon changes to role type not set <input type="checkbox"/> if the user or group does not inherit access roles, or to role type inherited <input checked="" type="checkbox"/> if the role type does inherit access roles.
<input checked="" type="checkbox"/>	Role type inherited from group.	Click to change to role type set <input checked="" type="checkbox"/> .

Table 222. Interacting with access role icons (continued)

Access role icon	Access role assignment state	User action
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

## Buttons

Add	Click to add users and groups to this resource.
Remove	Click to remove selected users and groups from all the role types for this resource.

## Destinations [Collection]

A bus destination is defined on a service integration bus, and is hosted by one or more locations within the bus. Applications can attach to the destination as producers, consumers, or both to exchange messages.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Identifier

The identifier by which this destination is known for administrative purposes.

**Bus** A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

**Type** Whether this bus destination is for a queue, topic space, or some other type of destination.

### Description

An optional description for the bus destination, for administrative purposes.

### Mediation

The name of the mediation that mediates this destination.

## Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.
Mediate	Apply a mediation to a destination, to modify the destination handling of messages.

Unmediate	Remove a mediation from the destination, to remove the effect of the mediation from the destination handling of messages.
-----------	---------------------------------------------------------------------------------------------------------------------------

---

## Destination defaults [Settings]

Properties to be applied when applications use destinations on this foreign bus when there is no explicit foreign destination definition.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Additional Properties] Destination defaults.**

These properties apply when there is no explicit foreign destination or alias destination defined on the local bus to provide destination defaults.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Default priority:**

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 9

#### **Default reliability:**

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

This reliability setting is used if a message has not set a reliability or if the Enable producers to override default reliability is set to False.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the Enable producers to override default reliability property is set to True. Otherwise, the Default reliability setting is used.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	drop-down list

## Range

### **Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

### **Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

### **Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

### **Reliable persistent**

Messages might be discarded when a messaging engine fails.

### **Assured persistent**

Messages are not discarded.

### ***Maximum reliability:***

The maximum reliability of messages accepted by this destination.

Producers cannot send messages to this destination with a reliability higher than the value specified for this property.

This attribute is not used for a temporary destination.

If the message exceeds the maximum reliability and the producer is local to the messaging engine, an exception is thrown.

If the message exceeds the maximum reliability and the producer is not local to the messaging engine, the message is sent to the exception destination that is defined for the target destination.

Dynamic updates to this property are effective immediately.

### **Required**

No

### **Data type**

drop-down list

## Range

### **Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

### **Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

### **Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

### **Reliable persistent**

Messages might be discarded when a messaging engine fails.

### **Assured persistent**

Messages are not discarded.

### ***Send allowed:***

Clear this option (setting it to false) to stop producers from being able to send messages to destinations on this foreign bus.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Boolean

### ***Enable producers to override default reliability:***

Select this option to enable producers to override the default reliability that is set on the destination.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the Enable producers to override default reliability property is set to True. Otherwise, the Default reliability setting is used.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Boolean

### ***Include an RFH2 message header when sending messages to WebSphere MQ.:***

If selected, messages sent to WebSphere MQ includes an RFH2 header. The RFH2 header stores additional information to that which is stored in the WebSphere MQ message header.

This property applies when a foreign bus connection represents a WebSphere MQ queue manager or queue-sharing group. When service integration converts a message from the service integration format to

WebSphere MQ format, by default it includes an MQRHF2 header in the WebSphere MQ message. This header contains message attributes, such as JMS message attributes, that are not WebSphere MQ message attributes and therefore do not appear in the WebSphere MQ message descriptor (MQMD). Some WebSphere MQ applications cannot process messages that include an MQRFH2 header. If messages sent to this destination will be processed by WebSphere MQ applications that cannot tolerate an MQRFH2, clear this option.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Boolean

## Additional Properties

### Context properties

Context information passed to the mediation.

---

## File store [Settings]

The persistent store for messages and other state managed by the messaging engine.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] Message store.**

If you make any changes to the properties of a file store, you must restart the messaging engine to make those changes take effect.

For more information on the log file, permanent store file, and temporary store file and appropriate parameter values refer to `../ae/cjm1450_.dita`.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **UUID:**

The universal unique identifier assigned by the system to this data store for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

#### **Log size:**

Size in megabytes of the log file.

<b>Required</b>	Yes
<b>Data type</b>	Long
<b>Range</b>	10 through 9223372036854775807

### ***Log directory path:***

Name of the log files directory.

When creating a messaging engine with a file store, you can select the Default log directory path radio button for this property. This option causes, the following default directory value to be used:

`${USER_INSTALL_ROOT}/filestores/com.ibm.ws.sib/messagingEngineName-messagingEngineUuid/log`  
where *messagingEngineName* and *messagingEngineUuid* are substituted from the Name and UUID properties of the messaging engine.

After you have created the file store, the Log directory path field displays the directory path used for log files.

**Important:** When adding a cluster as a bus member, you must configure the log file to be on a file system that is accessible to all members of a cluster.

<b>Required</b>	No
<b>Data type</b>	Text

### ***Minimum permanent store size:***

The minimum number of megabytes reserved by each of the permanent store files. The permanent store files are never smaller than the log file.

For more information about the store files and appropriate values for the log file parameters refer to `./ae/cjm1450_dita`.

<b>Required</b>	Yes
<b>Data type</b>	Long
<b>Range</b>	0 through 9223372036854775807

### ***Unlimited permanent store size:***

Indicates whether the permanent store files are unlimited in size.

<b>Required</b>	No
<b>Data type</b>	Custom

### ***Maximum permanent store size:***

The maximum size in megabytes for the permanent store files.

<b>Required</b>	Yes
<b>Data type</b>	Long
<b>Range</b>	50 through 9223372036854775807

### ***Permanent store directory path:***

Name of the permanent store files directory.

When creating a messaging engine with a file store, you can specify a non-default directory to be used for permanent store files. To do this, select the **Permanent store directory path** radio button, then type a directory path value in the field provided.

When creating a messaging engine with a file store, you can select the **Default permanent store directory path** radio button for this property. This option causes the following default directory value to be used: `${USER_INSTALL_ROOT}/filestores/com.ibm.ws.sib/messagingEngineName-messagingEngineUuid/` store where `messagingEngineName` and `messagingEngineUuid` are substituted from the Name and UUID properties of the messaging engine.

After you have created the file store, the **Permanent store directory path** field displays the directory path used for permanent store files.

**Important:** When adding a cluster as a bus member, you must configure the permanent store file to be on a file system that is accessible to all members of a cluster.

<b>Required</b>	No
<b>Data type</b>	Text

#### ***Minimum temporary store size:***

The minimum number of megabytes reserved by each of the temporary store files. The temporary store files are never smaller than the log file.

<b>Required</b>	Yes
<b>Data type</b>	Long
<b>Range</b>	0 through 9223372036854775807

#### ***Unlimited temporary store size:***

Indicates whether the temporary store files are unlimited in size.

<b>Required</b>	No
<b>Data type</b>	Boolean

#### ***Maximum temporary store size:***

The maximum size in megabytes for the temporary store files.

<b>Required</b>	Yes
<b>Data type</b>	Long
<b>Range</b>	50 through 9223372036854775807

#### ***Temporary store directory path:***

Name of the temporary store files directory.

When creating a messaging engine with a file store, you can specify a non-default directory to be used for temporary store files. To do this, select the Temporary store directory path radio button, then type a directory path value in the field provided.

When creating a messaging engine with a file store, you can select the **Default temporary store directory path** radio button for this property. This option causes the following default directory value to be used: `${USER_INSTALL_ROOT}/filestores/com.ibm.ws.sib/messagingEngineName-messagingEngineUuid/` store where *messagingEngineName* and *messagingEngineUuid* are substituted from the Name and UUID properties of the messaging engine.

After you have created the file store, the **Temporary store directory path** field displays the directory path used for temporary store files.

**Important:** When adding a cluster as a bus member, you must configure the temporary store file to be on a file system that is accessible to all members of a cluster.

<b>Required</b>	No
<b>Data type</b>	Text

---

## Foreign bus connections [Collection]

A foreign bus connection allows communication with another bus. The foreign bus can represent another Service Integration Bus, an instance of WebSphere MQ, or an indirect connection to another foreign bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

The physical link (also known as the routing type) between buses can be one of the following types:

- A *service integration bus link* from a messaging engine in the local bus to a messaging engine in the foreign bus.
- A *WebSphere MQ link* from a messaging engine in the local bus to a WebSphere MQ gateway queue manager. To the local bus the linked WebSphere MQ network appears as a foreign bus.
- An *indirect link*, which is a link that is made through one or more intermediate foreign buses.

**Name** The name of the bus with which this bus will exchange messages. This name must match exactly the name of the existing service integration bus that is defined as the foreign bus.

### Routing type

Routing type defines the type of link used to make the connection to the foreign bus. Use a service integration bus link for a connection to a foreign service integration bus, a WebSphere MQ link for a connection to a foreign WebSphere MQ network, or an indirect routing if the connection to the foreign bus is via another foreign bus.

### Description

An optional description for the foreign bus, for administrative purposes.

### Configuration Status

Indicates that the configuration was deleted with remaining runtime data. Select this foreign bus connection (by clicking the **Name** column) to resolve the remaining runtime data.

## Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.
Test connection	Test the foreign bus connection.  This button does not work if the selected foreign bus uses a WebSphere MQ link that is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

---

## Foreign bus [Settings]

This pane shows the role type assignments for the selected foreign buses.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Manage foreign bus access roles -> *foreign\_bus\_name* > Manage access roles.**

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This panel lists the users and groups that have been assigned access roles on the one or more selected foreign buses. Use this panel to add and remove users and groups to foreign bus access roles, and to manage existing role type assignments and inheritance for foreign buses.

The information for each foreign bus is contained within a section that you can expand and collapse. When collapsed, the section header displays the foreign bus name. When expanded, in addition to the header, the section displays an **Inherit from default** check box and a list of the users and groups that have been assigned role types on the foreign bus. Note that the only permitted role type for a foreign bus is Sender role.

### Expand/Collapse

Click icon to expand the section and display a list of users and groups that have been assigned role types for the selected foreign bus.

### Inherit from default

Select check box to have the selected foreign bus inherit access roles for users and groups from the default resource. Only access roles that apply to the selected foreign bus can be inherited.

## General Properties

**Select** A check box that you can use to select the users and groups for which you want to manage access roles.

**Name** The name of the user or group that has an access role for the selected resource. If the user is a group member, the user ID and the group name is displayed.

**Type** The type of the user or group. There are three types of user or group: “user”, “group” and “member”. A user that inherits its access roles from a group has the type “member”.

### Sender

Whether a user, group or member is in the sender role for a selected resource.

## Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 223. Interacting with access role icons

Access role icon	Access role assignment state	User action
	Role type not set.	Click to change to role type set  .
	Role type set.	Click to change to role type not set. The icon changes to role type not set  if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set  .
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

## Buttons

Add	Click to add users and groups to this resource.
Remove	Click to remove selected users and groups from all the role types for this resource.

## Foreign bus connections [Settings]

A foreign bus connection allows communication with another bus. The foreign bus can represent another Service Integration Bus, an instance of WebSphere MQ, or an indirect connection to another foreign bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name*.**

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Name:**

The name of the bus with which this bus will exchange messages. This name must match exactly the name of the existing service integration bus that is defined as the foreign bus. Precise guidelines for naming a foreign bus connection can be found in the related concept topic Foreign buses.

<b>Required</b>	No
<b>Data type</b>	String

#### **UUID:**

The universal unique identifier assigned by the system to this foreign bus for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

#### **Routing type:**

Routing type defines the type of link used to make the connection to the foreign bus. Use a service integration bus link for a connection to a foreign service integration bus, a WebSphere MQ link for a connection to a foreign WebSphere MQ network, or an indirect routing if the connection to the foreign bus is via another foreign bus.

<b>Required</b>	No
<b>Data type</b>	String

#### **Description:**

An optional description for the foreign bus, for administrative purposes.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Text area

#### **Send allowed:**

Clear this option (setting it to false) to stop producers from being able to send messages to this foreign bus.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Boolean

## Additional Properties

### Destination defaults

Properties to apply when applications use destinations on this foreign bus and there is no explicit foreign destination or alias destination defined on the local bus to provide destination defaults.

### *Additional property for when the routing definition is not yet defined:*

#### Create a routing definition

Select this link to define the routing definition for this foreign bus.

### *Additional property for direct service integration bus link foreign bus connections:*

#### Service integration bus link routing properties

The routing properties for a service integration bus link to a foreign service integration bus.

### *Additional property for direct WebSphere MQ link foreign bus connections:*

#### WebSphere MQ link routing properties

The routing properties for a link to a foreign bus that represents a WebSphere MQ network.

### *Additional property for indirect foreign bus connections:*

#### Indirect routing properties

The routing definition for the next service integration bus in a sequence of connected buses.

## Related Items

### *Related item for direct service integration bus link foreign bus connections:*

#### Service integration bus links

The associated service integration bus links for this foreign bus.

### *Related item for direct WebSphere MQ link foreign bus connections:*

#### WebSphere MQ links

The associated WebSphere MQ links for this foreign bus.

---

## Foreign destination [Settings]

The name by which this foreign destination is known for administrative purposes.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *destination\_name*.**

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### *Identifier:*

The identifier by which this destination is known for administrative purposes.

Type the name of the destination as configured on the foreign bus. This must match exactly the name of the target destination that exists in the foreign bus.

<b>Required</b>	No
<b>Data type</b>	String

***Bus:***

The name of the foreign bus on which this destination is defined.

This must match exactly the name of a foreign bus administrative object that is already defined on the bus on which this foreign destination is being created.

<b>Required</b>	No
<b>Data type</b>	String

***UUID:***

The universal unique identifier assigned by the system to this destination for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

***Type:***

Whether this bus destination is for a queue, topic space, or some other type of destination.

<b>Required</b>	No
<b>Data type</b>	String

***Description:***

An optional description for the bus destination, for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	Text area

***Enable producers to override default reliability:***

Select this option to enable producers to override the default reliability that is set on the destination.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the Enable producers to override default reliability property is set to True. Otherwise, the Default reliability setting is used.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Default reliability:***

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

This reliability setting is used if a message has not set a reliability or if the `SIBDestination.overrideOfQOSByProducerAllowed` is set to `False`.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the `Enable producers to override default reliability` property is set to `True`. Otherwise, the Default reliability setting is used.

**Required**  
**Data type**  
**Range**

No  
drop-down list

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

***Maximum reliability:***

The maximum reliability of messages accepted by this destination.

Producers cannot send messages to this destination with a reliability higher than the value specified for this property.

**Required**  
**Data type**

No  
drop-down list

**Range**

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

**Default priority:**

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 9

**Send allowed:**

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

**Include an RFH2 message header when sending messages to WebSphere MQ:**

If selected, messages sent to WebSphere MQ include an RFH2 header. The RFH2 header stores additional information to that which is stored in the WebSphere MQ message header.

This property applies when the foreign bus that hosts the target destination is a WebSphere MQ queue manager or queue-sharing group. When service integration converts a message from the service integration format to WebSphere MQ format, by default it includes an MQRHF2 header in the WebSphere MQ message. This header contains message attributes, such as JMS message attributes, that are not WebSphere MQ message attributes and therefore do not appear in the WebSphere MQ message descriptor (MQMD). Some WebSphere MQ applications cannot process messages that include an MQRFH2 header. If messages sent to this destination will be processed by WebSphere MQ applications that cannot tolerate an MQRFH2, clear this option.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Boolean

## Additional Properties

### Context properties

Context information passed to the mediation.

## Related Items

### Application resources topology

A expandable tree view of all applications and messaging resources that reference the current destination.

---

## Inbound messages [Collection]

The inbound message streams from the remote queue point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote queue points -> *identifier\_name* -> [Additional Properties] Inbound messages.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This is the collection of inbound message streams by quality of service (priority and reliability) for messages being sent to this queue point from the remote messaging engine.

### Priority

The stream priority.

### Reliability

The stream reliability.

### Number of messages

The current number of messages on the stream.

### Last delivered message sequence ID

The sequence ID of the last message delivered.

### Status

The status of the stream.

### Messages

View the messages on the stream.

---

## Indirect routing properties [Settings]

The routing definition for the next service integration bus in a sequence of connected buses.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Additional Properties] Indirect routing properties.**

You configure an indirect link when a service integration bus needs to communicate with a foreign bus through one or more intermediate buses.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### *Next bus in route:*

The name of the next service integration bus in the sequence of connected buses.

An intermediate bus can be a WebSphere MQ system rather than a service integration bus.

<b>Required</b>	No
<b>Data type</b>	drop-down list

---

## JFAP inbound channel [Settings]

A channel which can be used in combination with the TCP Channel - or other channels that support the same application interface to accept inbound connections to a WebSphere system integration bus messaging engine.

To view this page in the console, click the following path:

**Servers -> Server Types -> WebSphere application servers -> *server\_name* -> [Server messaging] Messaging engine inbound transports -> *chain\_name* > JFAP inbound channel.**

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### *Transport channel name:*

Specifies the unique name for a given layer in a network protocol stack.

<b>Required</b>	Yes
<b>Data type</b>	String

#### *Discrimination weight:*

Specifies the discrimination weight that is used to determine the order in which the channels obtain access to the incoming connection if the transport channels are shared amongst several transport chains. The transport channel with the lowest discrimination weight has the first opportunity to accept the incoming connection.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 2147483647

### ***Heart beat interval:***

The amount of idle time, in seconds, before the channel attempts to solicit a response from its peer to check that the peer is still active. The sum of this value and the heartbeat timeout value determines the maximum amount of time that it can take to discover that some types of network failure have occurred.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 2147483647

### ***Heart beat timeout:***

The amount of time, in seconds, to wait for a response from a peer after deciding to check that the peer is still alive.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 2147483647

## **Additional Properties**

### **Custom properties**

Specifies additional custom properties for this runtime component. Some components use custom configuration properties that can be defined here.

---

## **Known link transmitter inbound streams [Collection]**

This pane displays the inbound message streams from messaging applications that are connected to the remote messaging engine, and that are producing messages to this WebSphere MQ link sender channel transmitter.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel transmitters -> *WebSphere\_MQ\_sender\_channel\_name* -> Known link transmitters -> *messaging\_engine\_name***
- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel -> *sender\_channel\_link\_name* -> Known link transmitters -> *messaging\_engine\_name***

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Priority**

The priority of the messages on the given inbound stream.

**Reliability**

The reliability of the messages on the given inbound stream.

**Number of messages**

The number of messages pending receipt on the given inbound stream.

**Last delivered message sequence**

The sequence identifier of the last message delivered from the inbound stream to the sender channel transmitter.

**Status**

The runtime status of the inbound stream. Green (running), Amber (running but a problem exists), Red (stopped).

**Messages**

Select this link to view the message collection for messages on the given inbound stream.

---

**Known link transmitter stream messages [Collection]**

This pane displays current messages on the inbound message stream.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel transmitters -> *WebSphere\_MQ\_sender\_channel\_name* -> Known link transmitters -> *messaging\_engine\_name* -> Messages**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel -> *sender\_channel\_link\_name* -> Known link transmitters -> *messaging\_engine\_name* -> Messages**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Maximum messages displayed**

The maximum number of messages retrieved and displayed.

**Position**

The position on the inbound stream from the known link transmitter.

**Identifier**

The identifier of the message. Select this link to view the message detail panel for the selected message.

**Previous sequence identifier**

The identifier of the previous message on the queue point.

**State** The state of the message on the inbound stream ("Awaiting delivery").

## Buttons

Refresh	Refresh the collection with the current set of messages on the inbound stream. Only the number of messages up to the specified <b>Maximum messages displayed</b> are retrieved and displayed.
---------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

---

## Known link transmitters [Collection]

This pane displays the inbound receiver queues for messaging applications connected to remote messaging engines, that are producing messages to this WebSphere MQ link sender channel transmitter.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel transmitters -> *WebSphere\_MQ\_sender\_channel\_name* -> Known link transmitters**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel -> *sender\_channel\_link\_name* -> Known link transmitters**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Messaging engine

The messaging engine that has a link transmitter that is transmitting messages to this sender channel transmitter. Select the link to view the inbound streams for the messages from the known link transmitter.

### Current inbound messages

The total number of messages currently pending receipt on the inbound streams from this known link transmitter.

### Inbound messages received

The total number of messages that have been received on the inbound streams from this known link transmitter since the messaging engine started.

---

## Known remote publication points [Collection]

The remote messaging engines that have remote producers connected to this publication point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Message Points] Publication points > *identifier\_name* -> [Additional Properties] Known remote publication points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This collection represents all the remote publication points at remote messaging engines where there are applications or clients connected that are publishing messages to this local publication point.

### **Messaging engine**

The messaging engine where the remote publication point is located.

### **Current inbound messages**

The current number of queued inbound messages for the publication point.

### **Inbound messages received**

The total number of messages received on this publication point since the messaging engine started.

---

## **Known remote publication points [Settings]**

The remote messaging engines that have remote producers connected to this publication point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Message Points] Publication points > *identifier\_name* -> [Additional Properties] Known remote publication points -> *messaging\_engine\_name*.**

- “Runtime tab”

## **Runtime tab**

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## **General Properties**

### ***Messaging engine:***

The messaging engine where the remote publication point is located.

<b>Required</b>	No
<b>Data type</b>	String

### ***Current inbound messages:***

The current number of queued inbound messages for the publication point.

<b>Required</b>	No
<b>Data type</b>	String

### ***Inbound messages received:***

The total number of messages received on this publication point since the messaging engine started.

<b>Required</b>	No
<b>Data type</b>	String

## Additional Properties

### Inbound messages

The inbound message streams from the remote publication point.

---

## Queue [Settings]

A queue for point-to-point messaging.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *queue\_name*.**

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### **Identifier:**

The identifier by which this destination is known for administrative purposes.

Do not use an underscore character “\_” as the first character, because this naming convention is reserved for system use.

You can use a naming convention to suggest a hierarchical structure for destinations; for example, by using dotted notation for a destination name `Library.Shelf.Book1A`. Such structure can be useful for organizing queues into logical groups for ease of association, and to permit the use of wildcard notation in filters; for example, `Library.Shelf.*` or `*.Queue.accountXYZ`.

<b>Required</b>	No
<b>Data type</b>	String

### **UUID:**

The universal unique identifier assigned by the system to this destination for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

### **Type:**

Whether this bus destination is for a queue, topic space, or some other type of destination.

A queue for point-to-point messaging.

<b>Required</b>	No
<b>Data type</b>	String

### **Description:**

An optional description for the bus destination, for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	Text area

***Mediation:***

The name of the mediation that mediates this destination.

<b>Required</b>	No
<b>Data type</b>	String

***Enable producers to override default reliability:***

Select this option to enable producers to override the default reliability that is set on the destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Default reliability:***

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

***Maximum reliability:***

The maximum reliability of messages accepted by this destination.

<b>Required</b>	No
-----------------	----

**Data type**  
**Range**

drop-down list

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

**Default priority:**

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

**Required**  
**Data type**  
**Range**

No  
Integer  
0 through 9

**Exception destination:**

Use these properties to define what happens to any messages that cannot be delivered to this destination.

**None:**

The bus destination does not use an exception destination and undeliverable messages are not rerouted to an exception destination.

Attempts to redeliver the message continue, up to the maximum failed deliveries limit set for the bus destination. Then, attempts to redeliver the message continue with a time interval between retry attempts. This interval is either the Default blocked destination retry interval of the messaging engine that is associated with this destination, or the Blocked retry timeout that is set for this destination. The Default blocked destination retry interval value can be used by all queue and topic destinations associated with this messaging engine. To set a time interval specifically for this destination, select **Override messaging engine blocked retry timeout default**, then enter a blocked retry timeout value for this destination.

**Required**  
**Data type**  
**Default**

No  
Radio button  
Not selected

**Override messaging engine blocked retry timeout default:**

Override the blocked queue retry interval configured on the messaging engine owning the destination.

Select this property to set the blocked retry timeout for this destination. This property is available only when **None** is selected for the exception destination.

<b>Required</b>	Yes, if <b>None</b> is selected.
<b>Data type</b>	Boolean
<b>Default</b>	Unchecked. The Default blocked destination retry interval value of the associated messaging engine is used.

**Blocked retry timeout in milliseconds:**

When no exception destination is configured, the time interval to apply between retry attempts, after the maximum failed deliveries limit is reached, for this destination.

This property is available only when **Override messaging engine blocked retry timeout default** is selected in the exception destination properties.

<b>Required</b>	Yes, if Override messaging engine blocked retry timeout default is checked.
<b>Data type</b>	Integer

**System:**

The bus destination uses the system default exception destination.

Undeliverable messages are routed to the system default exception destination of the messaging engine that detects the problem: `_SYSTEM.Exception.Destination.messaging_engine_name`.

<b>Required</b>	No
<b>Data type</b>	Radio button
<b>Default</b>	Selected

**Specify:**

The bus destination uses the exception destination specified in this field.

The exception destination must be a queue, on the same bus or a foreign bus, and must exist when the exception destination processing is configured.

<b>Required</b>	No
<b>Data type</b>	Radio button
<b>Default</b>	Not selected

**Maximum failed deliveries per message:**

The maximum number of failed attempts to process a message. After this number of failed attempts, if an exception destination is configured, the message is forwarded from the intended destination to its exception destination. If an exception destination is not configured, a time interval between retry attempts is applied.

This interval is either the Default blocked destination retry interval of the messaging engine that is associated with this destination, or the Blocked retry timeout that is set for this destination.

<b>Required</b>	Yes, if an exception destination has been configured.
<b>Data type</b>	Integer
<b>Default</b>	5
<b>Range</b>	0 through 2147483647

***Send allowed:***

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Receive allowed:***

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Receive exclusive:***

Select this option to allow only one consumer to attach to each message point. If this option is not selected multiple consumers will be allowed to attach and receive messages from each message point.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Maintain strict message order:***

Enabling this option will maintain the strict ordering of messages for this destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Reply destination:***

The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination.

This property is intended for use with mediations on reply messages.

For more information about the use of this property, see “Configuring a destination reverse routing path” on page 2131.

<b>Required</b>	No
<b>Data type</b>	String

***Reply destination bus:***

The bus on which the reply destination exists.

This property is intended for use with mediations on reply messages.

For more information about the use of this property, see “Configuring a destination reverse routing path” on page 2131.

<b>Required</b>	No
<b>Data type</b>	String

### ***Default forward routing path:***

The value to which a message's forward routing path will be set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of line-delimited bus destinations specified as *bus:name*.

If you want to forward messages to one or more bus destinations, type a list of bus destinations. Type each destination entry on a separate line, and in the form *bus\_name:destination\_name* or *:destination\_name*

Where

*bus\_name*

Is the name of the service integration bus on which the destination is configured. If you do not specify a bus name, the destination is assumed to be on the same bus as the destination for which you are setting this property.

*destination\_name*

is the name of a bus destination.

<b>Required</b>	No
<b>Data type</b>	Text area

## **Message points**

### **Queue points**

Displays a list of queue points used to hold messages pending delivery to receiving applications.

### **Mediation points**

Displays a list of mediation points created when a mediation is associated with a bus destination.

## **Additional Properties**

### **Context properties**

Context information passed to the mediation.

### **Mediation execution points**

Mediation execution points for the processing of messages from mediation message points that are on a WebSphere MQ server.

## **Related Items**

### **Application resources for this destination**

This pane provides an expandable tree view of all the applications and messaging resources that reference the current destination, both directly and indirectly. As many of the references as possible are resolved to links to the associated configuration panel for the referenced object.

Use this panel to inspect the configuration from the queue or topic space (destination) to the application or other JMS resources to ensure that the configuration is correct.

---

## Remote queue points [Collection]

The remote queue points that are producing or consuming messages to or from queue points on remote messaging engines.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote queue points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This panel applies only to WebSphere Application Server Network Deployment or WebSphere Application Server for z/OS, with multiple messaging engines.

A remote queue point represents a remote proxy for a queue point that exists on a remote messaging engine (any other messaging engine on this bus). Messages are sent to or received from an application or client connected to the remote messaging engine. The remote queue point manages an outbound message stream to the queue point on the remote messaging engine, and an inbound message retrieval request stream for messages received from the queue point.

This collection gives an indication of the applications using these remote queue points, where the applications are connected and the associated message flow from each messaging engine.

### Identifier

The remote queue point identifier.

### Messaging engine

The remote messaging engine where this queue point is localized.

### Current outbound messages

The current number of outbound messages queued to the queue point.

### Outbound messages sent

The total number of messages sent to the queue point since the messaging engine started.

### Current message requests

The current number of active message retrieval requests sent to the queue point from this remote queue point.

### Completed message requests

The total number of completed message retrieval requests sent to the queue point from this remote queue point since the messaging engine started.

## Buttons

Delete all messages	Delete all messages from the outbound message stream of the selected remote queue point. Messages in "Pending Acknowledgment" state might already have been received at the remote queue point. You cannot delete messages in "Committing" state; you must first commit their transactions.
---------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Move all messages	Move all messages from the outbound message stream of the selected remote queue point to the exception destination configured for the destination. Messages in “Pending Acknowledgment” state might already have been received at the remote queue point. Moving these messages to the exception destination results in two copies of the message in the bus. You cannot move messages in “Committing” state; you must first commit their transactions.
-------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

---

## Known remote queue points [Collection]

The remote messaging engines that have remote producers or consumers connected to this queue point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Message Points] Queue points > *identifier\_name* -> Known remote queue points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This collection represents all the remote queue points at remote messaging engines that have applications or clients connected, where those applications or clients are either sending messages to or receiving messages from this local queue point.

### **Messaging engine**

The messaging engine where the remote queue point is located.

### **Current inbound messages**

The current number of queued inbound messages for the queue point.

### **Inbound messages received**

The total number of messages received on this queue point since the messaging engine started.

### **Current messages requests**

The current number of active message retrieval requests from the remote queue point.

### **Completed messages requests**

The total number of completed message retrieval requests from the remote queue point since the messaging engine started.

---

## Remote queue points [Settings]

The remote queue points that are producing/consuming messages to/from queue points on remote messaging engines.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote queue points -> *identifier\_name* .**

- “Runtime tab” on page 2222

## Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### *Identifier:*

The remote queue point identifier.

<b>Required</b>	No
<b>Data type</b>	String

#### *Messaging engine:*

The remote messaging engine where this queue point is localized.

<b>Required</b>	No
<b>Data type</b>	String

#### *Current outbound messages:*

The current number of outbound messages queued to the queue point.

<b>Required</b>	No
<b>Data type</b>	String

#### *Outbound messages sent:*

The total number of messages sent to the queue point since the messaging engine started.

<b>Required</b>	No
<b>Data type</b>	String

#### *Current message requests:*

The current number of active message retrieval requests sent to the queue point from this remote queue point.

<b>Required</b>	No
<b>Data type</b>	String

#### *Completed message requests:*

The total number of completed message retrieval requests sent to the queue point from this remote queue point since the messaging engine started.

<b>Required</b>	No
<b>Data type</b>	String

### ***Message requests issued:***

The total number of active and completed message retrieval requests sent to the queue point from this remote queue point since the messaging engine started.

<b>Required</b>	No
<b>Data type</b>	String

## **Additional Properties**

### **Outbound messages**

The outbound message streams from this remote message point to the remote localized message point.

### **Message Requests**

A snapshot of the current message retrieval requests from the message point.

---

## **Known remote queue points [Settings]**

The remote messaging engines that have remote producers or consumers connected to this queue point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Message Points] Queue points > *identifier\_name* -> Known remote queue points -> *messaging\_engine\_name* .**

- “Runtime tab”

## **Runtime tab**

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## **General Properties**

### ***Messaging engine:***

The messaging engine where the remote queue point is located.

<b>Required</b>	No
<b>Data type</b>	String

### ***Current inbound messages:***

The current number of queued inbound messages for the queue point.

<b>Required</b>	No
<b>Data type</b>	String

### ***Inbound messages received:***

The total number of messages received on this queue point since the messaging engine started.

**Required** No  
**Data type** String

***Current messages requests:***

The current number of active message retrieval requests from the remote queue point.

**Required** No  
**Data type** String

***Completed messages requests:***

The total number of completed message retrieval requests from the remote queue point since the messaging engine started.

**Required** No  
**Data type** String

***Message requests received:***

The total number of active and completed message retrieval from the remote queue point since the messaging engine started.

**Required** No  
**Data type** String

## **Additional Properties**

### **Inbound messages**

The inbound message streams from the remote queue point.

### **Message requests**

The message retrieval requests from the remote queue point.

---

## **Known remote subscription points [Collection]**

The remote messaging engines that have remote consumers connected to this subscription point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Message points] Publication points > *identifier\_name* -> [Additional Properties] Known remote subscriptions.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This collection represents all the remote subscription points (at remote messaging engines) where there are applications or clients connected that are receiving messages from a subscription that has its home on this local topic space.

## Messaging engine

The messaging engine where the remote subscription point is located.

## Current messages requests

The current number of active message retrieval requests from the remote subscription point.

## Completed messages requests

The total number of completed message retrieval requests from the remote subscription point since the messaging engine started.

---

## Known remote subscription points [Settings]

The remote messaging engines that have remote consumers connected to this subscription point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Message points] Publication points > *identifier\_name* -> [Additional Properties] Known remote subscriptions -> *messaging\_engine* .**

- “Runtime tab”

## Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### *Messaging engine:*

The messaging engine where the remote subscription point is located.

<b>Required</b>	No
<b>Data type</b>	String

### *Current messages requests:*

The current number of active message retrieval requests from the remote subscription point.

<b>Required</b>	No
<b>Data type</b>	String

### *Completed messages requests:*

The total number of completed message retrieval requests from the remote subscription point since the messaging engine started.

<b>Required</b>	No
<b>Data type</b>	String

### *Message requests received:*

The total number of active and completed message retrieval from the remote subscription point since the messaging engine started.

<b>Required</b>	No
<b>Data type</b>	String

## Additional Properties

### Message requests

The message retrieval requests from the remote subscription point.

---

## Link receiver stream messages [Collection]

This pane displays the current messages on the link receiver stream.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] Service integration bus links -> *link\_name* -> [Related Items] Link receivers -> *foreign\_messaging\_engine* -> Messages**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Position

The position in the queue of any pending messages that are waiting to be received.

### Identifier

The identifier of this message.

### Previous sequence identifier

The sequence identifier of the previous message.

**State** The state of the given message ("Awaiting delivery").

### Target bus

The target bus for the message.

### Target destination

The target destination for the message.

### Time on queue

The time since the message arrived on this messaging engine.

---

## Link receiver streams [Collection]

This pane displays the inbound message streams from messaging applications on the foreign bus for the link receiver.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] Service integration bus links -> *link\_name* -> [Related Items] Link receivers -> *foreign\_messaging\_engine***

•

- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] Service integration bus link receivers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

#### **Priority**

The priority of the messages on the given stream.

#### **Reliability**

The reliability of the messages on the given stream.

#### **Current inbound messages**

The number of messages pending receipt on this message stream.

#### **Messages received**

The number of messages received on this message stream since the messaging engine started.

#### **Last delivered message sequence ID**

The sequence identifier of the last message to be received.

#### **Status**

The status of the link receiver stream. Green (running), Amber (running but a problem exists), Red (stopped).

#### **Messages**

A link to view the messages on this link receiver stream.

---

## **Link receivers [Collection]**

A link can have multiple link receivers. For applications that use point-to-point messaging, there is one link receiver for each messaging engine in the foreign bus, that is, the bus that sends messages across the link. For applications that use publish/subscribe messaging, there is one link receiver for each topic space in the foreign bus. The link receiver acts as an inbound receiver queue for a messaging engine that has applications attached and that is producing messages across this service integration bus link.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] Service integration bus links -> *link\_name* -> [Related Items] Link receivers**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] Service integration bus links -> *link\_name* -> [Related Items] Link receivers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Foreign messaging engine**

The name of the messaging engine in the foreign bus that sends messages across the service integration bus link.

**Type** The message domain type of this link receiver, that is, point-to-point or publish/subscribe.

**Topic space**

For a publish/subscribe link receiver, the topic space from which this link receiver is receiving messages across the link. This field does not apply to point-to-point link receivers.

**Status**

The status of the link receiver. Green (running), Amber (running but a problem exists), Red (stopped).

**Current inbound messages**

The current number of messages pending receipt on the link receiver.

**Messages received**

The total number of messages received on the link receiver since the messaging engine started.

**Time since last message received**

The time since the last message was received on the link receiver or since the messaging engine started.

## Link transmitters [Collection]

A link can have multiple link transmitters. For applications that use point-to-point messaging, there is one link transmitter on each messaging engine in the source bus. For applications that use publish/subscribe messaging, there is one link transmitter for each topic space in the source bus. The link transmitter acts as a transmission queue where produced messages are persisted before transmission across the service integration bus link or WebSphere MQ link to the foreign bus.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] Service integration bus links -> *link\_name* -> [Related Items] Link transmitters**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] WebSphere MQ links -> *link\_name* -> [Related Items] Link transmitters**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Related Items] Link transmitters**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel -> *sender\_channel\_link\_name* -> [Related Items] Link transmitters**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Messaging engine**

The name of the messaging engine that hosts the link transmitter.

**Type** The message domain type of this link transmitter, that is, point-to-point or publish/subscribe.

### Topic space

For a publish/subscribe link transmitter, the topic space to which this link transmitter is transmitting messages across the link. This field does not apply to point-to-point link transmitters.

### Status

The status of the link transmitter. Green (running), Amber (running but a problem exists), Red (stopped).

### Current outbound messages

The number of currently queued messages that are to be transmitted.

### Messages sent

The number of messages sent from this link transmitter since the messaging engine started.

### Time since last message sent

The time since the last message was transmitted over the link or the messaging engine was started.

### Buttons

Delete all messages	Delete all available messages that are queued for the selected link transmitters.
Move all messages	Move all available messages that are queued for the selected link transmitters to the messaging engine exception destination that is local to the link transmitter.

---

## Link transmitter stream messages [Collection]

This pane displays the outbound messages to the foreign bus link, on the link transmitter stream.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] Service integration bus links -> *link\_name* -> [Related Items] Link transmitters -> *messaging\_engine* -> Messages**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] WebSphere MQ links -> *link\_name* -> [Related Items] Link transmitters -> *messaging\_engine\_name* -> Messages**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Related Items] Link transmitters -> *messaging\_engine\_name* -> Messages**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel -> *sender\_channel\_link\_name* -> [Related Items] Link transmitters -> *messaging\_engine\_name* -> Messages**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] WebSphere MQ link transmitters -> *link\_name* -> Messages**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Position**

The position of the message in the queue on this message stream.

**Identifier**

The message identifier.

**State** The state of the queued message.

**Committing**

The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction. While this message is in this state, no subsequent messages will be accepted by the queue point for which it is intended. There might be a build up of messages on this remote queue point.

**Complete**

Transmission of the message to the queue point has been completed. The local copy of the message is deleted automatically.

**Pending send**

The message is waiting to be sent to the queue point. Messages will be in this state if either of the following conditions apply:

- The messaging engine that owns the queue point is not currently available or accepting messages (for example, if its queue point has reached its high message threshold).
- The queue point already has a significant number of messages pending acknowledgement.

The message is sent when the condition no longer applies.

**Pending acknowledgement**

The message has been transmitted to the queue point and the messaging engine is waiting for an acknowledgement that the queue point has received the message correctly. If this state persists, the messaging engine to which the message was transmitted might not be reachable or a previous message on the remote queue point is still committing, and needs resolving.

**Transaction ID**

The transaction identifier if the message is locked within a transaction.

**Target bus**

The name of the target bus.

**Target destination**

The name of the target bus destination.

**Approximate message length (bytes)**

The approximate length of the message in bytes.

**Buttons**

Move	Move the selected messages to the local exception destination of the link transmitter.
Delete	Delete the selected messages.

---

**Link transmitter streams [Collection]**

This pane displays the outbound message streams, by quality of service, for the link transmitter.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] Service integration bus links -> *link\_name* -> [Related Items] Link transmitters -> *messaging\_engine***
- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] WebSphere MQ links -> *link\_name* -> [Related Items] Link transmitters -> *messaging\_engine\_name***
- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Related Items] Link transmitters -> *messaging\_engine\_name***
- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel -> *sender\_channel\_link\_name* -> [Related Items] Link transmitters -> *messaging\_engine\_name***

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

#### **Priority**

The priority of the messages on the given stream.

#### **Reliability**

The reliability of the messages on the given stream.

#### **Number of messages queued**

The number of messages on this message stream.

#### **Number of messages sent**

The number of messages sent from this message stream since the messaging engine started.

#### **Status**

The status of the message stream. Green (running), Amber (running but a problem exists), Red (stopped).

#### **Messages**

A link to view the messages on this message stream.

---

## **Manage foreign bus access roles [Collection]**

A foreign bus is another bus with which this bus can exchange messages.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Manage foreign bus access roles.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane displays the names of all the foreign buses defined on the selected bus. Use this pane to view and change the access roles defined for selected buses:

- To view and change the access roles defined for a single foreign bus, click the foreign bus name.
- To view and change the access roles defined for more than one foreign bus, select the check box in the **Select** column for each foreign bus, and click **Manage Access Roles**.

#### Foreign bus

The name of each foreign bus defined for the selected bus.

#### Buttons

Manage Access Roles	Click to view and manage users and groups assigned to the access role types for the selected resources.
---------------------	---------------------------------------------------------------------------------------------------------

---

### Mediation points [Collection]

Bus member (server or cluster) where the mediations for the destination run.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Message points] Mediation points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

#### Identifier

The system-generated name by which this message point is known.

#### Status

The runtime status of the mediation point.

#### Reason

#### Buttons

Start	Start selected items.
Stop	Stop selected items.

---

### Mediation points [Collection]

Bus member (server or cluster) where the mediations for the destination run.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Message points] Mediation points -> Runtime.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

#### Identifier

The system-generated name by which this message point is known.

#### Status

The runtime status of the mediation point.

#### Reason

#### Buttons

Start	Start selected items.
Stop	Stop selected items.

---

## Mediation points [Settings]

Bus member (server or cluster) where the mediations for the destination run.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Message points] Mediation points -> *mediation\_point\_name*.**

- “Configuration tab”
- “Runtime tab” on page 2234

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

#### Buttons

Refresh	Refresh the number of messages.
---------	---------------------------------

### General Properties

#### Identifier:

The system-generated name by which this message point is known.

<b>Required</b>	No
<b>Data type</b>	String

#### UUID:

The universal unique identifier assigned by the system to this message point for administrative purposes.

**Required** No  
**Data type** String

**High message threshold:**

A threshold above which the messaging system will take action to limit the addition of more messages to this message point.

**Required** No  
**Data type** Long  
**Range** 1 through 9223372036854775807

**Send allowed:**

Clear this option (setting it to false) to stop messages from being put onto this message point. This value will be overridden by the parent destination if that destination has sendAllowed disabled, which stops messages from being put onto all its message points.

**Required** No  
**Data type** Boolean

**Initial state:**

Whether the mediation point is started or stopped when the hosting messaging engine is first started. Until started, the mediation point is unavailable.

**Required** No  
**Data type** drop-down list  
**Range**

**Started**  
When the associated messaging engine is started, the mediation is started and is available to process messages.

**Stopped**  
When the associated messaging engine is started, the mediation is stopped and is not available to process messages.

**Target UUID:**

The UUID of the bus destination for which this is a message point.

**Required** No  
**Data type** String

**Runtime tab**

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime

property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## Buttons

Refresh	Refresh the number of messages.
---------	---------------------------------

## General Properties

### **Identifier:**

The system-generated name by which this message point is known.

<b>Required</b>	No
<b>Data type</b>	String

### **Run-time ID:**

The internal runtime identifier assigned to this message point.

<b>Required</b>	No
<b>Data type</b>	String

### **High message threshold:**

A threshold above which the messaging system will take action to limit the addition of more messages to this message point.

<b>Required</b>	No
<b>Data type</b>	String

### **Send allowed:**

Clear this option (setting it to false) to stop messages from being put onto this message point. This value will be overridden by the parent destination if that destination has sendAllowed disabled, which stops messages from being put onto all its message points.

<b>Required</b>	No
<b>Data type</b>	Boolean

### **Status:**

The runtime status of the mediation point.

<b>Required</b>	No
<b>Data type</b>	drop-down list

## Range

### Waiting

The mediation is waiting to start. This might be because the application server is not yet open for e-business, or because a previous instance of the mediation has not yet been deleted.

### Started

The mediation is started and is available to process messages.

### Stopping

The mediation is in the process of stopping.

### Stopped

The mediation is stopped. The reason why the mediation is stopped is shown in the Reason attribute.

### Deleting

The mediation is in the process of being deleted.

### Reason:

Required  
Data type

No  
Text area

### Current message depth:

The number of messages on the message point.

Required  
Data type

No  
String

## Additional Properties

### Messages

Messages queued on the mediation point.

---

## Mediation thread pool [Settings]

The thread pool used to allocate threads for the execution of mediation handlers.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] Mediation thread pool.**

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### **Minimum size:**

Minimum size of thread pool.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 2147483647

### **Maximum size:**

Maximum size of thread pool.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 2147483647

### **Thread inactivity timeout:**

Specifies the number of milliseconds of inactivity that should elapse before a thread is reclaimed.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 2147483647

### **Allow thread allocation beyond maximum thread pool size:**

Specifies whether the number of threads can increase beyond the maximum number configured for the thread pool.

<b>Required</b>	No
<b>Data type</b>	Boolean

---

## Mediations [Collection]

A mediation that is associated with a bus destination to apply processing to messages on that destination.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Mediations.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Mediation name**

The name by which this mediation is known for administrative purposes.

**Handler list name**

The name of the handler list that was defined when the mediation was deployed.

**Description**

An optional description for the mediation, for administrative purposes.

**Buttons**

New	Create a new administrative object of this type.
Delete	Delete the selected items.

**Mediations [Settings]**

A mediation that is associated with a bus destination to apply processing to messages on that destination.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Mediations -> *mediation\_name*.**

**Configuration tab**

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

**General Properties*****Mediation name:***

The name by which this mediation is known for administrative purposes.

**Required** No  
**Data type** String

***UUID:***

The universal unique identifier assigned by the system to this mediation for administrative purposes.

**Required** No  
**Data type** String

***Description:***

An optional description for the mediation, for administrative purposes.

**Required** No  
**Data type** Text area

***Handler list name:***

The name of the handler list that was defined when the mediation was deployed.

<b>Required</b>	Yes
<b>Data type</b>	String

***Global transaction:***

Whether or not a global transaction is started for each message processed.

**Cleared**

A local transaction is started for each message processed. You only need to select this option for mediations that access other resource managers such as databases, or interact with Enterprise JavaBeans that require a global transaction.

**Selected**

A global transaction is started for each message processed.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Allow concurrent mediation:***

Select this option (setting it to true) to apply the mediation to multiple messages concurrently. Message ordering is not preserved. The default option is false.

**Selected**

Apply the mediation to multiple messages concurrently, and preserve message ordering.

**Cleared**

Apply the mediation to a single message at a time. This setting is required to ensure that message ordering is preserved.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Selector:***

Controls which messages are sent to the mediation. If a message matches the rule defined by the selector text string, then the mediation is applied to the message.

If the message does not match the rule defined by the selector text string, then the message is not mediated. If a message contains both Selector and Discriminator, it must match both rules for the message to be mediated. If either the Selector or the Discriminator rule does not match, the message is not mediated.

You should base the content of the selector text string on an understanding of which messages should be processed by the mediation. The format of the selector string is the same as for JMS selectors.

<b>Required</b>	No
<b>Data type</b>	String

***Discriminator:***

Controls which messages have the mediation applied to them. If the topic of a message matches the rule specified by the discriminator text string, then the mediation is applied to the message. If both the selector and discriminator are specified, the message must match both rules for the mediation to be applied to the message.

Compare this property with the Selector property. The rule specified by the Selector examines the header and properties of the message, whereas the discriminator examines the topic of the message. If a message contains both Selector and Discriminator, it must match both rules for the message to be mediated. If either the Selector or the Discriminator rule does not match, the message is not mediated.

You should base the content of the discriminator text string on an understanding of which message topics should be processed by the mediation. The format of the discriminator is the same as the topic discriminator specification.

<b>Required</b>	No
<b>Data type</b>	String

## Additional Properties

### Context properties

Context information passed to the mediation.

---

## Message body [Settings]

The contents of the message body.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *queue\_name* -> [Message points] Queue points -> *queue\_point\_name* -> Runtime > Messages -> *message\_name* -> Message body.**

---

## Message points [Collection]

Queue points and publication points for the messaging engine.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] Message points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Identifier

The system-generated name by which this message point is known.

### Destination type

Whether the message point is a queue or topic space.

---

## Message Requests [Collection]

A snapshot of the current message retrieval requests from the message point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote Message Points] Remote publication points > *identifier\_name* -> [Inbound Properties] Remote subscriptions -> *subscription\_name* -> [Additional Properties] Message requests.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

The collection represents the currently active message retrieval requests by applications or clients connected to this messaging engine, for messages on the message point at the remote messaging engine. A message retrieval request represents a request from a client or application connected to one messaging engine, for a message from a queue point or a subscription on a different messaging engine. When the remote messaging engine has satisfied the message retrieval request, the application or client receives the message for processing.

#### **Request ID**

The request identifier.

#### **Times out at**

The time at which the message retrieval request will timeout.

#### **Selector**

The retrieval request message selection criteria.

#### **Status**

The state of the message retrieval request.

---

## **Message requests [Collection]**

A snapshot of the current message retrieval requests from the remote message point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote queue points -> *identifier\_name* -> [Additional Properties] Message requests.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

The collection represents the currently active message retrieval requests for messages on this message point, by applications or clients connected to the remote messaging engine. When a message satisfying a message retrieval request becomes available on this message point, the message is exclusively assigned to the request and sent to the remote messaging engine to be delivered to the requesting application. If the requesting application accepts the message, the local message is deleted from the message point. If the message is rejected, the local message is made available again for other applications to request.

**Request ID**

The request identifier.

**Times out at**

The time at which the message retrieval request will timeout.

**Selector**

The retrieval request message selection criteria.

**State** The state of the message retrieval request.

**Buttons**

Cancel request	Cancel the selected message retrieval request and make any message that is allocated to the request available to other application requests.
Cancel request and delete message	Cancel the selected message retrieval request and delete any message that is allocated to the request.

---

**Messages [Collection]**

A snapshot of the current outbound messages for the message point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote queue points -> *identifier\_name* -> [Additional Properties] Outbound messages.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Sequence ID**

The message sequence identifier.

**API message ID**

The API message identifier.

**Time produced**

The time the message was produced.

**State** The state of the queued message.

**Committing**

The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction. While this message is in this state, no subsequent messages will be accepted by the queue point for which it is intended. There might be a build up of messages on this remote queue point.

**Complete**

Transmission of the message to the queue point has been completed. The local copy of the message is deleted automatically.

### Pending send

The message is waiting to be sent to the queue point. Messages will be in this state if either of the following conditions apply:

- The messaging engine that owns the queue point is not currently available or accepting messages (for example, if its queue point has reached its high message threshold).
- The queue point already has a significant number of messages pending acknowledgement.

The message is sent when the condition no longer applies.

### Pending acknowledgement

The message has been transmitted to the queue point and the messaging engine is waiting for an acknowledgement that the queue point has received the message correctly. If this state persists, the messaging engine to which the message was transmitted might not be reachable or a previous message on the remote queue point is still committing, and needs resolving.

## Buttons

Delete	Delete the selected items.
Move	Move the selected outbound messages to the exception destination configured for the destination. Messages in "Pending Acknowledgment" state might already have been accepted to the remote queue point. Moving these messages to the exception destination results in two copies of the message in the bus. You cannot move messages in "Committing" state; you must first commit their transaction.

---

## Messages [Collection]

A snapshot of the current outbound messages for the message point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote publication points -> *identifier\_name* -> [Outbound Properties] Messages.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Sequence ID

The message sequence identifier.

### API message ID

The API message identifier.

### Time produced

The time the message was produced.

**State** The state of the queued message.

### Committing

The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction. While this message is in this state, no subsequent messages will be accepted by the queue point for which it is intended. There might be a build up of messages on this remote queue point.

### Complete

Transmission of the message to the queue point has been completed. The local copy of the message is deleted automatically.

### Pending send

The message is waiting to be sent to the queue point. Messages will be in this state if either of the following conditions apply:

- The messaging engine that owns the queue point is not currently available or accepting messages (for example, if its queue point has reached its high message threshold).
- The queue point already has a significant number of messages pending acknowledgement.

The message is sent when the condition no longer applies.

### Pending acknowledgement

The message has been transmitted to the queue point and the messaging engine is waiting for an acknowledgement that the queue point has received the message correctly. If this state persists, the messaging engine to which the message was transmitted might not be reachable or a previous message on the remote queue point is still committing, and needs resolving.

## Buttons

Delete	Delete the selected items.
--------	----------------------------

---

## Messages [Collection]

The messages on the message point.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *queue\_name* -> [Message points] Queue points -> *queue\_point\_name* -> Runtime > Messages**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Message points] Mediation points -> *mediation\_point\_name* -> Runtime > Messages**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A snapshot of the set of messages queued on the message point. You can display or remove selected messages from the list.

Because this is a snapshot of the message point, a message listed might no longer exist when you attempt to display it or act on it.

**Position**

The position of the message on the message point list.

**Messaging engine message identifier**

Messaging engine message identifier.

**State** The current state of the message related to a transaction that the message is part of. If the message is part of a transaction, the transaction identifier is shown in the Transaction ID field. The possible states are:

**Available**

The message is available for consumption.

**Locked**

The message is currently unavailable. The message is in this state temporarily, possibly because it is being consumed by a non-transacted consumer.

**Remote lock**

The message is currently locked to a consumer attached to another, remote, messaging engine in the bus. The message will remain locked until the remote messaging engine responds with a decision on the message. If the remote messaging engine is stopped, the message will remain locked until the messaging engine is restarted. A corresponding message request for a “known remote queue point” will identify the remote messaging engine that is making the request.

**Removing**

The message is currently being removed under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

**Committing**

The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

**Pending retry**

The message is currently unavailable before being eligible for a retry. This might be because a message-driven bean is configured to delay failing message retries.

**Blocked**

This message is currently unavailable because the message point is blocked by the first message on the queue. The first message has reached its maximum failed delivery limit but no exception destination is configured. Identify the first message and resolve the problem that is preventing it from being consumed.

**Transaction ID**

The local transaction identifier of the transaction that this message is currently part of.

**Buttons**

Delete	Delete the selected items.
Delete all	Delete all items in the list.
Refresh	Refresh the number of messages.

---

**Messages [Settings]**

The properties for a message on the message point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *queue\_name* -> [Message points] Queue points -> *queue\_point\_name* -> Runtime > Messages -> *message\_name*.

- “Runtime tab”

## Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### *Messaging engine message identifier:*

Messaging engine message identifier.

**Required** No  
**Data type** String

### *State:*

The current state of the message related to a transaction that the message is part of. If the message is part of a transaction, the transaction identifier is shown in the Transaction ID field.

*Table 224. Message transaction state.. The first column of the table lists the transaction state of the messages. The second column provides the transaction identifier if the message is part of a transaction. The third column provides the comments.*

State	Transaction ID	Comments
Locked	An identifier is shown.	The message is locked as part of the transaction identified. The message has not been consumed and the transaction is still in progress.
Locked	An identifier is not shown.	The message is locked, but the transaction has completed, so the message might not have been consumed. This indicates that some error might have occurred.

**Required** No  
**Data type** drop-down list

## Range

### Available

The message is available for consumption.

### Locked

The message is currently unavailable. The message is in this state temporarily, possibly because it is being consumed by a non-transacted consumer.

### Remote lock

The message is currently locked to a consumer attached to another, remote, messaging engine in the bus. The message will remain locked until the remote messaging engine responds with a decision on the message. If the remote messaging engine is stopped, the message will remain locked until the messaging engine is restarted. A corresponding message request for a “known remote queue point” will identify the remote messaging engine that is making the request.

### Removing

The message is currently being removed under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

### Committing

The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

### Pending retry

The message is currently unavailable before being eligible for a retry. This might be because a message-driven bean is configured to delay failing message retries.

### Blocked

This message is currently unavailable because the message point is blocked by the first message on the queue. The first message has reached its maximum failed delivery limit but no exception destination is configured. Identify the first message and resolve the problem that is preventing it from being consumed.

### **Transaction ID:**

The local transaction identifier of the transaction that this message is currently part of.

This field combined with the State field shows the state of the message related to the transaction. For more information about the combination of these fields, see Table 224 on page 2246.

**Required**  
**Data type**

No  
String

***Run-time message properties:***

***Message type:***

The type of the message (JMS, SDO, SUBSCRIPTION, TRM, BROKER\_CONTROL, BROKER\_RESPONSE, BROKER\_ADMIN).

<b>Required</b>	No
<b>Data type</b>	String

***Approximate length:***

The approximate length of the message.

<b>Required</b>	No
<b>Data type</b>	String

***Time stamp:***

The time stamp of when the message was originally sent.

<b>Required</b>	No
<b>Data type</b>	String

***Message wait time:***

The time the message has been waiting to be consumed.

<b>Required</b>	No
<b>Data type</b>	String

***Current messaging engine arrival time:***

The time that the message arrived on the current messaging engine.

<b>Required</b>	No
<b>Data type</b>	String

***Redelivered count:***

The number of times that the message has been redelivered.

<b>Required</b>	No
<b>Data type</b>	String

***Security user ID:***

The security user ID.

<b>Required</b>	No
<b>Data type</b>	String

***Producer type:***

The producer type (API, Core, TRM).

<b>Required</b>	No
<b>Data type</b>	String

***Exception destination timestamp:***

The timestamp at which the message was put to the exception destination.

<b>Required</b>	No
<b>Data type</b>	String

***Exception destination reason:***

The reason the message was put to the exception destination.

<b>Required</b>	No
<b>Data type</b>	Text area

***API Message properties:***

***Message ID:***

The message ID.

<b>Required</b>	No
<b>Data type</b>	String

***Correlation ID:***

The API correlation ID for request/response correlation.

<b>Required</b>	No
<b>Data type</b>	String

***User ID:***

The user ID.

<b>Required</b>	No
<b>Data type</b>	String

***Format:***

The Format of the message.

<b>Required</b>	No
<b>Data type</b>	String

***JMS Message properties:***

***JMS delivery mode:***

The JMS delivery mode (Persistent, Non-persistent).

<b>Required</b>	No
<b>Data type</b>	String

***JMS expiration:***

The JMS expiration.

<b>Required</b>	No
<b>Data type</b>	String

***JMS destination:***

The JMS destination.

<b>Required</b>	No
<b>Data type</b>	String

***JMS reply to destination:***

The JMS reply to destination.

<b>Required</b>	No
<b>Data type</b>	String

***JMS redelivered:***

The JMS redelivered flag.

<b>Required</b>	No
<b>Data type</b>	String

***JMS type:***

The JMS type field (Text, Byte, Stream, Object, Map).

<b>Required</b>	No
<b>Data type</b>	String

***JMSX delivery count:***

The JMSX delivery count.

<b>Required</b>	No
<b>Data type</b>	String

***JMSX application ID:***

The JMSX application ID.

<b>Required</b>	No
-----------------	----

**Data type** String

***Bus message properties:***

***Topic:***

The bus discriminator.

**Required** No  
**Data type** String

***Priority:***

The bus priority (0-9).

**Required** No  
**Data type** String

***Reliability:***

The bus reliability (Assured persistent, Reliable persistent, Reliable non-persistent, Express non-persistent, Best effort non-persistent).

**Required** No  
**Data type** String

***Time to live:***

The time to live of the message.

**Required** No  
**Data type** String

***Reply discriminator:***

The reply discriminator value of the bus.

**Required** No  
**Data type** String

***Reply priority:***

The reply priority value of the bus (0-9).

**Required** No  
**Data type** String

***Reply reliability:***

The reply reliability value of the bus (Assured persistent, Reliable persistent, Reliable non-persistent, Express non-persistent, Best effort non-persistent).

<b>Required</b>	No
<b>Data type</b>	String

***Reply time to live:***

The reply time to live value of the bus.

<b>Required</b>	No
<b>Data type</b>	String

***System message ID:***

The unique id of the message, assigned by the bus.

<b>Required</b>	No
<b>Data type</b>	String

## **Additional Properties**

**Message body**

The contents of the message body.

---

## **Messages [Settings]**

The properties for a message on the message point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *queue\_name* -> [Message points] Queue points -> *queue\_point\_name* -> Runtime > Messages -> *message\_name*.**

- “Runtime tab”

## **Runtime tab**

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## **General Properties**

***Messaging engine message identifier:***

Messaging engine message identifier.

<b>Required</b>	No
<b>Data type</b>	String

***State:***

The current state of the message related to a transaction that the message is part of. If the message is part of a transaction, the transaction identifier is shown in the Transaction ID field.

<b>Required</b>	No
-----------------	----

**Data type**  
**Range**

drop-down list

**Available**

The message is available for consumption.

**Locked**

The message is currently unavailable. The message is in this state temporarily, possibly because it is being consumed by a non-transacted consumer.

**Remote lock**

The message is currently locked to a consumer attached to another, remote, messaging engine in the bus. The message will remain locked until the remote messaging engine responds with a decision on the message. If the remote messaging engine is stopped, the message will remain locked until the messaging engine is restarted. A corresponding message request for a “known remote queue point” will identify the remote messaging engine that is making the request.

**Removing**

The message is currently being removed under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

**Committing**

The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

**Pending retry**

The message is currently unavailable before being eligible for a retry. This might be because a message-driven bean is configured to delay failing message retries.

**Blocked**

This message is currently unavailable because the message point is blocked by the first message on the queue. The first message has reached its maximum failed delivery limit but no exception destination is configured. Identify the first message and resolve the problem that is preventing it from being consumed.

***Transaction ID:***

The local transaction identifier of the transaction that this message is currently part of.

**Required**  
**Data type**

No  
String

***Run-time message properties:***

***Message type:***

The type of the message (JMS, SDO, SUBSCRIPTION, TRM, BROKER\_CONTROL, BROKER\_RESPONSE, BROKER\_ADMIN).

<b>Required</b>	No
<b>Data type</b>	String

***Approximate length:***

The approximate length of the message.

<b>Required</b>	No
<b>Data type</b>	String

***Time stamp:***

The time stamp of when the message was originally sent.

<b>Required</b>	No
<b>Data type</b>	String

***Message wait time:***

The time the message has been waiting to be consumed.

<b>Required</b>	No
<b>Data type</b>	String

***Current messaging engine arrival time:***

The time that the message arrived on the current messaging engine.

<b>Required</b>	No
<b>Data type</b>	String

***Redelivered count:***

The number of times that the message has been redelivered.

<b>Required</b>	No
<b>Data type</b>	String

***Security user ID:***

The security user ID.

<b>Required</b>	No
<b>Data type</b>	String

***Producer type:***

The producer type (API, Core, TRM).

<b>Required</b>	No
<b>Data type</b>	String

***Exception destination timestamp:***

The timestamp at which the message was put to the exception destination.

<b>Required</b>	No
<b>Data type</b>	String

***Exception destination reason:***

The reason the message was put to the exception destination.

<b>Required</b>	No
<b>Data type</b>	Text area

***API Message properties:***

***Message ID:***

The message ID.

<b>Required</b>	No
<b>Data type</b>	String

***Correlation ID:***

The API correlation ID for request/response correlation.

<b>Required</b>	No
<b>Data type</b>	String

***User ID:***

The user ID.

<b>Required</b>	No
<b>Data type</b>	String

***Format:***

The Format of the message.

<b>Required</b>	No
<b>Data type</b>	String

***JMS Message properties:***

***JMS delivery mode:***

The JMS delivery mode (Persistent, Non-persistent).

<b>Required</b>	No
<b>Data type</b>	String

***JMS expiration:***

The JMS expiration.

<b>Required</b>	No
<b>Data type</b>	String

***JMS destination:***

The JMS destination.

<b>Required</b>	No
<b>Data type</b>	String

***JMS reply to destination:***

The JMS reply to destination.

<b>Required</b>	No
<b>Data type</b>	String

***JMS redelivered:***

The JMS redelivered flag.

<b>Required</b>	No
<b>Data type</b>	String

***JMS type:***

The JMS type field (Text, Byte, Stream, Object, Map).

<b>Required</b>	No
<b>Data type</b>	String

***JMSX delivery count:***

The JMSX delivery count.

<b>Required</b>	No
<b>Data type</b>	String

***JMSX application ID:***

The JMSX application ID.

<b>Required</b>	No
-----------------	----

**Data type** String

***Bus message properties:***

***Topic:***

The bus discriminator.

**Required** No  
**Data type** String

***Priority:***

The bus priority (0-9).

**Required** No  
**Data type** String

***Reliability:***

The bus reliability (Assured persistent, Reliable persistent, Reliable non-persistent, Express non-persistent, Best effort non-persistent).

**Required** No  
**Data type** String

***Time to live:***

The time to live of the message.

**Required** No  
**Data type** String

***Reply discriminator:***

The reply discriminator value of the bus.

**Required** No  
**Data type** String

***Reply priority:***

The reply priority value of the bus (0-9).

**Required** No  
**Data type** String

***Reply reliability:***

The reply reliability value of the bus (Assured persistent, Reliable persistent, Reliable non-persistent, Express non-persistent, Best effort non-persistent).

<b>Required</b>	No
<b>Data type</b>	String

***Reply time to live:***

The reply time to live value of the bus.

<b>Required</b>	No
<b>Data type</b>	String

***System message ID:***

The unique id of the message, assigned by the bus.

<b>Required</b>	No
<b>Data type</b>	String

## **Additional Properties**

### **Message body**

The contents of the message body.

---

## **Messages [Settings]**

The properties for a message on the message point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *queue\_name* -> [Message points] Queue points -> *queue\_point\_name* -> Runtime > Messages -> *message\_name*.**

## **Runtime tab**

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## **General Properties**

### ***Messaging engine message identifier:***

Messaging engine message identifier.

<b>Required</b>	No
<b>Data type</b>	String

### ***State:***

The current state of this message on the message point. If the message is part of a transaction, the transaction identifier is shown in the Transaction ID field.

<b>Required</b>	No
-----------------	----

**Data type**  
**Range**

drop-down list

**Available**

The message is available for consumption.

**Locked**

The message is currently unavailable. The message is in this state temporarily, possibly because it is being consumed by a non-transacted consumer.

**Remote lock**

The message is currently locked to a consumer attached to another, remote, messaging engine in the bus. The message will remain locked until the remote messaging engine responds with a decision on the message. If the remote messaging engine is stopped, the message will remain locked until the messaging engine is restarted. A corresponding message request for a “known remote queue point” will identify the remote messaging engine that is making the request.

**Removing**

The message is currently being removed under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

**Committing**

The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

**Pending retry**

The message is currently unavailable before being eligible for a retry. This might be because a message-driven bean is configured to delay failing message retries.

**Blocked**

This message is currently unavailable because the message point is blocked by the first message on the queue. The first message has reached its maximum failed delivery limit but no exception destination is configured. Identify the first message and resolve the problem that is preventing it from being consumed.

***Transaction ID:***

The local transaction identifier of the transaction that this message is currently part of.

**Required**  
**Data type**

No  
String

***Run-time message properties:***

***Message type:***

The type of the message (JMS, SDO, SUBSCRIPTION, TRM, BROKER\_CONTROL, BROKER\_RESPONSE, BROKER\_ADMIN).

<b>Required</b>	No
<b>Data type</b>	String

***Approximate length:***

The approximate length of the message.

<b>Required</b>	No
<b>Data type</b>	String

***Time stamp:***

The time stamp of when the message was originally sent.

<b>Required</b>	No
<b>Data type</b>	String

***Message wait time:***

The time the message has been waiting to be consumed.

<b>Required</b>	No
<b>Data type</b>	String

***Current messaging engine arrival time:***

The time that the message arrived on the current messaging engine.

<b>Required</b>	No
<b>Data type</b>	String

***Redelivered count:***

The number of times that the message has been redelivered.

<b>Required</b>	No
<b>Data type</b>	String

***Security user ID:***

The security user ID.

<b>Required</b>	No
<b>Data type</b>	String

***Producer type:***

The producer type (API, Core, TRM).

<b>Required</b>	No
<b>Data type</b>	String

***Exception destination timestamp:***

The timestamp at which the message was put to the exception destination.

<b>Required</b>	No
<b>Data type</b>	String

***Exception destination reason:***

The reason the message was put to the exception destination.

<b>Required</b>	No
<b>Data type</b>	Text area

***API Message properties:***

***Message ID:***

The message ID.

<b>Required</b>	No
<b>Data type</b>	String

***Correlation ID:***

The API correlation ID for request/response correlation.

<b>Required</b>	No
<b>Data type</b>	String

***User ID:***

The user ID.

<b>Required</b>	No
<b>Data type</b>	String

***Format:***

The Format of the message.

<b>Required</b>	No
<b>Data type</b>	String

***Bus message properties:***

***Topic:***

The bus discriminator.

<b>Required</b>	No
<b>Data type</b>	String

***Priority:***

The bus priority (0-9).

<b>Required</b>	No
<b>Data type</b>	String

***Reliability:***

The bus reliability (Assured persistent, Reliable persistent, Reliable non-persistent, Express non-persistent, Best effort non-persistent).

<b>Required</b>	No
<b>Data type</b>	String

***Time to live:***

The time to live of the message.

<b>Required</b>	No
<b>Data type</b>	String

***Reply discriminator:***

The reply discriminator value of the bus.

<b>Required</b>	No
<b>Data type</b>	String

***Reply priority:***

The reply priority value of the bus (0-9).

<b>Required</b>	No
<b>Data type</b>	String

***Reply reliability:***

The reply reliability value of the bus (Assured persistent, Reliable persistent, Reliable non-persistent, Express non-persistent, Best effort non-persistent).

<b>Required</b>	No
<b>Data type</b>	String

***Reply time to live:***

The reply time to live value of the bus.

<b>Required</b>	No
<b>Data type</b>	String

### **System message ID:**

The unique id of the message, assigned by the bus.

<b>Required</b>	No
<b>Data type</b>	String

## **Additional Properties**

### **Message body**

The contents of the message body.

---

## **Messaging engine policy maintenance [Collection]**

This pane shows all the messaging engine policies for this cluster and their current settings, that is, the settings that determine messaging engine behavior. This list of policies comprises all the core group policies that are associated with the messaging engines in the cluster. If required, you can make a messaging engine policy conform to the currently selected messaging engine policy assistance type. You can also access the associated core group policy settings, although you should not change these settings unless you already have experience of doing so.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Bus members -> *bus\_member\_name* -> [Additional Properties] Messaging engine policy maintenance.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the button provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Name** The name of the messaging engine policy, that is, the name of the core group policy that is associated with a messaging engine in the current cluster. Select this name to view or change the core group policy settings, although you should not change these settings unless you already have experience of doing so.

### **Failover?**

A value that specifies whether the messaging engine that is associated with this policy can fail over to another server. Values can be Yes or No.

### **Fail back?**

A value that specifies whether the messaging engine that is associated with this policy can fail back to a more preferred server. Values can be Yes or No.

### **Preferred order of servers to run on**

The list of preferred servers for the messaging engine that is associated with this policy to run on. The list is in the order of preference.

### **Only run on preferred servers?**

A value that specifies whether the messaging engine that is associated with this policy can run only on the servers in the list of preferred servers, or can run on any server available in the cluster. Values can be Yes or No.

For example, if there is one server in the list of preferred servers and this value is Yes, the messaging engine is considered to be 'pinned' to that server; it cannot fail over to any other server. If there are two servers in the list of preferred servers and this value is No, the messaging engine can fail over to the servers in the list, in the order specified, and then to any other server available in the cluster.

### Details

Details of the messaging engine configuration. Either the message confirms that the core group policy, and therefore the messaging engine policy, is correct for the currently selected messaging engine policy assistance type, or the message suggests actions to change the messaging engine configuration. If the suggested action is to correct a core group policy, you can use the **Correct messaging engine policy** option. When the messaging engine policy assistance type is Custom, these details do not apply.

### Status

A green tick in a circle indicates that the messaging engine configuration is correct for the currently selected messaging engine policy assistance type. Otherwise, a warning triangle is displayed. When the messaging engine policy assistance type is Custom, this status does not apply.

### Buttons

Correct messaging engine policy	Change the settings of the selected messaging engine policies so that they are correct for the currently selected messaging engine policy assistance type. The <b>Details</b> and <b>Status</b> fields indicate whether you have to use this button. All the required settings are automatically changed and the fields on this panel are updated. This button is available for all messaging engine policy assistance types except Custom.
Create missing messaging engine policies	This button is available only when there is a messaging engine in the cluster that is not associated with any messaging engine policy. Use this button to create a messaging engine policy and associate it with the messaging engine. A messaging engine policy is created with the correct settings for the currently selected messaging engine policy assistance type, except when that type is Custom. For a Custom messaging engine policy type, a wizard is started that you can use to configure the messaging engine policy as you require.

---

## Messaging engines [Collection]

A messaging engine is a component, running inside a server, that manages messaging resources for a bus member. Applications are connected to a messaging engine when they access a service integration bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Name** The name of the messaging engine.

**Description**

An optional description for the messaging engine, for administrative purposes.

**Status**

The current status of the messaging engine. Status settings are started or stopped.

**Buttons**

<b>Enable policy assistance</b>	<p>This button only applies to messaging engines in a clustered environment.</p> <p>Start the wizard that provides messaging engine policy assistance, that is, guidance about creating one or more messaging engines for the cluster and configuring the messaging engine behavior. This button is available only when messaging engine policy assistance is not enabled already.</p>
<b>Add messaging engine</b>	<p>This button only applies to messaging engines in a clustered environment.</p> <p>Add a new messaging engine to the server cluster.</p>
<b>Remove messaging engine</b>	<p>This button only applies to messaging engines in a clustered environment.</p> <p>Remove the selected messaging engines from the server cluster.</p>
<b>Start</b>	<p>Start selected items.</p>

<p><b>Stop</b></p>	<p>Stop the selected messaging engines. You must first select the messaging engines to be stopped. You can select a Stop mode:</p> <p><b>Immediate</b></p> <p>The messaging engine stops after all messaging operations that are occurring at the time of the stop request have completed. After a stop request is issued, no new messaging operations can start.</p> <p>For each existing connection, the messaging engine waits for the current operation to complete, unless the operation is one that blocks processing in the messaging engine, such as a receive operation. In this case, the operation is interrupted. Asynchronous consumers can complete, even though they might take an arbitrary amount of time to process the current message. The messaging engine then backs out of active transactions and disallows any further operations on that connection. When all connections are in this invalidated state, the messaging engine stops.</p> <p><b>Force</b></p> <p>The messaging engine stops without allowing messaging operations to complete. Applications are forcefully disconnected.</p> <p>This mode completes the shutdown of the messaging engine in as short a time as possible. When a messaging engine that was stopped by using force mode is restarted, the restart might take longer than if it was stopped using immediate mode, because more recovery actions are needed. For example, messages might be left in an indoubt state and you must deal with these messages to resolve any indoubt transactions.</p> <p><b>Tip:</b> If an immediate stop takes too long, you can select the Force option to escalate it to a force stop. This overrides your previous selection of the Immediate option.</p>
--------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## Messaging engines [Settings]

A messaging engine is a component, running inside a server, that manages messaging resources for a bus member. Applications are connected to a messaging engine when they access a service integration bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name*.**

- “Configuration tab” on page 2267
- “Runtime tab” on page 2270

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Name:**

The name of the messaging engine.

<b>Required</b>	No
<b>Data type</b>	String

#### **UUID:**

The universal unique identifier assigned by the system to this messaging engine for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

#### **Description:**

An optional description for the messaging engine, for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	Text area

#### **Initial state:**

The initial state determines whether the messaging engine is started automatically.

If this property is selected, the messaging engine starts automatically when its associated application server is started. Until the messaging engine starts, it is unavailable.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	<b>Stopped</b> When the associated application server is started, the messaging engine is stopped and is not available to process messages. <b>Started</b> When the associated application server is started, the messaging engine is started and is available to process messages.

#### **Message store type:**

The type of message store used. Either file store or data store. Once the messaging engine has been created this cannot be changed, only configured.

**Required**  
**Data type**  
**Range**

No  
drop-down list

**File store**

A file store is a type of message store that directly uses files in a file system through the operating system.

**Data store**

A data store consists of the set of tables that a messaging engine uses to store persistent data in a database.

***High message threshold per message point:***

The number of messages queued on a message point on this messaging engine, at which point new messages are not accepted on the message point. However, certain messages that are already in the bus and that are being transmitted to this messaging engine might be accepted.

When the messaging engine is created, the high message threshold of the bus is used to set the default value for this property. When a message point is created on this messaging engine, the value of this property is used to set the default high message threshold for the message point.

**Required**  
**Data type**  
**Range**

No  
Integer  
1 through 9223372036854775807

**Note:** There are implications for the Java Virtual Machine (JVM) heap size when using a high message threshold, if large numbers of messages are held on a queue (each message consumes approximately 200 bytes of storage). Therefore if you increase the high message threshold because you are expecting large numbers of messages on your queues, you should also modify the JVM heap size of the server as appropriate.

***Default blocked destination retry interval:***

The time delay, in milliseconds, that is introduced by the system under certain circumstances before a failed message delivery to an application will be retried. This delay can be overridden by individual Queue destination configurations.

When you configure a bus destination, you can specify an associated exception destination and a maximum number of times that an individual message fails to be consumed before it is put on that exception destination. Alternatively, if you do not specify an associated exception destination, the system continues to try to deliver the message. In this situation, the system attempts to deliver the message, without applying any delay, until it reaches the maximum failed deliveries limit set for the bus destination (a queue or a topic space). After the maximum failed deliveries limit is reached, the default blocked destination retry interval is applied before the message is retried.

The Default blocked destination retry interval specifies the time interval between retry attempts, which will be used by all queue and topic destinations that are associated with this messaging engine. You can override this default value when you configure an individual queue or topic destination.

**Required**

No

<b>Data type</b>	Integer (milliseconds)
<b>Default</b>	The value taken from the sib.processor.blockedRetryTimeout custom property, if set. Otherwise it is set to 5000.
<b>Range</b>	1 through 9223372036854775807

### ***Target groups:***

A list of names of target groups with which the messaging engine will register.

Custom target groups are a type of target group used by JMS connection factories. When an application creates a connection to a service integration bus, it uses connection factory properties to specify suitable messaging engines to connect to. When a target type of “Custom” is specified in the connection factory **targetType** property, the application is connected to one of the messaging engines in the specified custom target group. A particular messaging engine is selected from the group according to the other connection factory properties that are specified.

<b>Required</b>	No
<b>Data type</b>	Text area

### ***Bus name:***

The name of the service integration bus on which the messaging engine is configured.

<b>Required</b>	No
<b>Data type</b>	String

### ***Bus UUID:***

The universal unique identifier of the service integration bus on which the messaging engine is configured.

<b>Required</b>	No
<b>Data type</b>	String

## **Message points**

### **Mediation points**

A mediation point is created on each messaging engine to which the mediation of a mediated destination is assigned. It is used to hold messages pending delivery to the mediation.

### **Queue points**

A queue point is created on each messaging engine to which a point-to-point destination is assigned. It is used to hold messages pending delivery to receiving applications.

### **Publication points**

A publication point is created on each messaging engine in the bus when a publish/subscribe destination is created. The publication point on a messaging engine is used to hold messages published by applications connected to that messaging engine until they are delivered to subscribers.

## Additional Properties

### Mediation execution points

Mediation execution points for the processing of messages from mediation message points that are on a WebSphere MQ server.

### Service integration bus links

A communications link between this messaging engine and a messaging engine in a foreign service integration bus.

### Mediation thread pool

The thread pool for allocating mediation handler threads.

### Message store

The properties for the message store in use by this messaging engine as determined by the message store type field. The message store can be either a file store or a data store.

### WebSphere MQ client links

A WebSphere MQ client link enables JMS client applications to connect, via this messaging engine, to the service integration bus, as though it were a WebSphere MQ queue manager.

### WebSphere MQ links

Links between the messaging engine and WebSphere MQ networks. Each WebSphere MQ link connects the messaging engine as a queue manager to WebSphere MQ, providing a bridge between the bus and a WebSphere MQ network.

### Custom properties

Arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

### Reliable messaging state

Use this page to view and manage the WS-ReliableMessaging runtime state.

## Related Items

### Bus member

The bus member associated with this messaging engine.

## Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### **Status:**

The current status of the messaging engine. Status settings are started or stopped.

To be able to retrieve the status of messaging engines, you must be logged into the administrative console with at least monitor authority. If you do not have this authority, the messaging engine status is displayed as "Unavailable", even if the messaging engine has started.

<b>Required</b>	No
<b>Data type</b>	String

## Message points

### Queue points

A queue point is created on each messaging engine to which a point-to-point destination is assigned. It is used to hold messages pending delivery to receiving applications.

### Publication points

A publication point is created on each messaging engine in the bus when a publish/subscribe destination is created. The publication point on a messaging engine is used to hold messages published by applications connected to that messaging engine until they are delivered to subscribers.

### Mediation points

A mediation point is created on each messaging engine to which the mediation of a mediated destination is assigned. It is used to hold messages pending delivery to the mediation.

## Remote message points

### Remote queue points

The remote queue points that are producing/consuming messages to/from queue points on remote messaging engines.

### Remote mediation points

The remote mediation points that are producing messages for mediation points on remote messaging engines.

### Remote publication points

The remote publication points that are producing messages for publication points on remote messaging engines.

---

## Messaging resources for this application

This pane provides an expandable tree view of all the references to messaging resources declared in the deployment descriptors for the current application. As many of the references as possible are resolved to links to the associated configuration panel for the referenced object.

To view this page in the console, click the following path:

**Applications -> Application Types -> WebSphere enterprise applications -> *application\_name* -> [Enterprise Java Bean Properties] Default messaging provider references.**

Use this panel to inspect the configuration from the application to the queue (destination) to ensure that the configuration is correct.

Using the default messaging provider, a JMS activation specification refers to a JMS destination (either a JMS Queue or JMS Topic) that in turn points to a service integration bus destination (either a queue destination or a topic space destination). JMS resources are referenced through Java Naming and Directory Interface (JNDI) names and service integration resources are referenced through bus and resource identifiers. This panel enables you to review the dependencies within your configuration, making it easier to detect inconsistencies, for example as a result of references being entered incorrectly, or JNDI or resource names being changed or deleted without the associated configuration having been updated.

Problems with the configuration are usually detected in one of two ways:

- An application can no longer send or receive messages.
- A destination becomes full and can no longer receive messages because the existing messages are not being consumed.

This panel can help you find the cause of the problem by giving you a high level view of many relevant resources.

**Note:** For a related view of the applications and JMS resources for a given destination, see the following panel: “Application resources for this destination” on page 2175.

- “Local Topology tab”

## Local Topology tab

Topology properties for this object. These properties detail how this object relates to other objects in the system topology.

---

## Permitted transports [Collection]

A permitted transport is a transport mechanism that this bus will allow remote clients to use.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Additional Properties] Permitted transports.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Transport Name

The name of the permitted transport.

## Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

---

## Port [Settings]

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *port\_name*.**

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### *Identifier:*

The identifier by which this destination is known for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

### *UUID:*

The universal unique identifier assigned by the system to this destination for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

***Type:***

Whether this bus destination is for a queue, topic space, or some other type of destination.

<b>Required</b>	No
<b>Data type</b>	String

***Description:***

An optional description for the bus destination, for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	Text area

***Mediation:***

The name of the mediation that mediates this destination.

<b>Required</b>	No
<b>Data type</b>	String

***Default reliability:***

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

<b>Required</b>	No
<b>Data type</b>	drop-down list

**Range**

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

**Maximum reliability:**

The maximum reliability of messages accepted by this destination.

**Required**  
**Data type**  
**Range**

No  
drop-down list

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

**Enable producers to override default reliability:**

Select this option to enable producers to override the default reliability that is set on the destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Default priority:***

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

<b>Required</b>	No
<b>Data type</b>	Custom

***Exception destination:***

Use these properties to define what happens to any messages that cannot be delivered to this destination.

Use this property to define what happens to any messages that cannot be delivered to this destination.

By default, such messages are routed to the system default exception destination of the messaging engine that discovers the problem: `_SYSTEM.Exception.Destination.engine_name`.

If you want messages to be sent to another exception destination, select Specify then type the exception destination name. The exception destination must be a queue, on the same bus or a foreign bus, and must exist when the destination is created.

If you do not want undeliverable messages to be sent to an exception destination, select None.

<b>Required</b>	No
<b>Data type</b>	String and Boolean

***Send allowed:***

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Receive allowed:***

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Receive exclusive:***

Select this option to allow only one consumer to attach to each message point. If this option is not selected multiple consumers will be allowed to attach and receive messages from each message point.

<b>Required</b>	No
<b>Data type</b>	Boolean

### ***Maintain strict message order:***

Enabling this option will maintain the strict ordering of messages for this destination.

<b>Required</b>	No
<b>Data type</b>	Custom

## **Additional Properties**

### **Context properties**

Context information passed to the mediation.

### **Message points**

#### **Queue points**

A queue point is created on each messaging engine to which a point-to-point destination is assigned. It is used to hold messages pending delivery to receiving applications.

#### **Mediation points**

A mediation point is a location in a messaging engine at which messages are mediated. A mediation point is created when a mediation is associated with a bus destination.

---

## **Property [Settings]**

Use this page to specify an arbitrary name and value pair. The value that is specified for the name and value pair is a string that can set internal system configuration properties.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Additional Properties] Custom properties -> *property\_name*.**

## **Configuration tab**

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### **General Properties**

#### ***Name:***

Specifies the name of the property.

<b>Required</b>	Yes
<b>Data type</b>	String

#### ***Value:***

Specifies the value that is paired with the specified name.

<b>Required</b>	Yes
<b>Data type</b>	String

#### ***Description:***

Specifies a description of the name and value pair. The description should help to differentiate this pair for other defined pairs.

<b>Required</b>	No
<b>Data type</b>	Text area

**Optional:**

Specifies an optional attribute that determines whether this property must have a value.

<b>Required</b>	No
<b>Data type</b>	Boolean

**Validation Expression:**

Specifies a value that the administrative console and some host tools use to validate the contents of the value of this property.

<b>Required</b>	No
<b>Data type</b>	String

---

## Publication points [Collection]

The message point for a topic space, for publish/subscribe messaging.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *topic\_space\_name* -> [Message points] Publication points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Identifier

The system-generated name by which this message point is known.

### Queue Depth

The total set of messages currently queued by the publication point for the attached subscriptions.

These messages can be:

- Shared across multiple local subscriptions
- Queued for a single subscription
- Queued for transmission to one or more remote publication points

Investigate the reason for queued messages, as follows:

- Display the runtime collection of subscriptions for this publication point and identify the subscriptions with non-zero queue depths.

- Also display the Remote publication point collection panel for this messaging engine and identify any remote publication points for the same topic space as this publication point that have a non-zero current outbound message value. If these exist, ensure that the target messaging engines are started.

---

## Publication points [Collection]

The message point for a topic space, for publish/subscribe messaging.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *topic\_space\_name* -> [Message points] Publication points -> Runtime.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Identifier

The system-generated name by which this message point is known.

---

## Publication points [Settings]

The message point for a topic space, for publish/subscribe messaging.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *topic\_space\_name* -> [Message points] Publication points -> *publication\_point\_name*.**

- “Configuration tab”
- “Runtime tab” on page 2279

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### Identifier:

The system-generated name by which this message point is known.

<b>Required</b>	No
<b>Data type</b>	String

#### UUID:

The universal unique identifier assigned by the system to this message point for administrative purposes.

<b>Required</b>	No
-----------------	----

**Data type** String

***Destination type:***

Whether the message point is a queue or topic space.

**Required** No  
**Data type** String

***High message threshold:***

A threshold above which the messaging system will take action to limit the addition of more messages to this message point.

A publication point stores a single copy of each message that is currently queued to a subscription on this publication point. Multiple subscriptions that are queueing the same message will result in a single copy of the message on the publication point. A publication point can reach its high message threshold because a single subscription has many messages queued to it or because many subscriptions have a few, different messages queued to them. If the high message threshold is reached, investigate the state of the individual subscriptions on this publication point to identify the cause.

**Required** No  
**Data type** Long  
**Range** 1 through 9223372036854775807

***Send allowed:***

Clear this option (setting it to false) to stop messages from being put onto this message point. This value will be overridden by the parent destination if that destination has sendAllowed disabled, which stops messages from being put onto all its message points.

**Required** No  
**Data type** Boolean

***Target UUID:***

The UUID of the bus destination for which this is a message point.

**Required** No  
**Data type** String

## **Runtime tab**

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### **Identifier:**

The system-generated name by which this message point is known.

<b>Required</b>	No
<b>Data type</b>	String

### **Run-time ID:**

The internal runtime identifier assigned to this message point.

<b>Required</b>	No
<b>Data type</b>	String

### **High message threshold:**

A threshold above which the messaging system will take action to limit the addition of more messages to this message point.

<b>Required</b>	No
<b>Data type</b>	String

### **Send allowed:**

Clear this option (setting it to false) to stop messages from being put onto this message point. This value will be overridden by the parent destination if that destination has sendAllowed disabled, which stops messages from being put onto all its message points.

<b>Required</b>	No
<b>Data type</b>	Boolean

## Additional Properties

### **Subscriptions**

The active subscriptions for the topic space.

### **Known remote publication points**

The remote messaging engines that have remote producers connected to this publication point.

---

## Publish/subscribe broker profiles [Collection]

Profiles used to define the topic mappings and transactionality for publishing and receiving (by subscription) topics across the publish/subscribe bridge between WebSphere Application Server and a message broker in a WebSphere MQ network.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Publish/subscribe broker profiles.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Name** The name of the publish/subscribe broker profile.

**Description**

An optional description for the publish/subscribe broker profile, for administrative purposes.

**Broker queue manager**

The name of the queue manager for the WebSphere MQ broker.

**Buttons**

New	Create a new administrative object of this type.
Delete	Delete the selected items.

---

## Publish/subscribe broker profiles [Settings]

Profiles used to define the topic mappings and transactionality for publishing and receiving (by subscription) topics across the publish/subscribe bridge between WebSphere Application Server and a message broker in a WebSphere MQ network.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile\_name*.**

- “Runtime tab”
- “Configuration tab” on page 2282

### Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

***Number of subscriptions:***

The current number of broker subscriptions for this broker profile.

<b>Required</b>	No
<b>Data type</b>	String

### Additional Properties

**Subscriptions**

The list of current broker subscriptions for this broker profile.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Name:**

The name of the publish/subscribe broker profile.

This name is only for administrative purposes. If you created this broker profile by using the foreign bus connection wizard, then this name is generated automatically by adding “\_broker\_profile” to the end of the broker queue manager name.

<b>Required</b>	Yes
<b>Data type</b>	String

#### **Description:**

An optional description for the publish/subscribe broker profile, for administrative purposes.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Text area

#### **Broker queue manager:**

The name of the queue manager for the WebSphere MQ broker.

This identifies the queue manager to which the message broker is connected in the WebSphere MQ network. It does not have to be the WebSphere MQ gateway queue manager.

<b>Required</b>	No
<b>Data type</b>	String

### Additional Properties

#### **Topic mappings**

Topic mappings for publishing and receiving (by subscription) messages across the publish/subscribe bridge between WebSphere Application Server and a message broker in a WebSphere MQ network.

---

## Queue points [Collection]

The message point for a queue, for point-to-point messaging.

To view this page in the console, click the following path:

**Service integration -> Buses -> bus\_name -> [Destination resources] Destinations -> queue\_name -> [Message points] Queue points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

#### Identifier

The system-generated name by which this message point is known.

---

## Queue points [Collection]

The message point for a queue, for point-to-point messaging.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *queue\_name* -> [Message points] Queue points -> Runtime.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

#### Identifier

The system-generated name by which this message point is known.

---

## Queue points [Settings]

The message point for a queue, for point-to-point messaging.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *queue\_name* -> [Message points] Queue points -> *queue\_point\_name*.**

- “Configuration tab”
- “Runtime tab” on page 2284

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### Buttons

Refresh	Refresh the number of messages.
---------	---------------------------------

## General Properties

#### Identifier:

The system-generated name by which this message point is known.

<b>Required</b>	No
<b>Data type</b>	String

***UUID:***

The universal unique identifier assigned by the system to this message point for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

***Destination type:***

Whether the message point is a queue or topic space.

<b>Required</b>	No
<b>Data type</b>	String

***High message threshold:***

A threshold above which the messaging system will take action to limit the addition of more messages to this message point.

<b>Required</b>	No
<b>Data type</b>	Long
<b>Range</b>	1 through 9223372036854775807

***Send allowed:***

Clear this option (setting it to false) to stop messages from being put onto this message point. This value will be overridden by the parent destination if that destination has sendAllowed disabled, which stops messages from being put onto all its message points.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Target UUID:***

The UUID of the bus destination for which this is a message point.

<b>Required</b>	No
<b>Data type</b>	String

## **Runtime tab**

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## Buttons

Refresh	Refresh the number of messages.
---------	---------------------------------

## General Properties

### *Identifier:*

The system-generated name by which this message point is known.

<b>Required</b>	No
<b>Data type</b>	String

### *Run-time ID:*

The internal runtime identifier assigned to this message point.

<b>Required</b>	No
<b>Data type</b>	String

### *High message threshold:*

A threshold above which the messaging system will take action to limit the addition of more messages to this message point.

<b>Required</b>	No
<b>Data type</b>	String

### *Send allowed:*

Clear this option (setting it to false) to stop messages from being put onto this message point. This value will be overridden by the parent destination if that destination has sendAllowed disabled, which stops messages from being put onto all its message points.

<b>Required</b>	No
<b>Data type</b>	Boolean

### *Current message depth:*

The number of messages on the message point.

<b>Required</b>	No
<b>Data type</b>	String

## Additional Properties

### Messages

Messages queued on the queue point.

### Known remote queue points

The remote messaging engines that have remote producers or consumers connected to this queue point.

---

## Redundant core group policies [Collection]

This pane shows all the core group policies that are associated with this cluster through their match criteria, but that are not associated with any messaging engine in this cluster. Use this pane to delete redundant core group policies that you do not want.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Bus members -> *bus\_member\_name* -> [Additional Properties] Redundant core group policies.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the button provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

When you use messaging engine policy assistance, for each messaging engine, an appropriate core group policy is created and associated with that messaging engine automatically. You do not have to create or manage core group policies directly. A redundant core group policy might occur if messaging engine policy assistance is not enabled and you remove a messaging engine without deleting its associated core group policy, or create a core group policy that is not associated with a messaging engine.

### Core group policy name

The name of the core group policy that is redundant, that is, a core group policy that is associated with this cluster through its match criteria, but it is not associated with any messaging engine that is currently in the cluster.

### Target messaging engine name

The name of the messaging engine that the core group policy is targeted at, that is, the name specified through the match criteria of the core group policy.

In this situation, the target messaging engine name will be the name of a messaging engine that does not exist, for example because the match criteria are not correct, or the messaging engine was removed.

### Failover?

A value that specifies whether the messaging engine that is associated with this policy can fail over to another server. Values can be Yes or No.

### Fail back?

A value that specifies whether the messaging engine that is associated with this policy can fail back to a more preferred server. Values can be Yes or No.

### Preferred order of servers to run on

The list of preferred servers for the messaging engine that is associated with this policy to run on. The list is in the order of preference.

### Only run on preferred servers?

A value that specifies whether the messaging engine that is associated with this policy can run only on the servers in the list of preferred servers, or can run on any server available in the cluster. Values can be Yes or No.

## Buttons

Delete	Delete the selected items.
--------	----------------------------

---

## Remote mediation points [Collection]

The remote mediation points that are producing messages to mediation points on remote messaging engines.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote mediation points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A remote mediation point represents a remote proxy for a mediation point that exists at a remote messaging engine to which messages are sent by an application or client connected to this messaging engine. The remote mediation point manages an outbound message stream to the mediation point at the remote messaging engine.

### Identifier

The remote mediation point identifier.

### Messaging engine

The remote messaging engine where this mediation point is localized.

### Current outbound messages

The current number of outbound messages queued to the mediation point.

### Outbound messages sent

The total number of messages sent to the mediation point since the messaging engine started.

## Buttons

Delete all messages	Delete all messages from the outbound message stream of the selected remote queue point. Messages in "Pending Acknowledgment" state might already have been received at the remote queue point. You cannot delete messages in "Committing" state; you must first commit their transactions.
Move all messages	Move all messages from the outbound message stream of the selected remote queue point to the exception destination configured for the destination. Messages in "Pending Acknowledgment" state might already have been received at the remote queue point. Moving these messages to the exception destination results in two copies of the message in the bus. You cannot move messages in "Committing" state; you must first commit their transactions.

---

## Remote mediation points [Settings]

The remote mediation points that are producing messages to mediation points on remote messaging engines.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote mediation points -> *identifier\_name* .**

- “Runtime tab”

### Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### *Identifier:*

The remote mediation point identifier.

<b>Required</b>	No
<b>Data type</b>	String

#### *Messaging engine:*

The remote messaging engine where this mediation point is localized.

<b>Required</b>	No
<b>Data type</b>	String

#### *Current outbound messages:*

The current number of outbound messages queued to the mediation point.

<b>Required</b>	No
<b>Data type</b>	String

#### *Outbound messages sent:*

The total number of messages sent to the mediation point since the messaging engine started.

<b>Required</b>	No
<b>Data type</b>	String

### Additional Properties

#### **Outbound messages**

The outbound message streams from this remote message point to the remote localized message point.

---

## Outbound messages [Collection]

The outbound message streams from this remote message point to the remote localized message point.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote queue points -> *identifier\_name* -> [Additional Properties] Outbound messages.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

The collection of outbound message streams ordered by quality of service (priority and reliability) for messages sent to a message point on a remote messaging engine.

### Priority

The stream priority.

### Reliability

The stream reliability.

### Number of messages

The current number of messages on the stream.

### Status

The status of the stream.

### Messages

View the messages on the selected stream.

---

## Remote Publication Points [Collection]

The remote publication points that are producing messages to publication points on remote messaging engines.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote publication points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A remote publication point represents a remote proxy for a publication point that exists at a remote messaging engine, for which publications are published to by an application or client connected to this messaging engine. The remote publication point manages an outbound message stream to the publication point at the remote messaging engine.

**Identifier**

The remote publication point identifier.

**Message engine**

The remote messaging engine where this publication point is localized.

**Current outbound messages**

The current number of outbound messages queued to the publication point.

**Outbound messages sent**

The total number of messages sent to the publication point since the messaging engine started.

**Buttons**

Delete all messages	Delete all messages from the outbound message stream of the selected remote queue point. Messages in "Pending Acknowledgment" state might already have been received at the remote queue point. You cannot delete messages in "Committing" state; you must first commit their transactions.
---------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Remote Publication Points [Settings]**

The remote publication points that are producing messages to publication points on remote messaging engines.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote publication points -> *identifier\_name* .**

- "Runtime tab"

**Runtime tab**

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

**General Properties****Identifier:**

The remote publication point identifier.

<b>Required</b>	No
<b>Data type</b>	String

**Message engine:**

The remote messaging engine where this publication point is localized.

<b>Required</b>	No
<b>Data type</b>	Text area

**Current outbound messages:**

The current number of outbound messages queued to the publication point.

<b>Required</b>	No
<b>Data type</b>	String

### ***Outbound messages sent:***

The total number of messages sent to the publication point since the messaging engine started.

<b>Required</b>	No
<b>Data type</b>	String

## **Outbound properties**

### **Messages**

The messages queued outbound to the publication point on the remote messaging engine.

### **Topics**

The topics that have been subscribed to from this remote messaging engine.

## **Inbound properties**

### **Remote subscriptions**

The subscriptions that have been made from this messaging engine to subscription homes on remote messaging engines.

---

## **Remote subscription [Collection]**

The subscription that has been made from this messaging engine to a subscription home on a remote messaging engine.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote Message Points] Remote publication points > *identifier\_name* -> [Inbound Properties] Remote subscriptions.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

The subscriptions that have been made by subscribing applications, or clients connected to this messaging engine, to the remote messaging engine where the subscriptions' "Homes" exist.

**Name** The name of the remote subscription.

### **Current message requests**

The current number of active message retrieval requests sent to the publication point from this remote subscription point.

### **Completed message requests**

The total number of completed message retrieval requests sent to the publication point from this remote subscription point since the messaging engine started.

---

## Remote subscription [Settings]

The subscription that has been made from this messaging engine to a subscription home on a remote messaging engine.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote Message Points] Remote publication points > *identifier\_name* -> [Inbound Properties] Remote subscriptions -> *subscription\_name* .**

- “Runtime tab”

### Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Name:**

The name of the remote subscription.

<b>Required</b>	No
<b>Data type</b>	String

#### **Current message requests:**

The current number of active message retrieval requests sent to the publication point from this remote subscription point.

<b>Required</b>	No
<b>Data type</b>	String

#### **Completed message requests:**

The total number of completed message retrieval requests sent to the publication point from this remote subscription point since the messaging engine started.

<b>Required</b>	No
<b>Data type</b>	String

### Additional Properties

#### **Message requests**

The total number of active and completed message retrieval requests sent to the publication point from this remote subscription point since the messaging engine started.

---

## WebSphere MQ sender channel saved batch status [Collection]

The saved status of message batches for the sender channel saved for transmission to WebSphere MQ. You can choose to commit or rollback each batch.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Sender channel -> *channel\_name* -> Runtime > Saved batch status.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Virtual queue manager name

The virtual queue manager name by which the local bus is known to a WebSphere MQ network.

### MQ channel name

The name of the channel used for the WebSphere MQ link sender channel.

### In doubt

Whether or not the saved batch is in doubt.

### Current LUWID

The current logical unit-of-work identifier for the saved batch.

### Current sequence number

The current sequence number for the saved batch.

### Last LUWID

The last logical unit-of-work identifier for the saved batch.

### Last sequence number

The last sequence number for the saved batch.

## Buttons

Commit	Commit the logical unit-of-work for the message batch.
Roll back	Roll back the logical unit-of-work for the message batch.

---

## WebSphere MQ receiver channel saved batch status [Collection]

The runtime status of message batches for the receiver channel of the WebSphere MQ link.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Receiver channel -> *channel\_name* -> Runtime > Saved batch status.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**WebSphere MQ Queue Manager name**

The name of the WebSphere MQ queue manager from which the message batch was received.

**MQ channel name**

The name of the WebSphere MQ sender channel from which the message batch was received.

**Last LUWID**

The last unit of work identifier for the message batch.

**Last sequence number**

The last sequence number for the message batch.

---

## Security domain configuration. [Settings]

Configure the security settings for the security domain to which your service integration bus is assigned.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Bus security domain] Configure security domain.**

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

Use this pane to create a customized security domain for the selected bus. By having a customized security domain for each bus in your bus topology, you can configure different security attributes for each bus within a cell. You can view the current security settings for the security domain to which the selected service integration bus is assigned, and to make changes to the existing domain configuration.

- “Configuration tab”

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

#### General Properties

***Domain name:***

The unique name for this security domain.

You must type a unique name for the security domain.

<b>Required</b>	No
<b>Data type</b>	String

***Domain description:***

A description of this security domain.

<b>Required</b>	No
<b>Data type</b>	String

### **User Realm::**

Specifies the settings for the user realm.

Click the **Expand** icon to display the options for configuring the user realm.

You can use existing global security settings, or customize a user realm specifically for this domain. If you customize a user realm, you must select the type of realm, and you might have to configure the user registry.

<b>Required</b>	No
<b>Data type</b>	Expand

### **JAAS System Logins::**

Specifies the settings for the JAAS system logins.

Click the **Expand** icon to display the options for configuring JAAS system logins.

<b>Required</b>	No
<b>Data type</b>	Expand

### **JAAS J2C Authentication Data::**

Specifies the settings for the JAAS J2C authentication data.

Click the **Expand** icon to display the options for configuring authentication data for JAAS Java Platform Enterprise Edition (Java EE) Connector Architecture authentication data.

<b>Required</b>	No
<b>Data type</b>	Expand

---

## **Security for bus *bus\_name* [Settings]**

Configure the security settings for your service integration bus.

To view this pane in the console, click one of the following paths:

**Service integration -> Buses -> *bus\_name* > [Additional Properties] Security.**

**Service integration -> Buses -> *security\_value*.**

The value of *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

## **Configuration tab**

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## Launch Bus Security Wizard

Click to start a wizard to configure the security settings bus for a bus. If the wizard detects that bus security is disabled, you are prompted to enable it.

### General Properties

#### *Enable bus security:*

Select this option to inherit the secure administration setting of the cell. Deselect this option if you always wish to disable bus security.

<b>Required</b>	No
<b>Data type</b>	Boolean

#### *Inter-engine authentication alias:*

The name of the authentication alias used to authorize communication between messaging engines on the bus.

You must specify an inter-engine authentication alias if the bus contains a WebSphere Application Server Version 6 bus member. When bus security is enabled, the bus uses the inter-engine authentication alias to authenticate incoming connections from other messaging engines. An unauthorized messaging engine cannot connect to the bus.

<b>Required</b>	No
<b>Data type</b>	drop-down list

#### *Permitted transports:*

Select the type of allowed permitted transports.

**Allow the use of all defined transport channel chains**

**Restrict the use of defined transport channel chains to those protected by SSL**

**Restrict the use of defined transport channel chains to the list of permitted transports**

To ensure that all ports used by the bus are secure, select **Restrict the use of defined transport channel chains to those protected by SSL**, or if your permitted transport chains are secure, select **Restrict the use of defined transport channel chains to the list of permitted transports**. This prevents the InboundBasicMessaging port being opened. Changes to this setting are effective when the server is restarted.

<b>Required</b>	No
<b>Data type</b>	Radio button

#### *Use the Server ID when running mediations:*

Check this option if you want to run mediations using the server identity, instead of using a mediation authentication alias.

Select this option if you want to run mediations on multiple servers in different domains. Using the server identity enables you to run mediations successfully across multiple security domains without having to specify a mediation authentication alias for each domain. You can also use this option when multiple domains are not in use.

**Required** No  
**Data type** Boolean

***Mediations authentication alias:***

The name of the authentication alias used to authorize mediations to access the bus.

You must specify a mediation authentication alias if the bus contains a WebSphere Application Server Version 6 bus member. The mediations authentication alias ensures that the bus operates securely. If a mediation authentication alias is specified for a bus that contains no Version 6 bus members, it is ignored.

**Required** No  
**Data type** drop-down list

***Bus security domain:***

Select one of the following options to assign the bus to a security domain:

**Use the global security domain**

Select this option to assign the bus to the global security domain. If you have a mixed-version bus, you must assign it to the global security domain.

**Required** No  
**Data type** Radio button

**Inherit the cell level security domain**

Select this option to let the bus inherit the cell level security domain. If no cell level domain is specified then the global security domain will be used.

**Required** No  
**Data type** Radio button

**Use the selected domain**

Select a custom security domain for this bus. This domain will be used for authentication and determining other security information.

**Required** No  
**Data type** Radio button

**Configure Security Domain...**

Select this link to configure security settings for a custom security domain. This link becomes active only after you have applied or saved the option to use a non-global domain.

***Performance:***

*Group cache timeout:*

The length of time, in minutes, that a security group will be cached for.

Increasing the timeout decreases the load on the user registry and improves performance but makes the system less responsive to changes in a user's group membership. To tune the user's group cache to the optimum setting, you have to balance the need for responsiveness with the registry load. The default value is 120 minutes. If the system must respond quickly to changes in a user's group membership, specify a timeout of approximately 15 minutes. If it is acceptable to update a user's group membership only once a

day, for example, as an overnight process, specify a timeout of 1440 minutes (24 hours). With a setting of 0, entries in the cache do not timeout, and so remain until the server is next restarted.

A change to this value is effective immediately and only affects the group cache of the bus for which the configuration was changed.

<b>Required</b>	No
<b>Data type</b>	Long
<b>Range</b>	0 through 99999

*Audit:*

*Enable the auditing service for this bus:*

<b>Required</b>	No
<b>Data type</b>	Boolean

## **Authorization Policy**

### **Users and groups in the bus connector role**

The list of users and groups in the bus connector role.

### **Manage default access roles**

Manage the assignment of default role types to users and groups

### **Manage destination access roles**

Manage the assignment of destination role types to users and groups

### **Manage foreign bus access roles**

Manage the assignment of foreign bus role types to users and groups

### **Manage temporary destination prefix access roles**

Manage the assignment of temporary destination prefix role types to users and groups

### **Manage topic access roles**

Manage the assignment of topic role types to users and groups

### **Manage users and groups not known to the user repository**

Manage users and groups not known to the user repository

## **Additional Properties**

### **Permitted transports**

The list of permitted transports.

## **Related Items**

### **JAAS - J2C authentication data**

Specifies a list of user identities and passwords for Java 2 connector security to use.

### **Secure Administration and Applications**

Link to configure WebSphere global security settings.

### **Security domains**

Security domain configuration.

### **Audit Service**

Configure the global audit settings

---

## Sender channel transmitters [Collection]

This pane displays the transmission queue for a WebSphere MQ link sender channel.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel transmitters**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel transmitters**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### WebSphere MQ link sender channel

The name of the WebSphere MQ link sender channel for which this is the channel transmitter. Select this link to view the message collection panel for the messages on the sender channel transmitter.

### Status

The runtime status of the WebSphere MQ link sender channel transmitter. Green (running), Amber (running but a problem exists), Red (stopped).

### Current outbound messages

The current number of messages on the sender channel transmitter.

### Outbound messages sent

The current number of messages on the sender channel transmitter.

### Time since last message sent

The amount of time since the last message was sent across the sender channel or since the messaging engine started.

### Known link transmitters

Select this link to view the known link transmitters for the sender channel transmitter.

## Buttons

Move all messages	Move all messages on the selected WebSphere MQ link sender channel to the link exception destination.
Delete all messages	Delete all messages on the selected WebSphere MQ link sender channel.

---

## WebSphere MQ link sender channel transmitter messages [Collection]

This pane displays the messages queued for transmission across the WebSphere MQ link sender channel.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel transmitters -> *WebSphere\_MQ\_sender\_channel\_name***

- Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel -> *sender\_channel\_link\_name* -> Sender channel transmitter -> *WebSphere\_MQ\_sender\_channel\_name*
- Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel transmitters -> *WebSphere\_MQ\_link\_sender\_channel\_name*
- Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] WebSphere MQ links -> *link\_name* -> [Additional properties] Sender channel -> *sender\_channel\_link\_name* -> Sender channel transmitter -> *WebSphere\_MQ\_link\_sender\_channel\_name*

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

#### Maximum messages displayed

The maximum number of messages retrieved and displayed.

#### Position

The position in the queue of the sender channel transmitter messages.

#### Identifier

The identifier of the message. Select this link to view the message detail panel for the selected message.

**State** The transaction state of the message (“Pending send”, “Pending acknowledgement”, “Committing”).

#### Transaction ID

The transaction identifier, if the message is locked under a transaction.

#### Target bus

The bus to which the message is targeted.

#### Target destination

The destination in the bus to which the message is targeted.

#### Approximate message length (bytes)

The approximate length of the message in bytes.

### Buttons

Move	Move the selected available messages to the link exception destination. Only messages with a <b>State</b> of “Pending send” are moved.
Delete	Delete the selected available messages. Only messages with a <b>State</b> of “Pending send” are deleted.
Commit Pending Acknowledge Batch	Commit the pending acknowledgement message batch as being received successfully by the WebSphere MQ network. The messages are removed from the sender channel transmitter.

Rollback Pending Acknowledge Batch	Roll back the pending acknowledgement message batch as not being received successfully by the WebSphere MQ network. The messages are restored to the sender channel transmitter.
Refresh	Refresh the collection with the current set of messages on the sender channel transmitter. Only the number of messages up to the specified "Maximum displayed messages" are retrieved and displayed.

---

## Service integration bus link routing properties [Settings]

The routing properties for a service integration bus link to a foreign service integration bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Additional Properties] Service integration bus link routing properties.**

After a routing definition is configured, service integration bus links must be created between messaging engines in the services integration buses to be connected.

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

#### General Properties

##### **Name:**

The name by which the routing definition is known.

<b>Required</b>	No
<b>Data type</b>	String

##### **UUID:**

The universal unique identifier assigned by the system to the routing definition (virtual link) for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

##### **Inbound user ID:**

The user ID applied to messages arriving from the foreign bus and used to authorize their access to destinations.

The inbound user ID is used to authorize individual messages arriving from the foreign bus to destinations in this bus. If this is not a secure bus, this property has no affect on messages. You might want to specify an inbound user ID:

- if the foreign bus is in a different security domain from this bus and user IDs from the foreign bus are not recognized in this bus

- to locally-control access of inbound messages to this bus.

If this is a secure bus and the foreign bus is not secure, and no inbound user ID is set, any inbound messages from the foreign bus will only be authorized to destinations that allow unauthenticated users access.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	String

### ***Outbound user ID:***

The user ID applied to messages sent to the foreign bus.

The outbound user ID replaces the user ID that identifies the source of a message in all messages being sent to the foreign bus. This user ID is also be used by the foreign bus to authorize the message to its destination if both buses are secure buses and the foreign bus has not overridden the user ID with its own inbound user ID.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	String

## **Additional Properties**

### **Topic space mapping**

The mapping between topic spaces in the local bus and topic spaces in the foreign bus.

---

## **Service integration bus links [Collection]**

This pane displays links between this messaging engine and messaging engines in foreign service integration buses.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] Service integration bus links**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

An individual messaging engine can have links to messaging engines in a number of different foreign buses. However, you can have only one service integration bus link between a pair of buses.

**Status** can take the following values:

Table 225. Status values and definitions. The first column of the table lists the status values of the service integration bus link. The second column contains a brief definition of the status.

Status	Meaning
Starting	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to enable the successful activation of a connection between the buses.
Started	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
Stopped	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
Unknown	The deployment manager cannot contact a remote server to determine the status.

**Name** The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

**Description**

An optional description for the service integration bus link, for administrative purposes.

**UUID** The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

**Local messaging engine**

The local messaging engine that this service integration bus link is hosted on.

**Foreign messaging engine**

The messaging engine on the foreign bus to which this service integration bus link connects.

**Status**

The runtime status of the service integration bus link.

**Current outbound messages**

The current total number of messages queued on the link transmitters to this service integration bus link.

**Messages sent**

The total number of messages sent on the link transmitters to this service integration bus link since the messaging engine was started.

**Current inbound messages**

The current total number of messages queued pending receipt on the link receivers for this service integration bus link.

**Messages received**

The total number of messages received on the link receivers for this service integration bus link since the messaging engine was started.

**Buttons**

Start	Start selected items.
Stop	Stop selected items.

---

## Service integration bus links [Settings]

This pane displays links between this messaging engine and messaging engines in foreign service integration buses.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] Service integration bus links -> *link\_name***

The messaging engine in the foreign bus must also have a service integration bus link to the local bus. For a connection to be active, the service integration bus links at both ends must be started.

- “Configuration tab”
- “Runtime tab” on page 2306

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

#### General Properties

##### **Name:**

The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

<b>Required</b>	Yes
<b>Data type</b>	String

##### **UUID:**

The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

##### **Description:**

An optional description for the service integration bus link, for administrative purposes.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Text area

##### **UUID:**

The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

<b>Required</b>	Yes
<b>Data type</b>	drop-down list

**Local messaging engine:**

The local messaging engine that this service integration bus link is hosted on.

**Required** Yes  
**Data type** drop-down list

**Foreign messaging engine:**

The messaging engine on the foreign bus to which this service integration bus link connects.

**Required** Yes  
**Data type** String

**Initial state:**

The initial state of the link, which shows whether the link is started automatically when the messaging engine is started.

Dynamic updates to this property are effective when the messaging engine is restarted or the service integration bus link is created. Use the Runtime tab to check the current state.

**Required** No  
**Data type** drop-down list  
**Range**

**Stopped**

When the associated messaging engine is started, the gateway link is in a stopped state and cannot process any new requests for connections.

**Started**

When the associated messaging engine is started, the gateway link is in a started state and can process any new requests for connections.

**Exception destination:**

The destination for an inbound message when the service integration bus link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

Dynamic updates to this property are effective immediately.

Select a radio button as required to configure the exception destination that this service integration bus link uses:

- Select **None** to specify that the service integration bus link does not use an exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery to the same destination. This option can be used to preserve message ordering.

- Select **System** to use the default exception destination. Messages that cannot be delivered to the bus destination are rerouted to the system default exception destination for the messaging engine that this link is assigned to: `_SYSTEM.Exception.Destinationmessaging_engine_name`.
- Select **Specify** and enter an exception destination to use the exception destination specified here. If the service integration bus link cannot use this exception destination, it uses the system exception destination.

<b>Required</b>	No
<b>Data type</b>	Radio button
<b>Default</b>	System

***Prefer queue points local to this link's messaging engine:***

When this check box is selected, the link prefers to send inbound messages to available queue points of target destinations that are located on the messaging engine on which the link is hosted.

When this check box is not selected, or if no local queue point is available for a target destination, the link workload balances the messages across all available queue points of the target destination. By default the check box is selected.

This option is supported on links running on WebSphere Application Server Version 7.0 or later. If you are running on an earlier version, the default behavior of preferring local queue points is applied.

<b>Required</b>	Yes
<b>Data type</b>	Boolean

## Related Items

### **JAAS - J2C authentication data .**

Specifies a list of user identities and passwords for Java 2 connector security to use. Refer to Java 2 Connector authentication data entry settings.

### **Foreign bus connection**

The associated foreign bus connection for this service integration bus link.

### **Messaging engine**

The remote messaging engine where this queue point is localized.

### **Link transmitters**

For applications that use point-to-point messaging, there is one link transmission message point located on each messaging engine in the source bus. For applications that use publish/subscribe messaging, there is one link transmission message point located on each topic space in the source bus. The link transmitter acts as a transmission queue where produced messages are persisted before transmission across the inter-bus link to the foreign bus.

## Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### **Status:**

The runtime status of the service integration bus link.

**Status** can take the following values:

*Table 226. Status values and definitions. The first column of the table lists the status values of the service integration bus link. The second column contains a brief definition of the status.*

Status	Meaning
Starting	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to enable the successful activation of a connection between the buses.
Started	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
Stopped	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
Unknown	The deployment manager cannot contact a remote server to determine the status.

**Required**  
**Data type**

No  
String

## Transmitter/Receiver Queues

### Link receivers

For applications that use point-to-point messaging, there is one link receiver for each messaging engine in the foreign bus. For applications that use publish/subscribe messaging, there is one link receiver for each topic space in the foreign bus. The link receiver acts as an inbound receiver queue for a message engine that has applications attached and that is producing messages across this service integration bus link.

### Link transmitters

For applications that use point-to-point messaging, there is one link transmission message point located on each messaging engine in the source bus. For applications that use publish/subscribe messaging, there is one link transmission message point located on each topic space in the source bus. The link transmitter acts as a transmission queue where produced messages are persisted before transmission across the inter-bus link to the foreign bus.

## Target inbound transport chain

The type of transport chain used for communication with the foreign bus.

The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

Dynamic updates to this property are effective when the link is restarted. Use the Runtime tab to check the current state.

**Required**  
**Data type**

No  
String

## Bootstrap endpoints

A comma-separated list of endpoint triplets, with the syntax `hostName:portNumber:chainName`, used to connect to a bootstrap server. For example

`Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging`. If `hostName` is not specified, the default is `localhost`. If `portNumber` is not specified, the default is `7276`. If `chainName` is not specified, the default is `BootstrapBasicMessaging`. Refer to the information center for more information.

This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings.

The port for the bootstrap endpoint is the port defined on the service integration bus endpoint address that is configured on the target application server on the foreign bus.

Dynamic updates to this property are effective when the link is restarted. Use the Runtime tab to check the current state.

You only have to modify this property if you have client applications running outside of an application server, or applications on a server in another cell, that want to use this connection factory to connect to the target service integration bus specified on the connection factory.

To use JMS destinations of the default messaging provider, an application connects to a messaging engine on the target service integration bus to which the destinations are assigned. For example, a JMS queue is assigned to a queue destination on a service integration bus.

Client applications running outside of an application server - for example, running in a client container or outside the WebSphere Application Server environment - cannot locate directly a suitable messaging engine to connect to in the target bus. Similarly, an application running on a server in one cell to connect to a target bus in another cell cannot locate directly a suitable messaging engine to connect to in the target bus.

In these scenarios, the clients (or servers in another bus) must complete a bootstrap process through a *bootstrap server* that is a member of the target bus. A bootstrap server is an application server running the SIB Service, but does not have to be running any messaging engines. The bootstrap server selects a messaging engine that is running in an application server that supports the required *target transport chain*. For the bootstrap process to be possible, you must configure one or more *provider end points* in the connection factory used by the client.

A bootstrap server uses a specific port and bootstrap transport chain. The port is the **SIB\_ENDPOINT\_ADDRESS** (or **SIB\_ENDPOINT\_SECURE\_ADDRESS** if security is enabled), of the messaging engine that hosts the remote end of the link. Together with host name, these form the *endpoint address* of the bootstrap server.

The properties of a JMS connection factory used by an application control the selection of a suitable messaging engine and how the application connects to the selected messaging engine.

- If no security credentials are provided, then by default
  - If no host is specified then localhost is used
  - If no port is specified then port 7276 is used
  - If no bootstrap channel chain is specified then bootstrap transport chain called `BootstrapBasicMessaging` is used
- If security credentials are provided, then by default
  - If no host is specified then localhost is used
  - If no port is specified then port 7286 is used
  - If no bootstrap channel chain is specified then bootstrap transport chain called `BootstrapBasicMessaging` is used

If you want an application to use a bootstrap server with a different endpoint address, you must specify the required endpoint address on the **Provider endpoints** property of the JMS connection factories that the client application uses. You can specify one or more endpoint addresses of bootstrap servers.

The endpoint addresses for bootstrap servers must be specified in every JMS connection factory that is used by applications outside of an application server. To avoid having to specify a long list of bootstrap

servers, you can provide a few highly-available servers as dedicated bootstrap servers. Then you only have to specify a short list of bootstrap servers on each connection factory.

**Note:** When configuring a connection to a non-default bootstrap server, specify the required values for the endpoint address and use colons as separators.

For example: for a server assigned non-secure port 7278, on host `boothost1`, that uses the default transport chain `BootstrapBasicMessaging`:

```
boothost1:7278:BootstrapBasicMessaging
or
boothost1:7278
```

and for a server assigned secure port 7289, on host `boothost2`, that uses the predefined transport chain `BootstrapTunneledSecureMessaging`:

```
boothost2:7289:BootstrapTunneledSecureMessaging
```

The syntax for an endpoint address is as follows:

```
[[host_name] [":" [port_number] [":" chain_name]]]
```

where:

*host\_name*

is the name of the host on which the server runs. It can be an IP address. For an IPv6 address, put square braces ([]) around *host\_name* as shown in the example below:

```
[2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
```

. If a value is not specified, the default is localhost.

*port\_number*

where specified, is one of the following addresses of the messaging engine that hosts the remote end of the link:

- **SIB\_ENDPOINT\_ADDRESS** if security is not enabled
- For secure connections, **SIB\_ENDPOINT\_SECURE\_ADDRESS** if security is enabled.

If *port\_number* is not specified, the default is 7276.

To find either of these values by using the administrative console, click **Servers -> Server Types -> WebSphere application servers -> server\_name -> [Communications] Ports**.

*chain\_name*

is the name of a predefined bootstrap transport chain used to connect to the bootstrap server. If not specified, the default is `BootstrapBasicMessaging`.

The following predefined bootstrap transport chains are provided:

#### **BootstrapBasicMessaging**

This corresponds to the server transport chain `InboundBasicMessaging` (JFAP-TCP/IP)

#### **BootstrapSecureMessaging**

This corresponds to the server transport chain `InboundSecureMessaging` (JFAP-SSL-TCP/IP)

#### **BootstrapTunneledMessaging**

Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers -> Server Types -> WebSphere application servers -> server\_name -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

#### **BootstrapTunneledSecureMessaging**

Before you can use this bootstrap transport chain, you must define a corresponding server

transport chain on the bootstrap server. (See **Servers -> Server Types -> WebSphere application servers -> *server\_name* -> [Server messaging] Messaging engine inbound transports.**) This transport chain tunnels JFAP and uses HTTP wrappers.

Specifying *host\_name : chain\_name* instead of *host\_name : : chain\_name* (with two colons) is incorrect. It is valid to enter nothing, or to enter any of the following: "a", "a:", ":7276", "::chain", and so on. The default value applies if you do not specify a value, but you must separate the fields with ":"s.

If you want to provide more than one bootstrap server, identify all the required endpoint addresses. Separate each endpoint address by a comma character. For example, to use the servers from the earlier example:

```
boothost1:7278:BootstrapBasicMessaging,
boothost2:7289:BootstrapTunneledSecureMessaging,
[2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
```

<b>Required</b>	No
<b>Data type</b>	Text area

## Authentication alias

The name of the authentication alias, used to authenticate access to the foreign bus.

You must have predefined a Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) authentication alias.

Dynamic updates to this property are effective when the link is restarted. Use the Runtime tab to check the current state.

Modified aliases are only visible after a server restart.

<b>Required</b>	No
<b>Data type</b>	drop-down list

---

## Subscriptions [Collection]

The active subscriptions for the topic space.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *topic\_space\_name* -> [Message points] Publication points -> *publication\_point\_name* -> Runtime -> Subscriptions.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Name** The name by which the active subscription is known for administrative purposes.

**Identifier**

The identifier by which this destination is known for administrative purposes.

**Topic** The name of the topic that this subscription is for.

### Queue Depth

The number of messages currently associated with this subscription.

### Buttons

Delete	Delete the selected items.
--------	----------------------------

---

## Broker profile subscriptions [Collection]

The list of current broker subscriptions for this broker profile.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile\_name* -> Runtime > Subscriptions.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Topic name

The topic name for this subscription.

### Topic space

The topic space for this subscription.

### Direction

Whether the subscription is for message flows to or from WebSphere MQ.

### Broker stream queue

The name of the WebSphere MQ broker stream queue that the topic publishes messages to.

### Subscription point

The name of the WebSphere MQ broker subscription point that the topic consumes messages from.

### Message count

The count of messages for this subscription.

### Status

The current status of this subscription.

### Buttons

Unsubscribe	Cancel all subscriptions.
-------------	---------------------------

---

## Subscriptions [Settings]

The active subscriptions for the topic space.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *topic\_space\_name* -> [Message points] Publication points -> *publication\_point\_name* -> Runtime -> Subscriptions -> *subscription\_name*.

- “Runtime tab”

## Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## Buttons

Refresh	Refresh the number of messages.
---------	---------------------------------

## General Properties

### **Name:**

The name by which the active subscription is known for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

### **Identifier:**

The identifier by which this destination is known for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

### **Topic:**

The name of the topic that this subscription is for.

<b>Required</b>	No
<b>Data type</b>	Text area

### **Selector:**

The text string that must be present in a message for the mediation to process the message.

<b>Required</b>	No
<b>Data type</b>	String

### **Current message depth:**

The number of messages on the message point.

<b>Required</b>	No
<b>Data type</b>	String

### **Subscriber ID:**

<b>Required</b>	No
<b>Data type</b>	String

## **Additional Properties**

### **Messages**

Messages being handled by this subscription.

### **Known remote subscription points**

The remote messaging engines that have remote consumers connected to this subscription point.

---

## **Temporary destination prefixes [Collection]**

A temporary destination prefix is a user-defined string that is used to create a temporary destination. When messaging security is enabled, users and groups require authority to create messages and send them to temporary destinations. The authority is configured in the temporary destination prefix.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Manage temporary destination prefix access roles**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

A list of all the temporary destination prefixes defined for the selected service integration bus is displayed. By default, the list is empty. Use this pane to create a new temporary destination prefix, and define its role type assignments, or remove existing temporary destination prefixes. You can also manage the role type assignments for existing temporary destination prefixes:

- To act on a single temporary destination prefix, click its name in the list.
- To act on more than one temporary destination prefix, select the check box next to the name of each destination you want to act on, then click **Manage Access Roles**.

### **Temporary destination prefix**

The name of each temporary destination prefix defined for the selected bus.

## **Buttons**

Manage Access Roles	Click to view and manage users and groups assigned to the access role types for the selected resources.
Add	Click to create a temporary destination prefix, and add users and groups to it.
Remove	Click to remove selected users and groups from all the role types for this resource.

---

## Temporary destination prefixes [Settings]

This pane displays the role type assignments for the selected temporary destination prefixes.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Manage temporary destination prefix access roles -> *temporary\_destination\_prefix* > Manage access roles**

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

A list of users and groups that have been added to access roles for the selected temporary destination prefixes is displayed. The access role information for the selected temporary destination prefix is contained within an expandable section. The access roles for temporary destination prefixes are creator and receiver. Users and groups in the creator role can create a new temporary destination prefix. You cannot remove users and groups from the creator role.

Use this pane to complete the following tasks:

- View users and groups that have creator and sender roles for a selected temporary destination prefix.
- Add or remove users and groups in the sender role for a selected temporary destination prefix.

### General Properties

**Select** A check box that you can use to select the users and groups for which you want to manage access roles.

**Name** The name of the user or group that has an access role for the selected resource. If the user is a group member, the user ID and the group name is displayed.

**Type** The type of the user or group. There are three types of user or group: “user”, “group” and “member”. A user that inherits its access roles from a group has the type “member”.

#### Sender

Whether a user, group or member is in the sender role for a selected resource.

#### Creator

Read only. The user or group is in the creator role for a selected temporary destination prefix. You cannot change this role type assignment.

### Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 227. Interacting with access role icons

Access role icon	Access role assignment state	User action
<input type="checkbox"/>	Role type not set.	Click to change to role type set  .
<input checked="" type="checkbox"/>	Role type set.	Click to change to role type not set. The icon changes to role type not set <input type="checkbox"/> if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set  .
<input type="checkbox"/>	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
<input checked="" type="checkbox"/>	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

## Topic Mapping [Collection]

The mapping between a topic on the service integration bus and a stream queue and subscription point provided by a WebSphere MQ broker.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile\_name* -> [Additional Properties] Topic mappings.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Dynamic updates to this list are effective immediately.

### Topic name

The name of the topic on the service integration bus. The name must be the same as the topic name on the message broker in a WebSphere MQ network.

### Topic space

The name of the topic space that contains the topic.

### Direction

Whether the mapping is for publishing message flows in both directions, or only to, or only from, WebSphere MQ.

### Broker stream queue

The name of the stream queue at the message broker in a WebSphere MQ network.

### Subscription point

The name of the WebSphere MQ broker subscription point that the topic consumes messages from.

### Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

---

## Topic Mapping [Settings]

The mapping between a topic on the service integration bus and a stream queue and subscription point provided by a WebSphere MQ broker.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile\_name* -> [Additional Properties] Topic mappings -> *mapping\_name*.**

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Topic name:**

The name of the topic on the service integration bus. The name must be the same as the topic name on the message broker in a WebSphere MQ network.

You can specify wildcard characters in topic name strings.

<b>Required</b>	Yes
<b>Data type</b>	String

#### **Topic space:**

The name of the topic space that contains the topic.

<b>Required</b>	No
<b>Data type</b>	drop-down list

#### **Direction:**

Whether the mapping is for publishing message flows in both directions, or only to, or only from, WebSphere MQ.

<b>Required</b>	No
<b>Data type</b>	drop-down list

**Range****Bi-directional**

Messages flow in both directions between the bus and WebSphere MQ.

**To WebSphere MQ**

Messages flow only from the bus to WebSphere MQ.

That is, from WebSphere Application Server to a message broker in the WebSphere MQ network.

**From WebSphere MQ**

Messages flow only to the bus from WebSphere MQ.

That is, from a message broker in the WebSphere MQ network to WebSphere Application Server.

***Broker stream queue:***

The name of the stream queue at the message broker in a WebSphere MQ network.

The broker stream queue in this instance is a queue on the WebSphere MQ queue manager to which the message broker is connected. This queue is being used as the input node for a message flow containing a publication node. Messages sent to this queue are processed by the message broker, then published to applications that have subscribed on the topic specified in the message.

Stream names are case sensitive.

After you type a new name, then save your changes, the name becomes available for selection in the drop-down list.

<b>Required</b>	No
<b>Data type</b>	Custom

***Subscription point:***

The name of the WebSphere MQ broker subscription point that the topic consumes messages from.

Type the name of the WebSphere MQ message broker subscription point from which the service integration bus receives messages.

After you type a new name, then save your changes, the name becomes available for selection in the drop-down list.

<b>Required</b>	No
<b>Data type</b>	Custom

---

**Topic [Settings]**

This pane displays the role type assignments for a topic. You can use this pane to add new assignments, and to modify and remove existing assignments.

To view this page in the console, click the following path:

**Service integration -> Buses -> security\_value -> [Authorization Policy] Manage topic access roles -> topic\_space\_name > topic\_name.**

In the path, security\_value is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane lists users and groups that have been assigned role types on the selected topic. The permitted access roles for topics are sender and receiver. Use this panel to view existing topic role assignments, add new users and groups to topic access roles, and remove users and groups from topic access roles.

The information for the selected topic is contained within a section that you can expand to display all the users and groups that have been assigned role types for the topic. The following options are available:

**Inherit sender role from parent topic**

Select the check box if you want the topic to inherit sender role assignments from the parent topic.

**Inherit receiver role from parent topic**

Select the check box if you want the topic to inherit receiver role assignments from the parent topic.

**General Properties**

**Select** A check box that you can use to select the users and groups for which you want to manage access roles.

**Name** The name of the user or group that has an access role for the selected resource. If the user is a group member, the user ID and the group name is displayed.

**Type** The type of the user or group. There are three types of user or group: “user”, “group” and “member”. A user that inherits its access roles from a group has the type “member”.

**Sender**

Whether a user, group or member is in the sender role for a selected resource.

**Receiver**

Whether a user, group or member is in the receiver role for a selected resource.

**Security access roles**

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

*Table 228. Interacting with access role icons*

Access role icon	Access role assignment state	User action
<input type="checkbox"/>	Role type not set.	Click to change to role type set <input checked="" type="checkbox"/> .

Table 228. Interacting with access role icons (continued)

Access role icon	Access role assignment state	User action
	Role type set.	Click to change to role type not set. The icon changes to role type not set <input type="checkbox"/> if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set <input checked="" type="checkbox"/> .
<input type="checkbox"/>	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
<input checked="" type="checkbox"/>	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

## Buttons

Add	Click to add users and groups to this resource.
Remove	Click to remove selected users and groups from all the role types for this resource.

## Topic space map entries [Collection]

The mapping between a topic space in the local bus and a topic space in the foreign bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Additional Properties] Service integration bus link routing properties -> [Additional Properties] Topic space map entries.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus, an equivalent topic space mapping is required by the foreign bus.

Dynamic updates to this list are effective immediately.

### Local topic space

The name of the topic space on this (local) bus that is mapped to the remote topic space on the foreign bus.

### Remote topic space

The name of the topic space on the foreign bus that is mapped to the local topic space.

## Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

---

## Topic space map entries [Settings]

The mapping between a topic space in the local bus and a topic space in the foreign bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Additional Properties] Service integration bus link routing properties -> [Additional Properties] Topic space map entries -> *map\_entry\_name*.**

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus an equivalent topic space mapping is required by the foreign bus.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### *Local topic space:*

The name of the topic space on this (local) bus that is mapped to the remote topic space on the foreign bus.

<b>Required</b>	Yes
<b>Data type</b>	Custom

#### *Remote topic space:*

The name of the topic space on the foreign bus that is mapped to the local topic space.

<b>Required</b>	Yes
<b>Data type</b>	String

---

## Topic space mapping [Settings]

The mapping between topic spaces in the local bus and topic spaces in the foreign bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile\_name* -> [Additional Properties] Topic space mapping.**

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus an equivalent topic space mapping is required by the foreign bus.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### *Description:*

An optional description for the topic space mapping, for administrative purposes.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Text area

### Additional Properties

#### **Topic space map entries**

The mapping between topic spaces in the local bus and topic spaces in the foreign bus.

---

## Topic space [Settings]

A topic space is a location for publish/subscribe messaging.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *topic\_space\_name*.**

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### *Identifier:*

The identifier by which this destination is known for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

#### *UUID:*

The universal unique identifier assigned by the system to this destination for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

#### *Type:*

Whether this bus destination is for a queue, topic space, or some other type of destination.

A topic space for publish/subscribe messaging.

<b>Required</b>	No
<b>Data type</b>	String

***Description:***

An optional description for the bus destination, for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	Text area

***Mediation:***

The name of the mediation that mediates this destination.

<b>Required</b>	No
<b>Data type</b>	String

***Enable producers to override default reliability:***

Select this option to enable producers to override the default reliability that is set on the destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Default reliability:***

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

<b>Required</b>	No
<b>Data type</b>	drop-down list

**Range**

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

**Maximum reliability:**

The maximum reliability of messages accepted by this destination.

**Required**

No

**Data type**

drop-down list

**Range**

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

**Default priority:**

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 9

### ***Exception destination:***

Use these properties to define what happens to any messages that cannot be delivered to this destination.

#### ***None:***

The bus destination does not use an exception destination and undeliverable messages are not rerouted to an exception destination.

Attempts to redeliver the message continue, up to the maximum failed deliveries limit set for the bus destination. Then, attempts to redeliver the message continue with a time interval between retry attempts. This interval is either the Default blocked destination retry interval of the messaging engine that is associated with this destination, or the Blocked retry timeout that is set for this destination. The Default blocked destination retry interval value can be used by all queue and topic destinations associated with this messaging engine. To set a time interval specifically for this destination, select **Override messaging engine blocked retry timeout default**, then enter a blocked retry timeout value for this destination.

<b>Required</b>	No
<b>Data type</b>	Radio button
<b>Default</b>	Not selected

### ***Override messaging engine blocked retry timeout default:***

Override the blocked queue retry interval configured on the messaging engine owning the destination.

Select this property to set the blocked retry timeout for this destination. This property is available only when **None** is selected for the exception destination.

<b>Required</b>	Yes, if <b>None</b> is selected.
<b>Data type</b>	Boolean
<b>Default</b>	Unchecked. The Default blocked destination retry interval value of the associated messaging engine is used.

### ***Blocked retry timeout in milliseconds:***

When no exception destination is configured, the time interval to apply between retry attempts, after the maximum failed deliveries limit is reached, for this destination.

This property is available only when **Override messaging engine blocked retry timeout default** is selected in the exception destination properties.

<b>Required</b>	Yes, if Override messaging engine blocked retry timeout default is checked.
<b>Data type</b>	Integer

### ***System:***

The bus destination uses the system default exception destination.

Undeliverable messages are routed to the system default exception destination of the messaging engine that detects the problem: `_SYSTEM.Exception.Destination.messaging_engine_name`.

<b>Required</b>	No
<b>Data type</b>	Radio button
<b>Default</b>	Selected

***Specify:***

Select this property to configure a specific exception destination.

The exception destination must be a queue, on the same bus or a foreign bus, and must exist when the exception destination processing is configured.

<b>Required</b>	No
<b>Data type</b>	Radio button
<b>Default</b>	Not selected

***Maximum failed deliveries per message:***

The maximum number of failed attempts to process a message. After this number of failed attempts, if an exception destination is configured, the message is forwarded from the intended destination to its exception destination. If an exception destination is not configured, a time interval between retry attempts is applied.

This interval is either the Default blocked destination retry interval of the messaging engine that is associated with this destination, or the Blocked retry timeout that is set for this destination.

<b>Required</b>	Yes, if an exception destination has been configured.
<b>Data type</b>	Integer
<b>Default</b>	5
<b>Range</b>	0 through 2147483647

***Send allowed:***

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Receive allowed:***

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Maintain strict message order:***

Enabling this option will maintain the strict ordering of messages for this destination.

<b>Required</b>	No
<b>Data type</b>	Custom

***Reply destination:***

The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination.

<b>Required</b>	No
<b>Data type</b>	String

***Reply destination bus:***

The bus on which the reply destination exists.

<b>Required</b>	No
<b>Data type</b>	String

***Allow auditing of Topic access checks:***

This option is only available if bus and cell level auditing are enabled. Check to enable auditing of Topic access checks.

<b>Required</b>	No
<b>Data type</b>	Boolean

**Topic access check required**

Whether or not authorization checks are required for access to topics.

When security is on, authorization checks are always performed at the topic space level. To add additional control, you can select this property to enable authorization checks at the topic level.

<b>Required</b>	No
<b>Data type</b>	Boolean

**Message points**

**Publication points**

A publication point is created on each messaging engine in the bus when a publish/subscribe destination is created. The publication point on a messaging engine is used to hold messages published by applications connected to that messaging engine until they are delivered to subscribers.

**Mediation points**

The mediation points for the topic space. The locations in the messaging engine at which messages on the topic space are mediated.

**Additional Properties**

**Context properties**

Context information passed to the mediation.

## Related Items

### Application resources topology

A expandable tree view of all applications and messaging resources that reference the current destination.

### Audit Service

Configure the global audit settings

---

## Topic spaces [Collection]

Topics are defined hierarchically within topic spaces. To view the access roles for a topic, first select the topic space that contains the topic to be viewed.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Manage topic access roles.**

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

The Topic spaces pane displays a list of topic spaces defined on the selected bus. A topic space is a hierarchy of topics used for publish/subscribe messaging. Use this pane to select the topic space that contain the topics for which you want to add, remove or modify role type assignments.

### Topic space

The name of each topic space defined for the selected bus.

---

## Topics [Collection]

Topics are defined hierarchically within topic spaces. To view a topic's access roles, select the topic from the hierarchical list of topics below.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Manage topic access roles**

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled. The Topics pane displays a list of topics defined for the selected topic space. The topics are displayed hierarchically beneath the root (/) topic. You can expand the topic space name to display all the topics, or collapse it to display the root topic only. By default, a topic space does not contain any topics. Use **Add** to add a new topic to the selected topic space, and to define its role type assignments.

**Topic** The name of each topic defined in the selected topic space.

## Buttons

Add	Click to create a topic, and add users and groups to it.
Show all	Click to expand a section to display a hierarchical list of all the topics defined in the topic space, starting with the root (/) topic.
Hide all	Click to collapse a section to display the root (/) topic only.

---

## Topics [Collection]

The topics that have been subscribed to from this remote messaging engine.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Remote message points] Remote publication points > > *identifier\_name* -> [Outbound properties] Topics.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**Topic** View the outbound topics for this publication point.

### Buttons

Clear all	Clear all messages from this message point.
-----------	---------------------------------------------

---

## Unknown user or group [Settings]

This panel lists users and groups that do not exist in the user repository but have access role definitions.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Manage users and groups not known to the user repository -> *user\_name* > Remove roles**

The Unknown users and groups pane lists access roles for bus resources that have been assigned to selected unknown users and groups.

The access role information for each unknown user or group is contained within an expandable section.

### General Properties

#### Resource

The selected unknown user or group has access roles for this bus resource.

#### Sender

Whether a user, group or member is in the sender role for a selected resource.

#### Receiver

Whether a user, group or member is in the receiver role for a selected resource.

#### Browser

Whether a user, group or member is in the browser role for a selected resource.

#### Creator

Whether a user, group or member is in the creator role for a selected resource.

#### Bus connector

Whether a user, group or member is in the bus connector role for a selected resource.

## Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 229. Interacting with access role icons

Access role icon	Access role assignment state	User action
	Role type not set.	Click to change to role type set  .
	Role type set.	Click to change to role type not set. The icon changes to role type not set  if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set  .
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

## Buttons

Remove	Click to remove access roles from the selected user or group.
--------	---------------------------------------------------------------

## Unknown users and groups [Collection]

The users and groups displayed here are not defined in the user registry, but do have roles defined. This could be because they were removed from the user repository after the role assignments were made.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Manage users and groups not known to the user repository**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane displays a list of user and group names that were previously created in the user repository, and granted access roles to selected resources, but the user and group names have since been removed from the user repository. Use this pane to remove the role type assignments from one or more users and groups that no longer exist in the user repository:

- To work with a single unknown user or group name, click the user or group name.
- To work with more than one unknown user or group name, select the check box in the **Select** column for each unknown user or group name, and click **Remove roles**.

**Name** The name of a user that has an access role definition, but is not defined in the user registry.

**Type** Whether the user is a user, a group, or a group member.

### Buttons

Remove roles	Click to remove access roles from the selected user or group.
--------------	---------------------------------------------------------------

---

## Users and groups in the bus connector role [Collection]

Users in the bus connector role are able to connect to the bus to perform messaging operations. Users can have this role either by specifically having that role, or because they are in a group with that role.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Users and groups in the bus connector role.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

**Name** The name of the user or group in the bus connector role.

**Type** The type of the user or group in the bus connector role.

### Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

---

## Add a user or group to the bus connector role [Settings]

Create a user or group in the bus connector role.

To view this page in the console, click the following path:

**Service integration -> Buses -> *security\_value* -> [Authorization Policy] Users and groups in the bus connector role -> *member\_name*.**

In the path, *security\_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

When messaging security is enabled, users must be authorized to connect to a local service integration bus before they can carry out messaging operations. To authorize a user or a group to connect to a local bus, you add the user or group name to the bus connector role for the bus. After the user connects to the bus, then can access local bus destinations, and send messages to destinations on foreign buses.

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### ***Bus Connector Role:***

The bus connector role. Users in this role are able to connect to the bus to perform messaging operations.

Select one of the options provided to choose the bus connector role. A user in the bus connector role has the authority to connect to the local service integration bus, and can carry out messaging operations at destinations on the bus.

<b>Required</b>	No
<b>Data type</b>	Custom

## Range

### Group name

Give a specific group the bus connector role. All users in the group can connect to the bus, and use it to undertake messaging operations. Type the name of the group in the field provided.

### User name

Give a user the bus connector role. Users with the specified user ID can connect to the bus, and use it to perform messaging operations. Type the user ID in the field provided.

### Server - Allow servers to connect to the bus

Give all application servers the bus connector role. This represents the identity of a WebSphere Application Server. This can be used by message-driven beans that want message delivery, without specifying an authentication alias, in a secured bus.

### All Authenticated - Allow all authenticated users to connect to the bus

Give only *authenticated* users the bus connector role. All users that have authenticated to the bus can use it to undertake messaging operations. This results in the group "AllAuthenticated" being added to the authorization model.

### Everyone - Allow unauthenticated users to connect to the bus

Give all users the bus connector role. All users that have connected to the bus can use it to undertake messaging operations. If this option is selected, then users are able to connect to the bus without authenticating. These users are treated as anonymous users.

---

## Web service [Settings]

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Destination resources] Destinations -> *web\_service\_name*.**

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### Identifier:

The identifier by which this destination is known for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

**UUID:**

The universal unique identifier assigned by the system to this destination for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

**Type:**

Whether this bus destination is for a queue, topic space, or some other type of destination.

<b>Required</b>	No
<b>Data type</b>	String

**Description:**

An optional description for the bus destination, for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	Text area

**Mediation:**

The name of the mediation that mediates this destination.

<b>Required</b>	No
<b>Data type</b>	String

**Default reliability:**

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

<b>Required</b>	No
<b>Data type</b>	drop-down list

**Range**

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

**Maximum reliability:**

The maximum reliability of messages accepted by this destination.

**Required**  
**Data type**  
**Range**

No  
drop-down list

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

**Enable producers to override default reliability:**

Select this option to enable producers to override the default reliability that is set on the destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Default priority:***

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

<b>Required</b>	No
<b>Data type</b>	Custom

***Exception destination:***

Use these properties to define what happens to any messages that cannot be delivered to this destination.

Use this property to define what happens to any messages that cannot be delivered to this destination.

By default, such messages are routed to the system default exception destination of the messaging engine that discovers the problem: `_SYSTEM.Exception.Destination.engine_name`.

If you want messages to be sent to another exception destination, select Specify then type the exception destination name. The exception destination must be a queue, on the same bus or a foreign bus, and must exist when the destination is created.

If you do not want undeliverable messages to be sent to an exception destination, select None.

<b>Required</b>	No
<b>Data type</b>	String and Boolean

***Send allowed:***

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Receive allowed:***

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Receive exclusive:***

Select this option to allow only one consumer to attach to each message point. If this option is not selected multiple consumers will be allowed to attach and receive messages from each message point.

<b>Required</b>	No
<b>Data type</b>	Boolean

### ***Maintain strict message order:***

Enabling this option will maintain the strict ordering of messages for this destination.

<b>Required</b>	No
<b>Data type</b>	Custom

## **Additional Properties**

### **Context properties**

Context information passed to the mediation.

## **Message points**

### **Mediation points**

A mediation point is a location in a messaging engine at which messages are mediated. A mediation point is created when a mediation is associated with a bus destination.

---

## **Client connections [Collection]**

The connection between a WebSphere MQ client and the bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] WebSphere MQ client links -> *link\_name* [Additional Properties] Client connections.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This panel lists all the connections for clients that use the related WebSphere MQ client link. You can select one or more connections to display more detail about their runtime status, or to stop them while leaving other connections active.

### **IP address**

The TCP/IP IP address of the WebSphere MQ client.

### **Status**

The runtime status of the WebSphere MQ client connection.

---

## **WebSphere MQ client connection [Settings]**

The connection between a WebSphere MQ client and the bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] WebSphere MQ client links -> *link\_name* [Additional Properties] Client connections -> *connection\_name*.**

- “Runtime tab” on page 2337

## Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### ***IP address:***

The TCP/IP IP address of the WebSphere MQ client.

<b>Required</b>	No
<b>Data type</b>	String

#### ***Status:***

The runtime status of the WebSphere MQ client connection.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	

#### **Inactive**

The WebSphere MQ client link is ready and enabled to receive inbound connections from clients, but no client connections have yet been established.

#### **Stopped**

The WebSphere MQ client link is in a stopped state and cannot process any new requests for inbound connections from clients.

#### **Starting**

The WebSphere MQ client link has received an inbound connection from a client, and is in the process of starting this connection.

#### **Binding**

The WebSphere MQ client link is performing channel negotiation and is not yet ready to transfer messages.

#### **Running**

The WebSphere MQ client link has an active session with a client, and data can be flowing between the client and the WebSphere MQ client link.

#### **Stopping**

The WebSphere MQ client link, or a connection with that link, is in the process of being stopped.

#### **Multiple**

The WebSphere MQ client link has established sessions with several clients, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

***Number of messages sent:***

The number of messages sent on the WebSphere MQ client link over the connection to a specific client.

<b>Required</b>	No
<b>Data type</b>	String

***Number of messages received:***

The number of messages received on the WebSphere MQ client link over the connection from a specific client.

<b>Required</b>	No
<b>Data type</b>	String

***Number of buffers sent:***

The number of message buffers sent on the WebSphere MQ client link over the connection to a specific client.

<b>Required</b>	No
<b>Data type</b>	String

***Number of buffers received:***

The number of message buffers received on the WebSphere MQ client link over the connection from a specific client.

<b>Required</b>	No
<b>Data type</b>	String

***Number of bytes sent:***

The number of bytes sent on the WebSphere MQ client link over the connection to a specific client.

<b>Required</b>	No
<b>Data type</b>	String

***Number of bytes received:***

The number of bytes received on the WebSphere MQ client link over the connection from a specific client.

<b>Required</b>	No
<b>Data type</b>	String

***Channel start time:***

The time at which the client connection channel was started.

<b>Required</b>	No
<b>Data type</b>	String

***Channel start date:***

The date on which the client connection channel was started.

<b>Required</b>	No
<b>Data type</b>	String

***Last message send time:***

The time at which the last message was sent on the client connection channel.

<b>Required</b>	No
<b>Data type</b>	String

***Last message send date:***

The date on which the last message was sent on the client connection channel.

<b>Required</b>	No
<b>Data type</b>	String

***Last message receive time:***

The time at which the last message was received on the client connection channel.

<b>Required</b>	No
<b>Data type</b>	String

***Last message receive date:***

The date on which the last message was sent on the client connection channel.

<b>Required</b>	No
<b>Data type</b>	String

***Heartbeat interval:***

The time, in seconds, between heartbeat flows passed from the WebSphere MQ client link to the WebSphere MQ classes for JMS that process JMS requests issued by the client application. This allows the WebSphere MQ client link to handle situations where the client connection created by the WebSphere MQ classes for JMS fails during a request.

<b>Required</b>	No
<b>Data type</b>	String

***Maximum message length:***

The maximum message length, in bytes, that can be transmitted using the WebSphere MQ client link. This is compared with the value for the partner WebSphere MQ client channel and the actual maximum used is the lower of the two values.

<b>Required</b>	No
<b>Data type</b>	String

### ***Stop requested:***

Whether or not a manual stop request has been made for the WebSphere MQ client link connection.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	<b>true</b> The channel is in doubt about which messages have been committed by WebSphere MQ for the unit of work that it has sent. <b>false</b> The channel is not in doubt about which messages have been committed by WebSphere MQ.

### ***Local address:***

The local address of the WebSphere MQ client connection.

<b>Required</b>	No
<b>Data type</b>	String

### ***Number of API calls serviced:***

The number of API calls serviced for the WebSphere MQ client connection.

<b>Required</b>	No
<b>Data type</b>	String

---

## **WebSphere MQ client link advanced properties [Settings]**

Advanced configurable properties, such as message reliability and broker queue names, for the WebSphere MQ client link.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] WebSphere MQ client links -> *link\_name* -> [Advanced properties] > *property\_name*.**

## **Configuration tab**

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## **General Properties**

### ***Inbound persistent message reliability:***

The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ client link, from Reliable to Assured, in order of increasing reliability.

**Required**  
**Data type**  
**Range**

No  
drop-down list

**Reliable**

Messages might be discarded when a messaging engine fails.

**Assured**

Messages are not discarded.

***Inbound nonpersistent message reliability:***

The acceptable reliability of message delivery for inbound nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability.

**Required**  
**Data type**  
**Range**

No  
drop-down list

**Best effort**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable**

Messages are discarded when a messaging engine stops or fails.

***Broker control queue:***

The name of the message broker control queue to which all command messages (except publications and requests to delete publications) are sent.

Publisher and subscriber applications, and other brokers, send all command messages (except publications and requests to delete publications) to this queue.

**Required**  
**Data type**

No  
Text

***Broker publication queue:***

The name of the message broker publication queue to which all publication messages for the default stream are sent.

This is the name of the broker input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

<b>Required</b>	No
<b>Data type</b>	Text

***Broker subscription queue:***

The name of the message broker subscription queue from which nondurable subscription messages are retrieved.

This is the broker queue from which nondurable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

<b>Required</b>	No
<b>Data type</b>	Text

***Broker durable subscription queue:***

The name of the message broker durable subscription queue from which durable subscription messages are retrieved.

This is the broker queue from which durable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a durable subscription.

<b>Required</b>	No
<b>Data type</b>	Text

***Broker connection consumer subscription queue:***

The name of the message broker connection consumer subscription queue from which nondurable subscription messages are retrieved for a connection consumer request.

This is the name of the broker queue from which nondurable subscription messages are retrieved for a ConnectionConsumer request.

<b>Required</b>	No
<b>Data type</b>	Text

***Broker connection consumer durable subscription queue:***

The name of the message broker connection consumer durable subscription queue from which nondurable subscription messages are retrieved for a connection consumer request.

This is the name of the broker queue from which durable subscription messages are retrieved for a ConnectionConsumer request.

<b>Required</b>	No
<b>Data type</b>	Text

***Default topic space:***

The name of the default topic space for the WebSphere MQ client link.

This topic space is used for publish/subscribe messages sent to Version 5.1 JMS topics for which the JMS topic connection factory connects to the node on which this WebSphere MQ client link is configured.

**Required**  
**Data type**

No  
Text

---

## WebSphere MQ client links [Collection]

A WebSphere MQ client link presents the messaging engine, and therefore the bus, as a WebSphere MQ queue manager to which WebSphere MQ clients can attach. This behavior enables WebSphere Application Server Version 5 JMS clients to use messaging resources on the bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] WebSphere MQ client links.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

**Name** The name of the WebSphere MQ client link.

### Description

An optional description for the WebSphere MQ client link, for administrative purposes.

### MQ channel name

The name of the channel for the WebSphere MQ client link, used to flow messages between WebSphere MQ clients and the bus.

### Queue manager name

The name of the WebSphere MQ queue manager on which the WebSphere MQ sender channel, that is connected to this MQ link receiver channel connection instance, is running.

### Default queue manager

Whether or not this is the default queue manager for the WebSphere MQ clients.

### Status

The runtime status of the WebSphere MQ client link.

## Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.
Start	Start selected items.  This button does not work if the selected WebSphere MQ client link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

Table 230. Stop modes. The table contains information about the target states and the corresponding stop mode behavior. There are two target states such as inactive and stopped, and there are two stop modes such as quiesce and force. The two rows in the table represent the two target states, and the two columns describes the two stop mode behaviors for each of the target state.

		Stop mode	
		Quiesce	Force
Target state	Inactive	The sender channel becomes inactive either when it has finished processing its current batch, or when it reaches a heartbeat interval.	The sender channel immediately becomes inactive.
	Stopped	The sender channel becomes stopped either when it has finished processing its current batch, or when it reaches a heartbeat interval.	The sender channel immediately becomes stopped.

This button does not work if the selected WebSphere MQ client link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

---

## WebSphere MQ client link [Settings]

A WebSphere MQ client link presents the messaging engine, and therefore the bus, as a WebSphere MQ queue manager to which WebSphere MQ clients can attach. This behavior enables WebSphere Application Server Version 5 JMS clients to use messaging resources on the bus.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional Properties] WebSphere MQ client links -> *link\_name*.**

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

- “Runtime tab”
- “Configuration tab” on page 2345

### Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### Status:

The runtime status of the WebSphere MQ client link.

**Required** No

**Data type**  
**Range**

drop-down list

**Inactive**

The WebSphere MQ client link is ready and enabled to receive inbound connections from clients, but no client connections have yet been established.

**Stopped**

The WebSphere MQ client link is in a stopped state and cannot process any new requests for inbound connections from clients.

**Starting**

The WebSphere MQ client link has received an inbound connection from a client, and is in the process of starting this connection.

**Binding**

The WebSphere MQ client link is performing channel negotiation and is not yet ready to transfer messages.

**Running**

The WebSphere MQ client link has an active session with a client, and data can be flowing between the client and the WebSphere MQ client link.

**Stopping**

The WebSphere MQ client link, or a connection with that link, is in the process of being stopped.

**Multiple**

The WebSphere MQ client link has established sessions with several clients, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

## Additional Properties

### Client connections

The client connections that exist on the WebSphere MQ client link.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

**Name:**

The name of the WebSphere MQ client link.

**Required**  
**Data type**

Yes  
String

**UUID:**

The universal unique identifier assigned by the system to this WebSphere MQ client link for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

**Description:**

An optional description for the WebSphere MQ client link, for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	Text area

**MQ channel name:**

The name of the channel for the WebSphere MQ client link, used to flow messages between WebSphere MQ clients and the bus.

The name of the WebSphere MQ server connection channel that this client link will use to represent itself to clients. It must exactly match the value specified by the client for a connection to be established. For Version 5 embedded messaging clients a value of "WAS.JMS.SVRCONN" must be specified. You should not define two MQ client links that share both channel name and queue manager name. However, it is possible to have client links with identical channel names if they specify different queue manager names.

<b>Required</b>	Yes
<b>Data type</b>	String

**Queue manager name:**

The name of the WebSphere MQ queue manager on which the WebSphere MQ sender channel, that is connected to this MQ link receiver channel connection instance, is running.

The WebSphere MQ client link for use by JMS applications on WebSphere Application Server Version 5.1 has the queue manager name `WAS_nodeName_jmsserver`. You should not use this name on any other WebSphere MQ client link that is assigned to a messaging engine on the same node.

<b>Required</b>	Yes
<b>Data type</b>	String

**Default queue manager:**

Whether or not this is the default queue manager for the WebSphere MQ clients.

If a client does not specify the name of the queue manager it is to connect to, it will be connected to an MQ client link with a matching channel name that has been marked as being the default, if one matching this criterion can be found.

<b>Required</b>	No
<b>Data type</b>	Boolean

**Maximum message size:**

The maximum message length, in bytes, that can be transmitted using the WebSphere MQ client link.

<b>Required</b>	No
<b>Data type</b>	Long
<b>Range</b>	0 through 104857600

### ***Heartbeat interval:***

The time, in seconds, to wait before checking that a client requesting an operation is still active.

This heartbeat interval allows a sending channel to verify that the receiving channel is still active just before committing a batch of messages. If the receiving channel is not active, the batch can be backed out rather than becoming indoubt, as would otherwise be the case. By backing out the batch, the messages remain available for processing so they can, for example, be redirected to another channel.

If the sending channel has had a communication from the receiving channel within the batch heartbeat interval, the receiving channel is assumed to be still active, otherwise a “heartbeat” signal is sent to the receiving channel to check.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 999999

A value of 0 (zero) indicates that the heartbeat mechanism is not used.

### ***Initial state:***

Whether the WebSphere MQ client link is started or stopped when the associated messaging engine is first started. Until started, the WebSphere MQ client link is unavailable.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	

#### **Stopped**

When the associated messaging engine is started, the WebSphere MQ client link is in a stopped state and cannot process any new requests for inbound connections from clients.

#### **Started**

When the associated messaging engine is started, the WebSphere MQ client link is ready and enabled to receive inbound connections.

## **Additional Properties**

### **Advanced properties**

Advanced configurable properties, such as message reliability and broker queue names, for the WebSphere MQ client link.

---

## WebSphere MQ links [Collection]

The WebSphere MQ link connects the messaging engine as a queue manager to WebSphere MQ, providing a bridge between the bus and a WebSphere MQ network.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> [Related Items] WebSphere MQ links**
- **Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

**Name** The name of the WebSphere MQ link, used for administrative purposes.

### Description

An optional description for the WebSphere MQ link, for administrative purposes.

### Local messaging engine

The local messaging engine that this WebSphere MQ link is hosted on.

### Virtual queue manager name

The virtual queue manager name by which the local bus is to be known to a WebSphere MQ network. It is generally recommended that you set the virtual queue manager name to match the name of the local bus. As WebSphere MQ queue manager names can be no longer than 48 characters, you must ensure that the length of the local bus name does not exceed 48 characters.

### Status

The runtime status of the WebSphere MQ link.

**Status** can take the following values:

*Table 231. Status definitions. The first column of the table lists the status values of WebSphere MQ link. The second column contains a brief definition of the status.*

Status	Meaning
Running	The WebSphere MQ link is running.
Stopped	The WebSphere MQ link is stopped.

### Current outbound messages

The current total number of messages queued on the sender channel transmitter and link transmitters for this WebSphere MQ link.

### Messages sent

The total number of messages sent, since the start of the messaging engine, on the sender channel transmitter to the foreign bus.

## Messages received

The total number of messages received, since the start of the messaging engine, on the link receiver connections for this WebSphere MQ link.

## Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.
Start	<p>Start selected items.</p> <p>This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.</p>
Stop	<p>Stop a selected WebSphere MQ link. You must first have selected the link to be stopped.</p> <p>You can choose the mode of stop action and the required state when the link has been stopped:</p> <p><b>Stop mode:</b></p> <p><b>Force</b> Stop the link immediately. You should only use this mode if a quiesce action does not work.</p> <p><b>Quiesce</b> Stop the link in a controlled manner.</p> <p><b>Target state:</b></p> <p><b>Inactive</b> Stop the link and set its state to Inactive. If an application tries to use the link, the link is started again.</p> <p><b>Stopped</b> Stop the link and set its state to Stopped. The link can only be started again by administrator action.</p> <p>This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.</p>

---

## WebSphere MQ link MQFAP inbound channel [Settings]

A channel that can be used in combination with the TCP Channel or other channels within the confines of WebSphere MQ support to facilitate communications between a WebSphere system integration bus and a WebSphere MQ client or queue manager.

To view this page in the console, click the following path:

**Servers -> Server Types -> WebSphere application servers -> *server\_name* -> [Server messaging]  
WebSphere MQ link inbound transports -> *chain\_name* -> MQFAP inbound channel.**

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### *Transport channel name:*

Specifies the unique name for a given layer in a network protocol stack.

<b>Required</b>	Yes
<b>Data type</b>	String

#### *Discrimination weight:*

Specifies the discrimination weight that is used to determine the order in which the channels obtain access to the incoming connection if the transport channels are shared amongst several transport chains. The transport channel with the lowest discrimination weight has the first opportunity to accept the incoming connection.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 2147483647

### Additional Properties

#### **Custom properties**

Specifies additional custom properties for this runtime component. Some components use custom configuration properties that can be defined here.

---

## WebSphere MQ link receiver channel [Collection]

The receiver channel that receives messages from the gateway WebSphere MQ queue manager. The receiver channel communicates with a WebSphere MQ sender channel on the gateway queue manager, and converts MQ format messages to service integration bus messages.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Receiver channel.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

#### **WebSphere MQ link receiver channel name**

The name of the receiver channel for the WebSphere MQ link, used to receive messages from WebSphere MQ onto the bus.

## Status

The runtime status of the receiver channel.

## Buttons

Start	<p>Start selected items.</p> <p>This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.</p>
Stop	<p>Stop a selected channel on this link. You must first have selected the channel to be stopped.</p> <p>You can choose the mode of stop action and the required state when the channel has been stopped:</p> <p><b>Stop mode:</b></p> <p><b>Force</b> Stop the channel immediately. You should only use this mode if a quiesce action does not work.</p> <p><b>Quiesce</b> Stop the channel in a controlled manner.</p> <p><b>Target state:</b></p> <p><b>Inactive</b> Stop the channel and set its state to Inactive. If an application tries to use the link, the channel is started again.</p> <p><b>Stopped</b> Stop the channel and set its state to Stopped. The channel can only be started again by administrator action.</p> <p>This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.</p>

---

## WebSphere MQ link receiver channel [Settings]

The receiver channel that receives messages from the gateway WebSphere MQ queue manager. The receiver channel communicates with a WebSphere MQ sender channel on the gateway queue manager, and converts MQ format messages to service integration bus messages.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Receiver channel -> *channel\_name*.**

- “Configuration tab” on page 2352
- “Runtime tab” on page 2353

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### ***WebSphere MQ link receiver channel name:***

The name of the receiver channel for the WebSphere MQ link, used to receive messages from WebSphere MQ onto the bus.

This name must be the same as the name of the sender channel on WebSphere MQ.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	String

#### ***Inbound nonpersistent message reliability:***

The acceptable reliability of message delivery for nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Best effort to Reliable, in order of increasing reliability.

This reliability delivery option is assigned to all WebSphere MQ nonpersistent messages flowing over this receiver channel.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	<b>Best effort</b> Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.
	<b>Express</b> Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.
	<b>Reliable</b> Messages are discarded when a messaging engine stops or fails.

#### ***Inbound persistent message reliability:***

The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	
	<b>Reliable</b>
	Messages might be discarded when a messaging engine fails.
	<b>Assured</b>
	Messages are not discarded.

***Prefer queue points local to this link's messaging engine:***

When this check box is selected, the link prefers to send inbound messages to available queue points of target destinations that are located on the messaging engine on which the link is hosted.

When this check box is not selected, or if no local queue point is available for a target destination, the link workload balances the messages across all available queue points of the target destination. By default the check box is selected.

This option is supported on links running on WebSphere Application Server Version 7.0 or later. If you are running on an earlier version, the default behavior of preferring local queue points is applied.

<b>Required</b>	Yes
<b>Data type</b>	Boolean

***Initial state:***

Whether the receiver channel is started or stopped when the associated WebSphere MQ link is first started. Until started, the channel is unavailable.

Dynamic updates to this property are effective on messaging engine restart or receiver channel creation. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	
	<b>Stopped</b>
	When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.
	<b>Started</b>
	When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

## Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime

property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### Status:

The runtime status of the receiver channel.

This shows the overall status for all receiver channels for the link.

**Required**  
**Data type**  
**Range**

No  
drop-down list

### Inactive

The WebSphere MQ link is ready and enabled to create connections, but no connections have yet been established.

### Stopped

The WebSphere MQ link is in a stopped state and cannot process any new requests for connections.

### Multiple

The WebSphere MQ link has established several sessions with WebSphere MQ, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

## Additional Properties

### Receiver channel connections

The connections that exist on the receiver channel of the WebSphere MQ link.

### Saved batch status

The runtime status of message batches for the receiver channel of the WebSphere MQ link.

---

## WebSphere MQ link routing properties [Settings]

The routing properties for a link to a foreign bus that represents a WebSphere MQ network.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Foreign bus connections -> *foreign\_bus\_name* -> *link\_name*.**

You must create one of these routing definitions before you can create a WebSphere MQ link.

For information about setting up communication with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### **Name:**

The name by which the routing definition is known.

<b>Required</b>	No
<b>Data type</b>	String

### **UUID:**

The universal unique identifier assigned by the system to the routing definition (virtual link) for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

### **Inbound user ID:**

The user ID applied to messages arriving from the foreign bus and used to authorize their access to destinations.

If you want to authenticate messages entering this bus, this user ID replaces the user ID in the inbound messages. You can specify an inbound user ID if this bus is to assign its own user IDs for all messages received from the foreign bus. If you do not authenticate inbound messages, all messages can enter this bus.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	String

### **Outbound user ID:**

The user ID applied to messages sent to the foreign bus.

The definitive check for access to the destination on the foreign bus takes place when the message enters the foreign bus. The check is against the permissions defined on the foreign bus by its administrator. The check is based on the user ID that is stored in the message. That user ID starts off as the user ID of the sender, but this bus might want to assign the same outbound user ID for all messages sent to the foreign bus.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	String

---

## WebSphere MQ link sender channel [Collection]

This pane displays the sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Sender channel.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**WebSphere MQ link sender channel name**

The name of the sender channel for the WebSphere MQ link, used to send messages from the bus to WebSphere MQ.

**Host name**

The hostname or TCP/IP IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

**Port** The TCP/IP port number on which the gateway queue manager is listening for the WebSphere MQ link.

**Status**

The runtime status of the sender channel.

**Buttons**

Reset	Reset a selected channel sequence number to 1. If the channel is running, the reset request will take effect only when the channel has been stopped and restarted.  This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.
Start	Start selected items.  This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

<p>Stop</p>	<p>Stop a selected channel on this link. You must first have selected the channel to be stopped.</p> <p>You can choose the mode of stop action and the required state when the channel has been stopped:</p> <p><b>Stop mode:</b></p> <p><b>Force</b> Stop the channel immediately. You should only use this mode if a quiesce action does not work.</p> <p><b>Quiesce</b> Stop the channel in a controlled manner.</p> <p><b>Target state:</b></p> <p><b>Inactive</b> Stop the channel and set its state to Inactive. If an application tries to use the link, the channel is started again.</p> <p><b>Stopped</b> Stop the channel and set its state to Stopped. The channel can only be started again by administrator action.</p> <p>This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.</p>

## WebSphere MQ link sender channel [Settings]

This pane displays the sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Sender channel -> *channel\_name*.**

- “Configuration tab”
- “Runtime tab” on page 2362

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### ***WebSphere MQ link sender channel name:***

The name of the sender channel for the WebSphere MQ link, used to send messages from the bus to WebSphere MQ.

This name must be the same as the name of the receiver channel on WebSphere MQ.

For information about choosing channel names, see the description of the Channel name (CHANNEL) property in the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

If the previous channel is unknown, restart is delayed until the uncertainty is resolved.

<b>Required</b>	No
<b>Data type</b>	String

### ***Single Connection:***

Use Single connection for the gateway queue manager that is used to connect into the WebSphere MQ network.

Select Single Connection to specify the host name and port for one target queue manager. If you have a high availability configuration, with one or more failover gateway queue managers available in the WebSphere MQ network in addition to the target queue manager, select **Multiple Connection Names List** instead.

If you do not specify any host names, either as a single connection or in a list of multiple connections, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

<b>Required</b>	No
<b>Data type</b>	Radio button

### ***Host name:***

The hostname or TCP/IP IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

This is the host name or IP address of the target queue manager in the WebSphere MQ network.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	String

### ***Port:***

The TCP/IP port number on which the gateway queue manager is listening for the WebSphere MQ link.

This is the port number on which the gateway queue manager is listening for the inbound communication requests.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
-----------------	----

<b>Data type</b>	Integer
<b>Range</b>	0 through 65535
<b>Default</b>	1414

**Multiple Connection Names List:**

Select Multiple Connection Names List if you have one or more failover gateway queue managers available in the WebSphere MQ network in addition to the target queue manager. If no failover gateway queue manager is available, you can select Single Connection instead.

If you do not specify any host names, either as a single connection or in a list of multiple connections, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

<b>Required</b>	No
<b>Data type</b>	Radio button

**Connection Names List:**

List of hostnames or TCP/IP IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

Specify a list of host names, or IP addresses, and ports for the active and standby WebSphere MQ queue managers in a high availability configuration. You may also use this field to specify a single host name and port.

Specify the host names, or IP addresses, and ports in the format `hostname1(nnnn),hostname2(nnnn)` separating each pair with a comma. Specify IP addresses in IPv4 format.

If you specify a port alone as an entry in the list, WebSphere Application Server uses the default host name `localhost` with the port. If you specify a host name alone as an entry in the list, WebSphere Application Server uses the default port number 1414 with the host name. For example, a connection names list consisting of the values `(1422),example.com` is interpreted as `localhost(1422),example.com(1414)`.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	Custom

**Transport chain:**

The type of channel chain used for communication with the foreign bus.

This must be one of the outbound transport chains in the application server, to be used when establishing a network connection to a WebSphere MQ queue manager receiver channel.

By default, this property can take one of the following values:

**OutboundBasicMLink**

Used to establish connections with WebSphere MQ queue manager receiver channels.

**OutboundSecureMLink**

Used to establish connections with WebSphere MQ queue manager receiver channels that have

been secured by using SSL. The SSL configuration used is taken from the default SSL repertoire for the application server being used to contact the queue manager.

You can also choose to specify another outbound transport chain that you have defined separately on the TransportChannelService object of the application server used for WebSphere MQ interoperation.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Modified transport chains are visible only after a server restart.

<b>Required</b>	Yes
<b>Data type</b>	Custom

### ***Disconnect interval:***

The time in seconds for which the sender channel waits for new messages to arrive on the transmission queue after sending a batch of messages. The channel disconnects after this interval, and must be restarted manually or by triggering.

The default value is a reasonable interval. Change this value only if you understand the implications for performance, and you need a different value for the requirements of the traffic flowing down your channels.

Performance is affected by the value specified for the disconnect interval. A very low value (a few seconds) can cause an unacceptable amount of processing in constantly starting up the channel. A very large value (more than an hour) might mean that system resources are unnecessarily held up.

If you want your channels to be active only when there are messages for them to transmit, you should set the disconnect interval to a fairly low value. Note that the default setting is quite high and so is not recommended for channels where this level of control is required. Because it is difficult to interrupt the receiving channel, the most economical option is to have the channel automatically disconnect and reconnect as the workload demands. For most channels, the appropriate setting of the disconnect interval can be established heuristically.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 999999

A value of 0 (zero) means never disconnect; the channel waits indefinitely for messages.

### ***Short retry count:***

The maximum number of times that the sender channel tries to restart after a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 999999999

***Short retry interval:***

The number of seconds between attempts by the sender channel to restart after a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 999999999

***Long retry count:***

The maximum number of times that the sender channel tries to restart after the short retry mechanism did not recover from a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped.

For more information about about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	Long
<b>Range</b>	0 through 999999999

***Long retry interval:***

The number of seconds between attempts by the sender channel to restart after the short retry mechanism did not recover from a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
-----------------	----

**Data type** Long  
**Range** 0 through 999999999

***Initial state:***

Whether the sender channel is started or stopped when the associated WebSphere MQ link is first started. Until started, the channel is unavailable.

Dynamic updates to this property are effective on messaging engine restart or sender channel creation. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	<b>Stopped</b> When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.
	<b>Started</b> When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

## Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

***WebSphere MQ link sender channel name:***

The name of the sender channel for the WebSphere MQ link, used to send messages from the bus to WebSphere MQ.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

If the previous channel is unknown, restart is delayed until the uncertainty is resolved.

***Virtual queue manager name:***

The virtual queue manager name by which the local bus is to be known to a WebSphere MQ network. It is generally recommended that you set the virtual queue manager name to match the name of the local bus. As WebSphere MQ queue manager names can be no longer than 48 characters, you must ensure that the length of the local bus name does not exceed 48 characters.

The bus appears to WebSphere MQ as if it is a WebSphere MQ queue manager or queue-sharing group. This field gives the queue manager name that WebSphere MQ uses to address the virtual queue manager represented by this bus.

<b>Required</b>	No
<b>Data type</b>	String

***/IP address:***

The TCP/IP IP address of the host on which the target queue manager runs.

<b>Required</b>	No
<b>Data type</b>	String

***Status:***

The runtime status of the sender channel.

<b>Required</b>	No
<b>Data type</b>	drop-down list

## Range

### Inactive

The WebSphere MQ link is ready and enabled to create connections, but no connections have yet been established.

### Starting

The WebSphere MQ link has received a connection request, and is in the process of starting this connection.

### Binding

The WebSphere MQ link is performing channel negotiation and is not yet ready to transfer messages.

### Initializing

The WebSphere MQ link is initializing the session for a connection and is not yet ready to transfer messages.

### Retrying

The WebSphere MQ link is retrying a failed connection.

### Standby

The channel is being used for standby purposes. Messages can be transferred only when the channel is active.

### Running

The WebSphere MQ link has an active session with WebSphere MQ, and data can be flowing between WebSphere MQ and the WebSphere MQ link.

### Stopping

The WebSphere MQ link, or a connection with that link, is in the process of being stopped.

### Paused

The channel is waiting for the message-retry interval to finish.

### Stopped

The WebSphere MQ link is in a stopped state and cannot process any new requests for connections.

### Multiple

The WebSphere MQ link has established several sessions with WebSphere MQ, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

### **Host name:**

The hostname or TCP/IP IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

**Port:**

The TCP/IP port number on which the gateway queue manager is listening for the WebSphere MQ link.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

**Transport chain:**

The type of channel chain used for communication with the foreign bus.

This must be one of the outbound transport chains in the application server, to be used when establishing a network connection to a WebSphere MQ queue manager receiver channel. For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Modified transport chains are visible only after a server restart.

**Disconnect interval:**

The time in seconds for which the sender channel waits for new messages to arrive on the transmission queue after sending a batch of messages. The channel disconnects after this interval, and must be restarted manually or by triggering.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

**Short retry count:**

The maximum number of times that the sender channel tries to restart after a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

**Short retry interval:**

The number of seconds between attempts by the sender channel to restart after a communication or partner failure.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

***Long retry count:***

The maximum number of times that the sender channel tries to restart after the short retry mechanism did not recover from a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

***Long retry interval:***

The number of seconds between attempts by the sender channel to restart after the short retry mechanism did not recover from a communication or partner failure.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

***Batch size:***

The maximum number of messages that a batch can contain.

<b>Required</b>	No
<b>Data type</b>	String

***Channel start time:***

The time at which the channel was last started.

<b>Required</b>	No
<b>Data type</b>	String

***Channel start date:***

The date on which the channel was last started.

<b>Required</b>	No
<b>Data type</b>	String

***Heartbeat interval:***

The negotiated time, in seconds, between heartbeat flows passed from the WebSphere MQ link sender channel to the WebSphere MQ receiver channel when there are no messages on the transmission queue.

<b>Required</b>	No
<b>Data type</b>	Integer

***Sequence wrap:***

The value at which message sequence numbers wrap to start again at 1.

This is the highest number the message sequence number reaches before it restarts at 1. The default value is 999999999.

For more information about choosing the value for this property, see the description of the Sequence Number wrap (SEQWRAP) property in the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	Long
<b>Range</b>	100 through 999999999

### ***Maximum message length:***

The negotiated maximum message length, in bytes, that can be transmitted on the channel. This value is compared with the value from the partner WebSphere MQ receiver channel, and the maximum message length used is the lower of the two values.

<b>Required</b>	No
<b>Data type</b>	Integer

### ***Stop requested:***

Whether or not a manual stop request has been made for the sender channel.

To make a stop request, use the buttons provided on the WebSphere MQ link sender channel collection panel.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	<b>true</b> The channel is in doubt about which messages have been committed by WebSphere MQ for the unit of work that it has sent. <b>false</b> The channel is not in doubt about which messages have been committed by WebSphere MQ.

### ***Current LUWID:***

The current logical unit-of-work identifier for the message on the channel.

Indoubt channel problems are usually resolved automatically. Sequence number and logical unit of work ID (LUWID) records are kept to help resolve indoubt channel problems when communication has been re-established. For information resolving indoubt channels, see the *Intercommunication* section of the WebSphere MQ information center.

<b>Required</b>	No
<b>Data type</b>	String

### ***Current sequence number:***

The current sequence number for the message on the channel.

Indoubt channel problems are usually resolved automatically. Sequence number and logical unit of work ID (LUWID) records are kept to help resolve indoubt channel problems when communication has been re-established. For information resolving indoubt channels, see the *Intercommunication* section of the WebSphere MQ information center.

<b>Required</b>	No
<b>Data type</b>	String

### ***In doubt:***

Whether the message on the channel is in an indoubt state.

Problems with a channel that is in an indoubt state are usually resolved automatically. Sequence number and logical unit of work ID (LUWID) records are kept to help resolve problems with an indoubt channel when communication has been re-established. For information about resolving indoubt channels, see the *Intercommunication* section of the WebSphere MQ information center.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	<b>true</b> The channel is in doubt about which messages have been committed by WebSphere MQ for the unit of work that it has sent. <b>false</b> The channel is not in doubt about which messages have been committed by WebSphere MQ.

### ***Last LUWID:***

The last logical unit-of-work identifier for a message on the channel.

To determine the last-committed logical unit of work ID (LUWID) for the channel, compare this value to the last-committed LUWID for the receiving side of the channel.

- If the two LUWIDs are the same, the receiving side has committed the unit of work that the sender considers to be in doubt. The sending side can now remove the indoubt messages from the transmission queue and re-enable it.
- If the two LUWIDs are different, the receiving side has not committed the unit of work that the sender considers to be in doubt. The sending side needs to retain the indoubt messages on the transmission queue and re-send them.

<b>Required</b>	No
<b>Data type</b>	String

### ***Last sequence number:***

The last sequence number for a message on the channel.

WebSphere MQ channels cannot initialize successfully if the channel negotiation detects that the message sequence number is different at each end. You might have to reset this manually.

To be effective, the sequence number must be reset in both the sender and the receiver channel definitions. The starting sequence number is not negotiated when a channel starts up, nor is there a default provided.

<b>Required</b>	No
<b>Data type</b>	String

***Messages in current batch:***

The number of messages in the current batch on the channel.

<b>Required</b>	No
<b>Data type</b>	String

***Number of batches sent:***

The number of batches that have been sent on the channel.

<b>Required</b>	No
<b>Data type</b>	String

***Number of messages sent:***

The number of messages that have been sent on the channel.

<b>Required</b>	No
<b>Data type</b>	String

***Buffers sent:***

The number of message buffers sent.

<b>Required</b>	No
<b>Data type</b>	String

***Buffers received:***

The number of message buffers received.

<b>Required</b>	No
<b>Data type</b>	String

***Bytes sent:***

The number of bytes sent.

<b>Required</b>	No
<b>Data type</b>	String

***Bytes received:***

The number of bytes received.

<b>Required</b>	No
<b>Data type</b>	String

***Last message send time:***

The time at which the last message was sent on the channel.

<b>Required</b>	No
<b>Data type</b>	String

***Last message send date:***

The date on which the last message was sent on the channel.

<b>Required</b>	No
<b>Data type</b>	String

***Remaining short retry starts:***

The remaining number of short retry attempts that can be used to start the sender channel. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked.

<b>Required</b>	No
<b>Data type</b>	String

***Remaining long retry starts:***

The remaining number of long retry attempts that can be used to start the sender channel. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped.

<b>Required</b>	No
<b>Data type</b>	String

***Nonpersistent message speed:***

The class of service for nonpersistent messages on the sender channel.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	<b>Fast</b> Nonpersistent messages can be lost if there is a transmission failure or if the channel stops when the messages are in transit.
	<b>Normal</b> Nonpersistent messages are not lost if there is a transmission failure or if the channel stops when the messages are in transit.

## Additional Properties

### Saved batch status

The runtime status of message batches for the sender channel of the WebSphere MQ link. You can choose to commit or roll back each batch.

---

## WebSphere MQ link [Settings]

The WebSphere MQ link connects the messaging engine as a queue manager to WebSphere MQ, providing a bridge between the bus and a WebSphere MQ network.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name***

For more information about choosing settings, see the *Intercommunication* section of the WebSphere MQ information center.

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

- “Configuration tab”
- “Runtime tab” on page 2376

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Name:**

The name of the WebSphere MQ link, used for administrative purposes.

<b>Required</b>	Yes
<b>Data type</b>	String

#### **UUID:**

The universal unique identifier assigned by the system to this WebSphere MQ link for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

#### **Description:**

An optional description for the WebSphere MQ link, for administrative purposes.

Dynamic updates to this property are effective immediately.

<b>Required</b>	No
<b>Data type</b>	Text area

***Foreign bus connection name:***

The foreign bus to which this link connects.

If you do not see the foreign bus connection name that you expected to see, you must create a new foreign bus connection.

<b>Required</b>	Yes
<b>Data type</b>	drop-down list

***Local messaging engine:***

The local messaging engine that this WebSphere MQ link is hosted on.

<b>Required</b>	Yes
<b>Data type</b>	drop-down list

***Virtual queue manager name:***

The virtual queue manager name by which the local bus is to be known to a WebSphere MQ network. It is generally recommended that you set the virtual queue manager name to match the name of the local bus. As WebSphere MQ queue manager names can be no longer than 48 characters, you must ensure that the length of the local bus name does not exceed 48 characters.

The bus appears to WebSphere MQ as if it is a WebSphere MQ queue manager or queue-sharing group. This field gives the queue manager name that WebSphere MQ uses to address the virtual queue manager represented by this bus. Any value that you specify must meet the following criteria:

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

<b>Required</b>	Yes
<b>Data type</b>	String

***Batch size:***

The maximum number of messages that can be sent through a channel before taking a checkpoint.

The batch size does not affect the way the sender and receiver channels for this link transfer messages; messages are always transferred individually, but are committed or backed out as a batch.

For information about choosing the batch size, see the description of the Batch size (BATCHSZ) property in the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	Integer

**Range** 1 through 9999

***Maximum message size:***

The maximum message length, in bytes, that can be transmitted on any channel for the WebSphere MQ link. This is compared with the value for the corresponding partner WebSphere MQ channel and the actual maximum used is the lower of the two values.

For more information about choosing a value for the maximum message size, see the description of the Maximum message length (**MAXMSGL**) property in the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 104857600

***Heartbeat interval:***

The negotiated time, in seconds, between heartbeat flows passed from the WebSphere MQ link sender channel to the WebSphere MQ receiver channel when there are no messages on the transmission point being served by the WebSphere MQ link sender channel.

Heartbeats give the receiving channel the opportunity to quiesce the channel connection.

For more information about choosing a value for this property, see the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	Integer
<b>Range</b>	0 through 999999

***Sequence wrap:***

The value at which message sequence numbers wrap to start again at 1.

For more information about choosing a value for this property, see the description of the Sequence Numberwrap (**SEQWRAP**) property in the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
-----------------	----

**Data type** Long  
**Range** 100 through 999999999

**Adoptable:**

Whether or not a running instance of a WebSphere MQ link receiver channel (associated with this MQ link) should be adopted or not. In the event of a communications failure, it is possible for a running instance of a WebSphere MQ link receiver channel to be left waiting for messages. When communication is re-established, and the partner WebSphere MQ sender channel next attempts to establish a session with the WebSphere MQ link receiver channel, the request will fail as there is already a running instance of the WebSphere MQ link receiver channel that believes it is in session with the partner WebSphere MQ sender channel. You can overcome this problem by selecting this option, which causes the already running instance of the WebSphere MQ link receiver channel to be stopped and a new instance to be started.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

**Required** No  
**Data type** Boolean

**Exception destination:**

The destination for an inbound message when the WebSphere MQ link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

Select a radio button as required to configure the exception destination that this WebSphere MQ link uses:

- Select **None** to specify that the WebSphere MQ link does not use an exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery through that link to the same bus. This option can be used to preserve message ordering.
- Select **System** to use the default exception destination. Messages that cannot be delivered to the bus destination are rerouted to the system default exception destination for the messaging engine that this link is assigned to: `_SYSTEM.Exception.Destinationmessaging_engine_name`.
- Select **Specify** and enter an exception destination to use the exception destination specified here. If the WebSphere MQ link cannot use this exception destination, it uses the system exception destination.

**Required** No  
**Data type** Custom  
**Default** System

**Initial state:**

Whether the WebSphere MQ link is started or stopped when the hosting messaging engine is first started. Until it is started, the WebSphere MQ link is unavailable.

Dynamic updates to this property are effective when the messaging engine restarts. Use the Runtime tab to check the current state.

**Required** No  
**Data type** drop-down list

## Range

### Stopped

When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

### Started

When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

### ***Nonpersistent message speed:***

The class of service for nonpersistent messages on channels of this WebSphere MQ link.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

#### Required

No

#### Data type

drop-down list

#### Range

**Fast** Nonpersistent messages can be lost if there is a transmission failure or if the channel stops when the messages are in transit.

#### Normal

Nonpersistent messages are not lost if there is a transmission failure or if the channel stops when the messages are in transit.

## Additional Properties

### **Publish/subscribe broker profiles**

Profiles used to define the topic mappings and transactionality for publishing and receiving (by subscription) topics across the publish/subscribe bridge between WebSphere Application Server and a WebSphere MQ network.

### **Receiver channel**

The receiver channel that receives messages from the gateway queue manager. The receiver channel communicates with a WebSphere MQ sender channel on the gateway queue manager, and converts MQ format messages to service integration bus messages.

### **Sender channel**

The sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

### **Sender channel transmitters**

The sender channel transmitters for the queueing of messages across the WebSphere MQ link.

## Related Items

### **Foreign bus connection**

The associated foreign bus for this WebSphere MQ link.

## Link transmitters

For applications that use point-to-point messaging, there is one link transmission message point located on each messaging engine in the source bus. For applications that use publish/subscribe messaging, there is one link transmission message point located on each topic space in the source bus. The link transmitter acts as a transmission queue where produced messages are persisted before transmission across the inter-bus link to the foreign bus.

## Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### *Status:*

The runtime status of the WebSphere MQ link.

<b>Required</b>	No
<b>Data type</b>	drop-down list

## Range

### Inactive

The WebSphere MQ link is ready and enabled to create connections, but no connections have yet been established.

### Starting

The WebSphere MQ link has received a connection request, and is in the process of starting this connection.

### Binding

The WebSphere MQ link is performing channel negotiation and is not yet ready to transfer messages.

### Initializing

The WebSphere MQ link is initializing the session for a connection and is not yet ready to transfer messages.

### Retrying

The WebSphere MQ link is retrying a failed connection.

### Standby

The channel is being used for standby purposes. Messages can be transferred only when the channel is active.

### Running

The WebSphere MQ link has an active session with WebSphere MQ, and data can be flowing between WebSphere MQ and the WebSphere MQ link.

### Stopping

The WebSphere MQ link, or a connection with that link, is in the process of being stopped.

### Paused

The channel is waiting for the message-retry interval to finish.

### Stopped

The WebSphere MQ link is in a stopped state and cannot process any new requests for connections.

### Multiple

The WebSphere MQ link has established several sessions with WebSphere MQ, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

## Additional Properties

### Sender channel transmitters

The sender channel transmitters for the queueing of messages across the WebSphere MQ link.

## Related Items

### Link transmitters

For applications that use point-to-point messaging, there is one link transmission message point

located on each messaging engine in the source bus. For applications that use publish/subscribe messaging, there is one link transmission message point located on each topic space in the source bus. The link transmitter acts as a transmission queue where produced messages are persisted before transmission across the inter-bus link to the foreign bus.

---

## Mediation execution points [Collection]

Mediation execution points for the processing of messages from mediation message points that are on a WebSphere MQ server.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Remote message points] WebSphere MQ Mediation Execution points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Identifier

The system-generated name by which this message point is known.

### Status

The runtime status of the mediation point.

### Buttons

Start	Start selected items.
Stop	Stop selected items.

---

## Mediation points [Collection]

Bus member (server or cluster) where the mediations for the destination run.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Message points] WebSphere MQ Mediation Execution points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### Buttons

Start	Start selected items.
Stop	Stop selected items.

---

## Mediation points [Settings]

Bus member (server or cluster) where the mediations for the destination run.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Remote message points] WebSphere MQ Mediation Execution points -> *mediation\_name* .**

- “Configuration tab”
- “Runtime tab”

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

#### General Properties

##### **Identifier:**

The system-generated name by which this message point is known.

<b>Required</b>	No
<b>Data type</b>	String

##### **UUID:**

The universal unique identifier assigned by the system to this message point for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

##### **Initial state:**

Whether the mediation point is started or stopped when the hosting messaging engine is first started. Until started, the mediation point is unavailable.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	

##### **Started**

When the associated messaging engine is started, the mediation is started and is available to process messages.

##### **Stopped**

When the associated messaging engine is started, the mediation is stopped and is not available to process messages.

### Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime

property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### **Identifier:**

The system-generated name by which this message point is known.

<b>Required</b>	No
<b>Data type</b>	String

### **Run-time ID:**

The internal runtime identifier assigned to this message point.

<b>Required</b>	No
<b>Data type</b>	String

### **Status:**

The runtime status of the mediation point.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	<b>Waiting</b> The mediation is waiting to start. This might be because the application server is not yet open for e-business, or because a previous instance of the mediation has not yet been deleted.
	<b>Started</b> The mediation is started and is available to process messages.
	<b>Stopping</b> The mediation is in the process of stopping.
	<b>Stopped</b> The mediation is stopped. The reason why the mediation is stopped is shown in the Reason attribute.
	<b>Deleting</b> The mediation is in the process of being deleted.

---

## WebSphere MQ mediation points [Collection]

A WebSphere MQ mediation point is a location from which a mediation takes messages.

To view this page in the console, click the following path:

**Service integration -> Buses -> bus\_name -> [Topology] Messaging engines -> engine\_name -> Runtime > [Message points] WebSphere MQ Mediation points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

#### Identifier

The system-generated name by which this message point is known.

---

## WebSphere MQ mediation points [Settings]

A WebSphere MQ mediation point is a location from which a mediation takes messages.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Message points] WebSphere MQ Mediation points -> *mediation\_name* .**

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

#### General Properties

##### **Identifier:**

The system-generated name by which this message point is known.

<b>Required</b>	No
<b>Data type</b>	String

##### **UUID:**

The universal unique identifier assigned by the system to this message point for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

##### **Target UUID:**

The UUID of the bus destination for which this is a message point.

<b>Required</b>	No
<b>Data type</b>	String

##### **WebSphere MQ queue name :**

The WebSphere MQ queue name as defined in WebSphere MQ.

<b>Required</b>	Yes
<b>Data type</b>	String
<b>Data type</b>	String

***Inbound nonpersistent reliability :***

The level of reliability to apply when a nonpersistent WebSphere MQ message is received.

**Required**  
**Data type**  
**Range**

No  
drop-down list

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

***Inbound persistent reliability :***

The level of reliability to apply when a persistent WebSphere MQ message is received.

**Required**  
**Data type**

No  
drop-down list

## Range

### **Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

### **Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

### **Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

### **Reliable persistent**

Messages might be discarded when a messaging engine fails.

### **Assured persistent**

Messages are not discarded.

## ***Include an RFH2 message header when sending messages to WebSphere MQ :***

If selected, messages sent to WebSphere MQ will include an RFH2 header. The RFH2 header stores additional information to that which is stored in the WebSphere MQ message header.

<b>Required</b>	No
<b>Data type</b>	Boolean
<b>Data type</b>	Boolean

---

## **WebSphere MQ queue points [Collection]**

A WebSphere MQ queue point is used when sending messages to and receiving messages from a WebSphere MQ queue.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Message points] WebSphere MQ Queue points.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

### **Identifier**

The system-generated name by which this message point is known.

---

## WebSphere MQ queue points [Settings]

A WebSphere MQ queue point is used when sending messages to and receiving messages from a WebSphere MQ queue.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> Runtime > [Message points] WebSphere MQ Queue points -> *queue\_point\_name*.**

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

#### General Properties

##### **Identifier:**

The system-generated name by which this message point is known.

<b>Required</b>	No
<b>Data type</b>	String

##### **UUID:**

The universal unique identifier assigned by the system to this message point for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	String

##### **Target UUID:**

The UUID of the bus destination for which this is a message point.

<b>Required</b>	No
<b>Data type</b>	String

##### **WebSphere MQ queue name :**

The WebSphere MQ queue name as defined in WebSphere MQ.

<b>Required</b>	Yes
<b>Data type</b>	String

##### **Inbound nonpersistent reliability :**

The level of reliability to apply when a nonpersistent WebSphere MQ message is received.

The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For nonpersistent WebSphere MQ messages received, you will probably choose one of the nonpersistent service integration qualities of service, that is reliable nonpersistent, best effort nonpersistent or express nonpersistent. However, you can choose any of the five possible service integration qualities of service:

**Best effort nonpersistent**

**Express nonpersistent**

**Reliable nonpersistent**

**Reliable persistent**

**Assured persistent**

For more information, see `../ae/rjc0014_.dita`.

**Required**

**Data type**

**Range**

No

drop-down list

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

***Inbound persistent reliability :***

The level of reliability to apply when a persistent WebSphere MQ message is received.

The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For persistent WebSphere MQ messages received, you will probably choose one of the persistent service integration qualities of service, that is either assured persistent or reliable persistent. However, you can choose any of the five possible service integration qualities of service:

**Best effort nonpersistent**

**Express nonpersistent**

**Reliable nonpersistent**

**Reliable persistent**

**Assured persistent**

For more information, see ../ae/rjc0014\_.dita.

**Required**

**Data type**

**Range**

No

drop-down list

**Best effort nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express nonpersistent**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable nonpersistent**

Messages are discarded when a messaging engine stops or fails.

**Reliable persistent**

Messages might be discarded when a messaging engine fails.

**Assured persistent**

Messages are not discarded.

***Include an RFH2 message header when sending messages to WebSphere MQ :***

If selected, messages sent to WebSphere MQ will include an RFH2 header. The RFH2 header stores additional information to that which is stored in the WebSphere MQ message header.

**Required**

**Data type**

No

Boolean

---

## **WebSphere MQ link receiver channel connections [Collection]**

A connection that exists on the receiver channel of the WebSphere MQ link.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Receiver channel -> *channel\_name* -> Runtime > Receiver channel connections.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

**WebSphere MQ Queue Manager name**

The name of the WebSphere MQ queue manager on which the WebSphere MQ sender channel, that is connected to this MQ link receiver channel connection instance, is running.

**IP address**

The IP address of the queue manager for the WebSphere MQ link receiver channel connection.

**Status**

The runtime status of the WebSphere MQ link receiver channel connection.

**WebSphere MQ link receiver channel connections [Settings]**

A connection that exists on the receiver channel of the WebSphere MQ link.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Messaging engines -> *engine\_name* -> [Additional properties] WebSphere MQ links -> *link\_name* -> [Additional Properties] Receiver channel -> *channel\_name* -> Runtime > Receiver channel connections -> *channel\_connection\_name*.**

**Runtime tab**

The Runtime tab shows runtime properties and current runtime state for this MQ link receiver channel connection. These properties are not preserved when the current runtime environment is stopped.

**General Properties*****WebSphere MQ link receiver channel name:***

The name of the receiver channel for the WebSphere MQ link, used to receive messages from WebSphere MQ onto the bus.

This name must be the same as the name of the sender channel on WebSphere MQ.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	String

***WebSphere MQ Queue Manager name:***

The name of the WebSphere MQ queue manager on which the WebSphere MQ sender channel, that is connected to this MQ link receiver channel connection instance, is running.

<b>Required</b>	No
<b>Data type</b>	String

***IP address:***

The IP address of the queue manager for the WebSphere MQ link receiver channel connection.

<b>Required</b>	No
<b>Data type</b>	String

**Status:**

The runtime status of the WebSphere MQ link receiver channel connection.

**Required**  
**Data type**  
**Range**

No  
drop-down list

**Inactive**

The WebSphere MQ link is ready and enabled to create connections, but no connections have yet been established.

**Starting**

The WebSphere MQ link has received a connection request, and is in the process of starting this connection.

**Binding**

The WebSphere MQ link is performing channel negotiation and is not yet ready to transfer messages.

**Initializing**

The WebSphere MQ link is initializing the session for a connection and is not yet ready to transfer messages.

**Retrying**

The WebSphere MQ link is retrying a failed connection.

**Standby**

The channel is being used for standby purposes. Messages can be transferred only when the channel is active.

**Running**

The WebSphere MQ link has an active session with WebSphere MQ, and data can be flowing between WebSphere MQ and the WebSphere MQ link.

**Stopping**

The WebSphere MQ link, or a connection with that link, is in the process of being stopped.

**Paused**

The channel is waiting for the message-retry interval to finish.

**Stopped**

The WebSphere MQ link is in a stopped state and cannot process any new requests for connections.

**Multiple**

The WebSphere MQ link has established several sessions with WebSphere MQ, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

**Batch size:**

The maximum number of messages that a batch can contain.

<b>Required</b>	No
<b>Data type</b>	String

***Channel start time:***

The time at which the channel was last started.

<b>Required</b>	No
<b>Data type</b>	String

***Channel start date:***

The date on which the channel was last started.

<b>Required</b>	No
<b>Data type</b>	String

***Heartbeat interval:***

The negotiated time, in seconds, between heartbeat flows passed from the WebSphere MQ sender channel to the WebSphere MQ link receiver channel when there are no messages on the transmission queue being served by the WebSphere MQ sender channel.

<b>Required</b>	No
<b>Data type</b>	String

***Sequence wrap:***

The value at which message sequence numbers wrap to start again at 1.

This is the highest number the message sequence number reaches before it restarts at 1. The default value is 999999999.

For information about how to choose an appropriate value for this property, see the description of the Sequence Numberwrap (SEQWRAP) property in the *WebSphere MQ Intercommunication* book.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	Long
<b>Range</b>	100 through 999999999

***Adoptable:***

Whether or not a running instance of a WebSphere MQ link receiver channel (associated with this MQ link) should be adopted or not. In the event of a communications failure, it is possible for a running instance of a WebSphere MQ link receiver channel to be left waiting for messages. When communication is re-established, and the partner WebSphere MQ sender channel next attempts to establish a session with the WebSphere MQ link receiver channel, the request will fail as there is already a running instance

of the WebSphere MQ link receiver channel that believes it is in session with the partner WebSphere MQ sender channel. You can overcome this problem by selecting this option, which causes the already running instance of the WebSphere MQ link receiver channel to be stopped and a new instance to be started.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	<b>true</b> <b>false</b>

**Maximum message length:**

The maximum message length, in bytes, that can be transmitted on the channel. This is compared with the value from the partner Websphere MQ sender channel and the actual maximum used is the lower of the two values.

<b>Required</b>	No
<b>Data type</b>	String

**Stop requested:**

Whether or not a manual stop request has been made for the receiver channel.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	<b>true</b> The channel is in doubt about which messages have been committed by WebSphere MQ for the unit of work that it has sent. <b>false</b> The channel is not in doubt about which messages have been committed by WebSphere MQ.

**Current LUWID:**

The current logical unit-of-work identifier of the WebSphere MQ link receiver channel connection.

<b>Required</b>	No
<b>Data type</b>	String

**Current sequence number:**

The current sequence number for the message on the channel.

You can reset the sequence number of an MQLinkReceiver channel by resetting the sequence number of the partner WebSphere MQ sender channel. For details of how to reset the sequence number of a WebSphere MQ sender channel, see the *WebSphere MQ Intercommunications Guide* section of the WebSphere MQ library.

<b>Required</b>	No
-----------------	----

**Data type** String

***Last LUWID:***

The last logical unit-of-work identifier for a message on the channel.

**Required** No  
**Data type** String

***Last Sequence number:***

The last sequence number for a message on the channel.

**Required** No  
**Data type** String

***Messages in current batch:***

The number of messages in the current batch on the channel.

**Required** No  
**Data type** String

***Number of batches received:***

The number of batches received on the channel.

**Required** No  
**Data type** String

***Number of messages received:***

The number of messages received on the channel.

**Required** No  
**Data type** String

***Buffers sent:***

The number of buffers sent on the channel.

**Required** No  
**Data type** String

***Buffers received:***

The number of buffers received on the channel.

**Required** No  
**Data type** String

***Bytes sent:***

The number of bytes sent on the channel.

<b>Required</b>	No
<b>Data type</b>	String

***Bytes received:***

The number of bytes received on the channel.

<b>Required</b>	No
<b>Data type</b>	String

***Last message receive time:***

The time at which the last message was received on the receiver channel connection.

<b>Required</b>	No
<b>Data type</b>	String

***Last message receive date:***

The date on which the last message was received on the receiver channel connection.

<b>Required</b>	No
<b>Data type</b>	String

***nonpersistent message speed:***

The class of service for nonpersistent messages on the receiver channel.

<b>Required</b>	No
<b>Data type</b>	drop-down list
<b>Range</b>	<b>Fast</b> Nonpersistent messages can be lost if there is a transmission failure or if the channel stops when the messages are in transit. <b>Normal</b> Nonpersistent messages are not lost if there is a transmission failure or if the channel stops when the messages are in transit.

***Inbound nonpersistent message reliability:***

The acceptable reliability of message delivery for nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Best effort to Reliable, in order of increasing reliability.

This reliability delivery option is assigned to all WebSphere MQ nonpersistent messages flowing over this receiver channel.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

**Required**  
**Data type**  
**Range**

No  
drop-down list

**Best effort**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable**

Messages are discarded when a messaging engine stops or fails.

***Inbound persistent message reliability:***

The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

**Required**  
**Data type**  
**Range**

No  
drop-down list

**Reliable**

Messages might be discarded when a messaging engine fails.

**Assured**

Messages are not discarded.

---

## WebSphere MQ server bus member [Settings]

A WebSphere MQ server bus member is used for assigning queue points and mediation points to WebSphere MQ queues.

To view this page in the console, click the following path:

**Service integration -> Buses -> *bus\_name* -> [Topology] Bus members -> *member\_name*.**

### Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

## General Properties

### **Name:**

The administrative name of the WebSphere MQ server bus member.

<b>Required</b>	No
<b>Data type</b>	String

### **UUID:**

The universal unique identifier is assigned automatically, for administrative purposes, when you create a new WebSphere MQ server definition.

<b>Required</b>	No
<b>Data type</b>	String

## Connection settings

### **Virtual queue manager name:**

When sending messages to WebSphere MQ, the WebSphere MQ gateway queue manager sees the bus as a remote queue manager. The virtual queue manager name is passed to WebSphere MQ as the name of the remote queue manager.

The default value is the name of the Service Integration bus. If this bus name is not a valid name for a WebSphere MQ queue manager, or if another WebSphere MQ queue manager already has the same name, replace the default value with a unique, valid name for a WebSphere MQ queue manager.

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

<b>Required</b>	Yes
<b>Data type</b>	String

### **Override WebSphere MQ Server connection properties:**

When you select this checkbox, the bus-specific properties override the WebSphere MQ server connection properties. To reset the connection settings to the WebSphere MQ server default values, deselect this checkbox and apply the change.

<b>Required</b>	No
<b>Data type</b>	Boolean

### **WebSphere MQ Host:**

The name of the WebSphere MQ server's host.

This is either the symbolic name or the IP address of the host to which a connection is established for communicating with the queue manager or queue-sharing group that this WebSphere MQ server represents. The value is a string and must be one of the following:

- Symbolic host name
- IPv4 address

- IPv6 address

<b>Required</b>	No
<b>Data type</b>	String

***Port:***

The WebSphere MQ server port. This value is the TCP/IP port number on which the queue manager or queue-sharing group that this WebSphere MQ server represents listens. This value is used when attempting to establish client transport mode connections to WebSphere MQ. The default value is 1414

<b>Required</b>	No
<b>Data type</b>	Integer

***Transport chain name:***

The name of the WebSphere MQ server transport chain. This is the transport chain that is used to establish an outbound network connection to the WebSphere MQ server.

<b>Required</b>	No
<b>Data type</b>	drop-down list

***WebSphere MQ channel:***

The name of the WebSphere MQ server's channel. This value is the WebSphere MQ client channel name to use when connecting to the queue manager or queue-sharing group that this WebSphere MQ server represents. The default value is SYSTEM.DEF.SVRCONN

<b>Required</b>	No
<b>Data type</b>	String

***Messaging authentication alias:***

The name of WebSphere MQ server's authentication alias. This is the name that is used for exchanging messages with WebSphere MQ.

<b>Required</b>	No
<b>Data type</b>	drop-down list

***Trust user identifiers received in messages:***

The WebSphere MQ server's trust user identifier setting. This value determines whether user identifiers that are received in messages from WebSphere MQ are propagated into the message (that is, whether user identifiers that are received as part of message data are used in the service integration bus).

If you select this checkbox, user identifiers that are received as part of WebSphere MQ messages are propagated into messages and used for security purposes within the bus. If you do not select this checkbox, the user identifier is overwritten with the WebSphere MQ server name.

<b>Required</b>	No
<b>Data type</b>	Boolean

***Test connection:***

After you have configured the Connection properties, click this button to test the connection to WebSphere MQ.

## Message points

### WebSphere MQ mediation points

Displays a list of WebSphere MQ mediation points assigned to this WebSphere MQ server bus member.

### WebSphere MQ queue points

Displays a list of WebSphere MQ queue points assigned to this WebSphere MQ server bus member.

## Related Items

### WebSphere MQ server

The WebSphere MQ server that was used to create this bus member.

### JAAS - J2C authentication data

Specifies a list of user identities and passwords for Java 2 connector security to use.

---

## WebSphere MQ servers [Collection]

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group.

To view this page in the console, click the following path:

**Servers -> Server Types -> WebSphere MQ servers.**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see "Disabling WebSphere MQ functionality in WebSphere Application Server" on page 952.

**Name** The administrative name of the WebSphere MQ Server.

### Description

An optional description for the WebSphere MQ server, for administrative purposes.

## Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Test connection	<p>Test the connection to WebSphere MQ.</p> <p>In a single server environment, any attempt to test the connection fails if WebSphere MQ functionality has been disabled. In a network deployment environment, any attempt to test the connection fails if WebSphere MQ functionality has been disabled at either the cell or deployment manager node scope. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.</p>
-----------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## WebSphere MQ server [Settings]

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. Use this panel to view or modify the details of a WebSphere MQ server definition.

To view this page in the console, click one of the following paths:

- **Servers** -> **New server**, choose a server type of “WebSphere MQ server”, then click **Next**.
- **Servers** -> **Server Types** -> **WebSphere MQ servers** -> **New**
- **Servers** -> **Server Types** -> **WebSphere MQ servers** -> *server\_name*
- **Service integration** -> **Buses** -> *bus\_name* -> [Topology] **Bus members** -> *member\_name* -> [Related Items] **WebSphere MQ server**

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

## Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

### General Properties

#### **Name:**

The administrative name of the WebSphere MQ Server.

The name that you use for this WebSphere MQ server definition must be unique.

<b>Required</b>	Yes
<b>Data type</b>	String

#### **UUID:**

The universal unique identifier assigned by the system to this WebSphere MQ server for administrative purposes.

This identifier is assigned automatically when you create a new WebSphere MQ server definition.

<b>Required</b>	No
<b>Data type</b>	String

**Description:**

An optional description for the WebSphere MQ server, for administrative purposes.

<b>Required</b>	No
<b>Data type</b>	Text area

**WebSphere MQ server name:**

The name of the WebSphere MQ queue manager or queue sharing group, as defined in WebSphere MQ.

<b>Required</b>	Yes
<b>Data type</b>	String

**Server Type:**

A server can be either a queue manager or queue sharing group. Select the appropriate type for the server you want to establish a connection to.

<b>Required</b>	No
<b>Data type</b>	Radio button
<b>Range</b>	

**Queue manager**

A WebSphere MQ queue manager on the WebSphere MQ network with which WebSphere Application Server applications undertake messaging.

**Queue sharing group**

A WebSphere MQ for z/OS queue-sharing group on the WebSphere MQ network with which WebSphere Application Server applications undertake messaging.

**Use bindings transport mode if available:**

When selected, bindings transport mode will be used in preference to client transport mode when establishing connections to the WebSphere MQ server. Otherwise client transport mode will always be used.

To connect to a WebSphere MQ queue manager or queue-sharing group in bindings mode, WebSphere Application Server needs to know where to load native libraries from. This information is stored in the **Native library path** property of the WebSphere MQ messaging provider. If you want to use a direct binding to WebSphere MQ, rather than a TCP/IP network connection, select this option and configure the **Native library path** property as described in “Configuring the WebSphere MQ messaging provider with native libraries information” on page 806.

**Note:** If you are using Resource Access Control Facility (RACF) as the security manager on your WebSphere MQ for z/OS system, and using bindings transport mode, you must specify in uppercase characters the user names and passwords for authentication aliases. If you are using RACF and client transport mode, you can specify the user names and passwords in either upper or lowercase characters.

<b>Required</b>	No
<b>Data type</b>	Boolean

***WebSphere MQ host:***

WebSphere MQ server host defined by either its symbolic host name or an IP address.

<b>Required</b>	Yes
<b>Data type</b>	String

***WebSphere MQ port:***

This is the port that will be used when attempting to establish client transport mode connections to WebSphere MQ.

<b>Required</b>	Yes
<b>Data type</b>	Integer
<b>Range</b>	0 through 65535

***Transport chain name:***

The transport chain used to establish an outbound network connection to the WebSphere MQ server.

<b>Required</b>	Yes
<b>Data type</b>	Custom

***WebSphere MQ channel:***

The WebSphere MQ server connection channel, as defined in WebSphere MQ.

<b>Required</b>	Yes
<b>Data type</b>	String

***Test connection:***

Test the connection to WebSphere MQ.

In a single server environment, any attempt to test the connection fails if WebSphere MQ functionality has been disabled. In a network deployment environment, any attempt to test the connection fails if WebSphere MQ functionality has been disabled at either the cell or deployment manager node scope. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

***Messaging authentication alias:***

WebSphere MQ server authentication alias name used when exchanging messages with WebSphere MQ.

<b>Required</b>	No
<b>Data type</b>	drop-down list

***Trust user identifiers received in messages:***

If selected user identifiers received as part of WebSphere MQ messages will be used for security purposes within the bus.

Select this option if you do not want the user IDs in messages to be overwritten with the administrative name of the WebSphere MQ server.

<b>Required</b>	No
<b>Data type</b>	Boolean

#### ***Automatic discovery of resources :***

When selected this enables the discovery of WebSphere MQ queue names to assist the administrator.

<b>Required</b>	No
<b>Data type</b>	Boolean

#### ***Resource discovery authentication alias:***

WebSphere MQ server authentication alias used for WebSphere MQ resource discovery.

<b>Required</b>	No
<b>Data type</b>	drop-down list

#### ***Reply-to queue :***

WebSphere MQ queue name used by the system to obtain messages used in the resource discovery process.

<b>Required</b>	No
<b>Data type</b>	Text

## **Related Items**

### **JAAS - J2C authentication data**

Specifies a list of user identities and passwords for Java 2 connector security to use.

This item is not available until after the WebSphere MQ server definition has been created.

---

## **Service integration custom properties**

Use custom properties to configure advanced settings for service integration objects such as messaging engines.

You can use the custom properties page to define the following service integration properties:

- “sib.msgstore.cachedDataBufferSize” on page 2401
- “sib.msgstore.discardableDataBufferSize” on page 2401
- “sib.msgstore.jdbcFailoverOnDBConnectionLoss” on page 2401
- “sib.msgstore.jdbcInitialDatasourceWaitTimeout” on page 2402
- “sib.msgstore.jdbcResAuthForConnections” on page 2402
- “sib.msgstore.jdbcStaleConnectionRetryDelay” on page 2402
- “sib.msgstore.storeFullWaitForCheckPoint” on page 2403
- “sib.msgstore.transactionSendLimit” on page 2403
- “sib.ra.zosMessageLockTimeout” on page 2403

- “sib.trm.retry” on page 2404
- “sib.wsrn.tokenLockTimeout” on page 2404

### **sib.msgstore.cachedDataBufferSize**

The size in bytes of the data buffer that the messaging engine uses to contain data for which the quality of service attribute is *better than* best effort nonpersistent and that is held in the data store. The default value is 320000, which is approximately 320 kilobytes.

The purpose of the cached data buffer is to optimize the performance of the messaging engine by caching in memory the data that the messaging engine might otherwise have to read from the data store. As it writes data to the data store and reads from the data store, the messaging engine attempts to add that data to the cached data buffer. The messaging engine might discard data already in the buffer to make space.

Data type	Bytes
Default	40000000

### **sib.msgstore.discardableDataBufferSize**

The size in bytes of the data buffer that the messaging engine uses to contain data for which the quality of service attribute is best effort nonpersistent. The default value is 320000, which is approximately 320 kilobytes.

The discardable data buffer contains all data for which the quality of service attribute is best effort nonpersistent. That data comprises both data that is involved in active transactions, and any other best effort nonpersistent data that the messaging engine has neither discarded nor consumed. The messaging engine holds this data entirely within this memory buffer and never writes the data to the data store. When the messaging engine adds data to the discardable data buffer, for example when the messaging engine receives a best effort nonpersistent message from a client, the messaging engine might discard data already in the buffer to make space. The messaging engine can discard only data that is not involved in active transactions. This behavior enables the messaging engine to discard best effort nonpersistent messages.

Increasing the size of the discardable data buffer allows more best effort nonpersistent data to be handled before the messaging engine begins to discard messages.

If the messaging engine attempts to add data to the discardable data buffer when insufficient space remains after discarding all the data that is not involved in active transactions, the messaging engine throws a `com.ibm.ws.sib.msgstore.OutOfCacheSpace` exception. Client applications can catch this exception, wrapped inside API-specific exceptions such as `javax.jms.JMSEException`.

Data type	Bytes
Default	1280000

### **sib.msgstore.jdbcFailoverOnDBConnectionLoss**

The property determines the behavior of the messaging engine and its hosting server in the event that the connection to the data store is lost.

Property value	Behavior when the data store connection is lost
true (default)	The high availability manager stops the messaging engine and its hosting application server when the next core group service <b>Is alive</b> check takes place (the default value is 120 seconds). If a node agent is monitoring the server, and you have enabled automatic restart in the monitoring policy for the server, the server restarts. The messaging engine starts when an appropriate server is available. <b>Note:</b> Messages with a reliability level that is lower than assured persistent might be accepted by the messaging engine during the interval between <b>Is alive</b> checks, and might be lost.
false	The messaging engine continues to run and accept work, and periodically attempts to regain the connection to the data store. If work continues to be submitted to the messaging engine while the data store is unavailable, the results can be unpredictable, and the messaging engine can be in an inconsistent state when the data store connection is restored. <b>Note:</b> If work continues to be submitted to the messaging engine, even nonpersistent messaging can fail because the messaging engine might need to use the data store, for example to allocate a unique ID to a message, or to move nonpersistent messages out of memory.

### **sib.msgstore.jdbcInitialDatasourceWaitTimeout**

The time, in milliseconds, to wait for the data store to become available. This time includes the time required to establish a connection to the database and to obtain the required table locks.

Data type	Milliseconds
Default	900000 (15 minutes)

### **sib.msgstore.jdbcResAuthForConnections**

The messaging engine resource authorization mechanism used when sharing connections. Default value is Container.

Data type	String
Default	Container

### **sib.msgstore.jdbcStaleConnectionRetryDelay**

The time, in milliseconds, to wait between attempts to connect to the data store.

For example, if you set the `sib.msgstore.jdbcInitialDatasourceWaitTimeout` property to 600000, and the `sib.msgstore.jdbcStaleConnectionRetryDelay` property to 3000, the messaging engine will attempt to connect every 3 seconds for 10 minutes.

Data type	Milliseconds
Default	2000 (2 seconds)

## **sib.msgstore.storeFullWaitForCheckPoint**

This property determines the action a messaging engine takes when a file store is full and applications try to send further messages.

When a file store is full, the messaging engine carries out a checkpoint of the log file to reconcile all message sends and receives since the last checkpoint. This process might take some time to complete. Between the time when the file store becomes full and the time when the checkpoint is complete, if applications try to send a message, the messaging engine throws the exception `ObjectStoreFullException` and issues message `CWSOM1042E`.

When an application thread that is sending a message finds that the file store is full, it requests a checkpoint. The default behavior, with the property value set to false, is that the application thread then throws the exception `ObjectStoreFullException` to the application immediately and returns. You can select an alternative behavior by setting the property value to true. With this property value, the application thread does not throw the exception, but waits until the checkpoint has completed. If the checkpoint frees space in the file store, the application thread proceeds and sends the messages before returning. If the file store is still full after the checkpoint, the application thread throws the exception to the application.

Set the property value to true, and make application threads wait for the checkpoint to be completed, if your applications delete all the messages in the file store, and so they logically know that the file store is no longer full. Although the applications must still wait until the checkpoint is complete, they do not receive exceptions while the checkpoint is being carried out, and they do not have to retry the send.

Data type	Boolean
Default	False

## **sib.msgstore.transactionSendLimit**

The maximum number of operations that the messaging engine includes in each transaction. For example, each JMS send or receive is an operation that counts towards the transaction send limit. The default value is 100.

Data type	Integer
Default	100

## **sib.ra.zosMessageLockTimeout**

The number of seconds that a message is locked in the messaging engine after that message has been submitted to Workload management (WLM) for z/OS for delivery to a message-driven bean.

WLM allocates the message to a servant region, which creates a connection to the messaging engine. The servant region then consumes the message and passes it to the `onMessage` method of the message-driven bean.

If the servant region fails to connect to the messaging engine and consume the message before passing it to the message-driven bean, the message remains locked until the timeout value is reached. When the timeout is reached, the message is unlocked and delivery is retried.

During startup of an application server, if WLM delivers a message to a servant region before the infrastructure that is required to connect to the messaging engine is available, that servant region might fail to connect to a messaging engine. Connection failures of this type are indicated by `CWSIV1052W` entries in the job log of the servant region. If you see such entries in the job log, and you have locked messages, consider using this property to make the Message Lock Timeout shorter.

Data type	Seconds
Default	300

### **sib.trm.retry**

The messaging engine to messaging engine connection retry interval, in seconds. The retry interval is the time delay left between attempts to contact neighboring messaging engines with which communications exist. The default retry interval is 30 seconds.

Data type	Seconds
Default	30

### **sib.wsrmtokenLockTimeout**

This property affects WS-ReliableMessaging managed qualities of service. Set this property on the messaging engine that is specified in the policy binding for the WS-ReliableMessaging application.

This property is the amount of time, in milliseconds, that a lock is held on a WS-ReliableMessaging message. If a server fails while processing a message, the lock is released at the end of this timeout period, so that other servers can continue the processing. If the original server recovers before the timeout period ends, it continues processing the message. The lock is released at the end of the timeout period even if the message is still being processed.

If your system is processing large messages, you might want to increase the value of this property. For example, if a message takes 12 minutes to process, the lock is released 2 minutes before processing is complete. To avoid this situation, change the property to a value that is greater than 12 minutes.

If your system is processing small messages, you might want to decrease the value of this property, so that if a failure occurs the lock is released more quickly, and other servers can continue the processing without delay.

#### **Note:**

If a servant region ends abnormally while processing a message, the control region starts a new servant region, which must wait for the message lock to be released before it can continue processing the message. If the servant region is inactive for too long, the control region ends it and starts another servant region. Also, if the servant region takes a long time to process a message, the control region might perceive the servant region to be inactive, and end it.

The amount of time that a servant region can remain inactive until the control region ends it is affected by various timeouts, such as the `control_region_wlm_dispatch_timeout` property. Examine the configuration of your system to determine what this period of time is for that system.

To avoid the control region ending the servant region before the message has been processed, set the value of the token lock timeout property to be less than the amount of time that the servant region can be inactive.

Data type	Milliseconds
Default	600000 (10 minutes)

---

## SIBAdminCommands: Bus administrative commands for the AdminTask object

You can use these administrative commands to manage service integration buses.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

---

### createSIBus command

Use the createSIBus command to create a new service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

This command creates a new service integration bus.

### Target object

None

### Required parameters

**-bus** *busname*

The name by which you want the service integration bus to be known. Choose a unique name.

### Conditional parameters

None.

## Optional parameters

### **-description** *text*

An optional description for the bus, for administrative purposes.

### **-secure** **TRUE** | **FALSE**

This parameter is deprecated for this version.

### **interEngineAuthAlias** *name*

The name of the authentication alias used to authorize communication between messaging engines on the bus.

You must specify an inter-engine authentication alias if the bus contains a WebSphere Application Server Version 6.x bus member. When bus security is enabled, the bus uses the inter-engine authentication alias to authenticate incoming connections from other messaging engines. An unauthorized messaging engine cannot connect to the bus.

### **-mediationsAuthAlias** *name*

The name of the authentication alias used to authorize mediations to access the bus.

### **-securityGroupCacheTimeout** *timeout\_value*

The length of time, in minutes, that a security group will be cached for. *timeout\_value* can be in the range 0 through 99999. The default value is 120.

Increasing the timeout decreases the load on the user registry and improves performance but makes the system less responsive to changes in a user's group membership. To tune the group cache to the optimum setting, you need to balance the need for responsiveness with the registry load. For example, if the system must respond quickly to changes in a user's group membership, specify a timeout of 15 minutes. If the system needs to respond less frequently, for example to respond to overnight changes, specify a timeout of 1440 minutes (24 hours). With a setting of 0, entries in the cache do not timeout, and so remain until the server is next restarted.

A change to this value is effective immediately and only affects the group cache of the bus for which the configuration was changed.

### **-protocol** *protocol*

The transport chain used for communication between messaging engines in this bus.

The transport chain must correspond to one of the transport chains defined in the Messaging engine inbound transports settings for the server. All servers automatically have a number of transport chains defined to them, and it is also possible to create new transport chains.

The default transport chain is InboundBasicMessaging.

### **-discardOnDelete** **TRUE** | **FALSE**

Set this option to TRUE if messages on a deleted message point can be discarded. Set this option to FALSE if messages on a deleted message point should be retained at a system exception destination.

### **highMessageThreshold** *number*

The maximum total number of messages that any messaging engine on the bus can place on its message points.

This value is used to set the default high message threshold for a messaging engine when the messaging engine is created.

### **configurationReloadEnabled** **TRUE** | **FALSE**

Set this option to TRUE to dynamically reload configuration files for this bus.

When this option is TRUE, certain changes to the bus configuration are applied without requiring the messaging engines to be restarted. These changes are applied when destinations or mediations are added to, or removed from, the bus. This option also controls whether automatic updates occur on all the messaging engines on the bus.

**-busSecurity TRUE | FALSE**

Set this option to TRUE to enforce the authorization policy for the bus, which also requires administrative security to be enabled. Set this option to FALSE if you always want to disable bus security. If administrative security is disabled, the bus is insecure.

**-bootstrapPolicy SIBSERVICE\_ENABLED | MEMBERS\_AND\_NOMINATED | MEMBERS\_ONLY**

Set one of three options to enforce a bus members policy for the bus.

**SIBSERVICE\_ENABLED**

Any server in the cell that has the SIB service enabled can service bootstrap requests.

**MEMBERS\_AND\_NOMINATED**

Only bus members or a nominated bootstrap server can service bootstrap requests.

**MEMBERS\_ONLY**

Only bus members can service bootstrap requests.

**-useServerIdForMediations TRUE | FALSE**

Set this option to TRUE if you want to run mediations using a single server identity for the bus. This option enables you to run mediations across multiple security domains without the need to specify a mediation authentication alias for each domain. You can use a server identity to run mediations on the global domain. Set this option to FALSE if you want to run mediations using a mediations authentication alias.

**-auditAllowed TRUE | FALSE**

Set this option to be TRUE to enable security auditing for the bus. Set this option to be FALSE to disable security auditing for the bus. The default value is TRUE. You must have Audit Administrator privileges to use this parameter.

## Example

```
AdminTask.createSIBus('[-bus bus1 -description [A new bus] -busSecurity false]')
'bus1(cells/cell01/buses/bus1|sib-bus.xml#SIBus_1213019988044)'
```

---

## deleteSIBus command

Use the deleteSIBus command to delete a specified service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

This command deletes a specified service integration bus, and deletes the artifacts that are related to the bus including queue points, publication points, and mediation points. This command also deletes the new artifacts that are created when queues are assigned or mediated to a WebSphere MQ server bus member, including the WebSphere MQ server bus members. This command does not delete the following:

- Queue managers that are associated with the bus through WebSphere MQ server definitions.

- Messages residing on WebSphere MQ queue managers.
- WebSphere MQ queues.

**CAUTION:**

**This command deletes everything on and related to the bus. There is no confirmation prompt before deleting the bus.**

### Target object

The specified service integration bus.

### Required parameters

**-bus** *busname*

The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

### Conditional parameters

None.

### Optional parameters

None.

### Example

```
AdminTask.deleteSIBus(['-bus bus1]')
```

---

## listSIBuses command

Use the listSIBuses command to list all service integration buses for a given scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

### Purpose

This command lists the names of all service integration buses for a given scope.

### Target object

A given scope.

### Required parameters

None.

## Conditional parameters

None.

## Optional parameters

None.

## Example

```
AdminTask.listSIBuses()
'bus1(cells/cell01/buses/bus1|sib-bus.xml)
bus2(cells/cell01/buses/bus2|sib-bus.xml)'
```

---

## modifySIBus command

Use the modifySIBus command to modify the properties of a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

This command modifies the properties of a service integration bus.

## Target object

A bus.

## Required parameters

**-bus** *busname*

The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

## Conditional parameters

None.

## Optional parameters

**-description** *text*

An optional description for the bus, for administrative purposes.

**-secure** TRUE | FALSE

This parameter is deprecated for this version.

**-mediationsAuthAlias** *name*

The name of the authentication alias used to authorize mediations to access the bus.

**-securityGroupCacheTimeout** *timeout\_value*

The length of time, in minutes, that a security group will be cached for. *timeout\_value* can be in the range 0 through 99999. The default value is 120.

Increasing the timeout decreases the load on the user registry and improves performance but makes the system less responsive to changes in a user's group membership. To tune the group cache to the optimum setting, you need to balance the need for responsiveness with the registry load. For example, if the system must respond quickly to changes in a user's group membership, specify a timeout of 15 minutes. If the system needs to respond less frequently, for example to respond to overnight changes, specify a timeout of 1440 minutes (24 hours). With a setting of 0, entries in the cache do not timeout, and so remain until the server is next restarted.

A change to this value is effective immediately and only affects the group cache of the bus for which the configuration was changed.

**-protocol** *protocol*

The transport chain used for communication between messaging engines in this bus.

**-discardOnDelete** TRUE | FALSE

Set this option to TRUE if messages on a deleted message point can be discarded. Set this option to FALSE if messages on a deleted message point should be retained at a system exception destination.

**-busSecurity** TRUE | FALSE

Set this option to TRUE to enforce the authorization policy for the bus, which also requires administrative security to be enabled. Set this option to FALSE if you always want to disable bus security. If administrative security is disabled the bus is not secured.

**-permittedChains** ALL | SSL\_ENABLED | LISTED

Set one of three options to enforce a transport policy for the bus.

**ALL** Allow the use of all defined transport channel chains.

**SSL\_ENABLED**

Restrict the use of defined transport channel chains to those protected by SSL.

**LISTED**

Restrict the use of defined transport channel chains to the list of protected transports.

**-bootstrapPolicy** SIBSERVICE\_ENABLED | MEMBERS\_AND\_NOMINATED | MEMBERS\_ONLY

Set one of three options to enforce a bus members policy for the bus.

**SIBSERVICE\_ENABLED**

Any server in the cell that has the SIB service enabled can service bootstrap requests.

**MEMBERS\_AND\_NOMINATED**

Only bus members or a nominated bootstrap server can service bootstrap requests.

**MEMBERS\_ONLY**

Only bus members can service bootstrap requests.

**-useServerIdForMediations** TRUE | FALSE

Set this option to TRUE if you want to run mediations using a single server identity for the bus. This option enables you to run mediations across multiple security domains without the need to specify a mediation authentication alias for each domain. You can use a server identity to run mediations on the global domain. Set this option to FALSE if you want to run mediations using a mediations authentication alias.

**-auditAllowed** TRUE | FALSE

Set this option to be TRUE to enable security auditing for the bus. Set this option to be FALSE to disable security auditing for the bus. The default value is TRUE. You must have Audit Administrator privileges to use this parameter.

## Example

```
AdminTask.modifySIBus('[-bus bus1 -description [A new description of the bus]]')
'bus1(cells/cell01/buses/bus1|sib-bus.xml)'
```

---

## showSIBus command

Use the showSIBus command to show the properties of a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

## Purpose

This command lists details about the properties of a service integration bus.

## Target object

A bus.

## Required parameters

**-bus** *busname*

The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

## Conditional parameters

None.

## Optional parameters

None.

## Example

```
AdminTask.showSIBus('[-bus bus1]')
'{secure=false, useServerIdForMediations=false, discardOnDelete=false,
auditAllowed=true, highMessageThreshold=50000, busName=bus1,
securityGroupCacheTimeout=120, configurationReloadEnabled=true,
bootstrapPolicy=SIBSERVICE_ENABLED, permittedChains=ALL}'
```

---

## addSIBusMember command

Use the addSIBusMember command to add a member to a service integration bus by using the wsadmin tool. A bus member can be an application server, a WebSphere MQ server, or a server cluster.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `addSIBusMember` command adds a new member to a service integration bus. When an application server is added as a member of a bus, a messaging engine with default settings is created automatically.

When a cluster is added as a member of a bus, if messaging engine policy assistance is not enabled, a messaging engine with default settings is created automatically. To create an additional messaging engine for a bus member, use the `createSIBEngine` command.

When a cluster is added to a bus, if messaging engine policy assistance is enabled and the high availability messaging engine policy type is specified, a messaging engine with settings that support the high availability policy is created automatically.

When a cluster is added to a bus, if messaging engine policy assistance is enabled and the scalability, or scalability with high availability, messaging engine policy type is specified, one messaging engine with settings that support the selected policy is created automatically. You must then use the `createSIBEngine` command to create additional messaging engines (one for each application server in the cluster). For each new messaging engine, the settings that support the selected policy are created automatically.

If you use the `addSIBusMember` command with messaging engine policy assistance enabled and the custom messaging engine policy type specified, you can set the behavior for the first messaging engine, then use the `createSIBEngine` command to create additional messaging engines.

When a WebSphere MQ server is added as a member of a bus, a server proxy is created that can override the parent connection properties (host, port, channel, and SSL security configuration alias) that are defined in the WebSphere MQ server. By this means, a different set of connection properties can be assigned to each bus membership.

## Target object

None.

A bus member object is created. If the bus member is a server or a server cluster, a messaging engine is also created.

## Required parameters

**-bus** *bus\_name*

The name by which the service integration bus is known. You can use the `listSIBuses` command to list the names of existing buses.

## Conditional parameters

**-node** *node\_name*

**-server** *server\_name*

To add an application server as a bus member, specify both the name of the node on which the server runs, and the name of the server.

If you specify these parameters, do not specify the **-cluster** or **-wmqServer** parameters.

**-cluster** *cluster\_name*

To add a server cluster as a bus member, specify the name of the cluster.

If you specify this parameter, do not specify the **-node**, **-server**, or **-wmqServer** parameters.

**-wmqServer**

To add a WebSphere MQ server as a bus member, specify the name of the WebSphere MQ server. This is the name that was specified in the **-name** parameter when the WebSphere MQ server was created.

If you specify this parameter, do not specify the **-cluster**, **-node**, or **-server** parameters.

## Optional parameters

**-description** *text*

An optional description for the bus member, for administrative purposes.

**-virtualQueueManagerName**

The override value for the name of the WebSphere MQ server virtual queue manager. When sending messages to WebSphere MQ, the WebSphere MQ gateway queue manager sees the bus as a remote queue manager. The virtual queue manager name is the name that is passed to WebSphere MQ as the name of this remote queue manager. The default value is the name of the bus. If this value is not a valid name for a WebSphere MQ queue manager, or if another WebSphere MQ queue manager already exists that has the same name, then replace the default value with another value that is a valid and unique name for a WebSphere MQ queue manager. To be valid, the name must meet the following criteria:

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

**-host**

The override value for the WebSphere MQ server bus member host attribute. This value is the host name or IP address of the host to which a connection is established to communicate with a queue manager or queue-sharing group. Use this parameter if the **-wmqServer** parameter is specified.

**-port**

The override value for the WebSphere MQ server bus member port attribute. The port number is monitored by a queue manager listener or queue-sharing group listener, which is listening for connections. The default value is 1414. Use this parameter if the **-wmqServer** parameter is specified.

**-channel**

The override value for the WebSphere MQ server bus member channel attribute. This is the name of the server connection channel that is used to establish a connection to the WebSphere MQ queue manager or WebSphere MQ for z/OS queue sharing group. The default value is SYSTEM.DEF.SVRCONN. Use this parameter if the **-wmqServer** parameter is specified.

**-securityAuthAlias**

The override value for the WebSphere MQ server bus member **securityAuthAlias** attribute. This is the authentication alias that is supplied when connecting to the WebSphere MQ server. This parameter has no default. Use this parameter if the **-wmqServer** parameter is specified.

**-transportChain**

The override value for the WebSphere MQ server bus member **transportChain** attribute. This is the name of the transport chain to use when communicating with WebSphere MQ. The default value is OutboundBasicWMQClient. Use this parameter if the **-wmqServer** parameter is specified.

**-trustUserIds** TRUE | FALSE

The override value for the WebSphere MQ server bus member **trustUserIds** attribute. This determines whether user IDs that are received in messages from WebSphere MQ are propagated into messages.

The application user ID is always set from the **jsAppUserIdRFH2** value. If this is not present (either because the key/value pair is not present in the <si b> folder of the RFH2 header, or because the message does not have a RFH2 header), this field is not set. This parameter has two possible values:

**TRUE** User IDs are propagated into messages.

**FALSE**

User IDs are not propagated into messages.

The default value is TRUE. Use this parameter if the **-wmqServer** parameter is specified.

**-enableAssistance TRUE | FALSE**

A parameter that specifies whether to enable messaging engine policy assistance. This parameter has two possible values:

**TRUE** Messaging engine policy assistance is enabled. You must supply a **-policyName** parameter.

**FALSE**

Messaging engine policy assistance is not enabled. This is the default value. Use this parameter if the **-cluster** parameter is specified.

**-policyName HA | SCALABILITY | SCALABILITY\_HA | CUSTOM**

The type of messaging engine policy to apply to the cluster. This parameter has four possible values:

**HA** Apply the high availability messaging engine policy to the cluster.

**SCALABILITY**

Apply the scalability messaging engine policy to the cluster.

**SCALABILITY\_HA**

Apply the scalability with high availability messaging engine policy to the cluster.

**CUSTOM**

Apply the custom messaging engine policy to the cluster.

This parameter has no default. Use this parameter if the **-cluster** parameter is specified and the **-enableAssistance** parameter is set to TRUE.

**-failover TRUE | FALSE**

A parameter that specifies whether the messaging engine in the cluster can fail over to another server in the cluster if the host server for the messaging engine fails. This parameter has two possible values:

**TRUE** The messaging engine can fail over.

**FALSE**

The messaging engine cannot fail over.

The default value is FALSE. Use this parameter if the **-cluster** parameter is specified, the **-enableAssistance** parameter is set to TRUE, and the **-policyName** parameter is set to CUSTOM.

**-fallback TRUE | FALSE**

A parameter that specifies whether the messaging engine in the cluster that has failed over can fail back to a more preferred server in the preferred servers list if that server becomes available again. This parameter has two possible values:

**TRUE** The messaging engine can fail back. If you use this option, supply a **-preferredServerList** parameter.

**FALSE**

The messaging engine cannot fail back.

The default value is FALSE. Use this parameter if the **-cluster** parameter is specified, the **-enableAssistance** parameter is set to TRUE, and the **-policyName** parameter is set to CUSTOM.

**-preferredServersOnly** TRUE | FALSE

A parameter that specifies whether the messaging engine in the cluster can run only on servers in the preferred servers list, or on any server in the cluster. This parameter has two possible values:

**TRUE** The messaging engine can run only on servers in the preferred servers list. If you use this option, supply a **-preferredServerList** parameter.

**FALSE**

The messaging engine can run on any server in the cluster.

The default value is FALSE. Use this parameter if the **-cluster** parameter is specified, the **-enableAssistance** parameter is set to TRUE, and the **-policyName** parameter is set to CUSTOM.

**-preferredServerList** *{{node\_name server\_name}}*

The list of servers, in order of preference, on which the messaging engine in the cluster prefers to run. For each server in the list, specify both the name of the node on which the server runs, and the name of the server. There is no default value for this parameter. Use this parameter if the **-cluster** parameter is specified, the **-enableAssistance** parameter is set to TRUE, and the **-policyName** parameter is set to CUSTOM.

**-fileStore**

Create a file store to use as a message store for the messaging engine. A file store is a type of message store that directly uses files in a file system through the operating system. The alternative is to use a data store. For more information, see the related links.

**-logSize** *logsize*

The size of the log file in MB. Use this parameter if the **-fileStore** parameter is specified.

**-logDirectory** *logdirectoryname*

The name of the log file directory if you do not want to use the default log directory. Use this parameter if the **-fileStore** parameter is specified.

**-minPermanentStoreSize** *minpermanentstoresize*

The minimum size of the permanent store file in MB. Use this parameter if the **-fileStore** parameter is specified.

**-minTemporaryStoreSize** *mintemporarystoresize*

The minimum size of the temporary store file in MB. Use this parameter if the **-fileStore** parameter is specified.

**-maxPermanentStoreSize** *maxpermanentstoresize*

The maximum size of the permanent store file in MB. Use this parameter if the **-fileStore** parameter is specified.

**-maxTemporaryStoreSize** *maxtemporarystoresize*

The maximum size of the temporary store file in MB. Use this parameter if the **-fileStore** parameter is specified.

**-unlimitedPermanentStoreSize** TRUE | FALSE

A parameter that specifies whether the permanent store size is unlimited. This parameter has two possible values:

**TRUE** The permanent store size is unlimited.

**FALSE**

The permanent store size is limited. If you use this option, supply a **-maxPermanentStoreSize** parameter.

Use this parameter if the **-fileStore** parameter is specified.

**-unlimitedTemporaryStoreSize** TRUE | FALSE

A parameter that specifies whether the temporary store size is unlimited. This parameter has two possible values:

**TRUE** The temporary store size is unlimited.

**FALSE**

The temporary store size is limited. If you use this option, supply a **-maxTemporaryStoreSize** parameter.

Use this parameter if the **-fileStore** parameter is specified.

**-permanentStoreDirectory** *permanentstoredirectoryname*

The name of the permanent store directory if you do not want to use the default permanent store directory. Use this parameter if the **-fileStore** parameter is specified.

**-temporaryStoreDirectory** *temporarystoredirectoryname*

The name of the temporary store directory if you do not want to use the default temporary store directory. Use this parameter if the **-fileStore** parameter is specified.

**-dataStore**

Create a data store to use as a message store for the messaging engine.

A data store consists of the set of tables that a messaging engine uses to store persistent data in a database. See “Data store tables” on page 2109 for a list of the tables that comprise a data store. All the tables in a data store are held in the same database schema. You can create multiple data stores in the same database, provided that you use a different schema name for each data store. The alternative is to use file store (the default). For more information, see the related links.

**-createDefaultDataSource** **TRUE** | **FALSE**

A parameter that specifies whether to create a default data source when the messaging engine is created. This parameter has two possible values:

**TRUE** Create a default data source.

**FALSE**

Do not create a default data source.

Use this parameter if the **-dataStore** parameter is specified. Do not use this parameter if the **-cluster** parameter is specified.

**-dataSourceJndiName** *jndiname*

The JNDI name of the data source that the messaging engine uses to access the relational database management system (RDBMS) for the data store. Use this parameter if the **-dataStore** parameter is specified.

**-authAlias** *authalias*

The name of the authentication alias that the messaging engine uses to connect to the database in its data store. Use this parameter if the **-dataStore** parameter is specified.

**-createTables** *datasource*

Create the database tables for the specified data source automatically. If this option is not specified, the database administrator must create the tables. Use this parameter if the **-dataStore** parameter is specified.

**-schemaName** *schemaname*

The name of the database schema that contains the tables for the data store, if you do not want to use the default schema name. For details about the default schema, see “Creating users and schemas in the database” on page 2100. Use this parameter if the **-dataStore** parameter is specified.

**-initialHeapSize** *size*

The initial Java virtual machine (JVM) heap size, in megabytes, of the server or of each server in a cluster. There is no default value. If this parameter is not specified, no change is made. If this parameter is specified, the supplied value must be greater than or equal to zero and less than or equal to 2048. If the parameter is supplied without a value, an error message is generated.

**Note:** This parameter is ignored if the server that is the subject of the `addSIBusMember` command is running on z/OS, or, if the subject is a cluster, any server in the cluster is running on z/OS.

**-maxHeapSize** *size*

The maximum JVM heap size, in megabytes, of the server or of each server in a cluster. There is no default value. If this parameter is not specified, no change is made. If this parameter is specified, the supplied value must be greater than or equal to zero and less than or equal to 2048. If the parameter is supplied without a value, an error message is generated.

**Note:** This parameter is ignored if the server that is the subject of the `addSIBusMember` command is running on z/OS, or, if the subject is a cluster, any server in the cluster is running on z/OS.

## Examples

Add a server1 on node1 as a member of bus1 with a default file store.

```
AdminTask.addSIBusMember('[-bus bus1 -node node1 -server server1]')
```

Add server1 as a member of bus1, and use a file store to save messages.

```
AdminTask.addSIBusMember('[-bus bus1 -node node1 -server server1 -fileStore]')
```

Add server1 as a member of bus1, and use a file store to save messages, with options.

```
AdminTask.addSIBusMember('[-bus bus1 -node node1 -server server1 -fileStore
-logSize 100 -logDirectory C:\filestore1]')
```

Add server1 as a member of bus1, and use a data store to save messages.

```
AdminTask.addSIBusMember('[-bus bus1 -node node1 -server server1 -dataStore]')
```

Add server1 as a member of bus1, and use a data store to save messages, with options.

```
AdminTask.addSIBusMember('[-bus bus1 -node node1 -server server1 -dataStore
-createDefaultDatasource true -datasourceJndiName myjndi]')
```

Add cluster1 to bus1 without using messaging engine policy assistance and use a file store as the message store for the messaging engine.

```
AdminTask.addSIBusMember('[-bus bus1 -cluster cluster1 -filestore true
-logDirectory C:\filestore1 -permanentStoreDirectory C:\filestore2
-temporaryStoreDirectory C:\filestore3]')
```

Add cluster1 to bus1 and use messaging engine policy assistance and the high availability messaging engine policy. Use a file store as the message store for the messaging engine.

```
AdminTask.addSIBusMember('[-bus bus1 -cluster cluster1 -enableAssistance true
-policyName HA -fileStore -permanentStoreDirectory C:\myfilestore1
-temporaryStoreDirectory C:\myfilestore1 -logDirectory C:\myfilestore]')
```

Add cluster1 to bus1 and use messaging engine policy assistance and the custom messaging engine policy. Use a file store as the message store for the messaging engine. Set the messaging engine to fail over, not to fail back, and to run only on server1 and server2.

```
AdminTask.addSIBusMember('[-bus bus1 -cluster cluster1 -enableAssistance true
-policyName CUSTOM -fileStore -permanentStoreDirectory C:\myfilestore1
-temporaryStoreDirectory C:\myfilestore1 -logDirectory C:\temp\myfilestore
-failover true -failback false -preferredServersOnly true
-preferredServerList [[node1 server1] [node2 server2]]]')
```

---

## listSIBusMembers command

Use the `listSIBusMembers` command to list the members of a service integration bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

## Purpose

This command lists the names of all members in a service integration bus. The list includes all WebSphere MQ servers that are bus members.

## Target object

A service integration bus.

## Required parameters

**-bus** *busname*

The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

## Conditional parameters

None.

## Optional parameters

None.

## Example

```
AdminTask.listSIBusMembers(['-bus Bus1 '])
```

```
[cells/9994GKCCe11/buses/Bus1|sib-bus.xml#SIBusMember_1092155259869]
[cells/9994GKCCe11/buses/Bus1|sib-bus.xml#SIBusMember_1092159844593]
[cells/9994GKCCe11/buses/Bus1|sib-bus.xml#SIBusMember_1092160253751]
```

---

## modifySIBusMemberPolicy command

Use the modifySIBusMemberPolicy command to change the messaging engine configuration for a cluster that is a member of a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

This command changes the messaging engine policy that is applied to a cluster that is a member of a service integration bus. You can enable or disable messaging engine policy assistance, or use messaging engine policy assistance to change the messaging engine configuration for a cluster. For example, you can change from a high availability messaging engine policy to a scalability messaging engine policy.

If you enable messaging engine policy assistance and select the high availability policy, the settings of the first messaging engine in the cluster are automatically set to support the policy. If there are currently additional messaging engines in the cluster, you might have to use the `deleteSIBEngine` command to remove unwanted messaging engines from the cluster and therefore conform with the policy.

If you enable messaging engine policy assistance and select the scalability or scalability with high availability policy, the settings of the messaging engines that are currently in the cluster are automatically set to support the selected policy. You might have to use the `createSIBEngine` command or `deleteSIBEngine` commands to achieve the number of messaging engines to conform with the policy (there should be one messaging engine for each application server in the cluster). For each new messaging engine that you create, the settings that support the selected policy are created automatically.

If you enable messaging engine policy assistance and select the custom policy, the settings of the messaging engines that are currently in the cluster are unchanged. You can use the `createMissingSIBEnginePolicy` command to specify the settings for each messaging engine in the cluster, or the `createSIBEngine` command to create additional messaging engines.

## Target object

None.

The configuration of the messaging engines in the cluster is changed to implement the specified messaging engine policy.

## Required parameters

**-bus** *busname*

The name of the service integration bus that the cluster belongs to. You can use the `listSIBuses` command to list the names of existing buses.

**-cluster** *cluster*

The name of the cluster that you want to change.

## Optional parameters

**-enableAssistance** **TRUE** | **FALSE**

Whether to enable messaging engine policy assistance. This parameter has two possible values:

**TRUE** Messaging engine policy assistance is enabled. You must supply a **-policyName** parameter.

**FALSE**

Messaging engine policy assistance is not enabled.

The default value is **FALSE**.

**-policyName** **HA** | **SCALABILITY** | **SCALABILITY\_HA** | **CUSTOM**

The type of messaging engine policy to apply to the cluster. This parameter has four possible values:

**HA** Apply the high availability messaging engine policy to the cluster.

**SCALABILITY**

Apply the scalability messaging engine policy to the cluster.

## SCALABILITY\_HA

Apply the scalability with high availability messaging engine policy to the cluster.

## CUSTOM

Apply the custom messaging engine policy to the cluster.

This parameter has no default. Use this parameter if the **-enableAssistance** parameter is set to TRUE.

## Example

Enable messaging engine policy assistance for cluster1, a member of bus1, and apply the scalability messaging engine policy:

```
AdminTask.modifySIBusMemberPolicy('[-bus bus1 -cluster cluster1
-enableAssistance true -policyName SCALABILITY]')
```

Disable messaging engine policy assistance for cluster1, a member of bus1:

```
AdminTask.modifySIBusMemberPolicy('[-bus bus1 -cluster cluster1
-enableAssistance false]')
```

---

## removeSIBusMember command

Use the removeSIBusMember command to remove a member from a service integration bus by using the wsadmin tool. A bus member can be an application server, a WebSphere MQ server, or a server cluster.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The removeSIBusMember command removes a bus member from the named bus. It cleans up artifacts that are associated with the removed membership, for example, associated WebSphere MQ server bus member artifacts, mediation execution points, or core group policies for messaging engines that are associated with the bus member. To remove a bus member by using this command, specify one of the following resources:

- The server and the node on which that server runs
- The cluster
- The WebSphere MQ server

This command does not delete messages from the associated WebSphere MQ queues, and it does not delete the queues.

## Target object

A service integration bus.

## Required parameters

**-bus** *bus\_name*

The name by which the service integration bus is known. You can use the `listSIBuses` command to list the names of existing buses.

## Conditional parameters

**-node** *node\_name*

**-server** *server\_name*

To remove an application server from a bus, specify both the name of the node on which the server runs and the name of the server.

If you specify these parameters, do not specify the **-cluster** or **-wmqServer** parameters.

**-cluster** *cluster*

To remove a server cluster from a bus, specify the name of the cluster.

If you specify this parameter, do not specify the **-node**, **-server**, or **-wmqServer** parameters.

**-wmqServer** *mqservername*

To remove a WebSphere MQ server from a bus, specify the name of the WebSphere MQ server. This is the name that was specified in the **-name** parameter when the WebSphere MQ server was created.

If you specify this parameter, do not specify the **-cluster**, **-node**, or **-server** parameters.

## Optional parameters

None.

## Example

Remove server1 from bus1.

```
AdminTask.removeSIBusMember(['-bus bus1 -node node1 -server server1]')
```

---

## showSIBusMember command

Use the `showSIBusMember` command to show the properties of a service integration bus member.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

## Purpose

This command lists the details of a specified member of a service integration bus. You can also use this command to list the details of a WebSphere MQ server bus member.

## Target object

A bus member.

## Required parameters

**-bus** *busname*

The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

**-wmqServer**

The name of the WebSphere MQ server bus member.

## Conditional parameters

**-node** *nodename* **-server** *servername*

To list details of an application server as a bus member, specify both the name of the node on which the server runs and the name of the server.

**-cluster** *cluster*

To list details of a server cluster, specify the name of the cluster.

## Optional parameters

None.

## Example

```
AdminTask.showSIBusMember(['-bus bus1 -node node1 -server server1'])
'{node=node1, server=server1}'
```

---

## listAllSIBBootstrapMembers command

Use the listAllSIBBootstrapMembers command to list all the bootstrap members that can bootstrap into a selected bus.

You can use this command to list all the bootstrap members for a specified bus, or you can use the administrative console, see “Listing the bootstrap members for a bus” on page 2028.

This command requires the name of the bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `listAllSIBBootstrapMembers` command lists all the servers and clusters that can bootstrap into a selected bus.

## Target object

Bootstrap members for a selected bus.

## Required parameters

### **-bus**

The name of the bus for which you want to list all the bootstrap members. The data type is string. There is no default value.

## Conditional parameters

None

## Optional parameters

None

## Example

The following example lists all the bootstrap members of bus1:

```
AdminTask.listAllSIBBootstrapMembers(['-bus bus1'])
```

---

## listSIBNominatedBootstrapMembers command

Use the `listSIBNominatedBootstrapMembers` command to list all the nominated bootstrap members for a specified bus.

You can use this command to list all the nominated bootstrap members for a specified bus, or you can use the administrative console, see “Listing the bootstrap members for a bus” on page 2028.

This command requires the name of the bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `listSIBNominatedBootstrapMembers` command lists all the nominated bootstrap members for a specified bus.

## Target object

Nominated bootstrap members.

## Required parameters

### **-bus**

The name of the bus for which you want to list all nominated bootstrap members. The data type is string. There is no default value.

## Conditional parameters

None

## Optional parameters

None

## Example

The following example lists the nominated bootstrap members for bus1:

```
AdminTask.listSIBBootstrapMembers(['-bus bus1'])
```

---

## addSIBBootstrapMember command

Use the `addSIBBootstrapMember` command to add a nominated bootstrap member to a specified bus.

You can use this command to add a nominated bootstrap member to a specified bus, or you can use the administrative console: “Nominating bootstrap members for a bus” on page 2029.

This command requires the name of a bus, and a node and server name, or a cluster name.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `addSIBBootstrapMember` command adds a nominated bootstrap member to the specified bus.

## Target object

A nominated bootstrap member.

## Required parameters

### **-bus**

The name of the bus to which the nominated bootstrap member is added.

## Conditional parameters

None

## Optional parameters

### **-node**

The name of the node on which the server you want to add exists. The data type is string. You must specify either the **node** or the **cluster** parameter. If you specify the **node** parameter, you must also specify the **server** parameter.

### **-server**

The name of the server that you want to add as a nominated bootstrap member. The data type is string. You must only use this parameter with the **node** parameter, not with the **cluster** parameter.

### **-cluster**

The name of the cluster that you want to add as a nominated bootstrap member. The data type is string. You must specify either the **cluster** or the **node** parameter. You cannot use the **cluster** parameter with the **node** or the **server** parameter.

## Example

The following example adds `server1` on `node1` as a nominated bootstrap member of `bus1`:

```
AdminTask.addSIBBootstrapMember('[-bus bus1 -node node1 -server server 1]')
```

---

## removeSIBBootstrapMember command

Use the `removeSIBBootstrapMember` command to remove a nominated bootstrap member from a selected bus.

You can use this command to remove a nominated bootstrap member from a selected bus, or you can use the administrative console: “Deleting nominated bootstrap members from a bus” on page 2029.

This command requires the name of a bus, and either the node and server name, or the cluster name, of an existing bootstrap member.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `removeSIBBootstrapMember` command removes a nominated bootstrap member from a selected bus.

## Target object

The nominated bootstrap member is removed from the selected bus.

## Required parameters

### -bus

The name of the bus from which you want to remove the nominated bootstrap member. The data type is string.

## Conditional parameters

None

## Optional parameters

### -node

The name of the node where the server you want to remove exists. The data type is string. You must specify either the **node** or the **cluster** parameter. If you specify the **node** parameter, you must also specify the **server** parameter.

### -server

The name of the server that you want to remove. The data type is string. You must only use this parameter with the **node** parameter, not with the **cluster** parameter.

### -cluster

The name of the cluster that you want to remove. The data type is string. You must specify either the **cluster** or the **node** parameter. You cannot use the **cluster** parameter with the **node** or the **server** parameter.

## Examples

The following example removes a nominated bootstrap member `cluster1` from `bus1`:

```
AdminTask.removeSIBBootstrapMember('[-bus bus1 -cluster cluster1]')
```

---

## SIBAdminCommands: Foreign bus administrative commands for the AdminTask object

You can use these administrative commands to manage foreign buses. A foreign bus represents a service integration bus with which another service integration bus can exchange messages.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and Jython.

To run these commands, use the `AdminTask` object of the `wsadmin` scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

---

## createSIBForeignBus command

Use the `createSIBForeignBus` command to create a new service integration foreign bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

This command creates a new foreign bus for a specified service integration bus. A foreign bus represents a bus with which another bus can exchange messages.

### Target object

A specified service integration bus.

### Required parameters

**-bus** *busname*

The name of the service integration bus for which you want to create the foreign bus. You can use the `listSIBuses` command to list the names of existing buses.

**-name** *busname*

The name by which you want the foreign bus to be known.

### Notes:

- When you create a foreign bus that represents another service integration bus, the name of the foreign bus must match the name of the other service integration bus.
- When you intend to link two buses directly, you must assign them unique names.
- You must not change the name of a foreign bus name after it has been configured.

**-routingType Direct | Indirect**

Create a foreign bus with the physical link (also known as the *routing type*) specified:

**Direct** A *service integration bus link* from a messaging engine in the local bus to a messaging engine in the foreign bus.

**Indirect**

An *indirect link*, that is, a link that is made through one or more intermediate foreign buses.

## Conditional parameters

None.

## Optional parameters

**-description** *text*

An optional description for the bus, for administrative purposes.

**-type** MQ | SIBus

Create a foreign bus with the type specified:

**MQ** Create a foreign bus to link the service integration bus to a WebSphere MQ network.

**SIBus** Create a foreign bus to link the service integration bus to another service integration bus.

**-sendAllowed** True | False

(Default: True) Whether producers can send messages to the foreign bus.

**False** Producers cannot send messages to the foreign bus.

**True** Producers can send messages to the foreign bus.

**-inboundUserid** *userID*

The inbound user ID is used to authorize inbound messages sent from a foreign bus to destinations in a secure service integration bus. If the bus is not secure, the inbound user ID property has no effect on messages. You might want to specify an inbound user ID for use in the following scenarios:

- The foreign bus and the secure service integration bus are in different security domains, and the foreign bus user IDs are not recognized by the secure bus.
- You want local control over access to the secure bus by inbound messages.

Note that if the receiving service integration bus is secure but the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.

**-outboundUserid** *userID*

The outbound user ID replaces the user ID that identifies the source of a message in all messages being sent to the foreign bus. This user ID is also used by the foreign bus to authorize the message to its destination if both buses are secure buses and the foreign bus has not overridden the user ID with its own inbound user ID.

**-nextHopBus** *bus\_name*

(If **-routingType** is Indirect) The name of the next service integration bus in the sequence of connected buses. An intermediate bus can be a WebSphere MQ system rather than a service integration bus.

**-topicSpaceMappings** *local topicSpace\_name : remote topicSpace\_name*

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus, an equivalent topic space mapping is required by the foreign bus. Topic space names for the local bus are mapped to topic space names defined on the foreign bus. It is common for these two names to match. Note that mapping two topic spaces implies that the topics within them are the same. You can specify multiple pairs of topic spaces.

## Example

```
AdminTask.createSIBForeignBus('[-bus bus1 -name foreignbus1 -routingType Direct
-type SIBus]')
'foreignbus1(cells/cell01/buses/bus1|sib-bus.xml#SIBForeignBus_1213023645293)'
```

---

## deleteSIBForeignBus command

Use the deleteSIBForeignBus command to delete a foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

This command deletes a foreign bus. The command does not affect the service integration bus for which the foreign bus was created.

### CAUTION:

**This command deletes the foreign bus and its additional property configuration. Although there is no confirmation prompt before deleting the bus, the bus is not deleted from the master configuration until you save your changes.**

## Target object

A foreign bus.

## Required parameters

**-bus** *busname*

The name of the service integration bus for which you want to delete a foreign bus. You can use the listSIBuses command to list the names of existing buses.

**-name** *busname*

The name of the foreign bus that you want to delete. You can use the listSIBForeignBuses command to list the names of existing buses.

## Conditional parameters

None.

## Optional parameters

None.

## Example

```
AdminTask.deleteSIBForeignBus('[-bus bus1 -name foreignbus1]')
```

---

## listSIBForeignBuses command

Use the listSIBForeignBuses command to list all foreign buses for a specified service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

## Purpose

This command lists the names of all foreign buses for a specified service integration bus. A foreign bus represents a bus in another cell (or within the same cell) or a WebSphere MQ network, with which a service integration bus can exchange messages.

## Target object

A bus.

## Required parameters

**-bus** *busname*

The name of the service integration bus for which you want to list foreign buses.

## Conditional parameters

None.

## Optional parameters

**-routingType** **Direct** | **Indirect**

List the foreign buses with the physical link (also known as the *routing type*) specified:

**Direct** A *service integration bus link* from a messaging engine in the local bus to a messaging engine in the foreign bus.

**Indirect**

An *indirect link*, that is, a link that is made through one or more intermediate foreign buses.

**-type** **MQ** | **SIBus**

List the foreign buses with the type specified:

**MQ** List the foreign buses that link the service integration bus to a WebSphere MQ network.

**SIBus** List the foreign buses that link the service integration bus to another service integration bus.

## Example

```
AdminTask.listSIBForeignBuses('[-bus Bus1]')
```

---

## modifySIBForeignBus command

Use the `modifySIBForeignBus` command to modify the properties of a foreign bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

This command modifies the properties of a foreign bus. A foreign bus represents a bus in another cell (or within the same cell) or a WebSphere MQ network, with which a service integration bus can exchange messages.

### Target object

A foreign bus.

### Required parameters

**-bus** *busname*

The name of the service integration bus for which you want to modify a foreign bus. You can use the `listSIBuses` command to list the names of existing buses.

**-name** *busname*

The name of the foreign bus that you want to modify. You can use the `listSIBForeignBuses` command to list the names of existing buses.

### Conditional parameters

None.

### Optional parameters

**-description** *text*

An optional description for the bus, for administrative purposes.

**-sendAllowed** **False** | **False**

(Default: True) Whether producers can send messages to the foreign bus.

**False** Producers cannot send messages to the foreign bus.

**True** Producers can send messages to the foreign bus.

**-inboundUserId** *userID*

The inbound user ID is used to authorize individual messages arriving from the foreign bus to destinations in the service integration bus. If this is not a secure bus, this property has no effect on messages. You might want to specify an inbound user ID:

- if the foreign bus is in a different security domain from this bus and user IDs from the foreign bus are not recognized in this bus
- to locally-control access of inbound messages to this bus.

If this is a secure bus and the foreign bus is not secure, and no inbound user ID is set, any inbound messages from the foreign bus are only authorized to destinations that allow unauthenticated users access.

**-outboundUserid** *userID*

The outbound user ID replaces the user ID that identifies the source of a message in all messages being sent to the foreign bus. This user ID is also used by the foreign bus to authorize the message to its destination if both buses are secure buses and the foreign bus has not overridden the user ID with its own inbound user ID.

**-nextHopBus** *bus\_name*

(If **-routingType** is Indirect) The name of the next service integration bus in the sequence of connected buses. An intermediate bus can be a WebSphere MQ system rather than a service integration bus.

**-topicSpaceMappings** *local topicSpace\_name : remote topicSpace\_name*

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus, an equivalent topic space mapping is required by the foreign bus. Topic space names for the local bus are mapped to topic space names defined on the foreign bus. It is common for these two names to match. Note that mapping two topic spaces implies that the topics within them are the same. You can specify multiple pairs of topic spaces.

## Example

The example below specifies the following additional optional properties for an existing foreign bus called *foreignbus1*:

- An inbound user identity called *iuserid* to authorize messages sent from *foreignbus1* to the local bus, when security is enabled on *foreignbus1*, and the local bus.
- An outbound user identity called *ouserid* to authorize messages sent from the local bus to *foreignbus1*, when security is enabled on *foreignbus1*, and the local bus.
- A topic space mapping between *Topic.Space1* on the local bus and *Topic.Space2* on *foreignbus1*. The mapping allows subscribers on *Topic.Space1* on the local bus to receive messages published in *Topic.Space2* on *foreignbus1*.

```
AdminTask.modifySIBForeignBus('[-bus bus1 -name foreignbus1 -inboundUserid iuserid
-outboundUserid ouserid -topicSpaceMappings [[Topic.Space1 Topic.Space2]]]')
'foreignbus1(cells/ce1101/buses/bus1|sib-bus.xml#SIBForeignBus_1213023645293)'
```

---

## showSIBForeignBus command

Use the showSIBForeignBus command to show the properties of a foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

## Purpose

This command lists details about the properties of a foreign bus. A foreign bus represents a bus in another cell (or within the same cell) or a WebSphere MQ network, with which a service integration bus can exchange messages.

## Target object

A foreign bus.

## Required parameters

**-bus** *busname*

The name of the service integration bus for which you want to show a foreign bus. You can use the `listSIBuses` command to list the names of existing buses.

**-name** *busname*

The name of the foreign bus that you want to show. You can use the `listSIBForeignBuses` command to list the names of existing buses.

## Conditional parameters

None.

## Optional parameters

None.

## Example

```
AdminTask.showSIBForeignBus('[-bus bus1 -name foreignbus1]')
'Foreign Bus Name = foreignbus1
Foreign Bus Uuid = 17B07B718182CDF6A73E75D2
Foreign Bus Description = A new foreign bus
Foreign Bus Send Allowed = true
mqRfh2 Allowed = false'
```

---

## SIBAdminCommands: WebSphere MQ link administrative commands for the AdminTask object

You can use these administrative commands to manage WebSphere MQ links. A WebSphere MQ link connects a messaging engine as a queue manager to WebSphere MQ, thereby providing a bridge between a service integration bus and a WebSphere MQ network.

These commands provide an alternative to using the administrative console or using the more complex syntax of `wsadmin` and `Jython`.

To run these commands, use the `AdminTask` object of the `wsadmin` scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in `Jython` and a brief description of each command, enter the following command at the `wsadmin` prompt:  

```
print AdminTask.help('SIBAdminCommands')
```
- For overview help on a given command, enter the following command at the `wsadmin` prompt:  

```
print AdminTask.help('command_name')
```

---

## createSIBMQLink command

Use the createSIBMQLink command to create a new WebSphere MQ link for a specified service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

The createSIBMQLink command creates a new WebSphere MQ link for a specified service integration bus. The WebSphere MQ link connects a messaging engine as a queue manager to WebSphere MQ, thereby providing a bridge between a service integration bus and a WebSphere MQ network.

### Target object

A bus.

### Required parameters

#### **-bus**

The name of the service integration bus for which you want to create the WebSphere MQ link. You can use the listSIBuses command to list the names of existing buses.

#### **-messagingEngine**

The name of the messaging engine for which you want to create the WebSphere MQ link. The WebSphere MQ link connects a messaging engine as a queue manager to WebSphere MQ, thereby providing a bridge between a service integration bus and a WebSphere MQ network.

#### **-name**

The name by which you want the WebSphere MQ link to be known.

#### **-foreignBusName**

The name of the foreign bus that defines the WebSphere MQ network for the WebSphere MQ link. You can use the listSIBForeignBuses command to list the names of existing foreign buses.

#### **-queueManagerName**

The name of the virtual queue manager associated with the messaging engine, and by which the messaging engine is known to a remote WebSphere MQ network.

The queue manager name must conform to the WebSphere MQ naming conventions; for example, the name must be a maximum of 48 characters.

#### **-senderChannelTransportChain OutboundBasicMQLink | OutboundSecureMQLink**

The name of the sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

## Conditional parameters

None.

## Optional parameters

### WebSphere MQ link configuration parameters:

#### -description

An optional description for the bus, for administrative purposes.

#### -exceptionDestination

The destination for an inbound message when the WebSphere MQ link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

#### System

The WebSphere MQ link uses the default exception destination. All messages that cannot be delivered to the bus destination are rerouted automatically to the system default exception destination for the messaging engine that this link is assigned to:  
`_SYSTEM.Exception.Destinationmessaging_engine_name`.

**None** The WebSphere MQ link has no exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery through the link to the same bus. This option can be used to preserve message ordering.

#### Specify

The WebSphere MQ link uses the exception destination specified here. If this is not possible, it uses the system exception destination.

#### -batchSize

The maximum number of messages that can be sent through a channel before taking a checkpoint.

The batch size does not affect the way the sender and receiver channels for this link transfer messages. Messages are always transferred individually, but are committed or backed out as a batch.

For more information about choosing the batch size, see the description of the batch size (**BATCHSZ**) property in the *Intercommunication* section of the WebSphere MQ information center.

<b>Default</b>	50
<b>Range</b>	1 through 9999

#### -maxMsgSize

The maximum message length, in bytes, that can be transmitted on any channel for the WebSphere MQ link. This is compared with the value for the corresponding partner WebSphere MQ channel and the actual maximum used is the lower of the two values.

For information about how to choose an appropriate number, see the description of the Maximum message length (**MAXMSGL**) property in the *Intercommunication* section of the WebSphere MQ information center.

<b>Default</b>	4194304 bytes (4MB)
<b>Range</b>	0 through 104857600

Specify 0 to use the largest value that the target queue manager will honor.

#### -heartBeat

The negotiated time, in seconds, between heartbeat flows passed from the WebSphere MQ link

sender channel to the WebSphere MQ receiver channel when there are no messages on the transmission point being served by the WebSphere MQ link sender channel.

Heartbeats give the receiving channel the opportunity to quiesce the channel connection.

For more information about choosing the value for this property, see the *Intercommunication* section of the WebSphere MQ information center.

<b>Default</b>	300 seconds
<b>Range</b>	0 through 999999

**-sequenceWrap**

The value at which message sequence numbers wrap to start again at 1. For example, if you specify a value of 1000, when the message sequence number reaches 1001 it will restart at 1.

For more information about choosing the value for this property, see the description of the Sequence Number wrap (**SEQWRAP**) property in the *Intercommunication* section of the WebSphere MQ information center.

<b>Default</b>	999999999
<b>Range</b>	1 through 999999999

**-nonPersistentMessageSpeed Fast | Normal**

The class of service for nonpersistent messages on channels of this WebSphere MQ link.

<b>Default</b>	Fast
<b>Range</b>	<b>Fast</b> Nonpersistent messages can be lost if there is a transmission failure or if the channel stops when the messages are in transit. <b>Normal</b> Nonpersistent messages are not lost if there is a transmission failure or if the channel stops when the messages are in transit.

**-adoptable True | False**

A property of the WebSphere MQ link, which shows whether a running instance of a WebSphere MQ link receiver channel (associated with this WebSphere MQ link) should be adopted. In the event of a communications failure, a running instance of a WebSphere MQ link receiver channel might be left waiting for messages. When communication is reestablished, and the partner WebSphere MQ sender channel next attempts to establish a session with the WebSphere MQ link receiver channel, the request will fail as there is already a running instance of the WebSphere MQ link receiver channel that believes it is in session with the partner WebSphere MQ sender channel. You can overcome this problem by selecting this option, which causes the already running instance of the WebSphere MQ link receiver channel to be stopped and a new instance to be started.

If you set this option to True, the WebSphere MQ sender channels might reestablish a connection to this WebSphere MQ link in the event that a communications failure has occurred and the link has not yet detected the failure condition.

<b>Default</b>	True
----------------	------

**-initialState Started | Stopped**

The state of the WebSphere MQ link, which shows whether the link is started or stopped when the hosting messaging engine is first started. Until it is started, the WebSphere MQ link is unavailable.

<b>Default</b>	Started
----------------	---------

**Range****Stopped**

When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

**Started**

When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

**WebSphere MQ link sender channel parameters:****-senderChannelName**

The sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

This name must be the same as the name of the receiver channel on WebSphere MQ.

For more information about choosing channel names, see the description of the channel name (**CHANNEL**) property in the *Intercommunication* section of the WebSphere MQ information center.

**-hostName**

The host name or TCP/IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

Type the host name or IP address of the host on which the gateway queue manager runs.

If this field is blank, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

**-port**

The TCP/IP port number on which the gateway queue manager is listening for the WebSphere MQ link.

**Default**  
**Range**

1414  
0 through 65535

**-connameList**

The connection name list for the gateway queue manager which is used to connect to the WebSphere MQ network. The connections are tried in the order in which they are specified in the connection name list until a connection is successfully established. If no connection is successful, the channel starts retry processing.

The connection names must be given as a comma separated list in the following format:

Dnsname1(portnumber1) , Dnsname2(portnumber2)

Type the DNS name or the IP address of the host on which the gateway queue manager is running. Type the port number in the range 0 through 65535.

If you do not specify the connection name list parameter, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

If you do specify the connection name list parameter, you must have already specified a value for the sender channel name parameter, otherwise the value that you specify for the connection name list parameter is ignored.

If you specify the host name and port parameter as well as the connection name list parameter, then at runtime the connection name list takes precedence and host name and port values are ignored.

### **-discInterval**

The time in seconds for which the sender channel waits for new messages to arrive on the transmission queue after sending a batch of messages. The channel disconnects after this interval, and must be restarted manually or by triggering.

The default value is a reasonable interval. Change this value only if you understand the implications for performance, and you need a different value for the requirements of the traffic flowing down your channels.

Performance is affected by the value specified for the disconnect interval. A very low value (a few seconds) can cause an unacceptable amount of processing in constantly starting up the channel. A very large value (more than an hour) might mean that system resources are unnecessarily held up.

If you want your channels to be active only when there are messages for them to transmit, you should set the disconnect interval to a fairly low value. Note that the default setting is quite high and so is not recommended for channels where this level of control is required. Because it is difficult to interrupt the receiving channel, the most economical option is to have the channel automatically disconnect and reconnect as the workload demands. For most channels, the appropriate setting of the disconnect interval can be established heuristically.

#### **Default**

900 seconds

#### **Range**

0 through 999999

A value of 0 (zero) means never disconnect; the channel waits indefinitely for messages.

### **-shortRetryCount**

The maximum number of times that the sender channel tries to restart after a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

#### **Default**

10

#### **Range**

0 through 999999999

### **-shortRetryInterval**

The number of seconds between attempts by the sender channel to restart after a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

#### **Default**

60 seconds

#### **Range**

0 through 999999

### **-longRetryCount**

The maximum number of times that the sender channel tries to restart after the short retry mechanism did not recover from a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

**Default** 999999999  
**Range** 0 through 999999999

**-longRetryInterval**

The number of seconds between attempts by the sender channel to restart after the short retry mechanism did not recover from a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

**Default** 1200 seconds  
**Range** 0 through 999999

**-senderChannelInitialState Started | Stopped**

The state of the WebSphere MQ link, which shows whether the sender channel is started or stopped when the associated WebSphere MQ link is first started. Until it is started, the channel is unavailable.

**Default** Started  
**Range**

**Stopped**

When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

**Started**

When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

**WebSphere MQ link receiver channel parameters:**

**-receiverChannelName**

The name of the receiver channel for the WebSphere MQ link, used to receive messages from WebSphere MQ onto the bus.

This name must be the same as the name of the sender channel on WebSphere MQ.

**-inboundNonPersistentReliability Best effort | Express | Reliable**

The acceptable reliability of message delivery for nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Best effort to Reliable, in order of increasing reliability.

This reliability delivery option is assigned to all WebSphere MQ nonpersistent messages flowing over this receiver channel.

**Default** Reliable

**Range****Best effort**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable**

Messages are discarded when a messaging engine stops or fails.

**-inboundPersistentReliability Reliable | Assured**

The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability.

**Default**

Assured

**Range****Reliable**

Messages might be discarded when a messaging engine fails.

**Assured**

Messages are not discarded.

**-receiverChannelInitialState Started | Stopped**

The state of the WebSphere MQ link, which shows whether the receiver channel is started or stopped when the associated WebSphere MQ link is first started. Until it is started, the channel is unavailable.

**Default**

Started

**Range****Stopped**

When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

**Started**

When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

**-preferLocal TRUE | FALSE**

This option indicates that the link prefers to send incoming messages to the queue point of the target destination that is located on the same messaging engine as the link, if available. The link must be owned by a messaging engine running on a WebSphere Application Server Version 7.0 or later server.

This option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

**Default**

TRUE

## Range

- TRUE** Send each incoming message to the queue point of the target destination that is located on the same messaging engine as the link, if available.
- FALSE** Send incoming messages to any queue points of the target destinations.

## Examples

```
AdminTask.createSIBMQLink('[-bus bus1 -messagingEngine cluster1.000-bus1
-name myMQLink2 -foreignBusName MQNetwork2 -queueManagerName MQMgrIPL
-senderChannelTransportChain OutboundBasicMQLink]')
'myMQLink2(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#
SIBMQLink_1132607756126)'
```

Create a SIBMQLink that uses queue points on the same messaging engine as the target destination, whenever possible.

```
AdminTask.createSIBMQLink('[-bus bus1 -messagingEngine cluster1.000-bus1
-name MyMQLink -foreignBusName -MQMgr1 -queueManagerName bus1
-senderChannelTransportChain OutboundBasicMQLink -preferLocal TRUE]')
```

---

## deleteSIBMQLink command

Use the deleteSIBMQLink command to delete a WebSphere MQ link from a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The deleteSIBMQLink command deletes a WebSphere MQ link from a bus.

### CAUTION:

**This command deletes the WebSphere MQ link and its additional property configuration. Although there is no confirmation prompt before deleting the WebSphere MQ link, the link is not deleted from the master configuration until you save your changes.**

## Target object

A bus.

## Required parameters

### -bus

The name of the service integration bus for which you want to delete a WebSphere MQ link. You can use the listSIBuses command to list the names of existing buses.

**-messagingEngine**

The name of the messaging engine to which the WebSphere MQ link was assigned when it was created. You can use the listSIBEngines command to list the names of existing messaging engines.

**-mqLink**

The name of the WebSphere MQ link that you want to delete.

**Conditional parameters**

None.

**Optional parameters**

None.

**Example**

```
AdminTask.deleteSIBMQLink('[-bus bus1 -messagingEngine cluster1.000-bus1
-mqLink myMQLink2]')
```

---

**listSIBMQLinks command**

Use the listSIBMQLinks command to list all WebSphere MQ links for a specified service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

**Purpose**

The listSIBMQLinks command lists the names of all WebSphere MQ links for a specified service integration bus. A WebSphere MQ link connects a messaging engine as a queue manager to WebSphere MQ, thereby providing a bridge between a service integration bus and a WebSphere MQ network.

**Target object**

A specified service integration bus.

**Required parameters****-bus**

The name of the service integration bus for which you want to list WebSphere MQ links.

**Conditional parameters**

None.

**Optional parameters****-node**

The name of the node for which you want to list WebSphere MQ links. This option restricts the list of WebSphere MQ links to those links assigned to the node.

**-server**

The name of the server for which you want to list WebSphere MQ links. This option restricts the list of WebSphere MQ links to those links assigned to the server.

**-cluster**

The name of the server cluster for which you want to list WebSphere MQ links. This option restricts the list of WebSphere MQ links to those links assigned to the server cluster.

**-messagingEngine**

The name of the messaging engine for which you want to list WebSphere MQ links. This option restricts the list of WebSphere MQ links to those links assigned to the messaging engine.

**Example**

```
AdminTask.listSIBMQLinks('[-bus bus1 -foreignBus foreignbus1]')
'foreignbus1(cells/ce1101/nodes/node01/servers/server1|sib-engines.xml#
SIBMQLink_1213002780841)'
```

---

**modifySIBMQLink command**

Use the modifySIBMQLink command to modify the properties of a WebSphere MQ link.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

**Purpose**

The modifySIBMQLink command modifies the properties of a WebSphere MQ link.

**Target object**

A WebSphere MQ link.

**Required parameters****-bus**

The name of the service integration bus for which you created the WebSphere MQ link. You can use the listSIBuses command to list the names of existing buses.

**-messagingEngine**

The name of the messaging engine for which you created the WebSphere MQ link. You can use the listSIBEngines command to list the names of existing messaging engines.

**-name**

The name of the WebSphere MQ link.

## Conditional parameters

None.

## Optional parameters

### WebSphere MQ link configuration parameters:

#### -queueManagerName

The name of the virtual queue manager associated with the messaging engine, and by which the messaging engine is known to a remote WebSphere MQ network.

The queue manager name must conform to the WebSphere MQ naming conventions; for example, the name must be a maximum of 48 characters.

#### -description

An optional description for the bus, for administrative purposes.

#### -exceptionDestination

The destination for an inbound message when the WebSphere MQ link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

#### System

The WebSphere MQ link uses the default exception destination. All messages that cannot be delivered to the bus destination are rerouted automatically to the system default exception destination for the messaging engine that this link is assigned to:  
`_SYSTEM.Exception.Destinationmessaging_engine_name`.

**None** The WebSphere MQ link has no exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery through the link to the same bus. This option can be used to preserve message ordering.

#### Specify

The WebSphere MQ link uses the exception destination specified here. If this is not possible, it uses the system exception destination.

#### -batchSize

The maximum number of messages that can be sent through a channel before taking a checkpoint.

The batch size does not affect the way the sender and receiver channels for this link transfer messages. Messages are always transferred individually, but are committed or backed out as a batch.

For more information about choosing the batch size, see the description of the batch size (**BATCHSZ**) property in the *Intercommunication* section of the WebSphere MQ information center.

<b>Default</b>	50
<b>Range</b>	1 through 9999

#### -maxMsgSize

The maximum message length, in bytes, that can be transmitted on any channel for the WebSphere MQ link. This is compared with the value for the corresponding partner WebSphere MQ channel and the actual maximum used is the lower of the two values.

For information about how to choose an appropriate number, see the description of the Maximum message length (**MAXMSGL**) property in the *Intercommunication* section of the WebSphere MQ information center.

<b>Default</b>	4194304 bytes (4MB)
----------------	---------------------

**Range** 0 through 104857600  
Specify 0 to use the largest value that the target queue manager will honor.

**-heartBeat**

The negotiated time, in seconds, between heartbeat flows passed from the WebSphere MQ link sender channel to the WebSphere MQ receiver channel when there are no messages on the transmission point being served by the WebSphere MQ link sender channel.

Heartbeats give the receiving channel the opportunity to quiesce the channel connection.

For more information about choosing the value for this property, see the *Intercommunication* section of the WebSphere MQ information center.

**Default** 300 seconds  
**Range** 0 through 9999999

**-sequenceWrap**

The value at which message sequence numbers wrap to start again at 1. For example, if you specify a value of 1000, when the message sequence number reaches 1001 it will restart at 1.

For more information about choosing the value for this property, see the description of the Sequence Number wrap (**SEQWRAP**) property in the *Intercommunication* section of the WebSphere MQ information center.

**Default** 999999999  
**Range** 100 through 999999999

**-nonPersistentMessageSpeed Fast | Normal**

The class of service for nonpersistent messages on channels of this WebSphere MQ link.

**Default** Fast  
**Range**

**Fast** Nonpersistent messages can be lost if there is a transmission failure or if the channel stops when the messages are in transit.

**Normal** Nonpersistent messages are not lost if there is a transmission failure or if the channel stops when the messages are in transit.

**-adoptable True | False**

A property of the WebSphere MQ link, which shows whether a running instance of a WebSphere MQ link receiver channel (associated with this WebSphere MQ link) should be adopted. In the event of a communications failure, a running instance of a WebSphere MQ link receiver channel might be left waiting for messages. When communication is reestablished, and the partner WebSphere MQ sender channel next attempts to establish a session with the WebSphere MQ link receiver channel, the request will fail as there is already a running instance of the WebSphere MQ link receiver channel that believes it is in session with the partner WebSphere MQ sender channel. You can overcome this problem by selecting this option, which causes the already running instance of the WebSphere MQ link receiver channel to be stopped and a new instance to be started.

If you set this option to True, the WebSphere MQ sender channels might reestablish a connection to this WebSphere MQ link in the event that a communications failure has occurred and the link has not yet detected the failure condition.

**Default** True

### **-initialState Started | Stopped**

The state of the WebSphere MQ link, which shows whether the link is started or stopped when the hosting messaging engine is first started. Until it is started, the WebSphere MQ link is unavailable.

**Default**  
**Range**

Started

#### **Stopped**

When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

#### **Started**

When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

### **WebSphere MQ link sender channel parameters:**

#### **-senderChannelName**

The sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

This name must be the same as the name of the receiver channel on WebSphere MQ.

For more information about choosing channel names, see the description of the channel name (**CHANNEL**) property in the *Intercommunication* section of the WebSphere MQ information center.

#### **-hostName**

The host name or TCP/IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

Type the host name or IP address of the host on which the gateway queue manager runs.

If this field is blank, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

#### **-port**

The TCP/IP port number on which the gateway queue manager is listening for the WebSphere MQ link.

**Default**

1414

**Range**

0 through 65535

#### **-connameList**

The connection name list for the gateway queue manager which is used to connect to the WebSphere MQ network. The connections are tried in the order in which they are specified in the connection name list until a connection is successfully established. If no connection is successful, the channel starts retry processing.

The connection names must be given as a comma separated list in the following format:

Dnsname1(portnumber1) , Dnsname2(portnumber2)

Type the DNS name or the IP address of the host on which the gateway queue manager is running. Type the port number in the range 0 through 65535.

If you do not specify the connection name list parameter, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

If you do specify the connection list parameter, you must have already specified a value for the sender channel name parameter, otherwise the value that you specify for the connection name list parameter is ignored.

If you specify the host name and port parameter as well as the connection name list parameter, then at runtime the connection name list takes precedence and host name and port values are ignored.

#### **-discInterval**

The time in seconds for which the sender channel waits for new messages to arrive on the transmission queue after sending a batch of messages. The channel disconnects after this interval, and must be restarted manually or by triggering.

The default value is a reasonable interval. Change this value only if you understand the implications for performance, and you need a different value for the requirements of the traffic flowing down your channels.

Performance is affected by the value specified for the disconnect interval. A very low value (a few seconds) can cause an unacceptable amount of processing in constantly starting up the channel. A very large value (more than an hour) might mean that system resources are unnecessarily held up.

If you want your channels to be active only when there are messages for them to transmit, you should set the disconnect interval to a fairly low value. Note that the default setting is quite high and so is not recommended for channels where this level of control is required. Because it is difficult to interrupt the receiving channel, the most economical option is to have the channel automatically disconnect and reconnect as the workload demands. For most channels, the appropriate setting of the disconnect interval can be established heuristically.

<b>Default</b>	900 seconds
<b>Range</b>	0 through 999999
	A value of 0 (zero) means never disconnect; the channel waits indefinitely for messages.

#### **-shortRetryCount**

The maximum number of times that the sender channel tries to restart after a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked.

<b>Default</b>	10
<b>Range</b>	0 through 999999999

#### **-shortRetryInterval**

The number of seconds between attempts by the sender channel to restart after a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

<b>Default</b>	60 seconds
<b>Range</b>	0 through 999999

#### **-longRetryCount**

The maximum number of times that the sender channel tries to restart after the short retry mechanism did not recover from a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

**Default** 999999999  
**Range** 0 through 999999999

**-longRetryInterval**

The number of seconds between attempts by the sender channel to restart after the short retry mechanism did not recover from a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

**Default** 1200 seconds  
**Range** 0 through 999999

**-senderChannelInitialState Started | Stopped**

The state of the WebSphere MQ link, which shows whether the sender channel is started or stopped when the associated WebSphere MQ link is first started. Until it is started, the channel is unavailable.

**Default** Started  
**Range** **Stopped**  
When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.  
**Started**  
When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

**WebSphere MQ link receiver channel parameters:**

**-receiverChannelName**

The name of the receiver channel for the WebSphere MQ link, used to receive messages from WebSphere MQ onto the bus.

This name must be the same as the name of the sender channel on WebSphere MQ.

**-inboundNonPersistentReliability Best effort | Express | Reliable**

The acceptable reliability of message delivery for nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Best effort to Reliable, in order of increasing reliability.

This reliability delivery option is assigned to all WebSphere MQ nonpersistent messages flowing over this receiver channel.

**Default** Reliable

**Range**

**Best effort**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**Express**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**Reliable**

Messages are discarded when a messaging engine stops or fails.

**-inboundPersistentReliability Reliable | Assured**

The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability.

**Default**

Assured

**Range**

**Reliable**

Messages might be discarded when a messaging engine fails.

**Assured**

Messages are not discarded.

**-receiverChannelInitialState Started | Stopped**

The state of the WebSphere MQ link, which shows whether the receiver channel is started or stopped when the associated WebSphere MQ link is first started. Until it is started, the channel is unavailable.

**Default**

Started

**Range**

**Stopped**

When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

**Started**

When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

**-preferLocal TRUE | FALSE**

This option indicates that the link prefers to send incoming messages to the queue point of the target destination that is located on the same messaging engine as the link, if available. The link must be owned by a messaging engine running on a WebSphere Application Server Version 7.0 or later server.

This option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

**Default**

TRUE

## Range

**TRUE** Send each incoming message to the queue point of the target destination that is located on the same messaging engine as the link, if available.

**FALSE** Send incoming messages to any queue points of the target destinations.

## Examples

Show the properties of a WebSphere MQ link, modify the link to change the batch size, then show the properties of the link again.

```
wsadmin>AdminTask.showSIBMQLink('[-bus myBus -messagingEngine myHostNode01.server1-myBus
-mqLink myMQLink]')
'{nonPersistentMessageSpeed=FAST, qmName=myBus, adoptable=false, sequenceWrap=999999999,
name=myMQLink, targetUuid=738AE126B908E5451A3D4691, initialState=STARTED,
senderChannel=null, brokerProfile=[], receiverChannel=null, preferLocalQueuePoints=true,
batchSize=50, uuid=6B89C4F08AB072C5, heartBeat=300, description=null, maxMsgSize=4194304,
exceptionDestination=_SYSTEM.Exception.Destination.myHostNode01.server1-myBus}'
wsadmin>
wsadmin>AdminTask.modifySIBMQLink('[-bus myBus -messagingEngine myHostNode01.server1-myBus
-name myMQLink -batchSize 100]')
'myMQLink(cells/ce1101/nodes/node01/servers/server1|sib-engines.xml#SIBMQLink_1132608724468)'
wsadmin>AdminTask.showSIBMQLink('[-bus myBus -messagingEngine myHostNode01.server1-myBus
-mqLink myMQLink]')
'{nonPersistentMessageSpeed=FAST, qmName=myBus, adoptable=false, sequenceWrap=999999999,
name=myMQLink, targetUuid=738AE126B908E5451A3D4691, initialState=STARTED,
senderChannel=null, brokerProfile=[], receiverChannel=null, preferLocalQueuePoints=true,
batchSize=100, uuid=6B89C4F08AB072C5, heartBeat=300, description=null, maxMsgSize=4194304,
exceptionDestination=_SYSTEM.Exception.Destination.myHostNode01.server1-myBus}'
wsadmin>
```

Modify a WebSphere MQ link so that the link has no preference for which queue points to use.

```
wsadmin>AdminTask.modifySIBMQLink('[-bus Bus1 -messagingEngine
node1.node1server1-Bus1 -name MQLink -queueManagerName QM2 -preferLocal FALSE]')
wsadmin>
```

---

## showSIBMQLink command

Use the showSIBMQLink command to show the properties of a WebSphere MQ link.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

## Purpose

The showSIBMQLink command lists details about the properties of a WebSphere MQ link.

## Target object

A WebSphere MQ link.

## Required parameters

### -bus

The name of the service integration bus for which you created the WebSphere MQ link. You can use the `listSIBuses` command to list the names of existing buses.

### -messagingEngine

The name of the messaging engine for which you created the WebSphere MQ link. You can use the `listSIBEngines` command to list the names of existing messaging engines.

### -name

The name of the WebSphere MQ link.

## Conditional parameters

None.

## Optional parameters

### javaFormat

The output from the command is a format suitable for Java program clients.

## Example

```
wsadmin>AdminTask.showSIBMQLink('[-bus myBus -messagingEngine myHostNode01.server1-myBus
-mqLink myMQLink]')
'{nonPersistentMessageSpeed=FAST, qmName=myBus, adoptable=false, sequenceWrap=999999999,
name=myMQLink, targetUuid=738AE126B908E5451A3D4691, initialState=STARTED,
senderChannel=null, brokerProfile=[], receiverChannel=null, preferLocalQueuePoints=true,
batchSize=50, uuid=6B89C4F08AB072C5, heartBeat=300, description=null, maxMsgSize=4194304,
exceptionDestination=_SYSTEM.Exception.Destination.myHostNode01.server1-myBus}'
wsadmin>
```

---

## SIBAdminCommands: Bus link administrative commands for the AdminTask object

You can use these administrative commands to manage service integration bus links. A service integration bus link defines a link between a messaging engine in one service integration bus and a messaging engine in a foreign service integration bus.

These commands provide an alternative to using the administrative console or using the more complex syntax of `wsadmin` and `Jython`.

To run these commands, use the `AdminTask` object of the `wsadmin` scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in `Jython` and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

---

## createSIBLink command

Use the createSIBLink command to create a new service integration bus link.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

The createSIBLink command creates a new bus link for a specified bus. A bus link defines a link between a messaging engine in one bus and a messaging engine in a foreign bus.

### Target object

None.

### Required parameters

#### -bus

The name of the service integration bus for which you want to create the service integration bus link. You can use the listSIBuses command to list the names of existing buses.

#### -messagingEngine

The name of the messaging engine for which you want to create the service integration bus link. The service integration bus link connects a messaging engine to another messaging engine in a different service integration bus, thereby providing a bridge between two service integration buses.

#### -name

The name by which you want the service integration bus link to be known.

#### -foreignBusName

The name of the foreign bus that defines the remote service integration bus for the service integration bus link. You can use the listSIBForeignBuses command to list the names of existing foreign buses.

#### -bootstrapEndpoints

The comma-separated list of endpoints used to connect to a bootstrap server.

This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see the steps relating to setting bootstrap endpoints in “Configuring a connection to a non-default bootstrap server” on page 612.

The port for the bootstrap endpoint is the port defined on the SIB endpoint address that is configured on the target application server on the foreign bus.

#### -remoteMessagingEngineName

The messaging engine on the foreign bus to which this link connects.

## Conditional parameters

None.

## Optional parameters

### -description

An optional description for the bus, for administrative purposes.

### -protocolName

The type of transport chain used for communication with the foreign bus.

The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

### -authAlias

The name of the authentication alias, used to authenticate access to the foreign bus.

You must have predefined a J2C authentication alias.

### -exceptionDestination

The destination for an inbound message when the service integration bus link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

#### System

The service integration bus link uses the default exception destination. All messages that cannot be delivered to the bus destination are rerouted automatically to the system default exception destination for the messaging engine that this link is assigned to:  
`_SYSTEM.Exception.Destination.messaging_engine_name`.

**None** The service integration bus link has no exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery to the same destination. This option can be used to preserve message ordering.

#### Specify

The service integration bus link uses the exception destination specified here. If this is not possible, it uses the system exception destination.

### -initialState Started | Stopped

The state of the gateway link, which shows whether the link is started automatically when the messaging engine is started.

#### Default

Started

#### Range

#### Stopped

When the associated messaging engine is started, the gateway link is in a stopped state and cannot process any new requests for connections.

#### Started

When the associated messaging engine is started, the gateway link is in a started state and can process any new requests for connections.

### -preferLocal TRUE | FALSE

Indicates that the link prefers to send incoming messages to the queue point of the target destination that is located on the same messaging engine as the link, if available. The link must be owned by a messaging engine running on a WebSphere Application Server Version 7.0 or later server.

This option is supported only when used by a JMS application that is running with a WebSphere Application ServerVersion 7.0 or later server or client, and that is connected to a messaging engine

running on WebSphere Application ServerVersion 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

<b>Default</b>	TRUE
<b>Range</b>	<b>TRUE</b> Send each incoming message to the queue point of the target destination that is located on the same messaging engine as the link, if available. <b>FALSE</b> Send incoming messages to any queue points of the target destinations.

## Examples

```
AdminTask.createSIBLink('[-bus bus1 -messagingEngine node01.server1-myBus
-name mySIBLink -foreignBusName bus2 -bootstrapEndpoints host1:1111:chain1
-remoteMessagingEngineName node02.server2-bus2]')
```

Create a service integration bus link that uses a queue point on the same messaging engine as the link, whenever possible.

```
AdminTask.createSIBLink('[-bus bus1 -messagingEngine node01.server1-bus1
-name mySIBLink -foreignBusName bus2 -bootstrapEndpoints host1:1111:chain1
-remoteMessagingEngineName node02.server2-bus2 -preferLocal TRUE]')
```

---

## deleteSIBLink command

Use the deleteSIBLink command to delete a service integration bus link from a bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The deleteSIBLink command deletes a bus link from a bus.

### CAUTION:

**This command deletes the service integration bus link and its additional property configuration. Although there is no confirmation prompt before deleting the service integration bus link, the link is not deleted from the master configuration until you save your changes.**

## Target object

A bus.

## Required parameters

### -bus

The name of the service integration bus for which you want to delete a service integration bus link. You can use the listSIBuses command to list the names of existing buses.

### -messagingEngine

The name of the messaging engine to which the service integration bus link was assigned when created. You can use the listSIBEngines command to list the names of existing messaging engines.

### -sibLink

The name of the service integration bus link that you want to delete.

## Conditional parameters

None.

## Optional parameters

None.

## Example

```
AdminTask.deleteSIBLink(['-bus bus1 -messagingEngine node01.server1-bus1 -sibLink mySIBLink'])
```

---

## listSIBLinks command

Use the listSIBLinks command to list all service integration bus links for a given bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

## Purpose

The listSIBLinks command lists the names of all service integration bus links for a specified service integration bus. A service integration bus link defines a link between a messaging engine in one service integration bus and a messaging engine in a foreign service integration bus.

## Target object

A bus.

## Required parameters

### -bus

The name of the service integration bus for which you want to list service integration bus links.

## Conditional parameters

None.

## Optional parameters

### **-node**

The name of the node for which you want to list service integration bus links. This option restricts the list of service integration bus links to those links assigned to the node.

### **-server**

The name of the server for which you want to list service integration bus links. This option restricts the list of service integration bus links to those links assigned to the server.

### **-cluster**

The name of the server cluster for which you want to list service integration bus links. This option restricts the list of service integration bus links to those links assigned to the server cluster.

This option is for use only in WebSphere Application Server environments that support server clusters.

### **-messagingEngine**

The name of the messaging engine for which you want to list service integration bus links. This option restricts the list of service integration bus links to those links assigned to the messaging engine.

## Example

```
AdminTask.listSIBLinks('[-bus bus1 -foreignBus bus2]')
'mySIBLink(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#
SIBLink_1212163147845)'
wsadmin>
```

---

## modifySIBLink command

Use the modifySIBLink command to modify the properties of a service integration bus link.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The modifySIBLink command modifies the properties of a service integration bus link.

## Target object

None.

## Required parameters

### **-bus**

The name of the service integration bus for which you want to modify the service integration bus link. You can use the listSIBuses command to list the names of existing buses.

**-messagingEngine**

The name of the messaging engine for which you want to modify the service integration bus link. The service integration bus link connects a messaging engine to another messaging engine in a different service integration bus, thereby providing a bridge between two service integration buses.

**-name**

The name by which you want the service integration bus link to be known.

**-foreignBusName**

The name of the foreign bus that defines the remote service integration bus for the service integration bus link. You can use the `listSIBForeignBuses` command to list the names of existing foreign buses.

## Conditional parameters

None.

## Optional parameters

**-bootstrapEndpoints**

The comma-separated list of endpoints used to connect to a bootstrap server. This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see the steps relating to setting bootstrap endpoints in “Configuring a connection to a non-default bootstrap server” on page 612.

The port for the bootstrap endpoint is the port defined on the SIB endpoint address that is configured on the target application server on the foreign bus.

**-remoteMessagingEngineName**

The messaging engine on the foreign bus to which this link connects.

**-description**

An optional description for the bus, for administrative purposes.

**-protocolName**

The type of transport chain used for communication with the foreign bus.

The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

**-authAlias**

The name of the authentication alias, used to authenticate access to the foreign bus.

You must have predefined a J2C authentication alias.

**-exceptionDestination**

The destination for an inbound message when the service integration bus link cannot deliver the message to its target destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

**System**

The service integration bus link uses the default exception destination. All messages that cannot be delivered to the bus destination are rerouted automatically to the system default exception destination for the messaging engine that this link is assigned to:

`_SYSTEM.Exception.Destination.messaging_engine_name_`

**None** The service integration bus link has no exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery to the same destination. This option can be used to preserve message ordering.

**Specify**

The service integration bus link uses the exception destination specified here. If this is not possible, it uses the system exception destination.

### **-initialState Started | Stopped**

The state of the gateway link, which shows whether the link is started automatically when the messaging engine is started.

**Default**  
**Range**

Started

#### **Stopped**

When the associated messaging engine is started, the gateway link is in a stopped state and cannot process any new requests for connections.

#### **Started**

When the associated messaging engine is started, the gateway link is in a started state and can process any new requests for connections.

### **-preferLocal TRUE | FALSE**

Indicates whether the link prefers to send incoming messages to the queue point of the target destination that is located on the same messaging engine as the link, if available. The link must be owned by a messaging engine running on a WebSphere Application Server Version 7.0 or later server.

This option is supported only when used by a JMS application that is running with a WebSphere Application ServerVersion 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application ServerVersion 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

**Default**  
**Range**

TRUE

**TRUE** Send each incoming message to the queue point of the target destination that is located on the same messaging engine as the link, if available.

**FALSE** Send incoming messages to any queue points of the target destinations.

## **Examples**

```
wsadmin>AdminTask.showSIBLink('[-bus bus1 -messagingEngine node01.server1-bus1 -sibLink mySIBLink]')
'{bootstrapEndpoints=host1:1111:chain1, protocolName=null, authAlias=null, preferLocalQueuePoints=true, name=mySIBLink, uuid=34647E59163B253D, remoteMessagingEngineName=node02.server2-bus2, description=null, targetUuid=BAD49BA75CD36D740E366978, initialState=STARTED, exceptionDestination=$DEFAULT_EXCEPTION_DESTINATION}'
```

```
wsadmin>AdminTask.modifySIBLink('[-bus bus1 -messagingEngine node01.server1-bus1 -name MySIBLink -foreignBusName -bus2 -bootstrapEndpoints anotherhost:2222:BootstrapBasicMessaging]')
```

```
wsadmin>AdminTask.showSIBLink('[-bus bus1 -messagingEngine node01.server1-bus1 -sibLink mySIBLink]')
'{bootstrapEndpoints=anotherhost:2222:BootstrapBasicMessaging, protocolName=null, authAlias=null, preferLocalQueuePoints=true, name=mySIBLink, uuid=34647E59163B253D, remoteMessagingEngineName=node02.server2-bus2, description=null, targetUuid=BAD49BA75CD36D740E366978, initialState=STARTED, exceptionDestination=$DEFAULT_EXCEPTION_DESTINATION}'
```

Modify a service integration bus link so that there is no preference for which queue points to use.

```
AdminTask.modifySIBLink('[-bus bus1 -messagingEngine cluster1.000-bus1 -name MyLink -foreignBusName -FB1 bootstrapEndpoints host1:1111:chain1 -remoteMessagingEngineName -cluster2.000-FB1 -preferLocal FALSE]')
```

---

## showSIBLink command

Use the showSIBLink command to show the properties of a service integration bus link.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

### Purpose

The showSIBLink command lists details about the properties of a service integration bus link.

### Target object

A bus link.

### Required parameters

#### -bus

The name of the service integration bus for which you created the service integration bus link. You can use the listSIBuses command to list the names of existing buses.

#### -messagingEngine

The name of the messaging engine for which you created the service integration bus link. You can use the listSIBEngines command to list the names of existing messaging engines.

#### -sibLink

The name of the service integration bus link.

### Conditional parameters

None.

### Optional parameters

None.

### Example

```
AdminTask.showSIBLink(['-bus bus1 -messagingEngine node01.server1-bus1
-sibLink mySIBLink'])
'{bootstrapEndpoints=host1:1111:chain1, protocolName=null, authAlias=null,
preferLocalQueuePoints=true, name=aSIBLink, uuid=34647E59163B253D,
remoteMessagingEngineName=wasinstallNode01.server1-MQServerBus, description=null,
targetUuid=BAD49BA75CD36D740E366978, initialState=STARTED,
exceptionDestination=_SYSTEM.Exception.Destination.node01.server1-bus1}'
```

---

## SIBAdminCommands: Messaging engine administrative commands for the AdminTask object

You can use these administrative commands to manage messaging engines.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and Jython.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

---

## createSIBEngine command

Use the createSIBEngine command to create a messaging engine for a server or cluster bus member by using the wsadmin tool. When you add a server or a cluster as a member of a service integration bus, at least one messaging engine is created automatically. Use the createSIBEngine command to create an additional messaging engine for a cluster bus member.

Each server bus member has exactly one messaging engine, but cluster bus members can support additional engines. If you create an additional messaging engine for a cluster, and you use a data store for the message store, you must explicitly configure both the data store and the JDBC data source that the messaging engine uses to interact with the data store. You must create the data source at cluster scope, not node scope. For more information about creating messaging engines, see “Configuring a data source for a messaging engine running in a cluster” on page 2105.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

The createSIBEngine command creates a new messaging engine for a server or cluster bus member. Use this command to create an additional messaging engine for a cluster bus member.

If the cluster has messaging engine policy assistance enabled and the scalability or scalability with high availability policy specified, the messaging engine settings are created automatically to conform with the specified policy.

After you use this command, if the cluster has messaging engine policy assistance enabled and the custom policy specified, you can create a core group policy for a messaging engine by using the createMissingSIBEnginePolicy command.

## Target object

None.

## Required parameters

**-bus** *bus\_name*

The name of the service integration bus on which the bus member is configured. You can use the `listSIBuses` command to list the names of existing buses.

## Conditional parameters

**-node** *node\_name*

**-server** *server\_name*

To create a messaging engine for a server that is a bus member, specify both the name of the node on which the server runs, and the name of the server.

**-cluster** *cluster\_name*

To create a messaging engine for a server cluster that is a bus member, specify the name of the cluster.

## Optional parameters

**-description** *text*

An optional description for the messaging engine, for administrative purposes.

**-initialState** **STARTED** | **STOPPED**

The initial state determines whether the messaging engine is started automatically when the server or server cluster is started.

### **STARTED**

When the associated application server is started, the messaging engine is started and is available to process messages.

### **STOPPED**

When the associated application server is started, the messaging engine is stopped and is not available to process messages.

**-highMessageThreshold** *number*

The maximum total number of messages that the messaging engine can place on its message points.

When the messaging engine is created, the high message threshold of the bus is used to set the default value for this property. When a message point is created on this messaging engine, the value of this property is used to set the default high message threshold for the message point.

**-failover** **TRUE** | **FALSE**

A parameter that specifies whether the messaging engine in the cluster can fail over to another server in the cluster if the host server for the messaging engine fails. This parameter has two possible values:

**TRUE** The messaging engine can fail over.

### **FALSE**

The messaging engine cannot fail over.

The default value is **FALSE**. Use this parameter if the cluster has messaging engine policy assistance enabled and the custom policy specified. To do this, use the `addSIBusMember` or `modifySIBusMemberPolicy` commands.

**-failback** **TRUE** | **FALSE**

A parameter that specifies whether the messaging engine in the cluster that has failed over can fail back to a more preferred server in the preferred servers list if that server becomes available again. This parameter has two possible values:

**TRUE** The messaging engine can fail back. If you use this option, supply a **-preferredServerList** parameter.

**FALSE**

The messaging engine cannot fail back.

The default value is **FALSE**. Use this parameter if the cluster has messaging engine policy assistance enabled and the custom policy set. To do this, you use the `addSIBusMember` or `modifySIBusMemberPolicy` commands.

**-preferredServersOnly TRUE | FALSE**

A parameter that specifies whether the messaging engine in the cluster can run only on servers in the preferred servers list, or on any server in the cluster. This parameter has two possible values:

**TRUE** The messaging engine can run only on servers in the preferred servers list. If you use this option, supply a `-preferredServerList` parameter.

**FALSE**

The messaging engine can run on any server in the cluster.

The default value is **FALSE**. Use this parameter if the cluster has messaging engine policy assistance enabled and the custom policy set. To do this, use the `addSIBusMember` or `modifySIBusMemberPolicy` commands.

**-preferredServerList {{node\_name server\_name}}**

The list of servers, in order of preference, on which the messaging engine in the cluster prefers to run. For each server in the list, specify both the name of the node on which the server runs, and the name of the server. There is no default value for this parameter. Use this parameter if the cluster has messaging engine policy assistance enabled and the custom policy set. To do this, use the `addSIBusMember` or `modifySIBusMemberPolicy` commands.

**-fileStore**

Create a file store to use as a message store for the messaging engine. A file store is a type of message store that directly uses files in a file system through the operating system. The alternative is to use a data store. For more information, see the related links.

**-logSize size**

The size of the log file in MB. Use this parameter if the **-fileStore** parameter is specified.

**-logDirectory directory\_name**

The name of the log file directory if you do not want to use the default log directory. Use this parameter if the **-fileStore** parameter is specified.

**-minPermanentStoreSize size**

The minimum size of the permanent store file in MB. Use this parameter if the **-fileStore** parameter is specified.

**-minTemporaryStoreSize size**

The minimum size of the temporary store file in MB. Use this parameter if the **-fileStore** parameter is specified.

**-maxPermanentStoreSize size**

The maximum size of the permanent store file in MB. Use this parameter if the **-fileStore** parameter is specified.

**-maxTemporaryStoreSize size**

The maximum size of the temporary store file in MB. Use this parameter if the `-fileStore` parameter is specified.

**-unlimitedPermanentStoreSize TRUE | FALSE**

A parameter that specifies whether the permanent store size is unlimited. This parameter has two possible values:

**TRUE** The permanent store size is unlimited.

**FALSE**

The permanent store size is limited. If you use this option, supply a **-maxPermanentStoreSize** parameter.

Use this parameter if the **-fileStore** parameter is specified.

**-unlimitedTemporaryStoreSize TRUE | FALSE**

A parameter that specifies whether the temporary store size is unlimited. This parameter has two possible values:

**TRUE** The temporary store size is unlimited.

**FALSE**

The temporary store size is limited. If you use this option, supply a **-maxTemporaryStoreSize** parameter.

Use this parameter if the **-fileStore** parameter is specified.

**-permanentStoreDirectory** *directory\_name*

The name of the permanent store directory if you do not want to use the default permanent store directory. Use this parameter if the **-fileStore** parameter is specified.

**-temporaryStoreDirectory** *directory\_name*

The name of the temporary store directory if you do not want to use the default temporary store directory. Use this parameter if the **-fileStore** parameter is specified.

**-dataStore**

Create a data store to use as a message store for the messaging engine.

A data store consists of the set of tables that a messaging engine uses to store persistent data in a database. See “Data store tables” on page 2109 for a list of the tables that comprise a data store. All the tables in a data store are held in the same database schema. You can create multiple data stores in the same database, provided that you use a different schema name for each data store. The alternative is to use file store (the default). For more information, see the related links.

**-createDefaultDatasource TRUE | FALSE**

A parameter that specifies whether to create a default data source when the messaging engine is created. This parameter has two possible values:

**TRUE** Create a default data source.

**FALSE**

Do not create a default data source.

Use this parameter if the **-dataStore** parameter is specified. Do not use this parameter if the **-cluster** parameter is specified.

**-datasourceJndiName** *jndi\_name*

The JNDI name of the data source that the messaging engine uses to access the relational database management system (RDBMS) for the data store. Use this parameter if the **-dataStore** parameter is specified.

**-authAlias** *auth\_alias*

The name of the authentication alias that the messaging engine uses to connect to the database in its data store. Use this parameter if the **-dataStore** parameter is specified.

**-createTables TRUE | FALSE**

A parameter that specifies whether to create the database tables for the data source automatically. This parameter has two possible values:

**TRUE** Create the database tables for the data source.

**FALSE**

Do not create the database tables for the data source. For the z/OS operating system, you must use this option because you must not create tables.

Use this parameter if the **-dataStore** parameter is specified.

**-schemaName** *schema\_name*

The name of the database schema that contains the tables for the data store, if you do not want to use the default schema name. For details about the default schema, see “Creating users and schemas in the database” on page 2100. Use this parameter if the **-dataStore** parameter is specified.

Depending on the choice of the message store and its attributes, you specify different combinations of the parameters. To avoid errors when you specify the message store for the messaging engine, see “Avoiding errors when creating a messaging engine with a file store or a data store by using the wsadmin tool” on page 2111.

## Examples

Create a messaging engine for cluster1 on bus1 that uses a default file store.

```
AdminTask.createSIBEngine ('[-bus bus1 -cluster cluster1]')
```

Create a messaging engine for cluster1 on bus1 that uses a file store with defaults.

```
AdminTask.createSIBEngine ('[-bus bus1 -cluster cluster1 -fileStore]')
```

Create a messaging engine for cluster1 on bus1 that uses a file store with options.

```
AdminTask.createSIBEngine ('[-bus bus1 -cluster cluster1 -fileStore
-logSize 3636363 -logDirectory C:\mylogdirectory]')
```

Create a messaging engine for cluster1 on bus1 that uses a data store with defaults.

```
AdminTask.createSIBEngine ('[-bus bus1 -cluster cluster1 -dataStore]')
```

Create a messaging engine for cluster1 on bus1 that uses a data store with options.

```
AdminTask.createSIBEngine ('[-bus bus1 -cluster cluster1 -dataStore
-createDefaultDataSource true -dataSourceJndiName myjndi]')
```

Add a new messaging engine to cluster1 that is a member of bus1 and that uses a file store as the message store for the messaging engine.

```
AdminTask.createSIBEngine('[-bus bus1 -cluster cluster1 -fileStore true
-logSize 100 -minPermanentStoreSize 200 -maxPermanentStoreSize 500
-unlimitedPermanentStoreSize false -permanentStoreDirectory C:\myfilestore
-minTemporaryStoreSize 200 -maxTemporaryStoreSize 500
-unlimitedTemporaryStoreSize false -temporaryStoreDirectory C:\myfilestore
-logDirectory C:\myfilestore]')
```

Add a new messaging engine to cluster1 that is a member of bus1, where cluster1 has messaging engine policy assistance enabled and the custom messaging engine policy specified. Use a file store as the message store for the messaging engine. Set the messaging engine to fail over, not to fail back, and to run only on server1 and server2.

```
AdminTask.createSIBEngine('[-bus bus1 -cluster cluster1 -fileStore true
-logSize 100 -minPermanentStoreSize 200 -maxPermanentStoreSize 500
-unlimitedPermanentStoreSize false -permanentStoreDirectory C:\myfilestore
-minTemporaryStoreSize 200 -maxTemporaryStoreSize 500
-unlimitedTemporaryStoreSize false -temporaryStoreDirectory C:\myfilestore
-logDirectory C:\myfilestore -failover true -failback false
-preferredServersOnly true -preferredServerList [[node1 server1] [node2 server2]]]')
```

---

## listSIBEngines command

Use the listSIBEngines command to list the messaging engines for a service integration bus member.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

### Purpose

This command lists all the messaging engines on a bus member.

### Target object

A bus member.

### Required parameters

**-bus** *busname*

The name of the service integration bus on which the bus member is configured. You can use the listSIBuses command to list the names of existing buses.

### Conditional parameters

**-node** *nodename* **-server** *servername*

To list the messaging engines for an application server as a bus member, specify both the name of the node on which the server runs and the name of the server.

**-cluster** *cluster*

To list the messaging engines for a server cluster as a bus member, specify the name of the cluster.

### Optional parameters

None.

### Example

```
AdminTask.listSIBEngines('[-bus bus1]')
'node01.server1-bus1(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#
SIBMessagingEngine_1212163145962)\r\n
node02.server2-bus2(cells/cell01/nodes/node02/servers/server2|sib-engines.xml#
SIBMessagingEngine_1212163146273)'
```

---

## modifySIBEngine command

Use the modifySIBEngine command to modify the properties of a messaging engine for a service integration bus member.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

This command modifies the properties of a messaging engine.

## Target object

A messaging engine.

## Required parameters

**-bus** *busname*

The name of the service integration bus on which the bus member is configured. You can use the `listSIBuses` command to list the names of existing buses.

## Conditional parameters

**-node** *nodename* **-server** *servername*

To change properties of a messaging engine for an application server as a bus member, specify both the name of the node on which the server runs and the name of the server.

**-cluster** *cluster*

To change properties of a messaging engine for a server cluster as a bus member, specify the name of the cluster.

**-engine** *enginename*

If the bus member has only one messaging engine, you do not need to specify the engine name. If the bus member has several messaging engines, you must specify the name of the engine for which you want to change properties.

## Optional parameters

**-description** *text*

An optional description for the messaging engine, for administrative purposes.

**-initialState** **STARTED** | **STOPPED**

The initial state determines whether the messaging engine is started automatically when the server or server cluster is started.

### Stopped

When the associated application server is started, the messaging engine is stopped and is not available to process messages.

### Started

When the associated application server is started, the messaging engine is started and is available to process messages.

**-highMessageThreshold** *number*

The maximum total number of messages that the messaging engine can place on its message points.

When the messaging engine is created, the high message threshold of the bus is used to set the default value for this property. When a message point is created on this messaging engine, the value of this property is used to set the default high message threshold for the message point.

## Example

```
wsadmin>AdminTask.showSIBEngine('[-bus bus1 -node node01 -server server1
-engine node01.server1-bus1]')
'{initialState=STARTED, targetGroups=[], name=node01.server1-bus1,
highMessageThreshold=50000, messageStoreType=FILESTORE, uuid=56F8FE11AB84188D,
busName=bus1, busUuid=6DF19B02BC879BD1}'
```

```
wsadmin>AdminTask.modifySIBEngine('[-bus bus1 -node node01 -server server1
-engine node01.server1-bus1 -initialState STOPPED]')
```

```
wsadmin>AdminTask.showSIBEngine('[-bus bus1 -node node01 -server server1
-engine node01.server1-bus1]')
'{initialState=STOPPED, targetGroups=[], name=node01.server1-bus1,
highMessageThreshold=50000, messageStoreType=FILESTORE, uuid=56F8FE11AB84188D,
busName=bus1, busUuid=6DF19B02BC879BD1}'
```

---

## showSIBEngine command

Use the showSIBEngine command to list properties of a messaging engine for a service integration bus member.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

## Purpose

This command lists details about properties of a messaging engine.

## Target object

A bus member.

## Required parameters

**-bus** *busname*

The name of the service integration bus on which the bus member is configured. You can use the listSIBuses command to list the names of existing buses.

## Conditional parameters

**-node** *nodename* **-server** *servername*

To list properties of a messaging engine for an application server as a bus member, specify both the name of the node on which the server runs and the name of the server.

**-cluster** *cluster*

To list properties of a messaging engine for a server cluster as a bus member, specify the name of the cluster.

**-engine** *enginename*

If the bus member has only one messaging engine, you do not need to specify the engine name. If the bus member has several messaging engines, you must specify the name of the engine for which you want to display details.

## Optional parameters

None.

## Example

```
AdminTask.showSIBEngine('[-bus bus1 -node node01 -server server1
-engine node01.server1-bus1]')
'{initialState=STARTED, targetGroups=[], name=node01.server1-bus1,
highMessageThreshold=50000, messageStoreType=FILESTORE, uuid=56F8FE11AB84188D,
busName=bus1, busUuid=6DF19B02BC879BD1}'
```

---

## deleteSIBEngine command

Use the deleteSIBEngine command to delete a messaging engine from a service integration bus member.

You should be wary of deleting and recreating messaging engines on bus members for which WS-Notification-administered subscribers have been configured, because in some cases this can leave the remote web service subscription active (and passing notification messages to the local server) even though there is no longer any record of it. For more information, see the WS-Notification troubleshooting tip Problems can occur when deleting administered subscribers and messaging engines.

If you promote a server bus member to a cluster that is not a member of the bus, do not delete then recreate the messaging engine. Use the migrateServerMEtoCluster command instead.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

This command deletes a messaging engine from a bus member. Any associated configurations of the messaging engine, such as core group policies or destinations, are also deleted. If the messaging engine uses a data store for the message store, objects in the data stores remain so that you can still access them. If you recreate the same messaging engine, you must remove any old data store tables before you start the new messaging engine.

This command also cleans up any mediation execution points that are on the messaging engine as the result of mediating a destination to a WebSphere MQ server bus member. The command unmediates the destination to which the mediation execution point corresponds.

## Target object

A messaging engine.

## Required parameters

**-bus** *bus\_name*

The name of the service integration bus on which the bus member is configured. You can use the `listSIBuses` command to list the names of existing buses.

## Conditional parameters

**-node** *node\_name*

**-server** *server\_name*

To delete a messaging engine from an application server that is a bus member, specify both the name of the node on which the server runs and the name of the server.

**-cluster** *cluster\_name*

To delete a messaging engine from a server cluster that is a bus member, specify the name of the cluster.

**-engine** *engine\_name*

If the bus member has only one messaging engine, you do not need to specify the engine name. If the bus member has several messaging engines, you must specify the name of the engine that you want to delete.

## Optional parameters

None.

## Examples

Delete the messaging engine from `server1` on `node1` that is a member of a bus1.

```
AdminTask.deleteSIBEngine ('[-bus bus1 -node node1 -server server1]')
```

List the messaging engines for `cluster1` that is a member of `bus1`, delete the messaging engine that is named `cluster1.001-bus1`, then list the messaging engines again.

```
AdminTask.listSIBEngines('[-bus bus1 -cluster cluster1]')
```

```
AdminTask.deleteSIBEngine('[-bus bus1 -cluster cluster1
-engine cluster1.001-clusterBus]')
```

```
AdminTask.listSIBEngines('[-bus bus1 -cluster cluster1]')
```

---

## createMissingSIBEnginePolicy command

Use the `createMissingSIBEnginePolicy` command to create a core group policy for a messaging engine in a cluster that is a member of a service integration bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use this command to create a core group policy for a messaging engine. For example, you must do this after you create a new messaging engine for the cluster by using the createSIBEngine command. Use this command only when the cluster has messaging engine policy assistance enabled and the custom policy specified. To do this, use the addSIBusMember or modifySIBusMemberPolicy commands.

## Target object

A messaging engine.

## Required parameters

**-name** *messaging\_engine\_name*

The name of the messaging engine for which to create a core group policy.

## Optional parameters

**-failover** **TRUE** | **FALSE**

A parameter that specifies whether the messaging engine in the cluster can fail over to another server in the cluster if the host server for the messaging engine fails. This parameter has two possible values:

**TRUE** The messaging engine can fail over.

**FALSE**

The messaging engine cannot fail over.

The default value is **FALSE**. Use this parameter if the cluster has messaging engine policy assistance enabled and the custom policy specified. To do this, use the addSIBusMember or modifySIBusMemberPolicy commands.

**-failback** **TRUE** | **FALSE**

A parameter that specifies whether the messaging engine in the cluster that has failed over can fail back to a more preferred server in the preferred servers list if that server becomes available again. This parameter has two possible values:

**TRUE** The messaging engine can fail back. If you use this option, supply a **-preferredServerList** parameter.

**FALSE**

The messaging engine cannot fail back.

The default value is **FALSE**. Use this parameter if the cluster has messaging engine policy assistance enabled and the custom policy set. To do this, use the addSIBusMember or modifySIBusMemberPolicy commands.

**-preferredServersOnly** **TRUE** | **FALSE**

A parameter that specifies whether the messaging engine in the cluster can run only on servers in the preferred servers list, or on any server in the cluster. This parameter has two possible values:

**TRUE** The messaging engine can run only on servers in the preferred servers list. If you use this option, supply a **-preferredServerList** parameter.

## FALSE

The messaging engine can run on any server in the cluster.

The default value is FALSE. Use this parameter if the cluster has messaging engine policy assistance enabled and the custom policy set. To do this, use the `addSIBusMember` or `modifySIBusMemberPolicy` commands.

### **-preferredServerList** `{{node server}}`

The list of servers, in order of preference, on which the messaging engine in the cluster prefers to run. For each server in the list, specify both the name of the node on which the server runs, and the name of the server. There is no default value for this parameter. Use this parameter if the cluster has messaging engine policy assistance enabled and the custom policy set. To do this, use the `addSIBusMember` or `modifySIBusMemberPolicy` commands.

## Example

Create a core group policy for the messaging engine cluster1.000-bus1. Configure the core group policy so that the messaging engine can fail over, cannot fail back, and can run only on server1 and server2:

```
AdminTask.createMissingSIBEnginePolicy('[-name cluster1.000-bus1
-failover true -failback false -preferredServersOnly true
-preferredServerList [[node1 server1] [node2 server2]]')
```

---

## correctSIBEnginePolicy command

Use the `correctSIBEnginePolicy` command to change a core group policy for a messaging engine in a cluster that is a member of a service integration bus, so that the core group policy conforms to the current messaging engine policy set for the cluster.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use this command when there is a messaging engine for the cluster that does not have the correct core group policy settings for the messaging engine policy that you want to use for the cluster. Use this command only when the messaging engine already exists, and the cluster has messaging engine policy assistance enabled and the high availability, scalability, or scalability with high availability messaging engine policy specified. To do this, you use the `addSIBusMember` or `modifySIBusMemberPolicy` commands.

## Target object

A core group policy.

## Required parameters

**-name** *messaging\_engine\_name*

The name of the messaging engine for which to correct the core group policy.

## Example

Correct the core group policy for the messaging engine cluster1.000-bus1.

```
AdminTask.correctSIBEnginePolicy ('[-name cluster1.000-bus1]')
```

---

## migrateServerMEtoCluster command

When a server that is a member of a bus is converted to a cluster, use the `migrateServerMEtoCluster` command to migrate the messaging engine (ME) in the server to cluster scope. During the conversion, the bus membership is not automatically transferred to cluster scope. If you want the cluster to be a member of the bus, use this command to perform that transfer.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `migrateServerMEtoCluster` command migrates a messaging engine in a server to the scope of a cluster. This is of use when a server that is a member of a service integration bus has been converted to a cluster. The conversion to a cluster does not automatically make the cluster a member of the bus. Use this command to transfer the bus membership to the cluster. This can be used to allow the messaging engine to be highly available or if you want to add further messaging engines to the cluster for scalability. In this situation, you must not delete the messaging engine at server scope and re-create it at cluster scope, because the unique identifier (UUID) of the messaging engine would be lost and the messaging engine would not work with previously configured destinations.

The `migrateServerMEtoCluster` command makes the new server cluster a member of the bus.

One example of a situation when this command is useful is after a server that is a member of a bus has been federated into a cell, by using the option to include the bus, then the server is promoted to a member of a cluster by creating a new cluster with the server as the first member.

## Target object

A messaging engine.

The messaging engine is copied to the scope of the cluster and all the destination localization references are copied, ensuring that it continues to function with previously configured destinations. The messaging engine definition at the scope of the server is deleted.

## Required parameters

**-bus** *bus\_name*

The name of the service integration bus that the server is a member of, when that server hosts the messaging engine to migrate. You can use the `listSIBuses` command to list the names of existing buses.

**-node** *node\_name*

The name of the node on which the server runs, when that server hosts the messaging engine to migrate.

**-server** *server\_name*

The name of the server that hosts the messaging engine to migrate.

The server must be a member of the bus specified and run on the node specified, and must already be converted to the cluster specified in the command.

**-cluster** *cluster\_name*

The name of the server cluster that the server has been converted to, and to which you want to migrate the messaging engine.

The cluster must exist and the server must be a member of the cluster. The cluster must not yet be a member of the service integration bus that the server is a member of.

## Optional parameters

**-rename** **TRUE** | **FALSE**

Whether to rename the messaging engine and message points and use the naming conventions for these resources in a cluster. For example, the name of a messaging engine on a server that uses the naming convention *node\_name.server\_name-bus\_name* changes to use the naming convention *cluster\_name.nnn-bus\_name*.

**TRUE** The messaging engine and message points are renamed using the naming conventions for these resources in a cluster.

**FALSE**

The messaging engine and message points are not renamed using the naming conventions for these resources in a cluster.

The default value is **FALSE**.

## Example

Migrate to `cluster1` a messaging engine that is currently configured on `node1` `server1`, and rename the messaging engine and all its message points to use cluster terminology. `Server1` is a member of `bus1` and has already been converted to `cluster1`. `Cluster1` is not yet a member of `bus1`.

```
AdminTask.migrateServerMEtoCluster ('-bus bus1 -node node1 -server server1 -cluster cluster1
-rename TRUE')
```

---

## SIBAdminCommands: Destination administrative commands for the AdminTask object

You can use these administrative commands to manage bus destinations.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and JACL.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

---

### createSIBDestination command

Use the createSIBDestination command to create a new bus destination for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

The createSIBDestination command creates a new bus destination for a service integration bus. With this command, a messaging destination can also be localized to a WebSphere MQ server bus member.

### Target object

A service integration bus.

### Required parameters

#### -bus

The name of the service integration bus on which to create the bus destination. To list the names of existing buses, use the listSIBuses command.

**-name**

The identifier by which this destination is known for administrative purposes.

**-type**

Indicates the type of bus destination that you want to create:

**Alias** An alias destination, that provides a level of abstraction between applications and the underlying target bus destinations that hold messages. Applications interact with the alias destination, so the target bus destination can be changed without changing the application.

**Foreign**

A foreign destination, which identifies a destination on another bus, and enables applications on one bus to access the destination on another bus directly.

**Port** Represents a particular message and transport binding for an outbound service that communicates with an externally-hosted target web service.

**Queue**

A queue, for point-to-point messaging.

**TopicSpace**

A topic space, for publish/subscribe messaging.

**WebService**

Represents an externally-hosted target web service.

## Conditional parameters

None.

## Optional parameters

**-cluster**

To assign the bus destination to a cluster bus member, specify the name of the cluster. Do not specify the **-node**, **-server** or **-wmqServer** parameters.

**-node**

To assign the bus destination to a server bus member, specify both the name of the node on which the server runs and the name of the server. Do not specify the **-cluster** or **-wmqServer** parameters.

**-server**

To assign the bus destination to a server bus member, specify both the name of the node on which the server runs and the name of the server. Do not specify the **-cluster** or **-wmqServer** parameters.

**-wmqServer**

To assign the bus destination to a WebSphere MQ queue, specify both the name of the WebSphere MQ server bus member where the destination is assigned (this parameter), and the name of the WebSphere MQ queue used to store messages sent to the destination (the **-wmqQueueName** parameter). Set the **-wmqServer** parameter to the name you gave when you created the WebSphere MQ server. Set the **-wmqQueueName** parameter to the name allocated to the WebSphere MQ queue by WebSphere MQ administration. Do not specify the **-cluster**, **-node** or **-server** parameters.

**-aliasBus**

If you are creating an alias destination, specify the source bus name of the alias mapping.

**-targetBus**

If you are creating an alias destination, specify the name of the bus to which the alias destination is mapped.

**-targetName**

If you are creating an alias destination, specify the name of the destination to which the alias destination is mapped.

**-foreignBus**

If you are creating a foreign destination, specify the name of the foreign bus.

**-description**

Specify a description for the bus destination, for administrative purposes.

**-reliability**

Specify the default reliability level to assign to a message produced to this destination when an explicit reliability has not been set by the producer application. Service integration supports five reliability levels (also known as delivery options or qualities of service):

**BEST\_EFFORT\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**EXPRESS\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**RELIABLE\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails.

**RELIABLE\_PERSISTENT**

Messages might be discarded when a messaging engine fails.

**ASSURED\_PERSISTENT**

Messages are not discarded.

**Note:** Higher levels of reliability have higher impacts on performance.

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

**-maxReliability**

Specify the maximum reliability level that is accepted for values specified by producer applications. Service integration supports five reliability levels (also known as delivery options or qualities of service):

**BEST\_EFFORT\_NONPERSISTENT**

**EXPRESS\_NONPERSISTENT**

**RELIABLE\_NONPERSISTENT**

**RELIABLE\_PERSISTENT**

**ASSURED\_PERSISTENT**

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

**-nonPersistentReliability**

Specify the service integration quality of service to use with nonpersistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For nonpersistent WebSphere MQ messages received, the default service integration quality of service is RELIABLE\_NONPERSISTENT. If you choose to override this default, you will probably choose one

of the other nonpersistent service integration qualities of service BEST\_EFFORT\_NONPERSISTENT or EXPRESS\_NONPERSISTENT. However, you can choose any of the five possible service integration qualities of service:

**BEST\_EFFORT\_NONPERSISTENT**

**EXPRESS\_NONPERSISTENT**

**RELIABLE\_NONPERSISTENT**

**RELIABLE\_PERSISTENT**

**ASSURED\_PERSISTENT**

For more information, see `../ae/rjc0014_.dita`.

**-persistentReliability**

Specify the service integration quality of service to use with persistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For persistent WebSphere MQ messages received, the default service integration quality of service is ASSURED\_PERSISTENT. If you choose to override this default, you will probably choose the other persistent service integration quality of service RELIABLE\_PERSISTENT. However, you can choose any of the five possible service integration qualities of service:

**BEST\_EFFORT\_NONPERSISTENT**

**EXPRESS\_NONPERSISTENT**

**RELIABLE\_NONPERSISTENT**

**RELIABLE\_PERSISTENT**

**ASSURED\_PERSISTENT**

For more information, see `../ae/rjc0014_.dita`.

**-overrideOfQOSByProducerAllowed TRUE | FALSE**

Controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination.

**-defaultPriority *number***

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

**-maxFailedDeliveries *number***

The maximum number of failed attempts to process a message. After this number of failed attempts, the message is forwarded from the intended destination to its exception destination. Specify a value in the range 0 through 2147483647. A value of 0 (zero) means that if a message cannot be delivered on the first attempt, it is either forwarded to the exception destination or discarded, as defined by the **-exceptionDestination** parameter.

**-exceptionDestination *value***

Use these properties to define what happens to any messages that cannot be delivered to this destination.

By default, all messages that cannot be delivered to this destination are rerouted to the system default exception destination for the messaging engine to which this destination is assigned (`._SYSTEM.Exception.Destination.messaging_engine_name`). Use this parameter to override the default value. You can set a specific exception destination for this destination, or you can specify that

undeliverable messages are not rerouted to an exception destination by entering an empty string (""), in which case the maximum failed deliveries count has no effect.

**Note:** An undeliverable message can block the processing of other messages waiting for delivery to the same destination.

You can use this option and specify no exception destination to preserve message ordering.

**-sendAllowed TRUE | FALSE**

Clear this option (setting it to FALSE) to stop producers from being able to send messages to this destination.

- For a queue point of a non-mediated destination, or a mediation point of a mediated destination, if you clear this option then new messages (from attached producers or forwarded from another destination) are redirected to any available message point. If no message points are available, then messages that have already been accepted onto the bus, and new messages from attached producers, are preserved by the bus until a message point becomes available. The only exception to this is the case of a destination with only one message point (queue point or mediation point depending on whether the destination is mediated or non-mediated), where the producer is attached to the same messaging engine. In this case, an exception message is generated on each send call. The exception message indicates that the only extant localization has been disabled for send. The producer remains open as usual, and any more send calls succeed if the **Send allowed** property of the localization is reselected (reset to TRUE).
- For a queue point of a mediated destination, if you clear this option then messages from mediation instances are redirected to any available message point. If no message points are available, then the messages are preserved by the bus until a message point becomes available. For any mediation instance (that is, on any server that has a mediation point), if the same server hosts a queue point, and that queue point is the only queue point for the destination, then the mediation changes to the “stopped on error” state.

**-receiveAllowed TRUE | FALSE**

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination. For the message point, if you clear this option then any open consumers change state and an exception is generated if the consumer requests a message. Messages can continue to be sent, and accumulate on the message point.

**-receiveExclusive TRUE | FALSE**

Select this option (setting it to TRUE) to allow only one consumer to attach to a destination. If you select this option, only a single consumer can be attached to each queue point of a queue destination at any one time. Subsequent consumers attempting to attach to a queue point with a consumer already attached are rejected.

**-maintainStrictMessageOrder TRUE | FALSE**

Select this option (setting it to TRUE) to maintain the order in which a producer sends messages to the destination.

At run time, this property has priority over other configuration property values. For information about the configuration properties that are overridden at run time, see Strict message ordering for bus destinations.

**-topicAccessCheckRequired**

Include this option if authorization checks are required for access to topics.

**-replyDestination**

The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination. This property is intended for use with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 2131.

**-replyDestinationBus**

The name of the bus on which the reply destination is configured. This property is intended for use

with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 2131.

**-delegateAuthorizationCheckToTarget**

Indicates whether the authorization check is performed on the alias or the target destination. Include this option if you want the authorization check to be performed on the target destination.

**-wmqQueueName**

To assign the bus destination to a WebSphere MQ queue, specify both the name of the WebSphere MQ server bus member where the destination is assigned (the **-wmqServer** parameter), and the name of the WebSphere MQ queue used to store messages sent to the destination (this parameter). Set the **-wmqServer** parameter to the name you gave when you created the WebSphere MQ server. Set the **-wmqQueueName** parameter to the name allocated to the WebSphere MQ queue by WebSphere MQ administration. Do not specify the **-cluster**, **-node** or **-server** parameters.

**-useRFH2 or -mqRfh2Allowed TRUE | FALSE**

Determines whether messages sent to the destination have an MQRFH2 header.

When service integration converts a message from the service integration format to WebSphere MQ format, by default it includes an MQRHF2 header in the WebSphere MQ message. This header contains message attributes, such as JMS message attributes, which are not WebSphere MQ message attributes and therefore do not appear in the WebSphere MQ message descriptor (MQMD). Some WebSphere MQ applications cannot process messages that include an MQRFH2 header. If messages sent to this destination will be processed by WebSphere MQ applications that cannot tolerate an MQRFH2, clear this option (setting it to FALSE).

If you are assigning a queue-type destination to a WebSphere MQ server bus member, use the **-useRFH2** parameter. If you are creating an alias destination or a foreign destination, use the **-mqRfh2Allowed** parameter.

**-auditAllowed TRUE | FALSE**

Clear this option (setting it to FALSE) to prevent the bus from auditing topic level authorization checks when the bus and application server have auditing enabled. The default value is TRUE. You must have Audit Administrator privileges to use this parameter. The parameter is ignored if it is used in the creation of other types of destination.

**-defaultForwardRoutingPath**

The value to which a message forward routing path is set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of bus destinations specified as *bus\_name:destination\_name*.

**-queuePoints**

A list of the queue points used by users of the alias destination. If no queue points are supplied, all queue points can be used. The target destination must be a queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple queue points.

A queue point is specified in the following form: *destination\_name@messaging\_engine\_name*

**-mediationPoints**

A list of the mediation points used by users of the alias destination. If no mediation points are supplied, all mediation points can be used. The target destination must be a mediated queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple mediation points.

A mediation point is specified in the following form: *destination\_name@messaging\_engine\_name*

## Example

- Using Jython:

```
wsadmin>AdminTask.createSIBDestination('[-bus bus1 -name myqueue -type QUEUE
-node node1 -server server1]')
'(cells/9994GKCCell01/buses/bus1|sib-destinations.xml#SIBQueue_1098215169998)'
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBDestination {-bus bus1 -name myqueue -type QUEUE
-node node1 -server server1}
(cells/9994GKCCell01/buses/bus1|sib-destinations.xml#SIBQueue_1098215169998)
```

### Example: Create a destination alias for "MyDestination1" called "MyAlias1" that can use two queue points:

- Using Jython:

```
wsadmin>AdminTask.createSIBDestination('[-bus bus1 -type ALIAS
-name MyAlias1 -aliasBus bus1 -targetName MyDestination1
-reliability INHERIT -maxReliability INHERIT
-overrideOfQOSByProducerAllowed INHERIT -sendAllowed INHERIT
-receiveAllowed INHERIT
-queuePoints [[-identifier MyDestination1@cluster1.001-bus1]
[-identifier MyDestination1@cluster1.002-bus1]]')
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBDestination {-bus bus1 -type ALIAS
-name MyAlias1 -aliasBus bus1 -targetName MyDestination1
-reliability INHERIT -maxReliability INHERIT
-overrideOfQOSByProducerAllowed INHERIT -sendAllowed INHERIT
-receiveAllowed INHERIT
-queuePoints {"MyDestination1@cluster1.001-bus1"}
{"MyDestination1@cluster1.002-bus1"}}
```

---

## createSIBDestinations command

Use the createSIBDestinations command to create new bus destinations for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

The createSIBDestinations command creates multiple new bus destinations for a service integration bus, all with the same properties. If the destinations created are alias destinations, they all target the same destination. With this command, the new bus destinations can also be localized to a WebSphere MQ server bus member.

### Target object

A service integration bus.

## Required parameters

### **-bus**

The name of the service integration bus on which to create the bus destinations. To list the names of existing buses, use the `listSIBuses` command.

### **-nameList**

The list of identifiers by which these destinations are known for administrative purposes.

### **-type**

Indicates the type of bus destination that you want to create:

**Alias** An alias destination, that provides a level of abstraction between applications and the underlying target bus destinations that hold messages. Applications interact with the alias destination, so the target bus destination can be changed without changing the application.

### **Foreign**

A foreign destination, which identifies a destination on another bus, and enables applications on one bus to access the destination on another bus directly.

**Port** Represents a particular message and transport binding for an outbound service that communicates with an externally-hosted target web service.

### **Queue**

A queue, for point-to-point messaging.

### **TopicSpace**

A topic space, for publish/subscribe messaging.

### **WebService**

Represents an externally-hosted target web service.

## Conditional parameters

None.

## Optional parameters

### **-cluster**

To assign the bus destinations to a cluster bus member, specify the name of the cluster. Do not specify the **-node**, **-server** or **-wmqServer** parameters.

### **-node**

To assign the bus destinations to a server bus member, specify both the name of the node on which the server runs and the name of the server. Do not specify the **-cluster** or **-wmqServer** parameters.

### **-server**

To assign the bus destinations to a server bus member, specify both the name of the node on which the server runs and the name of the server. Do not specify the **-cluster** or **-wmqServer** parameters.

### **-wmqServer**

To assign the bus destinations to a WebSphere MQ queue, specify both the name of the WebSphere MQ server bus member where the destination is assigned (this parameter), and the name of the WebSphere MQ queue used to store messages sent to the destinations (the **-wmqQueueName** parameter). Set the **-wmqServer** parameter to the name you gave when you created the WebSphere MQ server. Set the **-wmqQueueName** parameter to the name allocated to the WebSphere MQ queue by WebSphere MQ administration. Do not specify the **-cluster**, **-node** or **-server** parameters.

### **-aliasBus**

If you are creating alias destinations, specify the source bus name of the alias mapping.

**-targetBus**

If you are creating alias destinations, specify the name of the bus to which the alias destinations are mapped.

**-targetName**

If you are creating alias destinations, specify the name of the destination to which the alias destinations are mapped.

**-foreignBus**

If you are creating foreign destinations specify the name of the foreign bus.

**-description**

Specify a description for the bus destinations for administrative purposes.

**-reliability**

Specify the default reliability level to assign to messages produced to these destinations when an explicit reliability has not been set by the producer application. Service integration supports five reliability levels (also known as delivery options or qualities of service):

**BEST\_EFFORT\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

**EXPRESS\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

**RELIABLE\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails.

**RELIABLE\_PERSISTENT**

Messages might be discarded when a messaging engine fails.

**ASSURED\_PERSISTENT**

Messages are not discarded.

**Note:** Higher levels of reliability have higher impacts on performance.

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

**-maxReliability**

Specify the maximum reliability level that is accepted for values specified by producer applications. Service integration supports five reliability levels (also known as delivery options or qualities of service):

**BEST\_EFFORT\_NONPERSISTENT**

**EXPRESS\_NONPERSISTENT**

**RELIABLE\_NONPERSISTENT**

**RELIABLE\_PERSISTENT**

**ASSURED\_PERSISTENT**

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

**-nonPersistentReliability**

Specify the service integration quality of service to use with nonpersistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or

non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For nonpersistent WebSphere MQ messages received, the default service integration quality of service is `RELIABLE_NONPERSISTENT`. If you choose to override this default, you will probably choose one of the other nonpersistent service integration qualities of service `BEST_EFFORT_NONPERSISTENT` or `EXPRESS_NONPERSISTENT`. However, you can choose any of the five possible service integration qualities of service:

**BEST\_EFFORT\_NONPERSISTENT**

**EXPRESS\_NONPERSISTENT**

**RELIABLE\_NONPERSISTENT**

**RELIABLE\_PERSISTENT**

**ASSURED\_PERSISTENT**

For more information, see `./ae/rjc0014_.dita`.

#### **-persistentReliability**

Specify the service integration quality of service to use with persistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For persistent WebSphere MQ messages received, the default service integration quality of service is `ASSURED_PERSISTENT`. If you choose to override this default, you will probably choose the other persistent service integration quality of service `RELIABLE_PERSISTENT`. However, you can choose any of the five possible service integration qualities of service:

**BEST\_EFFORT\_NONPERSISTENT**

**EXPRESS\_NONPERSISTENT**

**RELIABLE\_NONPERSISTENT**

**RELIABLE\_PERSISTENT**

**ASSURED\_PERSISTENT**

For more information, see `./ae/rjc0014_.dita`.

#### **-overrideOfQOSByProducerAllowed TRUE | FALSE**

Controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination.

#### **-defaultPriority *number***

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

#### **-maxFailedDeliveries *number***

The maximum number of failed attempts to process a message. After this number of failed attempts, the message is forwarded from the intended destination to its exception destination. Specify a value in the range 0 through 2147483647. A value of 0 (zero) means that if a message cannot be delivered on the first attempt, it is either forwarded to the exception destination or discarded, as defined by the **-exceptionDestination** parameter.

#### **-exceptionDestination *value***

Use these properties to define what happens to any messages that cannot be delivered to this destination.

By default, all messages that cannot be delivered to this destination are rerouted to the system default exception destination for the messaging engine to which this destination is assigned (`_SYSTEM.Exception.Destination.messaging_engine_name`). Use this parameter to override the default value. You can set a specific exception destination for this destination, or you can specify that undeliverable messages are not rerouted to an exception destination by entering an empty string (""), in which case the maximum failed deliveries count has no effect.

**Note:** An undeliverable message can block the processing of other messages waiting for delivery to the same destination.

You can use this option and specify no exception destination to preserve message ordering.

**-sendAllowed TRUE | FALSE**

Clear this option (setting it to FALSE) to stop producers from being able to send messages to these destinations.

- For a queue point of a non-mediated destination, or a mediation point of a mediated destination, if you clear this option then new messages (from attached producers or forwarded from another destination) are redirected to any available message point. If no message points are available, then messages that have already been accepted onto the bus, and new messages from attached producers, are preserved by the bus until a message point becomes available. The only exception to this is the case of a destination with only one message point (queue point or mediation point depending on whether the destination is mediated or non-mediated), where the producer is attached to the same messaging engine. In this case, an exception message is generated on each send call. The exception message indicates that the only extant localization has been disabled for send. The producer remains open as usual, and any more send calls succeed if the **Send allowed** property of the localization is reselected (reset to TRUE).
- For a queue point of a mediated destination, if you clear this option then messages from mediation instances are redirected to any available message point. If no message points are available, then the messages are preserved by the bus until a message point becomes available. For any mediation instance (that is, on any server that has a mediation point), if the same server hosts a queue point, and that queue point is the only queue point for the destination, then the mediation changes to the “stopped on error” state.

**-receiveAllowed TRUE | FALSE**

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination. For the message point, if you clear this option then any open consumers change state and an exception is generated if the consumer requests a message. Messages can continue to be sent, and accumulate on the message point.

**-receiveExclusive TRUE | FALSE**

Select this option (setting it to true) to allow only one consumer to attach to a destination. If you select this option, only a single consumer can be attached to each queue point of a queue destination at any one time. Subsequent consumers attempting to attach to a queue point with a consumer already attached are rejected.

**-maintainStrictMessageOrder TRUE | FALSE**

Select this option (setting it to TRUE) to maintain the order in which a producer sends messages to a destination.

At run time, this property has priority over other configuration property values. For information about the configuration properties that are overridden at run time, see Strict message ordering for bus destinations.

**-topicAccessCheckRequired**

Include this option if authorization checks are required for access to topics.

**-replyDestination**

The name of a destination to be appended to any non-empty reverse routing path of messages sent to

this destination. This property is intended for use with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 2131.

**-replyDestinationBus**

The name of the bus on which the reply destination is configured. This property is intended for use with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 2131.

**-delegateAuthorizationCheckToTarget**

Indicates whether the authorization check is performed on the alias or the target destination. Include this option if you want the authorization check to be performed on the target destination.

**-wmqQueueName**

To assign these bus destinations to a WebSphere MQ queue, specify both the name of the WebSphere MQ server bus member where the destinations are assigned (the **-wmqServer** parameter), and the name of the WebSphere MQ queue used to store messages sent to these destinations (this parameter). Set the **-wmqServer** parameter to the name you gave when you created the WebSphere MQ server. Set the **-wmqQueueName** parameter to the name allocated to the WebSphere MQ queue by WebSphere MQ administration. Do not specify the **-cluster**, **-node** or **-server** parameters.

**-useRFH2 or -mqRfh2Allowed TRUE | FALSE**

Determines whether messages sent to these destinations have an MQRFH2 header.

When service integration converts a message from the service integration format to WebSphere MQ format, by default it includes an MQRHF2 header in the WebSphere MQ message. This header contains message attributes, such as JMS message attributes, which are not WebSphere MQ message attributes and therefore do not appear in the WebSphere MQ message descriptor (MQMD). Some WebSphere MQ applications cannot process messages that include an MQRFH2 header. If messages sent to this destination will be processed by WebSphere MQ applications that cannot tolerate an MQRFH2, clear this option (setting it to FALSE).

If you are assigning queue-type destinations to a WebSphere MQ server bus member, use the **-useRFH2** parameter. If you are creating alias destinations or foreign destinations, use the **-mqRfh2Allowed** parameter.

**-auditAllowed TRUE | FALSE**

Clear this option (setting it to FALSE) to prevent the bus from auditing topic level authorization checks when the bus and application server have auditing enabled. The default value is TRUE. You must have Audit Administrator privileges to use this parameter. The parameter is ignored if it is used in the creation of other types of destination.

**-defaultForwardRoutingPath**

The value to which a message forward routing path is set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of bus destinations specified as *bus\_name:destination\_name*.

**-queuePoints**

A list of the queue points used by users of the alias destination. If no queue points are supplied, all queue points can be used. The target destination must be a queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple queue points.

A queue point is specified in the form *destination\_name@messaging\_engine\_name*.

**-mediationPoints**

A list of the mediation points used by users of the alias destination. If no mediation points are

supplied, all mediation points can be used. The target destination must be a mediated queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple mediation points.

A mediation point is specified in the form *destination\_name@messaging\_engine\_name*.

## Example

- Using Jython:

```
wsadmin>AdminTask.createSIBDestinations('[-bus bus1 -type QUEUE
-cluster cluster1 -nameList [[-identifier myqueue1][-identifier myqueue2]]')
(cells/9994GKCCell01/buses/bus1|sib-destinations.xml#SIBQueue_1098215169998)'
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBDestinations {-bus bus1 -type QUEUE
-cluster cluster1 -nameList {{myqueue1} {myqueue2}}}
(cells/9994GKCCell01/buses/bus1|sib-destinations.xml#SIBQueue_1098215169998)
```

## Example: Create aliases for "MyDestination1" called "MyAlias1" and "MyAlias2". These alias destinations give access to a single queue point of the target destination:

- Using Jython:

```
wsadmin>cluster=AdminConfig.list("ServerCluster").splitlines()[0]
wsadmin>AdminTask.createSIBDestinations('[-bus bus1 -type ALIAS
-nameList [[-identifier MyAlias1][-identifier MyAlias2]] -aliasBus bus1
-targetName MyDestination1 -reliability INHERIT -maxReliability INHERIT
-overrideOfQoSByProducerAllowed INHERIT -sendAllowed INHERIT
-receiveAllowed INHERIT -queuePoints [[-identifier MyDestination1@cluster1.001-bus1]
[-identifier MyDestination1@cluster1.002-bus1]]')'
```

- Using Jacl:

```
wsadmin>set cluster [lindex [$AdminConfig list ServerCluster] 1]
wsadmin>$AdminTask createSIBDestinations {-bus bus1 -type ALIAS
-nameList {{MyAlias1} {MyAlias2}} -aliasBus bus1
-targetName MyDestination1 -reliability INHERIT -maxReliability INHERIT
-overrideOfQoSByProducerAllowed INHERIT -sendAllowed INHERIT
-receiveAllowed INHERIT -queuePoints {"MyDestination1@cluster1.001-bus1"}
{"MyDestination1@cluster1.002-bus1"}}
```

---

## deleteSIBDestination command

Use the deleteSIBDestination command to delete a bus destination.

This command deletes the named destination on the named bus, and deletes all related message points.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `deleteSIBDestination` command deletes the named destination on the named bus, and deletes all related message points. This command also finds and cleans up all destinations that are assigned to WebSphere MQ server bus members, and all destinations that are mediated to a WebSphere MQ queue. This command does not delete messages from WebSphere MQ queues, and it does not delete the queues.

## Target object

A bus destination.

## Required parameters

### **-bus**

The name of the service integration bus on which the bus destination is configured. You can use the `listSIBuses` command to list the names of existing buses.

### **-name**

The identifier by which this destination is known for administrative purposes.

### **-aliasBus**

If the destination to be deleted is an alias destination and was created with the **aliasBus** parameter, then the same value must be used to delete the destination.

### **-foreignBus**

If the destination to be deleted is a foreign destination, then the foreign destination parameter must be supplied.

## Conditional parameters

None.

## Optional parameters

None.

## Example

- Using Jython:

```
wsadmin>AdminTask.deleteSIBDestination("-bus abus -name myqueue")

wsadmin>AdminConfig.save()
```
- Using Jacl:

```
wsadmin>$AdminTask deleteSIBDestination {-bus abus -name myqueue}

wsadmin>$AdminConfig save
```

---

## deleteSIBDestinations command

Use the `deleteSIBDestinations` command to delete bus destinations.

This command deletes the named destinations on the named bus, and deletes all related message points.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when it is used with WebSphere Application Server Version 6.1.0 (Fix Pack 15) or later. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `deleteSIBDestinations` command deletes the named destinations on the named bus, and deletes all related message points. This command also finds and cleans up all destinations that are assigned to WebSphere MQ server bus members, and all destinations that are mediated to a WebSphere MQ queue. This command does not delete messages from WebSphere MQ queues, and it does not delete the queues.

## Target object

Bus destinations.

## Required parameters

### **-bus**

The name of the service integration bus on which the bus destination is configured. You can use the `listSIBuses` command to list the names of existing buses.

### **-nameList**

The identifiers by which these destinations are known for administrative purposes.

### **-aliasBus**

If the destination to be deleted is an alias destination and was created with the **aliasBus** parameter, then the same value must be used to delete the destination.

### **-foreignBus**

If the destination to be deleted is a foreign destination, then the foreign destination parameter must be supplied.

## Conditional parameters

None.

## Optional parameters

None.

## Example

- Using Jython:

```
wsadmin>AdminTask.deleteSIBDestinations(["-bus" , "abus" , "-nameList" , [{"myqueue1"} ,{"myqueue2"}]])
```

```
wsadmin>$AdminConfig save
```

- Using Jacl:

```
wsadmin>$AdminTask deleteSIBDestinations {-bus myBus -nameList {{myqueue1} {myqueue2}} }
wsadmin>$AdminConfig save
```

---

## listSIBDestinations command

Use the listSIBDestinations command to list the bus destinations for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

### Purpose

This command lists all the bus destinations on a bus.

### Target object

A bus.

### Required parameters

**-bus** *busname*

The name of the service integration bus on which the bus destinations are configured. You can use the listSIBuses command to list the names of existing buses.

### Conditional parameters

None.

### Optional parameters

**-type** *Queue* | *TopicSpace* | *WebService* | *Port*

To list destinations of the specified type.

### Example

- Using Jython:

```
wsadmin>AdminTask.listSIBDestinations("-bus abus")
'(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098181503600)
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098184221748)'
```

```
AdminTask.listSIBDestinations("-bus abus -type TopicSpace")
'(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)'
```

- Using Jacl:

```
wsadmin>$AdminTask listSIBDestinations {-bus abus}
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098181503600)
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098184221748)
```

```
wsadmin>$AdminTask listSIBDestinations {-bus abus -type TopicSpace}
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)
```

---

## mediateSIBDestination command

Use the `mediateSIBDestination` command to mediate a bus destination for a service integration bus.

Mediating a destination associates a mediation with a selected bus destination. At run time, the mediation applies some message processing to the messages handled by the bus destination. Note that you can only mediate a destination with a single mediation at a time. You can mediate more than one destination with the same mediation.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

This command mediates a bus destination for a service integration bus. There are parameters that you can use to create a mediation queue point on a WebSphere MQ server, and create the corresponding mediation execution point on a cluster or a server.

### Target object

None.

### Required parameters

**-bus** *bus\_name* **-destinationName** *destination\_name*  
The destination to be mediated.

**-mediationName** *mediation\_name*  
The name of the mediation to be applied to the bus destination. This mediation must exist before this command can be used.

### Conditional parameters

**-wmqServer** *mq\_server\_name* **-wmqQueueName** *mq\_queue\_name*  
[Queue or web service destination] To assign the mediation point to a WebSphere MQ queue, specify both the name of the WebSphere MQ server bus member where the mediation point is to be assigned, and the name of the WebSphere MQ queue to be used to store messages ready for mediation. *mq\_server\_name* is the name of the WebSphere MQ server as specified in the **-name** parameter when creating the WebSphere MQ server. *mq\_queue\_name* is the name allocated to the WebSphere MQ queue by WebSphere MQ administration.

**-node** *node\_name* **-server** *server\_name*  
[Not topic space] To mediate the bus destination to a server bus member, specify both the name of the node on which the server runs and the name of the server.

**-cluster** *cluster\_name*

[Not topic space] To mediate the bus destination to a cluster bus member, specify the name of the cluster.

## Optional parameters

### **-nonPersistentReliability**

Specify the service integration quality of service to use with nonpersistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For nonpersistent WebSphere MQ messages received, the default service integration quality of service is **RELIABLE\_NONPERSISTENT**. If you choose to override this default, you will probably choose one of the other nonpersistent service integration qualities of service **BEST\_EFFORT\_NONPERSISTENT** or **EXPRESS\_NONPERSISTENT**. However, you can choose any of the five possible service integration qualities of service:

#### **BEST\_EFFORT\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

#### **EXPRESS\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

#### **RELIABLE\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails.

#### **RELIABLE\_PERSISTENT**

Messages might be discarded when a messaging engine fails.

#### **ASSURED\_PERSISTENT**

Messages are not discarded.

**Note:** Higher levels of reliability have higher impacts on performance.

For more information, see `../ae/rjc0014_.dita`.

### **-persistentReliability**

Specify the service integration quality of service to use with persistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For persistent WebSphere MQ messages received, the default service integration quality of service is **ASSURED\_PERSISTENT**. If you choose to override this default, you will probably choose the other persistent service integration quality of service **RELIABLE\_PERSISTENT**. However, you can choose any of the five possible service integration qualities of service:

#### **BEST\_EFFORT\_NONPERSISTENT**

#### **EXPRESS\_NONPERSISTENT**

#### **RELIABLE\_NONPERSISTENT**

#### **RELIABLE\_PERSISTENT**

## ASSURED\_PERSISTENT

For more information, see ../ae/rjc0014\_.dita.

### -useRFH2

Determines whether service integration technologies includes an RFH2 header in messages it places on the mediation point. Possible values are:

**TRUE**

**FALSE**

The default value is TRUE.

### -maintainStrictMessageOrder

Maintain strict message order. Possible values are:

#### Selected

Maintains the order in which a producer sends messages to the destination.

At run time, this property has priority over other configuration property values. For information on the configuration properties that are overridden at run time, see Strict message ordering for bus destinations.

#### Cleared

Message order is not preserved for this destination.

## Example

- Using Jython:

```
wsadmin>AdminTask.mediateSIBDestination("-bus abus -destinationName myqueue
-mediationName filterMed -cluster cluster1")
```

- Using Jacl:

```
wsadmin>${AdminTask} mediateSIBDestination {-bus abus -destinationName myqueue
-mediationName filterMed -cluster cluster1}
```

---

## modifySIBDestination command

Use the modifySIBDestination command to change properties of a bus destination for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The modifySIBDestination changes properties of a bus destination for a service integration bus.

## Target object

A bus destination.

## Required parameters

### -bus

The name of the service integration bus on which the bus destination is configured. You can use the `listSIBuses` command to list the names of existing buses.

### -name

The identifier by which this destination is known for administrative purposes.

## Conditional parameters

None.

## Optional parameters

### -description

Specify a description for the bus destination, for administrative purposes.

### -reliability

Specify the default reliability level to assign to a message produced to this destination when an explicit reliability has not been set by the producer application. Service integration supports five reliability levels (also known as delivery options or qualities of service):

#### **BEST\_EFFORT\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

#### **EXPRESS\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

#### **RELIABLE\_NONPERSISTENT**

Messages are discarded when a messaging engine stops or fails.

#### **RELIABLE\_PERSISTENT**

Messages might be discarded when a messaging engine fails.

#### **ASSURED\_PERSISTENT**

Messages are not discarded.

**Note:** Higher levels of reliability have higher impacts on performance.

For more information about service integration reliability levels, see [Message reliability levels - JMS delivery mode and service integration quality of service](#).

### -overrideOfQOSByProducerAllowed **TRUE** | **FALSE**

Controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination.

### -defaultPriority *number*

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

### -maxFailedDeliveries *number*

The maximum number of failed attempts to process a message. After this number of failed attempts, the message is forwarded from the intended destination to its exception destination. Specify a value in

the range 0 through 2147483647. A value of 0 (zero) means that if a message cannot be delivered on the first attempt, it is either forwarded to the exception destination or discarded, as defined by the **-exceptionDestination** parameter.

**-exceptionDestination** *value*

Use these properties to define what happens to any messages that cannot be delivered to this destination.

By default, all messages that cannot be delivered to this destination are rerouted to the system default exception destination for the messaging engine to which this destination is assigned (`_SYSTEM.Exception.Destination.messaging_engine_name`). Use this parameter to override the default value. You can set a specific exception destination for this destination, or you can specify that undeliverable messages are not rerouted to an exception destination by entering an empty string (""), in which case the maximum failed deliveries count has no effect.

**Note:** An undeliverable message can block the processing of other messages waiting for delivery to the same destination.

You can use this option and specify no exception destination to preserve message ordering.

**-sendAllowed** **TRUE** | **FALSE**

Clear this option (setting it to **FALSE**) to stop producers from being able to send messages to this destination.

- For a queue point of a non-mediated destination, or a mediation point of a mediated destination, if you clear this option then new messages (from attached producers or forwarded from another destination) are redirected to any available message point. If no message points are available, then messages that have already been accepted onto the bus, and new messages from attached producers, are preserved by the bus until a message point becomes available. The only exception to this is the case of a destination with only one message point (queue point or mediation point depending on whether the destination is mediated or non-mediated), where the producer is attached to the same messaging engine. In this case, an exception message is generated on each send call. The exception message indicates that the only extant localization has been disabled for send. The producer remains open as usual, and any more send calls succeed if the **Send allowed** property of the localization is reselected (reset to **TRUE**).
- For a queue point of a mediated destination, if you clear this option then messages from mediation instances are redirected to any available message point. If no message points are available, then the messages are preserved by the bus until a message point becomes available. For any mediation instance (that is, on any server that has a mediation point), if the same server hosts a queue point, and that queue point is the only queue point for the destination, then the mediation changes to the “stopped on error” state.

**-receiveAllowed** **TRUE** | **FALSE**

Clear this option (setting it to **false**) to prevent consumers from being able to receive messages from this destination. For the message point, if you clear this option then any open consumers change state and an exception is generated if the consumer requests a message. Messages can continue to be sent, and accumulate on the message point.

**-receiveExclusive** **TRUE** | **FALSE**

Select this option (setting it to **true**) to allow only one consumer to attach to a destination. If you select this option, only a single consumer can be attached to each queue point of a queue destination at any one time. Subsequent consumers attempting to attach to a queue point with a consumer already attached are rejected.

**-maintainStrictMessageOrder** **TRUE** | **FALSE**

Select this option (setting it to **TRUE**) to maintain the order in which a producer sends messages to the destination.

At run time, this property has priority over other configuration property values. For information about the configuration properties that are overridden at run time, see Strict message ordering for bus destinations.

**-topicAccessCheckRequired**

Include this option if authorization checks are required for access to topics.

**-replyDestination**

The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination. This property is intended for use with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 2131.

**-replyDestinationBus**

The name of the bus on which the reply destination is configured. This property is intended for use with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 2131.

**-delegateAuthorizationCheckToTarget**

Indicates whether the authorization check is performed on the alias or the target destination. Include this option if you want the authorization check to be performed on the target destination.

**-auditAllowed TRUE | FALSE**

Clear this option (setting it to FALSE) to prevent the bus from auditing topic level authorization checks when the bus and application server have auditing enabled. The default value is TRUE. You must have Audit Administrator privileges to use this parameter. The parameter is ignored if it is used in the creation of other types of destination.

**-defaultForwardRoutingPath**

The value to which a message forward routing path is set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of bus destinations specified as *bus\_name:destination\_name*.

**-queuePoints**

A list of the queue points used by users of the alias destination. If no queue points are supplied, all queue points can be used. The target destination must be a queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple queue points.

A queue point is specified in the following form: *destination\_name@messaging\_engine\_name*

**-useAllQueuePoints TRUE | FALSE**

If you set this option to TRUE all available queue points are used whereas, if you set this option to FALSE, only those queue points in the list specified by the **-queuePoints** option are used.

**-mediationPoints**

A list of the mediation points used by users of the alias destination. If no mediation points are supplied, all mediation points can be used. The target destination must be a mediated queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple mediation points.

A mediation point is specified in the following form: *destination\_name@messaging\_engine\_name*

**-useAllMediationPoints TRUE | FALSE**

If you set this option to TRUE all available queue points are used whereas, if you set this option to FALSE, only those queue points in the list specified by the **-mediationPoints** option are used.

## Example

- Using Jython:

```
wsadmin>AdminTask.showSIBDestination(["-bus", "abus", "-name", "myqueue"])
'{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
exceptionDestination=_SYSTEM.Exception.Destination.node01.aserver-abus,
uuid=97CC75AC71E5932CAB3417AC, overrideOfQOSByProducerAllowed=true,
sendAllowed=true, maxFailedDeliveries=5,
maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
receiveAllowed=true, identifier=myqueue}'
```

```
wsadmin>AdminTask.modifySIBDestination(["-bus", "abus", "-name", "myqueue",
"-receiveAllowed", "FALSE"])
```

```
wsadmin>AdminTask.showSIBDestination(["-bus", "abus", "-name", "myqueue"])
'{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
exceptionDestination=_SYSTEM.Exception.Destination.node01.aserver-abus,
uuid=97CC75AC71E5932CAB3417AC, overrideOfQOSByProducerAllowed=true,
sendAllowed=true, maxFailedDeliveries=5,
maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
receiveAllowed=false, identifier=myqueue}'
```

- Using Jacl:

```
wsadmin>$AdminTask showSIBDestination {-bus abus -name myqueue}
{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
exceptionDestination=_SYSTEM.Exception.Destination.node01.aserver-abus,
uuid=97CC75AC71E5932CAB3417AC, overrideOfQOSByProducerAllowed=true,
sendAllowed=true, maxFailedDeliveries=5,
maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
receiveAllowed=true, identifier=myqueue}
```

```
wsadmin>$AdminTask modifySIBDestination {-bus abus -name myqueue
-receiveAllowed FALSE}
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098215169998)
```

```
wsadmin>$AdminTask showSIBDestination {-bus abus -name myqueue}
{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
exceptionDestination=_SYSTEM.Exception.Destination.node01.aserver-abus,
uuid=97CC75AC71E5932CAB3417AC, overrideOfQOSByProducerAllowed=true,
sendAllowed=true, maxFailedDeliveries=5,
maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
receiveAllowed=false, identifier=myqueue}
```

## Example: Modify a destination alias "MyAlias2" to use a subset of the available queue points and mediation points:

- Using Jython:

```
cluster=AdminConfig.list("ServerCluster").splitlines()[0]
Qp1=AdminConfig.list("SIBQueueLocalizationPoint", cluster).splitlines()[0]
Mp1=AdminConfig.list("SIBMediationLocalizationPoint").splitlines()[0]
AdminTask.modifySIBDestination(["-bus", "bus1", "-name", "MyAlias2",
"-queuePoints", [[Qp1]], "-mediationPoints", [[Mp1]])
```

- Using Jacl:

```
set cluster [lindex [$AdminConfig list ServerCluster] 1]
set Qp1 [lindex [$AdminConfig list SIBQueueLocalizationPoint $cluster] 0]
set Mp1 [lindex [$AdminConfig list SIBMediationLocalizationPoint] 0]
$AdminTask modifySIBDestination {-bus bus1 -name MyAlias2
-queuePoints [[$Qp1]] -mediationPoints [[$Mp1]]}
```

## Example: Modify a destination alias to remove any limitation on the queue points used:

- Using Jython:

```
AdminTask.modifySIBDestination(["-bus", "bus1", "-name", "MyAlias2",
"-queuePoints", [[]]])
```

- Using Jacl:

```
$AdminTask modifySIBDestination {-bus bus1 -name MyAlias2
-useAllQueuePoints=true -useAllMediationPoints=true}
```

---

## showSIBDestination command

Use the showSIBDestination command to list the property values for a bus destination.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

### Purpose

This command lists details about properties of a bus destination.

### Target object

A bus destination.

### Required parameters

**-bus** *busname*

The name of the service integration bus on which the bus destination is configured. You can use the listSIBuses command to list the names of existing buses.

**-name** *destname*

The identifier by which this destination is known for administrative purposes.

### Conditional parameters

None.

### Optional parameters

None.

### Example

- Using Jython:

```
wsadmin>AdminTask.showSIBDestination("-bus abus -name myqueue")
'{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
exceptionDestination=_SYSTEM.Exception.Destination.node01.server1-abus,
uuid=97CC75AC71E5932CAB3417AC, overrideOfQOSByProducerAllowed=true,
sendAllowed=true, maxFailedDeliveries=5,
maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
receiveAllowed=true, identifier=myqueue}'
```

- Using Jacl:

```
wsadmin>$AdminTask showSIBDestination {-bus abus -name myqueue}
{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
exceptionDestination=_SYSTEM.Exception.Destination.node01.server1-abus,
```

```
uuid=97CC75AC71E5932CAB3417AC, overrideOfQOSByProducerAllowed=true,
sendAllowed=true, maxFailedDeliveries=5,
maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
receiveAllowed=true, identifier=myqueue}
```

---

## unmediateSIBDestination command

Use the `unmediateSIBDestination` command to remove a mediation from a service integration bus destination.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

This command removes a mediation from a bus destination for a service integration bus. The mediation is left on the bus, in case it is needed to mediate other bus destinations.

If you unmediate a destination that is assigned to a WebSphere MQ server bus member, or a destination that has a mediation point on a WebSphere MQ server bus member, the mediation process stops, and messages already queued on the mediation point are not mediated.

### Target object

None.

### Required parameters

**-bus** *busname*

The name of the service integration bus on which the bus destination is to be created. You can use the `listSIBuses` command to list the names of existing buses.

**-destinationName** *destname*

The identifier by which this destination is known for administrative purposes.

### Conditional parameters

None.

### Optional parameters

None.

### Example

- Using Jython:

```
wsadmin>AdminTask.listSIBMediations(["-bus", "abus"])
'(cells/9994GKCCell01/buses/abus|sib-mediations.xml#
SIBDestinationMediation_1098217858584)'
```

```
wsadmin>AdminTask.unmediateSIBDestination(["-bus", "abus", "-destinationName", "myqueue"])
```

- Using Jacl:

```
wsadmin>$AdminTask listSIBMediations {-bus abus}
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098217858584)
```

```
wsadmin>$AdminTask unmediateSIBDestination {-bus abus -destinationName myqueue}
```

---

## SIBAdminCommands: Mediation administrative commands for the AdminTask object

You can use these administrative commands to manage mediations.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and JACL.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

---

### createSIBMediation command

Use the createSIBMediation command to create a new mediation.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

This command creates a new mediation.

## Target object

None.

## Required parameters

**-bus** *busname*

The name of the service integration bus on which the mediation is to be created. You can use the `listSIBuses` command to list the names of existing buses.

**-mediationName** *mediation\_name*

The name by which this mediation is known for administrative purposes.

**-handlerListName**

The name of the handler list that was defined when the mediation was deployed.

## Conditional parameters

None.

## Optional parameters

**-description** *text*

An optional description for the mediation, for administrative purposes.

**-globalTransaction** **TRUE** | **FALSE**

Whether or not a global transaction is started for each message processed.

**FALSE**

A local transaction is started for each message processed. You only have to select this option for mediations that access other resource managers such as databases, or interact with enterprise beans that require a global transaction.

**TRUE** A global transaction is started for each message processed.

**-allowConcurrentMediation** **TRUE** | **FALSE**

Select this option (setting it to true) to apply the mediation to multiple messages concurrently. Message ordering is not preserved. The default option is false.

**TRUE** Apply the mediation to multiple messages concurrently, and preserve message ordering.

**FALSE**

Apply the mediation to a single message at a time. This setting is required to ensure that message ordering is preserved.

**-selector** *text*

Controls which messages are sent to the mediation. If a message matches the rule defined by the selector text string, then the mediation is applied to the message.

If the message does not match the rule defined by the selector text string, then the message is not mediated. If a message contains both Selector and Discriminator, it must match both rules for the message to be mediated. If either the Selector or the Discriminator rule does not match, the message is not mediated.

**-discriminator** *text*

Discriminator

Compare this property with the selector property. The rule specified by the selector examines the header and properties of the message, whereas the discriminator examines the topic of the message. If a message contains both selector and discriminator, it must match both rules for the message to be mediated. If either the selector or the discriminator rule does not match, the message is not mediated.

## Example

- Using Jython:

```
wsadmin>AdminTask.createSIBMediation("-bus abus -mediationName switchMed
-handlerListName switchHandler")
'(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098219493014)'
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBMediation {-bus abus -mediationName switchMed
-handlerListName switchHandler}
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098219493014)
```

---

## deleteSIBMediation command

Use the deleteSIBMediation command to delete a mediation.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

This command deletes a mediation. If the mediation point relates to a WebSphere MQ queue, the contents of the mediation point are not deleted.

## Target object

None.

## Required parameters

**-bus** *busname*

The name of the service integration bus on which the mediation is to be created. You can use the listSIBuses command to list the names of existing buses.

**-mediationName** *mediation\_name*

The name by which this mediation is known for administrative purposes.

## Conditional parameters

None.

## Optional parameters

None.

## Example

- Using Jython:  

```
wsadmin>AdminTask.deleteSIBMediation(["-bus", "abus", "-mediationName", "switchMed"])
```
- Using Jacl:  

```
wsadmin>$AdminTask deleteSIBMediation {-bus abus -mediationName switchMed}
```

---

## listSIBMediations command

Use the listSIBMediations command to list mediations on a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

## Purpose

This command lists all mediations on a service integration bus.

## Target object

A service integration bus

## Required parameters

**-bus** *busname*

The name of the service integration bus on which the mediations are configured. You can use the listSIBBuses command to list the names of existing buses.

## Conditional parameters

None.

## Optional parameters

None.

## Example

- Using Jython:  

```
wsadmin>AdminTask.listSIBMediations("-bus abus")
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098217858584)
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098220051588)
```
- Using Jacl:  

```
wsadmin>$AdminTask listSIBMediations {-bus abus}
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098217858584)
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098220051588)
```

---

## modifySIBMediation command

Use the `modifySIBMediation` command to change the properties of a mediation.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

This command changes properties of a mediation.

### Target object

A mediation.

### Required parameters

**-bus** *busname*

The name of the service integration bus on which the mediation is to be created. You can use the `listSIBuses` command to list the names of existing buses.

**-mediationName** *mediation\_name*

The name by which this mediation is known for administrative purposes.

### Conditional parameters

None.

### Optional parameters

**-description** *text*

An optional description for the mediation, for administrative purposes.

**-handlerListName**

The name of the handler list that was defined when the mediation was deployed.

**-globalTransaction** **TRUE** | **FALSE**

Whether or not a global transaction is started for each message processed.

**FALSE**

A local transaction is started for each message processed. You only have to select this option for mediations that access other resource managers such as databases, or interact with enterprise beans that require a global transaction.

**TRUE** A global transaction is started for each message processed.

### **-allowConcurrentMediation TRUE | FALSE**

Select this option (setting it to true) to apply the mediation to multiple messages concurrently. Message ordering is not preserved. The default option is false.

**TRUE** Apply the mediation to multiple messages concurrently, and preserve message ordering.

### **FALSE**

Apply the mediation to a single message at a time. This setting is required to ensure that message ordering is preserved.

### **-selector text**

Controls which messages are sent to the mediation. If a message matches the rule defined by the selector text string, then the mediation is applied to the message.

If the message does not match the rule defined by the selector text string, then the message is not mediated. If a message contains both Selector and Discriminator, it must match both rules for the message to be mediated. If either the Selector or the Discriminator rule does not match, the message is not mediated.

### **-discriminator text**

Discriminator

Compare this property with the selector property. The rule specified by the selector examines the header and properties of the message, whereas the discriminator examines the topic of the message. If a message contains both selector and discriminator, it must match both rules for the message to be mediated. If either the selector or the discriminator rule does not match, the message is not mediated.

## **Example**

- Using Jython:

```
wsadmin>AdminTask.showSIBMediation("-bus abus -mediationName switchMed")
{uuid 39588C4821BB046E}
{selector {}}
{contextInfo {}}
{discriminator {}}
{allowConcurrentMediation false}
{globalTransaction false}
{mediationName switchMed}
{handlerListName switchHandler}
{description {}}
```

```
wsadmin>AdminTask.modifySIBMediation(["-bus", "abus",
"-mediationName", "switchMed",
"-selector", ["JMSXDeliveryCount > 1000"]])
```

```
wsadmin>AdminTask.showSIBMediation("-bus abus
-mediationName switchMed")
{uuid 39588C4821BB046E}
{selector {JMSXDeliveryCount > 1000}}
{contextInfo {}}
{discriminator {}}
{allowConcurrentMediation false}
{globalTransaction false}
{mediationName switchMed}
{handlerListName switchHandler}
{description {}}
```

- Using Jacl:

```
wsadmin>$AdminTask showSIBMediation {-bus abus -mediationName switchMed}
{uuid 39588C4821BB046E}
{selector {}}
{contextInfo {}}
{discriminator {}}
{allowConcurrentMediation false}
```

```

{globalTransaction false}
{mediationName switchMed}
{handlerListName switchHandler}
{description {}}

wsadmin>$AdminTask modifySIBMediation {-bus abus -mediationName switchMed
-selector {JMSXDeliveryCount > 1000}}

wsadmin>$AdminTask showSIBMediation {-bus abus -mediationName switchMed}
{uuid 39588C4821BB046E}
{selector {JMSXDeliveryCount > 1000}}
{contextInfo {}}
{discriminator {}}
{allowConcurrentMediation false}
{globalTransaction false}
{mediationName switchMed}
{handlerListName switchHandler}
{description {}}

```

---

## showSIBMediation command

Use the showSIBMediation command to list the property values for a mediation.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

### Purpose

This command changes properties of a mediation.

### Target object

A mediation.

### Required parameters

**-bus** *busname*

The name of the service integration bus on which the mediation is to be created. You can use the listSIBuses command to list the names of existing buses.

**-mediationName** *mediation\_name*

The name by which this mediation is known for administrative purposes.

### Conditional parameters

None.

### Optional parameters

None.

### Example

- Using Jython:

```
wsadmin>AdminTask.showSIBMediation("-bus abus -mediationName switchMed")
{uuid 39588C4821BB046E}
{selector {JMSXDeliveryCount > 1000}}
{contextInfo {}}
{discriminator {}}
{allowConcurrentMediation false}
{globalTransaction false}
{mediationName switchMed}
{handlerListName switchHandler}
{description {}}
```

- Using Jacl:

```
wsadmin>AdminTask showSIBMediation {-bus abus -mediationName switchMed}
{uuid 39588C4821BB046E}
{selector {JMSXDeliveryCount > 1000}}
{contextInfo {}}
{discriminator {}}
{allowConcurrentMediation false}
{globalTransaction false}
{mediationName switchMed}
{handlerListName switchHandler}
{description {}}
```

---

## SIBAdminCommands: WebSphere MQ server administrative commands for the AdminTask object

Use command scripts to create, modify, list, show and delete WebSphere MQ servers and server bus members. These commands do not support the automatic resource discovery feature provided by the administrative console.

Decide which method to use to configure these resources. You can configure WebSphere MQ server resources by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Using a WebSphere MQ server to integrate WebSphere MQ queues into a bus” on page 655.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

**Note:** To add a WebSphere MQ server as a bus member, use the addSIBusMember command.

---

## createSIBWMQServer command

Use the createSIBWMQServer command to create a new WebSphere MQ server at cell scope.

You can create a new WebSphere MQ server by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Creating a WebSphere MQ server definition” on page 656.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command creates a new WebSphere MQ server at cell scope, and uses the supplied values to populate its parameters.

**Note:** When creating a WebSphere MQ server, it is important to understand the significance of the **-name** and **-serverName** parameters. For example, if WebSphere Application Server administration created a WebSphere MQ server object with the name “My European area server” that represented a WebSphere MQ queue manager with the **serverName** QM1. WebSphere Application Server administration could then create a second WebSphere MQ server object with the name “My UK country server”, that also represented the same WebSphere MQ queue manager with the **serverName** QM1.

## Target object

A WebSphere Application Server cell.

## Required parameters

### **-name**

The name of the WebSphere MQ server. This value is for administrative purposes only and can be decided by the administrator. The name is only meaningful inside WebSphere Application Server administration, and must be unique at cell level. There is no default value. This parameter cannot be modified.

### **-serverName**

The name of the queue manager or queue-sharing group. This value is the name by which the queue manager or queue-sharing group is identified, and is allocated by WebSphere MQ administration to that WebSphere MQ object. The WebSphere Application Server administrator must always use the name allocated by WebSphere MQ administration.

### **-host**

The host to which a connection is established for communicating with a queue manager or queue-sharing group. This value is the host name or the IP address of the queue manager or queue-sharing group, that this WebSphere MQ server represents. The value is a string and must be one of the following:

- symbolic host name
- IPv4 address
- IPv6 address

**-transportChain**

The channel framework outbound transport chain to use when establishing a connection with WebSphere MQ. If you do not specify this option, a default value of OutboundBasicWMQClient is assumed.

**Conditional parameters**

None

**Optional parameters**

The optional host, port, channel, and authentication alias attributes together specify the connection access path to this WebSphere MQ server, for messaging applications running in service integration. For more information, see WebSphere MQ server: Connection and authentication.

**-port**

The TCP/IP port number on which the queue manager or queue-sharing group that this WebSphere MQ server represents listens. The default value is 1414.

**-channel**

The WebSphere MQ client channel name to use when connecting to the queue manager or queue-sharing group that this WebSphere MQ server represents. This value is the name allocated by WebSphere MQ administration to the WebSphere MQ object, and must always be used by WebSphere Application Server administration. The default value is SYSTEM.DEF.SVRCONN.

**-description**

A short description of the WebSphere MQ server. This value is used for administrative purposes only.

**-securityAuthAlias**

The authentication alias to use when connecting to a queue manager or queue-sharing group. This parameter should not be confused with the discovery authentication alias.

**-trustUserIds**

Determines whether user IDs received in messages from WebSphere MQ are passed on with the messages by the service integration bus. The application user ID is always set from the **jsAppUserId** RFH2 value. If this is not present (either because the key/value pair is not present in the RFH2 header, or because the message does not have a RFH2 header), this field is not set. If you set this value to **FALSE**, the user ID is overwritten with the WebSphere MQ server name. This parameter has two possible values:

**TRUE** User IDs are propagated into messages.

**FALSE**

User IDs are not propagated into messages.

The default is **TRUE**.

**-allowDiscovery**

Determines whether automated discovery of WebSphere MQ resources is performed. This parameter has two possible values:

**TRUE** Automated discovery is used.

**FALSE**

Automated discovery is not used.

The default is **TRUE**.

### **-discoveryAuthAlias**

The authentication alias to use when establishing a resource discovery connection to the queue manager or queue-sharing group. This value should not be confused with the security authentication alias.

### **-replyToQueue**

The reply-to queue to use for resource discovery. This value is the name allocated by WebSphere MQ administration to the WebSphere MQ object, and must be the name of a model queue for a temporary dynamic queue. The WebSphere Application Server administrator must always use the name allocated by WebSphere MQ administration. The default is SYSTEM.DEFAULT.MODEL.QUEUE.

### **-type**

Determines whether the WebSphere MQ server object is either a queue manager or a queue-sharing group, as determined by WebSphere Application Server administration. This parameter had two possible values:

#### **MQ\_QUEUE\_MANAGER**

The WebSphere MQ server represents a queue manager. If you select this value, the resource discovery process retrieves queue names that belong to queue managers.

#### **MQ\_QUEUE\_SHARING\_GROUP**

The WebSphere MQ server represents a queue-sharing group. If you select this value, the resource discovery process retrieves queue names that belong to queue-sharing groups.

### **-bindingsMode**

Determines whether bindings transport mode connections are used when connecting to a queue manager or queue-sharing group. Bindings mode connection is available if the application server and the queue manager are on the same node. It is only possible to connect to a single queue manager in bindings mode, even if multiple queue managers exist on the same node. This parameter has two possible values:

**TRUE** Bindings mode is used if available. If you select this option and bindings mode is not available, the connections mechanism defaults to client transport mode.

**FALSE**  
Client mode is always used.

## **Example**

- Using Jython:

```
wsadmin>AdminTask.createSIBWMQServer(["-name", "Finance dept QM",
"-serverName", "FDQM", "-type", "MQ_QUEUE_MANAGER", "-bindingsMode", "true",
"-host", "findep01.ibm.com", "-port", 1414,
"-transportChain", "OutboundSecureWMQClient"]])
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBWMQServer {-name "Finance dept QM"
-serverName FDQM -type MQ_QUEUE_MANAGER -bindingsMode true
-host findep01.ibm.com -port 1414
-transportChain OutboundSecureWMQClient}
```

---

## **modifySIBWMQServer command**

Use the modifySIBWMQServer command to modify a WebSphere MQ server.

You can modify a WebSphere MQ server by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Modifying a WebSphere MQ server definition” on page 657.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command modifies a WebSphere MQ server. It is not possible to modify the name or type attributes by using this command.

**Note:** When modifying a WebSphere MQ server, it is important to understand the significance of the **name** and **serverName** attributes. For example, if a WebSphere Application Server administrator creates a WebSphere MQ server called “My European Area Server” that represents a WebSphere MQ queue manager with the **serverName** QM1, it would then be possible for the administrator to create a second WebSphere MQ server called “My UK Country Server”, which also represents the same queue manager.

## Target object

A selected WebSphere MQ server.

## Required parameters

### -name

The name of the WebSphere MQ server. The name is specified when creating the WebSphere MQ server definition.

## Conditional parameters

None

## Optional parameters

### -serverName

Name of the queue manager or queue-sharing group. This is the name by which the queue manager or queue-sharing group is identified. The value is allocated by WebSphere MQ administration to that WebSphere MQ resource. The administrator always uses the name that is allocated by WebSphere MQ administration.

### -host

New value for the **host** attribute. This value is the name or the IP address of the host to which a connection is established when communicating with a queue manager or queue-sharing group that this WebSphere MQ server represents. The value is a string and must be one of the following:

- Symbolic host name
- IPv4 address
- IPv6 address

### -bindingsMode

New value for the **bindingsMode** attribute. This value determines whether bindings transport mode

connections are used when connecting to a queue manager or queue-sharing group. Bindings mode connection is possible if the application server and the queue manager are on the same node, but connection is only allowed to a single queue manager, even if multiple queue managers exist on the same node. This parameter has two possible values:

**TRUE** Bindings mode is used if available. If you select this option and bindings mode is not available, the connections mechanism defaults to client transport mode.

**FALSE**  
Client mode is always used.

The default is TRUE.

**-port**

New value for the WebSphere MQ **port** attribute. This value is the TCP/IP port number on which the queue manager or queue-sharing group that this WebSphere MQ server represents listens. The default value is 1414.

**-channel**

New value for the WebSphere MQ **channel** attribute. This value is the WebSphere MQ client channel name to use when connecting to the queue manager or queue sharing group that this WebSphere MQ server represents. This name is allocated by WebSphere MQ administration to the WebSphere MQ object, and must always be used by the WebSphere Application Server administrator. The default value is SYSTEM.DEF.SVRCONN.

**-description**

New value for the **description** attribute. This value is a short description of the WebSphere MQ server, and is used for administrative purposes only.

**-securityAuthAlias**

New value for the **securityAuthorizationAlias** attribute. This value is the authentication alias to use when connecting to a queue manager or queue-sharing group. This parameter is not the same as the discovery authentication alias.

**-transportChain**

New value for the **transportChain** attribute. This value is the outbound transport chain to use when establishing a connection with WebSphere MQ. The default value is OutboundBasicWMQClient.

**-trustUserIds**

New value for the **trustUserIds** attribute. Determines whether user IDs received in messages from WebSphere MQ are propagated into the message or not (that is, whether user IDs received as part of message data are used in the service integration bus). The application user ID is always set from the **jsAppUserId** RFH2 value. If this is not present (either because the key/value pair is not present in the RFH2 header, or because the message does not have a RFH2 header), this field is not set. If you set this value to FALSE, the user ID is overwritten with the WebSphere MQ server name. This parameter has two possible values:

**TRUE** User IDs are propagated into messages.

**FALSE**  
User IDs are not propagated into messages.

The default is TRUE.

**-allowDiscovery**

New value for the **allowDiscovery** attribute. This value determines whether automated discovery of WebSphere MQ resources is performed. This parameter has two possible values:

**TRUE** Automatic resource discovery is enabled.

**FALSE**  
Automatic resource discovery is disabled.

The default is TRUE.

#### **-discoveryAuthAlias**

New value for the **discoveryAuthAlias** attribute. This value is the authentication alias to use when establishing a resource discovery connection to a queue manager or queue-sharing group, and is not the same as the security authentication alias parameter.

#### **-replyToQueue**

New value for the **replyToQueue** attribute. This value is the reply-to queue to use for resource discovery, is the name allocated by WebSphere MQ administration to the WebSphere MQ object, and must be the name of a model queue for a temporary dynamic queue. WebSphere Application Server administration must always use the name that is agreed with WebSphere MQ administration. The default is SYSTEM.DEFAULT.MODEL.QUEUE.

### **Example**

- Using Jython:

```
wsadmin>AdminTask.modifySIBWMServer(["-name", "Finance dept QM",
"-allowDiscovery", "false"])
```

- Using Jacl:

```
wsadmin>${AdminTask} modifySIBWMServer {-name "Finance dept QM"
-allowDiscovery false}
```

---

## **listSIBWMServers command**

Use the listSIBWMServers command to list the WebSphere MQ servers known to a cell.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

### **Purpose**

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command lists the WebSphere MQ servers known to the cell.

### **Target object**

The current cell.

### **Required parameters**

None

### **Conditional parameters**

None

### **Optional parameters**

None

## Example

- Using Jython:  

```
wsadmin>AdminTask.listSIBWMQServers()
```
- Using Jacl:  

```
wsadmin>$AdminTask listSIBWMQServers
```

---

## showSIBWMQServer command

Use the showSIBWMQServer command to show details of a WebSphere MQ server.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

## Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command shows the details of a WebSphere MQ server.

## Target object

A selected WebSphere MQ server.

## Required parameters

### -name

The name of the WebSphere MQ server. This value is the name that you specified in the **-name** parameter when creating the WebSphere MQ server.

## Conditional parameters

None

## Optional parameters

None

## Example

- Using Jython:  

```
AdminTask.showSIBWMQServer(["-name", "Finance dept QM"])
```
- Using Jacl:  

```
$AdminTask showSIBWMQServer {-name "Finance dept QM"}
```

---

## deleteSIBWMQServer command

Use the deleteSIBWMQServer command to delete a specified WebSphere MQ server and remove the associated WebSphere MQ server bus members, assigned queue points and mediation points.

You can delete a WebSphere MQ server by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Deleting a WebSphere MQ server definition” on page 658.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command deletes a specified WebSphere MQ server and removes any associated WebSphere MQ server bus members, assigned queue points and mediation points. This operation does not remove the corresponding WebSphere MQ queue manager or queue-sharing group, and it does not remove messages from any queues that are assigned to corresponding WebSphere MQ server bus members. The bus members for a given WebSphere MQ server are those created when the server is added to a bus.

## Target object

A selected WebSphere MQ server.

## Required parameters

### -name

The name of the WebSphere MQ server to delete. This value is specified for the **-name** parameter (not the **-serverName** parameter), when the WebSphere MQ server is created, and is the name of the WebSphere Application Server administrative object, not the name of the WebSphere MQ object. If you issue the delete command, it is the WebSphere Application Server administrative object that is deleted, not the WebSphere MQ resource.

## Conditional parameters

None

## Optional parameters

None

## Example

- Using Jython:

```
AdminTask.deleteSIBWMServer(["-name", "Finance dept QM"])
```

- Using Jacl:

```
$AdminTask deleteSIBWMServer {-name "Finance dept QM"}
```

---

## modifySIBWMQServerBusMember command

Use the `modifySIBWMQServerBusMember` command to modify the attributes of a WebSphere MQ server bus member.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

A WebSphere MQ server bus member is used for assigning queue points and mediation points to WebSphere MQ queues. This command modifies the attributes of a WebSphere MQ server bus member.

### Target object

A selected WebSphere MQ server bus member.

### Required parameters

#### **-name**

The administrative name of the WebSphere MQ server bus member. This value is the name specified in the **-name** parameter when creating the WebSphere MQ server definition.

#### **-bus**

The name of the service integration bus of which the WebSphere MQ server is a member.

### Conditional parameters

None

### Optional parameters

#### **-virtualQueueManagerName**

When sending messages to WebSphere MQ, the WebSphere MQ gateway queue manager sees the bus as a remote queue manager. The virtual queue manager name is the name that is passed to WebSphere MQ as the name of this remote queue manager.

The default value is the name of the Service Integration bus. If this bus name is not a valid name for a WebSphere MQ queue manager, or if another WebSphere MQ queue manager already has the same name, replace the default value with a unique, valid name for a WebSphere MQ queue manager.

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

#### **-host**

The new value for the overridden **host** attribute. This value is the name or the IP address of the host

to which a connection is established for communicating with a queue manager or queue-sharing group that this WebSphere MQ server represents. The value is a string and must be one of the following:

- Symbolic host name
- IPv4 address
- IPv6 address

**-port**

The new value for the overridden **port** attribute. This value is the TCP/IP port number on which the queue manager or queue-sharing group that this WebSphere MQ server represents listens. The default value is 1414.

**-channel**

The new value for the overridden channel attribute. This value is the WebSphere MQ client channel name to use when connecting to the queue manager or queue-sharing group that this WebSphere MQ server represents. The default value is SYSTEM.DEF.SVRCONN.

**-securityAuthAlias**

The new value for the overridden **securityAuthAlias** attribute. This value is the authentication alias to use when connecting to a queue manager or queue-sharing group. This parameter is not the same as the discovery authentication alias.

**-transportChain**

The new value for the overridden **transportChain** attribute. This value is the outbound transport chain to use when establishing a connection with WebSphere MQ. The default value is OutboundBasicWMQClient.

**-trustUserIds TRUE | FALSE**

The new value for the overridden **trustUserIds** attribute. This value determines whether user identifiers that are received in messages from WebSphere MQ are propagated into the message (that is, whether user identifiers that are received as part of message data are used in the service integration bus). The application user identifier is always set from the **jsAppUserId** RFH2 value. If this is not present (either because the key/value pair is not present in the RFH2 header, or because the message does not have a RFH2 header), this field is not set. If you set this value to FALSE, the user identifier is overwritten with the WebSphere MQ server name. This parameter has two possible values:

**TRUE** User identifiers are propagated into messages.

**FALSE** User identifiers are not propagated into messages.

The default is TRUE.

## Example

- Using Jython:

```
wsadmin>AdminTask.modifySIBWMQServerBusMember(["-name", "Finance dept QM-Bus1",
"-bus", "Bus1", "-trustUserIds", "false"])
```

- Using Jacl:

```
wsadmin>AdminTask modifySIBWMQServerBusMember {-name "Finance dept QM-Bus1"
-bus Bus1 -trustUserIds false}
```

---

## listSIBWMQServerBusMembers command

Use the listSIBWMQServerBusMembers command to list the WebSphere MQ server bus members known to the bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

## Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command lists the WebSphere MQ server bus members known to the bus.

## Target object

The current cell.

## Required parameters

**-bus**

The name of the service integration bus of which the WebSphere MQ server is a member.

## Conditional parameters

None

## Optional parameters

None

## Example

- Using Jython:  

```
AdminTask.listSIBWMQServerBusMembers(["-bus", "Bus1"])
```
- Using Jacl:  

```
$AdminTask listSIBWMQServerBusMembers {-bus Bus1}
```

---

## showSIBWMQServerBusMember command

Use the showSIBWMQServerBusMember command to show a list of attributes for a WebSphere MQ server bus member.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

## Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command shows details of a WebSphere MQ server bus member as a set of key/value pairs. The command shows details for those attributes that have a value.

## Target object

A selected WebSphere MQ server.

## Required parameters

### -name

The name of the WebSphere MQ server bus member. This value is the name specified in the -name parameter when creating the WebSphere MQ server definition.

### -bus

The name of the bus for which the WebSphere MQ server is a member.

## Conditional parameters

None

## Optional parameters

None

## Example

- Using Jython:

```
wsadmin>AdminTask.showSIBWMQServerBusMember(["-name", "Finance Dept. QM-Bus1",
"-bus", "Bus1"])
```

- Using Jacl:

```
wsadmin>${AdminTask} showSIBWMQServerBusMember {-name "Finance Dept. QM-Bus1"
-bus Bus1}
```

---

## SIBAdminBusSecurityCommands command group for the AdminTask object

You can use these administrative commands to manage service integration bus security.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and JACL.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

---

## populateUniqueNames command

Use the populateUniqueNames command to add missing unique names to the authorization policy for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `populateUniqueNames` command queries the user repository for missing unique names, and adds the missing unique names to the authorization policy for a selected service integration bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

## Conditional parameters

None.

## Optional parameters

**-force** **TRUE** | **FALSE**

Whether to update all unique names, or only those that are missing in the authorization policy. This parameter has two possible values:

**TRUE** All unique names are updated.

**FALSE**

Missing unique names only are updated.

The default is **FALSE**.

## Example

The following example queries the user repository for `Bus1` for unique names, and updates all the unique names in the authorization policy.

```
AdminTask.populateUniqueNames('[-bus Bus1 -force TRUE]')
```

---

## listGroupsInBusConnectorRole command

Use the `listGroupsInBusConnectorRole` command to list all the groups in the connector role for a local bus.

To run the command, use the `AdminTask` object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `listGroupsInBusConnectorRole` command to list the groups in the bus connector role for a local bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

## Conditional parameters

None.

## Optional parameters

**-showUniqueNames** **TRUE** | **FALSE**

Whether to display unique names. This parameter has two possible values:

**TRUE** Unique names are displayed.

**FALSE**

Security names are displayed.

The default is **FALSE**.

## Example

The following example lists all the groups in the bus connector role for a bus called `Bus1`.

```
AdminTask.listGroupsInBusConnectorRole ('[-bus Bus1]')
```

---

## addGroupToBusConnectorRole command

Use the `addGroupToBusConnectorRole` command to add a group to the connector role for a local bus.

To run the command, use the `AdminTask` object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `addGroupToBusConnectorRole` command to add a group to the bus connector role for a local bus. This command grants the group permission to connect to local destinations.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-group** *groupName*

The name of a group you want to add to the bus connector role for the local bus. You can type a specific group name, or use one of the following specialized group names:

### Server

This group contains application servers.

### AllAuthenticated

This group contains authenticated users only.

### Everyone

This group contains all users. Each user is anonymous.

## Conditional parameters

None.

## Optional parameters

**-uniqueName** *uniqueName*

Specify the name that uniquely defines the group in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the group. You can specify values for both **-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

## Examples

The following example adds a group with the group name `Group1`, and the unique name `Group1` to the bus connector role for a bus called `Bus1`.

```
AdminTask.addGroupToBusConnectorRole ('[-bus Bus1 -group Group1 -uniqueName SalesGroup]')
```

The following example adds the Server group to the bus connector role for a bus called Bus1.

```
AdminTask.addGroupToBusConnectorRole ('[-bus Bus1 -group Server]')
```

The following example adds the AllAuthenticated group to the bus connector role for a bus called Bus1.

```
AdminTask.addGroupToBusConnectorRole ('[-bus Bus1 -group AllAuthenticated]')
```

The following example adds the Everyone group to the bus connector role for a bus called Bus1.

```
AdminTask.addGroupToBusConnectorRole ('[-bus Bus1 -group Everyone]')
```

---

## removeGroupFromBusConnectorRole command

Use the `removeGroupFromBusConnectorRole` command to remove a group from the connector role for a local bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

Use the `removeGroupFromBusConnectorRole` command to remove a group from the bus connector role for a local bus. Removing a group from this role prevents the group from accessing local destinations, or sending messages to destinations on foreign buses.

### Target object

None.

### Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-group** *groupName* | *uniqueName*

The name of a group you want to remove from the bus connector role for the local bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

#### **Server**

This group contains application servers.

**AllAuthenticated**

This group contains authenticated users only.

**Everyone**

This group contains all users. Each user is anonymous.

- A unique group name.

**Conditional parameters**

None.

**Optional parameters**

None.

**Examples**

The following example removes a group called Group1 from the bus connector role for a bus called Bus1.

```
AdminTask.removeGroupFromBusConnectorRole ('[-bus Bus1 -group Group1]')
```

The following example removes the Server group from the bus connector role for a bus called Bus1.

```
AdminTask.removeGroupFromBusConnectorRole ('[-bus Bus1 -group Server]')
```

---

**listUsersInBusConnectorRole command**

Use the listUsersInBusConnectorRole command to list users in the connector role for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

**Purpose**

Use the listUsersInBusConnectorRole command to list all the users in the bus connector role for a selected local bus.

**Target object**

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

## Conditional parameters

None.

## Optional parameters

**-showUniqueNames** TRUE | FALSE

Whether to display unique names. This parameter has two possible values:

**TRUE** Unique names are displayed.

**FALSE**  
Security names are displayed.

The default is FALSE.

## Example

The following example lists users in the bus connector role for a bus called Bus1.

```
AdminTask.listUsersInBusConnectorRole ('[-bus Bus1]')
```

---

## addUserToBusConnectorRole command

Use the addUserToBusConnectorRole command to add a user to the connector role for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the addUserToBusConnectorRole command to add a user to the bus connector role for a local bus. This command grants the user permission to connect to local destinations.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

**-user** *userName*

The name of a user you want to add to the bus connector role for the local bus.

## Conditional parameters

None.

## Optional parameters

**-uniqueName** *uniqueName*

Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the user. You can specify values for both

**-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

## Examples

The following example adds a user called User1 to the bus connector role for a bus called Bus1.

```
AdminTask.adduserToBusConnectorRole ('[-bus Bus1 -user User1]')
```

---

## removeUserFromBusConnectorRole command

Use the removeUserFromBusConnectorRole command to remove a user from the connector role for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the removeUserFromBusConnectorRole command to remove a user from the bus connector role for a local bus. Removing a user from this role prevents the user from accessing local destinations, or sending messages to destinations on foreign buses.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

**-user** *userName* or *uniqueName*

The name of a user you want to remove from the bus connector role for the local bus. You can type one of the following names:

- A security user name.
- A unique user name.

## Conditional parameters

None.

## Optional parameters

None.

## Examples

The following example removes a user called User1 from the bus connector role for a bus called Bus1.

```
AdminTask.removeUserFromBusConnectorRole ('[-bus Bus1 -user User1]')
```

The following example removes the Server user from the bus connector role for a bus called Bus1.

```
AdminTask.removeUserFromBusConnectorRole ('[-bus Bus1 -user Server]')
```

---

## listGroupsInDefaultRole command

Use the listGroupsInDefaultRole command to list the groups in the default roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the listGroupsInDefaultRole command to list the groups in the default roles for a selected local bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-role** *roleType*

The role type for which you want to list groups.

### Sender

This role type is authorized to send messages to destinations on the local bus.

### Receiver

This role type is authorized to receive messages from destinations on the local bus.

### Browser

This role type is authorized to browse messages on destinations on the local bus.

### Creator

This role type is authorized to create messages on destinations on the local bus.

## Conditional parameters

None.

## Optional parameters

**-showUniqueNames** `TRUE` | `FALSE`

Whether to display unique names. This parameter has two possible values:

**TRUE** Unique names are displayed.

**FALSE** Security names are displayed.

The default is `FALSE`.

## Examples

The following example lists the groups in the Sender role for a bus called Bus1.

```
AdminTask.listGroupsInDefaultRole ('[-bus Bus1 -role Sender]')
```

---

## addGroupToDefaultRole command

Use the `addGroupToDefaultRole` command to add a group to the default roles for a local bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:  

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```
- For overview help on a given command, enter the following command at the `wsadmin` prompt:  

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

AdminConfig.save()

## Purpose

Use the `addGroupToDefaultRole` command to grant a group default access to all local bus destinations for the specified roles. Adding a group to the default role does not grant access to local destinations where the inheritance of default access is disallowed. To grant access to a local destination where inheritance is disallowed, you must add the group to a destination role. For more information, see “`addGroupToDestinationRole` command” on page 2550.

You can use this command to define the access control policy for a messaging resource that does not yet exist. This approach ensures that the messaging resource is secure from the moment it is created.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-role** *roleType*

The role type to which you want to assign the group. You can assign a group to the following role types:

### Sender

This role type is authorized to send messages to destinations on the local bus.

### Receiver

This role type is authorized to receive messages from destinations on the local bus.

### Browser

This role type is authorized to browse messages on destinations on the local bus.

### Creator

This role type is authorized to create messages on destinations on the local bus.

**-group** *groupName*

The name of a group you want to add to default roles for the local bus. You can type a specific group name, or use one of the following specialized group names:

### Server

This group contains application servers.

### AllAuthenticated

This group contains authenticated users only.

### Everyone

This group contains all users. Each user is anonymous.

## Conditional parameters

None.

## Optional parameters

**-uniqueName** *uniqueName*

Specify the name that uniquely defines the group in the user registry. If an LDAP user registry is in

use, the unique name is the distinguished name (DN) for the group. You can specify values for both **-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

## Examples

The following example adds a group with the group name Group1, and the unique name SalesGroup, to the sender role type for a bus called Bus1.

```
AdminTask.addGroupToDefaultRole ('[-bus Bus1 -role Sender -group Group1 uniqueName SalesGroup]')
```

The following example adds the AllAuthenticated group to the browser role for a bus called Bus1.

```
AdminTask.addGroupToDefaultRole ('[-bus Bus1 -role Browser -group AllAuthenticated]')
```

---

## removeGroupFromDefaultRole command

Use the `removeGroupFromDefaultRole` command to remove a group from the default roles for a local bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `removeGroupFromDefaultRole` command to remove a group from the default roles for a local bus. Removing a group from the default roles prevents access to the local bus in the default roles.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-role** *roleType*

The role type from which you want to remove the group.

**Sender**

This role type is authorized to send messages to destinations on the local bus.

**Receiver**

This role type is authorized to receive messages from destinations on the local bus.

## Browser

This role type is authorized to browse messages on destinations on the local bus.

## Creator

This role type is authorized to create messages on destinations on the local bus.

**-group** *groupName* or *uniqueName*

The name of a group you want to remove from the default roles for the local bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

### Server

This group contains application servers.

### AllAuthenticated

This group contains authenticated users only.

### Everyone

This group contains all users. Each user is anonymous.

- A unique group name.

## Conditional parameters

None.

## Optional parameters

None.

## Examples

The following example removes a group called Group1 from the default Sender role type for a bus called Bus1.

```
AdminTask.removeGroupFromDefaultRole ('[-bus Bus1 -role Sender -group Group1]')
```

The following example removes the AllAuthenticated group from the default browser role for a bus called Bus1.

```
AdminTask.removeGroupFromDefaultRole ('[-bus Bus1 -role Browser -group AllAuthenticated]')
```

---

## listUsersInDefaultRole command

Use the listUsersInDefaultRole command to list users in the default roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

AdminConfig.save()

## Purpose

Use the listUsersInDefaultRole command to list all the users in the default roles for a selected local bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

**-role** *roleType*

The role type for which you want to list users. You can specify the following role types:

### Sender

This role type is authorized to send messages to destinations on the local bus.

### Receiver

This role type is authorized to receive messages from destinations on the local bus.

### Browser

This role type is authorized to browse messages on destinations on the local bus.

### Creator

This role type is authorized to create messages on destinations on the local bus.

## Conditional parameters

None.

## Optional parameters

**-showUniqueNames** TRUE | FALSE

Whether to display unique names. This parameter has two possible values:

**TRUE** Unique names are displayed.

**FALSE** Security names are displayed.

The default value is FALSE.

## Example

The following example lists users in the Sender role type for a bus called Bus1.

```
AdminTask.listUsersInDefaultRole ('[-bus Bus1 -role Sender]')
```

---

## addUserToDefaultRole command

Use the addUserToDefaultRole command to add a user to the default roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `addUserToDefaultRole` command to grant a user default access to all local bus destinations for the specified roles. Adding a user to the default role does not grant access to local destinations where the inheritance of default access is disallowed. To grant access to a local destination where inheritance is disallowed, you must add the user to a destination role. For more information, see “`addUserToDestinationRole` command” on page 2555.

You can use this command to define the access control policy for a messaging resource that does not yet exist. This approach ensures that the messaging resource is secure from the moment it is created.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-role** *roleType*

The role type to which you want to assign the user. You can assign a user to the following role types:

### Sender

This role type is authorized to send messages to destinations on the local bus.

### Receiver

This role type is authorized to receive messages from destinations on the local bus.

### Browser

This role type is authorized to browse messages on destinations on the local bus.

### Creator

This role type is authorized to create messages on destinations on the local bus.

**-user** *userName*

The name of a user you want to add to the bus connector role for the local bus.

## Conditional parameters

None.

## Optional parameters

**-uniqueName** *uniqueName*

Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use,

the unique name is the distinguished name (DN) for the user. You can specify values for both **-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

## Examples

The following example adds a user called User1 to the sender role type for a bus called Bus1.

```
AdminTask.addUserToDefaultRole ('[-bus Bus1 -role Sender -user User1]')
```

---

## removeUserFromDefaultRole command

Use the `removeGroupFromDefaultRole` command from `remove` to remove a user from the default roles for a local bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:  

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```
- For overview help on a given command, enter the following command at the `wsadmin` prompt:  

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `removeUserFromDefaultRole` command to remove user from default roles for a local bus. Removing a user from the default roles prevents access to the local bus in the default roles.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-role** *roleType*

The role type you want to remove the user from. You can remove a user from the following role types:

### Sender

This role type is authorized to send messages to destinations on the local bus.

### Receiver

This role type is authorized to receive messages from destinations on the local bus.

### Browser

This role type is authorized to browse messages on destinations on the local bus.

### Creator

This role type is authorized to create messages on destinations on the local bus.

**-user** *userName* or *uniqueName*

The name of a user you want to remove from the default roles for the local bus. You can type one of the following names:

- A security user name.
- A unique user name.

### Conditional parameters

None.

### Optional parameters

None.

### Examples

The following example removes a user called User1 from the Sender role type for a bus called Bus1.

```
AdminTask.removeUserFromDefaultRole ('[-bus Bus1 -role Sender -User User1]')
```

---

## listGroupsInTopicRole command

Use the listGroupsInTopicRole command to list the groups in topic roles for a topic space on a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

Use the listGroupsInTopicRole command to list the groups in topic roles for a selected topic in the topic hierarchy for a selected local bus.

You can use this command to define the access control policy for a topic that does not yet exist.

### Target object

None.

## Required parameters

- bus** *busName*  
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.
- topicSpace** *topicSpaceName*  
The name of the topic space.
- topic** *topicName*  
The name of the topic.
- role** *roleType*  
You can specify the Sender or Receiver roles for a topic.

## Conditional parameters

None.

## Optional parameters

- showUniqueNames** **TRUE** | **FALSE**  
Whether to display unique names. This parameter has two possible values:
    - TRUE** Unique names are displayed.
    - FALSE** Security names are displayed.
- The default value is FALSE.

## Examples

The following example lists the groups in the Sender role for a topic called `football`, in the topic space called `Sport`, on a local bus called `Bus1`.

```
listGroupsInTopicRole { -bus Bus1 -topicSpace Sport -topic football -role Sender }
```

---

## addGroupToTopicRole command

Use the `addGroupToTopicRole` command to add a group to a topic role within a specified topic space.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```
- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `addGroupToTopicRole` command to add a group to the sender or receiver roles for a topic anywhere in the topic hierarchy for a local bus. The roles that you specify for the topic are additional to any roles that the topic inherits from its parent in the topic hierarchy.

You can use this command to define the access control policy for a topic that does not yet exist. By defining the access control policy first, you ensure that the topic is secure from the moment it is created.

## Target object

None.

## Required parameters

- bus** *busName*  
The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.
- topicSpace** *topicSpaceName*  
The name of the topic space.
- topic** *topicName*  
The name of the topic.
- role** *roleName*  
You can specify the Sender or Receiver roles for a topic.
- group** *groupName*  
The name of the group that you want to add to the sender or receiver roles for a topic. You can specify a group name, or one of the following specialized group names:
  - Server**  
This group contains application servers.
  - AllAuthenticated**  
This group contains authenticated users only.
  - Everyone**  
This group contains all users. Each user is anonymous.

## Conditional parameters

None.

## Optional parameters

- uniqueName** *uniqueName*  
Specify the name that uniquely defines the group in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the group. You can specify values for both **-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

## Examples

The following example adds a group with the group name `Group1`, and the unique name `SalesGroup`, to the Sender role for a topic called `football`, in the topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.addGroupToTopicRole ('[-bus Bus1 -topicSpace Sport
-topic football -role Sender -group Group1 -uniqueName SalesGroup]')
```

---

## removeGroupFromTopicRole command

Use the `removeGroupFromTopicRole` command to remove a group from a topic role within a specified topic space.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

Use the `removeGroupFromTopicRole` command to remove a group from the sender or receiver roles for a topic anywhere in the topic hierarchy for a local bus. Removing a group from topic roles prevents the group from accessing the topic space in the topic roles.

### Target object

None.

### Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-topicSpace** *topicSpaceName*

The name of the topic space.

**-topic** *topicName*

The name of the topic.

**-role** *roleName*

You can specify the Sender or Receiver roles for a topic.

**-group** *groupName* or *uniqueName*

The name of a group you want to remove from the topic roles for the local bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

**Server**

This group contains application servers.

**AllAuthenticated**

This group contains authenticated users only.

**Everyone**

This group contains all users. Each user is anonymous.

- A unique group name.

## Conditional parameters

None.

## Optional parameters

None.

## Examples

The following example removes a group called Group1, from the Sender role for a topic called football, in the topic space called Sport, on a local bus called Bus1.

```
removeGroupFromTopicRole { -bus Bus1 -topicSpace Sport -topic football -role Sender -group Group1}
```

---

## listUsersInTopicRole command

Use the listUsersInTopicRole command to list users in the topic roles within a specified topic space.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the listUsersInTopicRole command to list users in the topic roles for a selected topic in the topic hierarchy for a selected local bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

**-topicSpace** *topicSpaceName*

The name of the topic space.

**-topic** *topicName*

The name of the topic.

**-role** *roleType*

You can specify the Sender or Receiver roles for a topic.

## Conditional parameters

None.

## Optional parameters

**-showUniqueNames** TRUE | FALSE

Whether to display unique names. This parameter has two possible values:

**TRUE** Unique names are displayed.

**FALSE**  
Security names are displayed.

The default is FALSE.

## Example

The following example lists the users in the Sender role for a topic called `football`, in the topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.listUsersInTopicRole ('[-bus Bus1 -topicSpace Sport -topic football -role Sender]')
```

---

## addUserToTopicRole command

Use the `addUserToTopicRole` command to add a user to a topic role within a specified topic space.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `addUserToTopicRole` command to add a user to the sender or receiver roles for a topic anywhere in the topic hierarchy for a local bus. The roles that you specify for the topic are additional to any roles that the topic inherits from its parent in the topic hierarchy.

You can use this command to define the access control policy for a topic that does not yet exist. By defining the access control policy first, you ensure that the topic is secure from the moment it is created.

## Target object

None.

## Required parameters

- bus** *busName*  
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.
- topicSpace** *topicSpaceName*  
The name of the topic space.
- topic** *topicName*  
The name of the topic.
- role** *roleName*  
You can specify the Sender or Receiver roles for a topic.
- user** *userName*  
The name of the user that you want to add to the Sender or Receiver roles for a topic.

## Conditional parameters

None.

## Optional parameters

- uniqueName** *uniqueName*  
Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the user. You can specify values for both **-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

## Examples

The following example adds a user called User1, to the Sender role for a topic called football, in the topic space called Sport, on a local bus called Bus1.

```
AdminTask.addUserToTopicRole ('[-bus Bus1 -topicSpace Sport -topic football -role Sender -user User1]')
```

---

## removeUserFromTopicRole command

Use the removeUserFromTopicRole command to remove a user from a topic role within a specified topic space.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

AdminConfig.save()

## Purpose

Use the `removeUserFromTopicRole` command to remove a user from the sender or receiver roles for a topic anywhere in the topic hierarchy for a local bus. Removing a user from topic roles prevents the user from accessing the topic space in the topic roles.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-topicSpace** *topicSpaceName*

The name of the topic space.

**-topic** *topicName*

The name of the topic.

**-role** *roleType*

You can specify the Sender or Receiver roles for a topic.

**-user** *userName* or *uniqueName*

The name of a user you want to remove from the topic roles for the local bus. You can type one of the following names:

- A security user name.
- A unique user name.

## Conditional parameters

None.

## Optional parameters

None.

## Examples

The following example removes a user called `User1`, from the Sender role for a topic called `football`, in the topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.removeUserFromTopicRole ('[-bus Bus1 -topicSpace Sport
-topic football -role Sender -user User1]')
```

---

## listGroupsInTopicSpaceRootRole command

Use the `listGroupInTopicSpaceRootRole` command to list all the groups in topic space roles on the topic space root for a local bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  
`print AdminTask.help('SIBAdminBusSecurityCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:  
`print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `listGroupsInTopicRootSpaceRole` command to list groups in topic space root roles for a selected topic space on a selected local bus.

## Target object

None.

## Required parameters

- bus** *busName*  
The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.
- topicSpace** *topicSpaceName*  
The name of the topic space.
- role** *roleType*  
You can specify the Sender or Receiver roles for a topic.

## Conditional parameters

None.

## Optional parameters

- showUniqueNames** **TRUE** | **FALSE**  
Whether to display unique names. This parameter has two possible values:
  - TRUE** Unique names are displayed.
  - FALSE** Security names are displayed.

The default is **FALSE**.

## Examples

The following example lists groups in the Sender role for the topic space root, for a topic space called Sport, on a local bus called Bus1.

```
AdminTask.listGroupsInTopicSpaceRootRole ('[-bus Bus1 -topicSpace Sport -role Sender]')
```

---

## addGroupToTopicSpaceRootRole command

Use the `addGroupToTopicSpaceRootRole` command to add a group to topic space roles on the topic space root.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

Use the `addGroupToTopicRootSpaceRole` command to grant a group permission to access the topic space root in the sender and receiver roles. This is in addition to any access permissions granted to the topics in the topic space.

You can use this command to define the access control policy for a topic that does not yet exist. By defining the access control policy first, you ensure that the topic is secure from the moment it is created.

### Target object

None.

### Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-topicSpace** *topicSpaceName*

The name of the topic space.

**-role** *roleName*

You can specify the Sender or Receiver roles for a topic.

**-group** *groupName*

The name of the group that you want to add to the Sender or Receiver roles for the topic space root. You can specify a group name, or one of the following specialized group names:

#### Server

This group contains application servers.

#### AllAuthenticated

This group contains authenticated users only.

#### Everyone

This group contains all users. Each user is anonymous.

## Conditional parameters

None.

## Optional parameters

**-uniqueName** *uniqueName*

Specify the name that uniquely defines the group in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the group. You can specify values for both **-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

## Examples

The following example adds a group called Group1, and the unique name SalesGroup to the Sender role for the topic space root, for a topic space called Sport, on a local bus called Bus1.

```
AdminTask.addGroupToTopicSpaceRootRole ('[-bus Bus1 -topicSpace Sport
-role Sender -group Group1 uniqueName SalesGroup]')
```

---

## removeGroupFromTopicSpaceRootRole command

Use the `removeGroupFromTopicSpaceRootRole` command to remove a group from access roles on the topic space root.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `removeGroupFromTopicSpaceRootRole` command to remove a group from the Sender and Receiver roles for the topic space root.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-topicSpace** *topicSpaceName*  
The name of the topic space.

**-role** *roleName*  
You can specify the Sender or Receiver roles for a topic.

**-group** *groupName* or *uniqueName*  
The name of a group you want to remove from the topic space root roles for the local bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

**Server**

This group contains application servers.

**AllAuthenticated**

This group contains authenticated users only.

**Everyone**

This group contains all users. Each user is anonymous.

- A unique group name.

## Conditional parameters

None.

## Optional parameters

None.

## Examples

The following example removes a group called Group1 from the Sender role for the topic space root, for a topic space called Sport, on a local bus called Bus1.

```
AdminTask.removeGroupFromTopicSpaceRootRole ('[-bus Bus1 -topicSpace Sport -role Sender -group Group1]')
```

---

## listUsersInTopicSpaceRootRole command

Use the listUsersInTopicSpaceRootRole command to list the users in the sender and receiver roles on the topic space root.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `listUsersInTopicSpaceRootRole` command to list users in the topic space root roles for a selected local bus.

## Target object

None.

## Required parameters

- bus** *busName*  
The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.
- topicSpace** *topicSpaceName*  
The name of the topic space.
- role** *roleType*  
You can specify the Sender or Receiver roles for the topic space root.

## Conditional parameters

None.

## Optional parameters

- showUniqueNames** **TRUE** | **FALSE**  
Whether to display unique names. This parameter has two possible values:
  - TRUE** Unique names are displayed.
  - FALSE** Security names are displayed.The default value is **FALSE**.

## Example

The following example lists users in the Sender role for the topic space root, for a topic space called Sport, on a local bus called Bus1.

```
Admin.TasklistUsersInTopicSpaceRootRole { -bus Bus1 -topicSpace Sport -role Sender}
```

---

## addUserToTopicSpaceRootRole command

Use the `addUserToTopicSpaceRootRole` command to add a user to the sender and receiver roles on the topic space root.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```
- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `addUserToTopicSpaceRootRole` command to grant a user permission to access the topic space root in the sender and receiver roles. This is in addition to any access permissions granted to the topics in the topic space.

You can use this command to define the access control policy for a topic that does not yet exist. By defining the access control policy first, you ensure that the topic is secure from the moment it is created.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-topicSpace** *topicSpaceName*

The name of the topic space.

**-role** *roleName*

You can specify the Sender or Receiver roles for the topic space root.

**-user** *userName*

The name of the user that you want to add to the Sender or Receiver roles for the topic space root.

## Conditional parameters

None.

## Optional parameters

**-uniqueName** *uniqueName*

Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the user. You can specify values for both

**-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

## Examples

The following example adds a user called `User1`, to the Sender role for the topic space root, for a topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.addUserToTopicSpaceRootRole ('[-bus Bus1 -topicSpace Sport -role Sender -user User1]')
```

---

## removeUserFromTopicSpaceRootRole command

Use the `removeUserFromTopicSpaceRootRole` command to remove a user from access roles on the topic space root.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `removeUserFromTopicSpaceRootRole` command to remove a user from the Sender and Receiver roles for the topic space root.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-topicSpace** *topicSpaceName*

The name of the topic space.

**-role** *roleType*

You can specify the Sender or Receiver roles for a topic.

**-user** *userName* or *uniqueName*

The name of a user you want to remove from the topic space root roles for the local bus.

## Conditional parameters

None.

## Optional parameters

None.

## Examples

The following example removes a user called `User1` from the Sender role for the topic space root, for a topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.removeUserFromTopicSpaceRootRole ('[-bus Bus1 -topicSpace Sport -role Sender -user User1]')
```

---

## listGroupsInDestinationRole command

Use the listGroupsInDestinationRole command to list the groups in the destination roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

Use the listGroupsInDestinationRole command to list all the groups in destination roles for a selected local bus. The roles you can specify depend on the type of destination.

### Target object

None.

### Required parameters

**-type** *destinationType*

You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination
- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 2133.

If you are specifying a *destinationType* that is either foreignDestination or alias, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of queue or topic, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

**-role** *roleType*

You can specify one of the following role types, depending on the **-type** you have specified.

#### Sender

This role type is authorized to send messages to destinations on the local bus.

#### Receiver

This role type is authorized to receive messages from destinations on the local bus.

## Browser

This role type is authorized to browse messages on destinations on the local bus.

## Conditional parameters

None.

## Optional parameters

**-showUniqueNames** TRUE | FALSE

Whether to display unique names. This parameter has two possible values:

**TRUE** Unique names are displayed.

**FALSE**  
Security names are displayed.

The default value is FALSE.

## Examples

The following example lists groups in the Sender role for a queue type destination called Queue1, on a local bus called Bus1.

```
AdminTask.listGroupsInDestinationRole ('[-type queue -bus Bus1 -destination Queue1 -role Sender]')
```

The following example lists groups in the Receiver role for a queue type destination called Queue2, on a local bus called Bus1.

```
AdminTask.listGroupsInDestinationRole ('[-type queue -bus BusName -destination Queue2 -role Receiver]')
```

---

## addGroupToDestinationRole command

Use the addGroupToDestinationRole command to add a group to the destination roles for a local or foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the addGroupToDestinationRole command to grant a group access to local bus destinations for the specified roles. The roles you can specify depend on the type of destination.

## Target object

None.

## Required parameters

### **-type** *destinationType*

You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination
- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 2133.

If you are specifying a *destinationType* that is either `foreignDestination` or `alias`, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of `queue` or `topic`, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

### **-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

### **-role** *roleType*

You can specify one of the following role types, depending on the **-type** you have specified.

#### **Sender**

This role type applies to `alias`, `foreignDestination`, `port`, `queue`, and `topicSpace` destination types.

#### **Receiver**

This role type applies to `alias`, `port`, `queue`, and `topicSpace` destination types.

#### **Browser**

This role type applies to `alias`, `port`, and `queue` destination types.

### **-group** *groupName*

The name of the group that you want to add to the destination role type for the local bus. You can specify a group name, or one of the following specialized group names:

#### **Server**

This group contains application servers.

#### **AllAuthenticated**

This group contains authenticated users only.

#### **Everyone**

This group contains all users. Each user is anonymous.

## Conditional parameters

None.

## Optional parameters

### **-foreignBus** *foreignBusName*

Specify the name of the foreign bus. If you are adding a group to a destination on a foreign destination or an alias, you must specify the name of the foreign bus that hosts the foreign destination or the alias.

### **-uniqueName** *uniqueName*

This parameter is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions. Specify the name that uniquely defines the

group in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the group. You can specify values for both **-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

## Examples

The following example adds a group with the group name Group1, and the unique name SalesGroup to the sender role on a queue type destination called Queue1, on a local bus called Bus1.

```
AdminTask.addGroupToDestinationRole ('[-type queue -bus Bus1
-destination Queue1 -role Sender -group Group1 -uniqueName SalesGroup]')
```

The following example adds a group called Group2 to the receiver role on a queue type destination called Queue2, on a local bus called Bus1.

```
AdminTask.addGroupToDestinationRole ('[-type queue -bus Bus1
-destination Queue2 -role Receiver -group Group2]')
```

---

## removeGroupFromDestinationRole command

Use the `removeGroupFromDestinationRole` command to remove a group from the destination roles for a local or foreign bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `removeGroupFromDestinationRole` command to remove a group from destination roles for a selected local bus. By removing a group from destination roles, you prevent the group from accessing the local bus.

## Target object

None.

## Required parameters

**-type** *destinationType*

You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination
- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 2133.

If you are specifying a *destinationType* that is either *foreignDestination* or *alias*, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of *queue* or *topic*, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-role** *roleType*

You can specify one of the following role types, depending on the *destinationType* you have specified.

#### **Sender**

This role type is authorized to send messages to destinations on the local bus.

#### **Receiver**

This role type is authorized to receive messages from destinations on the local bus.

#### **Browser**

This role type is authorized to browse messages on destinations on the local bus.

**-group** *groupName* or *uniqueName*

The name of a group you want to remove from the destination roles for the local bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

#### **Server**

This group contains application servers.

#### **AllAuthenticated**

This group contains authenticated users only.

#### **Everyone**

This group contains all users. Each user is anonymous.

- A unique group name.

## **Conditional parameters**

None.

## **Optional parameters**

**-foreignBus** *foreignBusName*

Specify the name of the foreign bus. If you are removing a group from a destination role on a foreign destination or an alias, you must specify the name of the foreign bus that hosts the foreign destination or the alias.

## **Examples**

The following example removes a group called `Group1` from the `Sender` role for a `queue` type destination called `Queue1`, on a local bus called `Bus1`.

```
removeGroupFromDestinationRole { -type queue -bus Bus1
 -destination Queue1 -role Sender -group Group1}
```

The following example removes a group called `Group2` from the `Receiver` role for a `queue` type destination called `Queue2`, on a local bus called `Bus1`.

```
removeGroupFromDestinationRole { -type queue -bus Bus1
 -destination Queue2 -role Receiver -group Group2}
```

---

## listUsersInDestinationRole command

Use the listUsersInDestinationRole command to list users in the destination roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

Use the listUsersInDestinationRole command list the users in destination roles for a selected local bus. The roles you can specify depend on the type of destination.

### Target object

None.

### Required parameters

**-type** *destinationType*

You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination
- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 2133.

If you are specifying a *destinationType* that is either foreignDestination or alias, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of queue or topic, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

**-role** *roleType*

You can specify one of the following role types, depending on the **-type** you have specified.

#### Sender

This role type applies to alias, foreignDestination, port, queue, and topicSpace destination types.

#### Receiver

This role type applies to alias, port, queue, and topicSpace destination types.

## Browser

This role type applies to alias, port, and queue destination types.

## Conditional parameters

None.

## Optional parameters

### **-foreignBus** *foreignBusName*

Specify the name of the foreign bus if you have specified a ForeignDestination or Alias destination type.

### **-showUniqueNames** TRUE | FALSE

Whether to display unique names. This parameter has two possible values:

**TRUE** Unique names are displayed.

**FALSE**

Security names are displayed.

The default is FALSE.

## Example

The following example lists users in the Sender role on a queue type destination called Queue1, on a local bus called Bus1.

```
AdminTask.listUsersInDestinationRole ('[-type queue -bus Bus1 -destination Queue1 -role Sender]')
```

---

## addUserToDestinationRole command

Use the addUserToDestinationRole command to add a user to the destination roles for a local or foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the addUserToDestinationRole command grant a user access to local bus destinations for the specified roles. The roles you can specify depend on the type of destination.

## Target object

None.

## Required parameters

### **-type** *destinationType*

You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination
- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 2133.

If you are specifying a *destinationType* that is either `foreignDestination` or `alias`, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of `queue` or `topic`, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

### **-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

### **-role** *roleType*

You can specify one of the following role types, depending on the **-type** you have specified.

#### **Sender**

This role type is authorized to send messages to destinations on the local bus.

#### **Receiver**

This role type is authorized to receive messages from destinations on the local bus.

#### **Browser**

This role type is authorized to browse messages on destinations on the local bus.

### **-user** *userName*

The name of the user that you want to add to the destination role type for the local bus.

## Conditional parameters

None.

## Optional parameters

### **-foreignBus** *foreignBusName*

Specify the name of the foreign bus. If you are adding a user to a destination on a foreign destination or an alias, you must specify the name of the foreign bus that hosts the foreign destination or the alias.

### **-uniqueName** *uniqueName*

This parameter is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions. Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the user. You can specify values for both **-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

## Examples

The following example adds a user called `User1` to the sender role on a queue type destination called `Queue1`, on a local bus called `Bus1`.

```
Admintask.addUserToDestinationRole ('[-type queue -bus Bus1
-destination Queue1 -role Sender -user User1]')
```

The following example adds a user called User2 to the receiver role on a queue type destination called Queue2, on a local bus called Bus1.

```
AdminTask.addUserToDestinationRole ('[-type queue -bus Bus1
-destination Queue2 -role Receiver -user User2]')
```

---

## removeUserFromDestinationRole command

Use the `removeUserFromDestinationRole` command to remove a user from the destination roles for a local or foreign bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

Use the `removeUserFromDestinationRole` command to remove a user from destination roles for a selected local bus. By removing a user from destination roles, you prevent the user from accessing the local bus.

### Target object

None.

### Required parameters

**-type** *destinationType*

You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination
- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 2133.

If you are specifying a *destinationType* that is either `foreignDestination` or `alias`, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of `queue` or `topic`, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-role** *roleType*

You can specify one of the following role types, depending on the **-type** you have specified.

**Sender**

This role type is authorized to send messages to destinations on the local bus.

**Receiver**

This role type is authorized to receive messages from destinations on the local bus.

**Browser**

This role type is authorized to browse messages on destinations on the local bus.

**-user** *userName* or *uniqueName*

The name of a user you want to remove from the destination roles for the local bus. You can type one of the following names:

- A security user name.
- A unique user name.

**Conditional parameters**

None.

**Optional parameters**

**-foreignBus** *foreignBusName*

Specify the name of the foreign bus. If you are removing a user from a destination role on a foreign destination or an alias, you must specify the name of the foreign bus that hosts the foreign destination or the alias.

**Examples**

The following example removes a user called User1 from the Sender role for a queue type destination called Queue1, on a local bus called Bus1.

```
AdminTask.removeUserFromDestinationRole ('[-type queue -bus Bus1
-destination Queue1 -role Sender -user User1]')
```

The following example removes a user called User2 from the Receiver role for a queue type destination called Queue2, on a local bus called Bus1.

```
AdminTask.removeUserFromDestinationRole ('[-type queue -bus Bus1
-destination Queue2 -role Receiver -user User2]')
```

---

**listGroupsInForeignBusRole command**

Use the `listGroupsInForeignBusRole` command to list the groups in the sender role for a foreign bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

AdminConfig.save()

## Purpose

Use the listGroupsInForeignBusRole command to list the groups that can send messages from a local bus to a foreign bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

**-foreignBus** *foreignBusName*

The name of the foreign bus.

**-role** **Sender**

You can only specify the Sender role for a foreign bus.

## Conditional parameters

None.

## Optional parameters

**-showUniqueNames** **TRUE** | **FALSE**

Whether to display unique names. This parameter has two possible values:

**TRUE** Unique names are displayed.

**FALSE**

Security names are displayed.

The default value is FALSE.

## Examples

The following example lists the groups in the Sender role for a foreign bus called ForeignBus1. The local bus is called Bus1.

```
AdminTask.listGroupsInForeignBusRole ('[-bus Bus1 -foreignBus ForeignBus1 -role Sender]')
```

---

## addGroupToForeignBusRole command

Use the addGroupToForeignBusRole command to grant a group permission to access a foreign bus from a local bus, in the sender role.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `addGroupToForeignBusRole` command to grant a group permission to send messages from a local bus to a foreign bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-foreignBus** *foreignBusName*

The name of the foreign bus.

**-role** *Sender*

You can only specify the Sender role for a foreign bus.

**-group** *groupName*

The name of the group that you want to add to the sender role for the foreign bus. You can specify a group name, or one of the following specialized group names:

### Server

This group contains application servers.

### All Authenticated

This group contains authenticated users only.

### Everyone

This group contains all users. Each user is anonymous.

## Conditional parameters

None.

## Optional parameters

**-uniqueName** *uniqueName*

Specify the name that uniquely defines the group in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the group. You can specify values for both

**-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

## Examples

The following example adds a group with the group name `Group1`, and the unique name `SalesGroup` to the sender role for a foreign bus called `ForeignBus1`. The local bus is called `Bus1`.

```
AdminTask.addGroupToForeignBusRole ('[-bus Bus1 -ForeignBus ForeignBus1
-role Sender -group Group1 -uniqueName SalesGroup]')
```

---

## removeGroupFromForeignBusRole command

Use the `removeGroupFromForeignBusRole` command to remove a group from the sender role for a foreign bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

### Purpose

Use the `removeGroupFromForeignBusRole` command to remove a group from the sender role for a foreign bus. This prevents the group from sending messages from a local bus to a foreign bus.

### Target object

None.

### Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-foreignBus** *foreignBusName*

The name of the foreign bus.

**-role** `Sender`

You can only specify the `Sender` role for a foreign bus.

**-group** *groupName* or *uniqueName*

The name of a group you want to remove from the sender role for a foreign bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

**Server**

This group contains application servers.

**AllAuthenticated**

This group contains authenticated users only.

**Everyone**

This group contains all users. Each user is anonymous.

- A unique group name.

## Conditional parameters

None.

## Optional parameters

None.

## Examples

The following example removes a group called Group1 from the Sender role for a foreign bus called ForeignBus1. The local bus is called Bus1.

```
AdminTask.removeGroupFromForeignBusRole (['-bus Bus1 -ForeignBus ForeignBus1 -role Sender -group Group1'])
```

---

## listUsersInForeignBusRole command

Use the listUsersInForeignBusRole command to list users that can send messages from a local bus to a foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```
- For overview help on a given command, enter the following command at the wsadmin prompt:  

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the listUsersInForeignBusRole command to list all the users that can send messages from a selected local bus to a selected foreign bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

**-foreignBus** *foreignBusName*

The name of the foreign bus.

**-role** **Sender**

You can specify the Sender role only for a foreign bus.

## Conditional parameters

None.

## Optional parameters

**-showUniqueNames** TRUE | FALSE

Whether to display unique names. This parameter has two possible values:

**TRUE** Unique names are displayed.

**FALSE**  
Security names are displayed.

The default value is FALSE.

## Example

The following example lists users in the Sender role for a foreign bus called ForeignBus1. The local bus is called Bus1.

```
AdminTask.listUsersInForeignBusRole ('[-bus Bus1 -foreignBus ForeignBus1 -role Sender],')
```

---

## addUserToForeignBusRole command

Use the addUserToForeignBusRole command to grant a user permission to access a foreign bus from a local bus, in the sender role.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the addUserToForeignBusRole command grant a user permission to send messages from a local bus to a foreign bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

**-foreignBus** *foreignBusName*  
The name of the foreign bus.

**-role** **Sender**  
You can specify the Sender role only for a foreign bus.

**-user** *userName*  
The name of the user that you want to add to the Sender role for the foreign bus.

## Conditional parameters

None.

## Optional parameters

**-uniqueName** *uniqueName*  
Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the user. You can specify values for both **-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

## Examples

The following example adds a user called User1 to the Sender role for a foreign bus called ForeignBus1. The local bus is called Bus1.

```
AdminTask.addUserToForeignBusRole ('[-bus Bus1 -foreignBus ForeignBus1 -role Sender -user User1]')
```

---

## removeUserFromForeignBusRole command

Use the `removeUserFromForeignBusRole` command to remove a user from the sender role for a foreign bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `removeUserFromForeignBusRole` command to remove a user from the sender role for a foreign bus. This prevents the user from sending messages from a local bus to a foreign bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

**-foreignBus** *foreignBusName*

The name of the foreign bus.

**-role** **Sender**

You can only specify the Sender role for a foreign bus.

**-user** *userName* **or** *uniqueName*

The name of a user you want to remove from the sender role for a foreign bus. You can type one of the following names:

- A security user name
- A unique user name.

## Conditional parameters

None.

## Optional parameters

None.

## Examples

The following example removes a user called User1 from the Sender role for a foreign bus called ForeignBus1. The local bus is called Bus1.

```
AdminTask.removeUserFromForeignBusRole ('[-bus Bus1 -ForeignBus ForeignBus1 -role Sender -user User1]')
```

---

## removeGroupFromAllRoles command

Use the removeGroupFromAllRoles command to remove a group from all access roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `removeGroupFromAllRoles` command to remove a group from all access roles for a local bus. This prevents the group from accessing the local bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-group** *groupName*

The name of the group that you want to remove from all roles for the bus. You can specify a group name, or one of the following specialized group names:

### Server

This group contains application servers.

### AllAuthenticated

This group contains authenticated users only.

### Everyone

This group contains all users. Each user is anonymous.

## Conditional parameters

None.

## Optional parameters

None.

## Examples

The following example removes a group called `Group1` from all roles for a local bus called `Bus1`.

```
removeGroupFromAllRoles { -bus Bus1 -group Group1 }
```

---

## removeUserFromAllRoles command

Use the `removeUserFromAllRoles` command to remove a user from all access roles for a local bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

Use the `removeUserFromAllRoles` command to remove a user from all access roles for a local bus. This prevents the user from accessing the local bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-user** *userName* **or** *uniqueName*

The name of a user you want to remove from the bus connector role for the local bus. You can type one of the following names:

- A security group name.
- A unique group name.

## Conditional parameters

None.

## Optional parameters

None.

## Examples

The following example removes a user called `User1` from all roles for a local bus called `Bus1`.

```
AdminTask.removeUserFromAllRoles ('[-bus Bus1 -user User1]')
```

---

## Determining destination defaults inheritance by using the `wsadmin` tool

By default, the inheritance of default permissions by destinations is allowed for all local destinations. Use this command to determine whether the inheritance of default permissions is enabled or disabled for a local destination.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

## Command

To determine whether a specified destination inherits default destination user roles, use the following command:

- Using Jython:

```
AdminTask.isInheritDefaultsForDestination("-type destinationType -bus busName
-destination destinationName")
```

- Using Jacl:

```
$AdminTask isInheritDefaultsForDestination {-type destinationType -bus busName
-destination destinationName}
```

This command will return either True or False.

---

## Defining destination defaults inheritance by using the wsadmin tool

By default, the inheritance of default permissions by destinations is allowed for all local destinations. Use this command to override inheritance for an individual destination, or to restore default inheritance in cases where you have previously overridden it.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Command

**Note:** When a user or group tries to access a destination for which you have overridden default inheritance, the default permissions are not checked. Only the permissions that you specify for the destination itself are checked.

To override or restore the inheritance of default permissions for a destination, use the following command:

- Using Jython:

```
AdminTask.setInheritDefaultsForDestination("-type destinationType -bus busName
-destination destinationName -inherit <true|false>")
```

- Using Jacl:

```
$AdminTask setInheritDefaultsForDestination {-type destinationType -bus busName
-destination destinationName -inherit <true|false>}
```

The *destinationType* must be a local destination type: *foreignDestination* is not allowed.

Set **-inherit** to false to override defaults inheritance, or to true to restore defaults inheritance.

---

## Defining topic role inheritance by using the wsadmin tool

Use these commands to define the inheritance of topic roles by child topics within a topic hierarchy.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Commands

### Defining Sender role inheritance

To set or disable Sender role inheritance for a topic within the specified topic space, use the following command:

- Using Jython:

```
AdminTask.setInheritSenderForTopic("-bus busName
-topicSpace topicSpaceName
-topic topicName -inherit <true|false>")
```

- Using Jacl:

```
$AdminTask setInheritSenderForTopic {-bus busName
-topicSpace topicSpaceName
-topic topicName -inherit <true|false>}
```

### Defining Receiver role inheritance

To set or disable Receiver role inheritance for a topic within the specified topic space, use the following command:

- Using Jython:

```
AdminTask.setInheritReceiverForTopic("-bus busName
-topicSpace topicSpaceName -topic topicName
-inherit <true|false>")
```

- Using Jacl:

```
$AdminTask setInheritReceiverForTopic {-bus busName
-topicSpace topicSpaceName
-topic topicName -inherit <true|false>}
```

---

## Determining topic role inheritance by using the wsadmin tool

Use these commands to list whether the child topics within a topic hierarchy currently have inheritance set or disabled.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

## Commands

### Determining Inherit Receiver for Topic

To determine whether a role is inheritance Receiver for a topic within the specified topic space, use the following command:

- Using Jython:

```
AdminTask.isInheritReceiverForTopic("-bus busName -type typeName
-destination destinationName")
```

- Using Jacl:

```
$AdminTask isInheritReceiverForTopic {-bus busName -type typeName
-destination destinationName}
```

### Determining Inherit Sender for Topic

To determine whether a role is inheritance Sender for a topic within the specified topic space, use the following command:

- Using Jython:

```
AdminTask.isInheritSenderForTopic("-bus busName -type typeName
-destination destinationName")
```

- Using Jacl:

```
$AdminTask isInheritSenderForTopic {-bus busName -type typeName
-destination destinationName}
```

---

## Listing security roles for service integration by using the wsadmin tool

When you are administering messaging security, use these commands to list the security roles that are associated with service integration bus destinations, foreign buses, topics within a topic space, users and groups.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

## Commands

### Listing all destinations with roles

To list all destinations that have roles defined for them, use the following command:

- Using Jython:

```
AdminTask.listAllDestinationsWithRoles("-bus busname
-type destinationType")
```

- Using Jacl:

```
$AdminTask listAllDestinationsWithRoles {-bus busname
-type destinationType}
```

### Listing all foreign buses with roles

To list all foreign buses that have roles defined for them, use the following command:

- Using Jython:

```
AdminTask.listAllForeignBusesWithRoles("-bus busname")
```

- Using Jacl:

```
$AdminTask listAllForeignBusesWithRoles {-bus busname}
```

### Listing all topics within a topic space with roles

To list all topics within a topic space that have roles defined for them, use the following command:

- Using Jython:

```
AdminTask.listAllTopicsWithRoles("-bus busname
-topicSpace topicSpaceName")
```

- Using Jacl:

```
$AdminTask listAllTopicsWithRoles {-bus busname
-topicSpace topicSpaceName}
```

### Listing user roles

To list all the roles that a user belongs to, use the following command in wsadmin:

- Using Jython:

```
AdminTask.listAllRolesForUser("-bus busname -user userName")
```

- Using Jacl:

```
$AdminTask listAllRolesForUser {-bus busname -user userName}
```

### Listing group roles

To list all the roles that a group belongs to, use the following command in wsadmin:

- Using Jython:

```
AdminTask.listAllRolesForGroup("-bus busname -group groupName")
```

- Using Jacl:

```
$AdminTask listAllRolesForGroup {-bus busname -group groupName}
```

---

## Removing users and groups by using the wsadmin tool

Use these commands to remove a user or group. Removing a user or group withdraws the authorization permissions for all roles to which they have previously been added.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Commands

### Removing a user

To remove a user from all the roles that they belong to, use the following command:

- Using Jython:

```
AdminTask.removeUserFromAllRoles("-bus busname -user userName")
```

- Using Jacl:

```
$AdminTask removeUserFromAllRoles {-bus busname -user userName}
```

### Removing a group

To remove a group from all the roles that it belongs to, use the following command:

- Using Jython:

```
AdminTask.removeGroupFromAllRoles("-bus busname -group groupName")
```

- Using Jacl:

```
$AdminTask removeGroupFromAllRoles {-bus busname -group groupName}
```

After using these commands, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

---

## Removing authorization data by using the wsadmin tool

Use these commands to remove authorization data for the default roles, or for a destination or a foreign bus.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Commands

### Removing authorization data for the defaults

To remove all users and groups from every role (sender, receiver and so on) in the defaults, use the following command:

- Using Jython:

```
AdminTask.removeDefaultRoles("-bus busname")
```

- Using Jacl:

```
$AdminTask removeDefaultRoles {-bus busname}
```

## Removing all authorization data for a destination

To delete all authorization data for a destination, use the following command:

- Using Jython:

```
AdminTask.removeDestinationRoles("-type destinationType -bus busname
-foreignBus foreignBusName -destination destinationName")
```

- Using Jacl:

```
AdminTask.removeDestinationRoles("-type destinationType -bus busname
-foreignBus foreignBusName -destination destinationName")
```

### Notes:

- This command deletes all authorization data for the specified destination. If the destination is a topic space, the command removes all authorization data for the virtual root and for the topics within the topic space, as well as for the topic space itself.
- You can use this command if you are deleting the destination and want to remove all associated authorization permissions, or if you want to block all access to a destination by removing all authorization permissions for it. In this second case a user might still be able to access the destination if they have been granted default authorization permissions. If you have specified default authorization permissions and you want to block all access to the destination, you must stop the destination inheriting the default permissions by using the command `setInheritDefaultsForDestinations` (see “Defining destination defaults inheritance by using the wsadmin tool” on page 2568). You should use the `removeDestinationRoles` command first, followed by the `setInheritDefaultsForDestinations` command.

## Removing all authorization data for a foreign bus

To delete all authorization data for the specified foreign bus, use the following command:

- Using Jython:

```
AdminTask.removeForeignBusRoles("-bus busname
-foreignBus foreignBusName")
```

- Using Jacl:

```
$AdminTask removeForeignBusRoles {-bus busname
-foreignBus foreignBusName}
```

After using these commands, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

---

## listSIBPermittedChain command

Use the `listSIBPermittedChain` command to list the permitted transport chains for a service integration bus.

To run the command, use the `AdminTask` object of the wsadmin scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `listSIBPermittedChain` command lists the permitted transport chains for a selected service integration bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

## Conditional parameters

None.

## Optional parameters

None.

## Example

The following example lists the permitted transport chains for a bus called `Bus1`.

```
AdminTask.listSIBPermittedChain(['-bus Bus1'])
```

---

## addSIBPermittedChain command

Use the `addSIBPermittedChain` command to add a new transport mechanism to the list of permitted transports for a service integration bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `addSIBPermittedChain` command add a new transport chain to the list of permitted transports for a selected service integration bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the `listSIBuses` command to list the names of existing buses.

**-chain** *chainName*

The name of the transport chain you want to add to the list of permitted transports.

## Conditional parameters

None.

## Optional parameters

None.

## Example

The following example adds the transport chain `MyTransportChain` to a bus called `Bus1`.

```
AdminTask.addSIBPermittedChain(['-bus Bus1 -chain MyTransportChain'])
```

---

## removeSIBPermittedChain command

Use the `removeSIBPermittedChain` command to remove a selected transport chain from the list of permitted transport chains for a selected service integration bus.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

## Purpose

The `removeSIBPermittedChain` command removes a selected transport chains from the list of permitted transport chains for a selected service integration bus.

## Target object

None.

## Required parameters

**-bus** *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

**-chain** *chainName*

The name of the transport chain you want to remove from the list of permitted transports.

## Conditional parameters

None.

## Optional parameters

None.

## Example

The following example removes the transport chain called MyTransportChain from the list of permitted transport chains for a bus called Bus1.

```
AdminTask.removeSIBPermittedChain('[-bus Bus1 -chain MyTransportChain]')
```

---

## sibDDLGenerator command

A messaging engine needs data definition language (DDL) statements to create the DBMS (Database Management System) resources. These DBMS resources are generated by the sibDDLGenerator command.

### Syntax

```
▶▶ sibDDLGenerator [--system—DBMS name] [--version—DBMS version]
▶ [--platform—DBMS platform] [--schema—schema name] [--user—user name] [--create] [--drop]
▶ [--database—database] [--storagegroup—storage group] [--catalog—high level qualifier]
▶ [--bufferpool—buffer pool] [--statementend—statement end] [--nolinebreaks]
▶ [--noblanklines] [--firstline—first line] [--lastline—last line] [--permanent—number]
▶ [--temporary—number] ▶▶
```

## Purpose

A messaging engine needs DBMS resources, such as database tables, which it can create when starting. If your installation has a policy that only a database administrator has the authority to create database tables, use the sibDDLGenerator command to enable your database administrator to create the DBMS

resources that the messaging engine needs. The sibDDLGenerator command generates the DDL statements that your database administrator can save, and later process, to create the DBMS resources that are listed in “Data store tables” on page 2109.

The command also generates DDL statements that grant the appropriate authorities to allow a messaging engine use these tables.

**Note:** The sibDDLGenerator command is able to generate the DDL statements for creating or dropping all of the data store tables. It is less well suited for adding more item tables to an existing data store. However, it is possible to reissue the DDL statements to create existing tables without harming the data store.

## Optional parameters

**Tip:** The sibDDLGenerator command is case-sensitive. For example, the parameter value Oracle is not the same as the parameter value oracle.

Some parameters apply to a specific DBMS only, as indicated in the parameter list; for example:

**-database** [Applies only to DB2 for z/OS]

### **-system**

Identifies the type of DBMS on which the administrator will process the DDL statements. Valid values are:

- db2
- oracle
- sqlserver
- sybase
- informix
- derby
- cloudscape

If you do not supply a **-system** parameter, the default value is derby.

### **-version**

The version number of the DBMS identified by the **-system** parameter. The following table shows the default value that is used if you do not supply a **-version** parameter.

If you receive a CWSIS1595E or CWSIS1503E error when you run the tool, consult the notes after the table to determine whether an alternative **-version** parameter value can be used for your database version.

*Table 232. Values for the -version parameter. The first column of the table lists the -system parameter values. The second column of the table lists the -platform parameter values. The third column of the table lists the default values of the -version parameters. The fourth column of the table lists the other accepted values of the -version parameters.*

<b>-system parameter value</b>	<b>-platform parameter value</b>	<b>Default value for the -version parameter</b>	<b>Other accepted -version parameter values</b>
db2	zos	7.1	8.1, 9.1 (see Note 1)
db2	unix, windows	8.1	9.1 (see Note 1)
db2	iseries	5.2 (see Note 2)	5.3 (see Note 2)
oracle		8i	9i, 10g, 11g (see Note 3)
sqlserver		2000	2005
sybase		12.0	12.5, 15.0
informix		9.3	7.3, 9.4, 10.0, 11.0 (see Note 4)

Table 232. Values for the **-version** parameter (continued). The first column of the table lists the **-system** parameter values. The second column of the table lists the **-platform** parameter values. The third column of the table lists the default values of the **-version** parameters. The fourth column of the table lists the other accepted values of the **-version** parameters.

<b>-system parameter value</b>	<b>-platform parameter value</b>	<b>Default value for the -version parameter</b>	<b>Other accepted -version parameter values</b>
derby		10.1	

**Notes:**

1. The DDL generated for DB2 for UNIX or Windows by using **-version** parameter values 8.1, and 9.1 is identical. The DDL generated for DB2 for z/OS by using **-version** parameter values 7.1, 8.1, and 9.1 is identical.
2. For IBM i, the DB2 database is part of the operating system, so the version number given is for the OS/400 version.
3. The DDL generated for Oracle by using **-version** parameter values 9i, 10g, and 11g is identical.
4. The DDL generated for Informix by using **-version** parameter values 9.4, 10.0, and 11.0 is identical.

**-platform**

The operating system platform on which the DBMS runs. Valid values are:

- iseries
- unix
- windows
- zos

**-schema**

The name of the schema that contains all the objects used by the messaging engine. If you do not supply a **-schema** parameter, the default value is IBMWSSIB.

**-user**

The name of the user ID that is used to interact with the DBMS. If you do not supply a **-user** parameter, the default value is IBMUSER.

**-create | -drop**

Indicates whether the DDL statements create the DBMS resources or delete them. If you do not supply either parameter, the default value is **-create**.

**-database [Applies only to DB2 for z/OS]**

The name of the database that is allocated for the messaging engine tables. If you do not supply a **-database** parameter, the default value is SIBDB.

**-storagegroup [Applies only to DB2 for z/OS]**

The name of the storage group that is allocated for the messaging engine tables.

- If you supply both the **-storagegroup** and the **-catalog** parameters, the sibDDLGenerator command includes both values in the CREATE STOGROUP statement.
- If you supply only a **-storagegroup** parameter, the sibDDLGenerator command uses the storage group name in other statements but does not create a CREATE STOGROUP statement.
- If you supply only a **-catalog** parameter, the sibDDLGenerator command displays the usage statement and then terminates.
- If you omit both parameters, the sibDDLGenerator command uses the default value SIBSG for the storage group name in other statements but does not create a CREATE STOGROUP statement.

**-catalog [Applies only to DB2 for z/OS]**

The name of the high level qualifier for the storage group that is allocated for the messaging engine tables. For information about defaults, refer to the **-storagegroup** parameter.

**-bufferpool [Applies only to DB2 for z/OS]**

The name of the buffer pool that is allocated for the messaging engine tables. If you do not supply a **-bufferpool** parameter, the default value is BP1.

**-statementend**

Appends *statement\_end* to each DDL statement. For example, you can use ; to append a semicolon to each DDL statement. By default, the sibDDLGenerator command appends nothing to each statement.

**Tip:** On UNIX platforms, escape the semicolon to prevent the shell from interpreting it.

**-nolinebreaks**

Places each statement on a single line, with no line breaks. By default, the sibDDLGenerator command breaks statements across lines to improve readability.

**-noblanklines**

Omits blank lines between each statement. By default, the sibDDLGenerator command inserts a blank line between each statement to improve readability.

**-firstline**

Generates *first\_line* as the first line of output. For example, you can use *first\_line* to identify the target database. By default, the sibDDLGenerator command does not generate a first line.

**-lastline**

Generates *last\_line* as the last line of output. For example, you can use *last\_line* to invoke a command that executes the commands in the script. By default, the sibDDLGenerator command does not generate a last line.

**Tip:** The optional parameters that control the format of the DDL statements, for example **-statementend**, enable you to generate output that is suitable for particular scripting tools, for example the DB2 CLP. By default, the sibDDLGenerator command generates blank lines between each DDL statement but does not append a semicolon at the end of each DDL statement.

The following two optional parameters are used for spreading the data store across multiple tables:

**-permanent**

The number of permanent tables, with

- Default value: 1
- Minimum value: 1
- Maximum value: see **Note**

**-temporary**

The number of temporary tables, with

- Default value: 1
- Minimum value: 1
- Maximum value: see **Note**

**Note:** The maximum number of SIB*nnn* tables that can be used by a messaging engine is 32. This includes all stream, permanent and temporary tables.

## Examples

- **sibDDLGenerator -system db2 -version 8.1 -platform zos**

Generates DDL statements for DB2 8.1, running on z/OS, with a default schema, user ID, database, storage group, and buffer pool.

- **sibDDLGenerator -system db2 -version 8.1 -platform windows -statementend ;**  
Generates DDL statements for DB2 8.1, running on Windows, with a default schema, user ID, and database. You can input the statements directly to the DB2 CLP, which requires that each statement is terminated with a semicolon.
- **sibDDLGenerator -system oracle -version 8i -schema SIB -user fred**  
Generates DDL statements for Oracle 8i.
- **sibDDLGenerator -system oracle -schema SIB -user fred**  
A concise version of the preceding example.

## Access role assignments for bus security resources

Icons are used in the administrative console to represent users and groups that have access roles for service integration bus resources.

### Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 233. Interacting with access role icons

Access role icon	Access role assignment state	User action
	Role type not set.	Click to change to role type set  .
	Role type set.	Click to change to role type not set. The icon changes to role type not set  if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set  .
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

## Message properties support for mediations

The SMessage metadata properties enable the main data types, and are supported by JMS Message Selectors.

## Syntax

The selector syntax is the same as for JMS Message Selectors. For more information, refer to the JMS specification.

## Supported types

Support is provided for the following data types:

- Boolean
- Byte and byte[]
- Integer
- Long
- Float
- Double
- String

The data types listed above are supported by JMS Message Selectors with the exception of byte[].

## Properties

For more information about each property, refer to “JMS\_IBM properties and equivalent SI\_system properties” on page 2583.

---

## SIMessage metadata properties

The SIMessage metadata properties contain message metadata that you can use in mediation configuration selectors. You can work with these properties by using the SIMessage interface.

You can access and modify the SIMessage metadata properties using individual SIMessage get and set methods. You cannot set or access these properties by using the methods `getMessageProperty()`, `setMessageProperty()`, or `deleteMessageProperty()`.

The method `clearMessageProperty()` does not clear these properties.

Property name	Data type	Comments
SI_NextDestination	String	Name of the first destination in the Forward Routing Path.
SI_Reliability	String	Value of <code>getReliability.toString()</code> .
SI_Priority	Integer	
SI_TimeToLive	Long	
SI_Discriminator	String	
SI_ReplyPriority	Integer	
SI_ReplyReliability	String	Value of <code>getReliability.toString()</code> .
SI_ReplyTimeToLive	Long	
SI_ReplyDiscriminator	String	
SI_RedeliveredCount	Integer	
SI_MessageID	String	
SI_CorrelationID	String	
SI_Userid	String	

Property name	Data type	Comments
SI_Format	String	

## JMS headers

Support is provided by the `SIMessage` interface and the mediation configuration selector for JMS headers properties. JMS headers properties match in the `SIMessage` interface in the same way as they do for the JMS API, but you can only modify properties that map to `SIMessage` metadata.

The method `getMessageProperty()` method supports all of these properties.

The methods `setMessageProperty()` and `deleteMessageProperty()` only support `JMSType`.

The method `clearMessageProperties()` only clears `JMSType`.

Property name	Can be matched?	Can be modified?	Data type	Comments
JMSDestination	No	Indirectly	Byte array	<code>getMessageProperty()</code> returns opaque byte array.
JMSDeliveryMode	Yes	Yes, by using <code>setReliability</code> .	String	String value, as for JMS.
JMSMessageID	Yes	Yes, by using <code>setMessageID</code> .	String	Equivalent to <code>SI_MessageID</code> .
JMSTimestamp	Yes	No	Long	
JMSExpiration	Yes	Indirectly, by using <code>setTimeToLive</code> or <code>setRemainingTimeToLive</code> .	Long	
JMSRedelivered	Yes	No	Boolean	
JMSPriority	Yes	Yes, by using <code>setPriority</code> .	Integer	Equivalent to <code>SI_Priority</code> .
JMSReplyTo	No	Indirectly	Byte array	<code>getMessageProperty()</code> returns opaque byte array.
JMSCorrelationID	Yes	Yes, by using <code>setCorrelationId</code> .	String	Equivalent to <code>SI_CorrelationID</code> .
JMSType	Yes	Yes, by using <code>setMessageProperty()</code> .	String	

## JMSX properties

Support is provided by the `SIMessage` interface and the mediation configuration selector for JMSX properties. You can use the `SIMessage` interface to match and access supported JMSX properties defined in the JMS API. You can only use the `SIMessage` interface to set properties that are not defined as set by the JMS provider.

The methods `getMessageProperty()`, `setMessageProperty()` and `deleteMessageProperty()` provide access and, where supported, modification.

The method `clearMessageProperties()` does not clear properties that cannot be set.

Property name	Can be matched?	Can be modified?	Data type	Comments
JMSXUserID	Yes	Yes	String	
JMSXAppID	Yes	Yes	String	

Property name	Can be matched?	Can be modified?	Data type	Comments
JMSXProducerTXID	No	No		Not supported
JMSXConsumerTXID	No	No		Not supported
JMSXRcvTimestamp	No	No		Not supported
JMSXDeliveryCount	Yes	No	Integer	
JMSXState	No	No		Not supported
JMSXGroupID	Yes	Yes	String	
JMSXGroupSeq	Yes	Yes	Integer	

## JMS\_IBM properties and equivalent SI\_system properties

Support is provided by the `SIMessage` interface and the mediation configuration selector for `JMS_IBM` properties and the equivalent `SI_system` properties. You can access `JMS_IBM_` properties through the JMS API. Many of the values held by `JMS_IBM_` properties apply to an `SIMessage` and have `SI_` synonyms. You can access all these properties through the `SIMessage` interface, and can match and set many of them. You cannot set exception properties because they are controlled by the messaging engine.

You can match `SI_ExceptionReason`, `JMS_IBM_ExceptionReason` and `JMS_IBM_ExceptionTimestamp`. The method `clearMessageProperties()` does not clear properties that cannot be set.

Where the data types are different, the equivalent values are modified before being returned to the JMS API caller. For example with `JMS_IBM_Report_XXX`, the `JMS_IBM_Report...` and `JMS_IBM_Feedback` values are modified before being returned to the JMS API caller. The values used by service integration and WebSphere Application Server are different, however they are modified before being returned by the JMS API caller, so that they can then be passed to WebSphere MQ.

For information about the mapping of message fields and properties between WebSphere MQ and JMS see Mapping the message header fields and properties to and from WebSphere MQ format.

In the following table, the `SIMessage` API data type column indicates the data type of the property if accessed by a mediation handler, or when specifying the selectors for a mediation handler. The JMS API data type column indicates the data type of the property if accessed by a JMS application, either when specifying selectors or when using the get and set property methods:

*Table 234. JMS\_IBM properties and SIMessage properties. The first column of the table provides the JMS\_IBM property names. The second column provides the equivalent SIMessage property names if available. The third column indicates if the properties can be matched. The fourth column indicates the state of `setMessageProperty`. The fifth column contains the data type of the SIMessage API property if accessed by a mediation handler or when specifying the selectors for the mediation handler. The sixth column contains the data type of the JMS API property if accessed by a JMS application.*

JMS_IBM property name	Equivalent SIMessage property	Can be matched?	setMessageProperty	SIMessage API data type	JMS API data type
<code>JMS_IBM_Format</code>		Yes	Yes	String	String
<code>JMS_IBM_MsgType</code>		Yes	Yes	Integer	Integer
<code>JMS_IBM_Feedback</code>	<code>SI_ReportFeedback</code>	Yes	Yes	Integer	Integer
<code>JMS_IBM_PutAppType</code>		Yes	Yes	Integer	Integer
<code>JMS_IBM_Report_Exception</code>	<code>SI_ReportException</code>	Yes	Yes	Byte	Integer
<code>JMS_IBM_Report_Expiration</code>	<code>SI_ReportExpiry</code>	Yes	Yes	Byte	Integer
<code>JMS_IBM_Report_COA</code>	<code>SI_ReportCOA</code>	Yes	Yes	Byte	Integer
<code>JMS_IBM_Report_COD</code>	<code>SI_ReportCOD</code>	Yes	Yes	Byte	Integer
<code>JMS_IBM_Report_PAN</code>	<code>SI_ReportPAN</code>	Yes	Yes	Boolean	Integer
<code>JMS_IBM_Report_NAN</code>	<code>SI_ReportNAN</code>	Yes	Yes	Boolean	Integer

Table 234. JMS\_IBM properties and SIMessage properties (continued). The first column of the table provides the JMS\_IBM property names. The second column provides the equivalent SIMessage property names if available. The third column indicates if the properties can be matched. The fourth column indicates the state of setMessageProperty. The fifth column contains the data type of the SIMessage API property if accessed by a mediation handler or when specifying the selectors for the mediation handler. The sixth column contains the data type of the JMS API property if accessed by a JMS application.

JMS_IBM property name	Equivalent SIMessage property	Can be matched?	setMessageProperty	SIMessage API data type	JMS API data type
JMS_IBM_Report_Pass_Msg_ID	SI_ReportPassMsgID	Yes	Yes	Boolean	Integer
JMS_IBM_Report_Pass_Correl_ID	SI_ReportPassCorrelID	Yes	Yes	Boolean	Integer
JMS_IBM_Report_Discard_Msg	SI_ReportDiscardMsg	Yes	Yes	Boolean	Integer
JMS_IBM_Last_Msg_In_Group		Yes	Yes	Boolean	Boolean
JMS_IBM_PutDate		Yes	Yes	String	String
JMS_IBM_PutTime		Yes	Yes	String	String
JMS_IBM_Encoding		Yes	Yes	Integer	Integer
JMS_IBM_Character_Set		Yes	Yes	String	String
JMS_IBM_ExceptionMessage		No	No	String	String
JMS_IBM_ExceptionTimestamp	SI_ExceptionTimestamp	Yes	No	Long	Long
JMS_IBM_ExceptionReason	SI_ExceptionReason	Yes	No	Integer	Integer
JMS_IBM_ExceptionProblemDestination	SI_ExceptionProblemDestination	Yes	No	String	String
N/A	SI_ExceptionInserts	No	No	List of strings	n/a
JMS_IBM_System_MessageID	SI_SystemMessageID	Yes	No	String	String

## Using the JMS\_IBM Feedback property

The JMS\_IBM\_Feedback property identifies the type of report a message contains.

Property	Type	Values
JMS_IBM_Feedback	Integer	<ul style="list-style-type: none"> <li>REPORT_EXPIRY=3</li> <li>REPORT_EXCEPTION=4</li> <li>REPORT_COA=5</li> <li>REPORT_COD=6</li> </ul>

If a report message is generated as a result of a message expiry, the value of the JMS\_IBM\_Feedback property is 3.

## User properties

Support for user properties is provided by the SIMessage interface and the mediation configuration selector. The JMS API supports user properties of primitive wrapper or string types. The property name can be any valid Java identifier providing it does not have the prefix JMS. The SIMessage API also supports user properties of primitive wrapper or string types, and additionally supports byte[] and serializable types. Arbitrary serializable objects are stored as byte arrays, and are selected on as byte arrays only (using equals only).

User properties supported by the SIMessage API must have the prefix user. You can set and access these properties using getMessageProperty, setMessageProperty and deleteMessageProperty.

## Interaction with JMS

Alternatively, you can set and access user properties by using `xxxUserProperty` methods. In this case, the prefix `user` must be omitted. The property name, excluding the prefix `user`, exists in the same namespace as the JMS user properties.

For example, a JMS application calls a property as follows:

```
setStringProperty("color", "green");
```

A mediation can access the property by making one of the following calls:

- `getMessageProperty("user.color");`
- `getUserProperty("color");`

**Note:** Mediation message selectors must contain the user prefix.

JMS property methods only affect user properties that have types supported by the JMS API:

- `clearProperties()` clears only those properties supported by JMS.
- `propertyExists()` returns true only when the property type is supported by JMS.
- `getPropertyNames()` includes only those properties with types supported by JMS.
- `setObjectProperty("xxxx", null);` clears a property only if it is supported by JMS.

Note that `setxxxxProperty("xxxx", value)` overrides a user property of any type when the value is non-null.

---

## Error handling in mediations

The actions taken in the event of an error occurring during mediation processing are summarized in the following table:

*Table 235. Actions and errors in mediation processing. The first column of the table lists the errors that occur during the mediation processing. The second column describes the actions to be taken when the errors occur.*

Error	Action taken
Unchecked runtime exception	<ul style="list-style-type: none"><li>• The message is sent to the exception destination.</li><li>• Any transaction is rolled back.</li></ul>
Checked message context exception	<ul style="list-style-type: none"><li>• The message is sent to the exception destination.</li><li>• Any transaction is committed.</li></ul>
Enterprise JavaBeans (EJB) exception	<ul style="list-style-type: none"><li>• Message is eligible for re-mediation.</li></ul>
An error occurs in the process of calling a mediation.	<ul style="list-style-type: none"><li>• The mediation is not called.</li><li>• The message is eligible for re-mediation.</li></ul>
The mediation returns true, and the message is not well formed.	<ul style="list-style-type: none"><li>• The original pre-mediated message is sent to the exception destination.</li><li>• Any transaction is committed.</li></ul>

---

## WebSphere MQ naming restrictions

The naming restrictions for WebSphere MQ queues, queue managers, and queue-sharing groups are more restrictive than those that apply to equivalent objects in WebSphere Application Server. Use this information to help you administer the WebSphere Application Server objects, so that the names of these objects can be passed successfully to and from WebSphere MQ.

## Rules for naming WebSphere MQ objects

- A WebSphere MQ object cannot have the same name as any other object of the same type.
- Names in WebSphere MQ are case sensitive.
- In WebSphere MQ, the names of queues can have up to 48 characters. The names of queue managers can have also have up to 48 characters, except in the case of WebSphere MQ for z/OS, where both queue manager and queue sharing group names are limited to four non-blank characters.
- The character set to use for naming all WebSphere MQ objects is as follows:
  - Uppercase A-Z
  - Lowercase a-z (but there are restrictions on the use of lowercase letters for z/OS console support)
  - Numerics 0-9
  - Period (.)
  - Forward slash (/).
  - Underscore (\_)
  - Percent sign (%).
- Leading or embedded blanks are not allowed.
- Any structure to the names (for example, the use of the period or underscore) is not significant to the queue manager.

For further details, see the WebSphere MQ information center.

---

## Mediation thread pool properties

The table below describes the default thread pool properties for the mediationsThreadPool object for a messaging engine.

Property name	Description	Data type	Comment
minimumSize	Specifies the minimum number of threads to allow in the pool.	integer	Default value is 1.
maximumSize	Specifies the maximum number of threads to allow in the pool.	integer	Default value is 5.
isGrowable	Can the pool grow beyond the maximumSize	boolean	true or false. Default is false.
inactivityTimeout	Specifies the number of milliseconds of inactivity that should elapse before a thread is reclaimed. A value of 0 indicates not to wait and a negative value (less than 0) means to wait forever.	integer, units milliseconds.	Default value: 3500

---

## Chapter 24. Administering Session Initiation Protocol (SIP) applications

This page provides a starting point for finding information about SIP applications, which are Java programs that use at least one Session Initiation Protocol (SIP) servlet written to the JSR 116 specification.

SIP is used to establish, modify, and terminate multimedia IP sessions including IP telephony, presence, and instant messaging.

---

### Deploying SIP applications

Use the administrative console to customize your Session Initiation Protocol (SIP) application installation

#### About this task

When you deploy a Session Initiation Protocol (SIP) application, you can perform various tasks such as installing, starting, stopping, upgrading, and uninstalling the application.

SIP applications are installed as Java Platform, Enterprise Edition (Java EE) applications. You can deploy a SIP application from a graphical interface or from a command line.

### Deploying SIP applications through the console

You can deploy a Session Initiation Protocol (SIP) application through the administrative console.

#### Before you begin

SIP applications are deployed as Java 2 Platform Enterprise Edition (J2EE) applications. In order to process requests, a virtual host must be defined when deploying the SIP application. If there is no virtual host defined for the configured SIP container listen port, the installed application will be inaccessible.

#### Procedure

1. Open the administrative console.  
In a browser, go to URL `http://hostname:9090/admin`, where *hostname* is the name of the host computer. Enter the appropriate login information, and click **OK**.
2. In the left frame click **Applications > Install New Application**.
3. Browse and select a SAR file. Specify the context root, beginning with a slash (/), in the **Context Root** field. For example, if your application is named ThisApplication, type `/ThisApplication`.
4. Click **Next** (under the **Context Root** field not beside the WebSphere Status title). If the SAR file has been assembled correctly, the screen will still have the title "Preparing for the application installation", but the content will change. If an error message appears, check the contents of the SAR file; in particular, verify the `web.xml` file contents, and try to reload the SAR file.
5. Click **Next**. If you see a screen indicating "Application Security Warnings", click **Continue**.
6. The **Install New Application** screen should appear with "Step 1: Select application options" highlighted. Select the options you need and click **Next**.
7. "Step 2: Map modules to servers" should appear highlighted now. You can choose the cluster or server where you want to install the application's modules.
  - If you are installing the application in a stand-alone system, click **Next**.
  - If you are installing the application in a clustered system, select **WebSphere:cell=cellname,cluster=cluster\_name** in the **Clusters and Servers** field, select the check box beside the web module that you want to install, and click **Apply** and **Next**.

8. Now “Step 3: Map virtual hosts for web modules” should appear highlighted. To the right of the application name there should be a drop-down labeled **Virtual Host**.
  - If you are installing the application in a stand-alone system, set the value of the drop-down to **default\_host**, and click **Next**.
  - If you are installing the application in a clustered system, set the value of the drop-down to the name of the virtual host that was chosen during setup, and click **Next**.

**Remember:** You must define a virtual host for your configured SIP container listen port or else you will not be able to access the application.

9. You should now see “Step 4: Summary” highlighted. In the right panel you will see a **Summary of installation options** table that details your selected options and their values. If you need to change an option, click **Previous** to return to the section where you can make your change. Click **Finish** to install the application with your settings. The screen should display, Application *appname\_sar* installed successfully, where *appname* is the name of the application.
10. Click the **Save to Master Configuration** link. A Save to Master Configuration window appears.
11. In the Save to Master Configuration window, click **Save**. The application has now been saved in the current configuration.
12. To confirm that the installation succeeded, in the left frame click **Applications > Enterprise Applications**. The newly installed application should appear in the list of installed applications as *appname\_sar*.
13. To start the application so that it can service SIP requests, check the box beside *appname\_sar*, and click **Start**. You might also want to look at the logs for a successful startup message.

## Results

The application can service SIP requests now.

## Deploying SIP applications through scripting

You can deploy a Session Initiation Protocol (SIP) application not only from the administrative console but also from a command line.

### About this task

**Note:** To deploy a SIP application, the application must exist with an enterprise archive (EAR) file, a Session Initiation Protocol (SIP) module (SAR file), or a web application archive (WAR) file.

Use the wsadmin scripting tool to deploy applications from a command line.

### Procedure

- Launch a scripting client.  
For more information, see AdminApp object for scripted administration.
- List applications.  
For more information, see Listing applications using the wsadmin scripting tool.
- Install stand-alone archive files.  
For more information about installation, see Installing enterprise applications using wsadmin scripting and Installation options for the AdminApp object.
- Edit application configurations.  
For more information, see Editing application configurations using the wsadmin scripting tool.
- Uninstall applications.  
For more information, see Uninstalling enterprise applications using the wsadmin scripting tool.

## Upgrading SIP applications

Follow these steps to upgrade SIP applications.

### About this task

Use the following application upgrade procedure to install a new version of a previously installed application without any outage.

### Procedure

1. Install version 1 of the application in cluster 1.
2. Create cluster 2.
3. Set cluster 1 as the default cluster.
4. Install version 2 of the application in cluster 2.
5. Change the default cluster at proxy to cluster 2.
6. To shut down Version 1, monitor PMI and watch for the application session for this application to come to zero. When it is at zero or a level you consider okay to lose, stop the application.

### Results

New calls will be routed to cluster 2. Old calls will continue to be routed to cluster 1.

---

## Administering SIP applications

### Configuring the SIP container

Configure the Session Initiation Protocol (SIP) container to adjust message response times or set a custom property.

### About this task

Use the administrative console to configure SIP container settings. Complete the following steps to find and configure the SIP container settings.

### Procedure

1. Start WebSphere Application Server.
2. From the administrative console, click **Servers > Server Types > WebSphere application servers > server\_name**.
3. From **Container Settings**, expand **SIP Container Settings**, and click **SIP Container**. Select the container settings that you want to change.
  - From **General Properties**, you can configure session, message, and response time maximums. See *Session Initiation Protocol container settings* and *SIP container custom properties*.
  - From **Additional Properties**, you can define custom properties, manage transport chains or inbound channel settings, or configure the session manager.
4. After configuring the SIP container, click **Apply** to save the changes.
5. Restart WebSphere Application Server.

### Results

Changes to the SIP container settings take effect after you restart WebSphere Application Server.

**gotcha:** As the number of SIP containers grow in a deployment, the larger the heap settings need to be on the SIP proxy server. For example, a deployment of 20 containers requires a minimum heap

size of 60 MB, so a `-Xmo60m` parameter should be added to the Generic JVM arguments field on the Java virtual machine panel of the admin console. However, a deployment of 70 containers requires a larger value such as 200 MB (`-Xmo200m`). See the information center topic *Java virtual machine settings* for more information about Generic JVM arguments.

## Enabling Session Initiation Protocol (SIP) flow token security

The Session Initiation Protocol (SIP) container supports client-initiated connection reuse. SIP flow token security enables you to establish communication between a server and SIP clients in situations where the SIP clients can create a connection to the server, but are not prepared to accept connections from the server.

### About this task

Managing client-initiated connections in the SIP container involves generating flow tokens, as described in the SIP standard RFC 5626. When the SIP container delivers a flow token to the network, it encodes the token in a way that prevents anyone from modifying this token. When the container receives a flow token that it previously generated, it decodes the flow token and verifies its integrity.

WebSphere Application Server SIP flow token security implements the outbound SIP protocol extension, as defined in RFC 5626, with the following exceptions:

- Only TCP and TLS stream transports are supported.
- UDP flows are not reused.
- TCP keepalives are supported, but STUN keepalives are not.
- Support of this protocol extension is provided for SIP applications that act as a proxy/registrar, as described in RFC 5626, but not as a user agent, as described in this RFC.

Encoding and decoding the flow token requires a pre-defined key. The SIP container obtains this security key from your SIP container settings. Complete the following steps to configure the SIP container to support flow token security.

### Procedure

1. Create a key set, if one does not already exist.  
If you already have a key set configured, you can use that key set as the key set for SIP flow token security.  
If you need to create a new key set, the scope of the key set must be at the cell level. See the topic *Creating a key set configuration* for a description of how to create a new key set.
2. Add the `com.ibm.ws.sip.key.set` custom property to the SIP container settings.
  - a. In the administrative console, expand **Servers > Server Types > WebSphere application servers > *server\_name*** to open the configuration tab for the server.
  - b. From **Container settings**, expand **SIP Container settings**, and click **SIP container**.
  - c. From **Additional properties**, select **Custom Properties > New**.
  - d. On the settings page, specify `com.ibm.ws.sip.key.set` in the **Name** field, and the name of the key set to use for flow token security in the **Value** field.
  - e. Click **Apply** or **OK**.
  - f. Click **Save** on the console task bar to save your configuration changes.
  - g. Restart the server.

### Results

SIP flow token security is enabled for the SIP container.

## SIP container custom properties

You can add any of the following custom properties to the configuration settings for a Session Initiation Protocol (SIP) container.

To specify custom properties for a specific SIP container, navigate to the custom properties page, and then specify a value for the custom property.

**Important:** The custom properties are supported as the primary method of configuration. Therefore, if a custom property is set and then you set the corresponding setting in the administrative console, the custom property value is used.

1. In the administrative console, expand **Servers > Server Types > WebSphere application servers > *server\_name*** to open the configuration tab for the server.
2. From **Container settings**, expand **SIP Container settings**, and click **SIP container**.
3. From **Additional properties**, select **Custom Properties > New**.
4. On the settings page, type the custom property to configure in the **Name** field, and then type the value of the custom property in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

The following list of SIP container custom properties is provided with the product. These properties are not shown on the settings page for the container.

You can define the following SIP container custom properties that are provided with the product. These properties are not shown on the settings page for the container.

- “auth.int.enable” on page 2592
- “com.ibm.sip.sm.lnm.size” on page 2592
- “com.ibm.websphere.sip.security.digest.ldap.cachecleanperiod” on page 2592
- “com.ibm.websphere.sip.security.tai.usercachecleanperiod” on page 2593
- “com.ibm.ws.sip.key.set” on page 2593
- “com.ibm.ws.sip.tai.DisableSIPBasicAuth” on page 2593
- “DigestPasswordServerClass” on page 2593
- “enable.system.headers.modify” on page 2593
- “end.of.service.replication” on page 2593
- “immediate.replication” on page 2594
- “javax.servlet.sip.ar.dar.configuration” on page 2594
- “javax.servlet.sip.ar.spi.SipApplicationRouterProvider” on page 2594
- “javax.sip.bind.retries” on page 2594
- “javax.sip.bind.retry.delay” on page 2594
- “javax.sip.detect.pre.escaped.params” on page 2594
- “javax.sip.force.connection.reuse” on page 2595
- “javax.sip.hide.message.body” on page 2595
- “javax.sip.hide.message.headers” on page 2595
- “javax.sip.hide.request.uri” on page 2596
- “javax.sip.OUTBOUND\_PROXY” on page 2596

- “javax.sip.stat.report.interval” on page 2596
- “javax.sip.trace.msg.in” on page 2597

- “javax.sip.trace.msg.out” on page 2597
- “javax.sip.transaction.invite.auto100” on page 2597
- “javax.sip.transaction.timer.a” on page 2597
- “javax.sip.transaction.timer.b” on page 2597
- “javax.sip.transaction.timer.cancel” on page 2598
- “javax.sip.transaction.timer.d” on page 2598
- “javax.sip.transaction.timer.e” on page 2598
- “javax.sip.transaction.timer.f” on page 2598
- “javax.sip.transaction.timer.g” on page 2599
- “javax.sip.transaction.timer.h” on page 2599
- “javax.sip.transaction.timer.i” on page 2599
- “javax.sip.transaction.timer.invite.server” on page 2600
- “javax.sip.transaction.timer.j” on page 2600
- “javax.sip.transaction.timer.k” on page 2600
- “javax.sip.transaction.timer.non.invite.server” on page 2600
- “javax.sip.transaction.timer.t1” on page 2601
- “javax.sip.transaction.timer.t2” on page 2601
- “javax.sip.transaction.timer.t4” on page 2601
- “on.outgoing.message.replication” on page 2601
- “pws\_atr\_name” on page 2601
- “replicate.with.confirmed.dialog.only” on page 2602
- “sip.container.heartbeat.enabled” on page 2602
- “sip.jsr289.parse.address” on page 2602
- “SIP\_RFC3263\_nameserver” on page 2602
- “thread.message.queue.max.size” on page 2603
- “weight.overload.watermark” on page 2603

***auth.int.enable:***

Specifies the **auth-int** quality of protection (QOP) for digest authentication. Digest authentication defines two types of QOP: **auth** and **auth-int**. By default, **auth** is used. When this custom property is set to True, the highest level of protection is used, which is the **auth-int** QOP.

<b>Data type</b>	String
<b>Default</b>	False

***com.ibm.sip.sm.lnm.size:***

Specifies the number of logical names in the application server. Each SIP object that can be replicated, such as a SIP session, is associated with a logical name. All objects with the same logical name are replicated to the same back-up container. The proxy can route messages to the correct container using the logical name found in the message. The value must be greater than 1.

<b>Data type</b>	String
<b>Default</b>	10

***com.ibm.websphere.sip.security.digest ldap.cachecleanperiod:***

Specifies the clean Lightweight Directory Access Protocol (LDAP) cache period in minutes.

<b>Data type</b>	String
<b>Default</b>	120

***com.ibm.websphere.sip.security.tai.usercachecleanperiod:***

Specifies the clean security subject cache period in minutes.

<b>Data type</b>	String
<b>Default</b>	15

***com.ibm.ws.sip.key.set:***

Specifies the key to use for SIP flow token security. When a value is specified for this property, SIP flow token security is automatically enabled.

<b>Data type</b>	String
<b>Default</b>	There is no default value

***com.ibm.ws.sip.tai.DisableSIPBasicAuth:***

Specifies whether to allow basic authentication for SIP.

<b>Data type</b>	String
<b>Default</b>	False

***DigestPasswordServerClass:***

Specifies types of user registries that are supported, except LDAP. To configure DigestTAI without the LDAP user registry, complete the following steps.

1. Create a class that implements this interface: `com.ibm.ws.sip.security.digest.DigestPasswordServer`
2. Add the following property to the SIP container custom property:  
Default `LdapPasswordServer`
3. Ensure that all users declared by the impl class are declared in the user registry configured for the product security.

<b>Data type</b>	String
<b>Default</b>	impl

***enable.system.headers.modify:***

Specifies whether the application has access to headers that are otherwise restricted.

<b>Data type</b>	String
<b>Default</b>	False

***end.of.service.replication:*** Specifies whether changes are buffered until the thread for a siplet is about to end. If the value is set to `true`, then each change is buffered until the thread for the siplet is about to end.

<b>Data type</b>	Boolean
<b>Default</b>	true

***immediate.replication:*** Specifies whether each change is immediately sent to the Data Replication Service. When this property is set to `true`, when replication is issued from a non-SIP container thread, the replication is immediately performed on the calling thread. When this property is set to `false`, the changes are buffered, and replication does not occur until all changes are made.

Setting this property to `true` might have a negative impact on performance.

<b>Data type</b>	Boolean
<b>Default</b>	<code>false</code>

***javax.servlet.sip.ar.dar.configuration:***

Specifies the location of the default application router (DAR) properties file. The properties file defines the order in which the application router sends SIP requests to applications as described in Appendix C of the JSR 289 specification.

<b>Data type</b>	String
<b>Default</b>	Null

***javax.servlet.sip.ar.spi.SipApplicationRouterProvider:***

Specifies the custom application router implementation fully qualified class name as described in section 15.4.2 of the JSR 289 specification. The custom application router implementation class defines the order in which the application router sends SIP requests to applications.

<b>Data type</b>	String
<b>Default</b>	Null

***javax.sip.bind.retries:***

Specifies the amount of time, in milliseconds, between attempts to start the SIP channel if the SIP port is busy with another process during server startup.

<b>Data type</b>	String
<b>Default</b>	<code>60</code>

***javax.sip.bind.retry.delay:***

Specifies the delay, in milliseconds, between attempts to start the SIP channel if the SIP port is busy with another process during server startup.

<b>Data type</b>	String
<b>Default</b>	<code>5000</code>

***javax.sip.detect.pre.escaped.params:***

Specifies whether to prevent the container from re-escaping Uniform Resource Identifier (URI) parameters that were pre-escaped by the application.

Enabling this property provides the application with more control over escaping URI parameters, when calling the `javax.servlet.sip.SipFactory.createURI()` and the `javax.servlet.sip.SipURI.setParameter()` parameters.

By default, the container only escapes characters that it must encode according to the RFC 3261 25.1 specification. In some cases, however, escaping additional characters might be required. Due to a limitation in the JSR 116 (5.2.1) specification, the application cannot perform its own escaping. Because of this limitation, attempts by the application to encode URI parameters causes the container to re-encode the percent sign. If the value of this property is set to true, the container cannot re-encode the percent sign.

Setting the value to true is not in compliance with the JSR 116 (5.2.1) specification, but provides the application with greater control over URI parameter escaping. APAR PK37192 describes the problem and the workaround.

<b>Data type</b>	String
<b>Default</b>	False

***javax.sip.force.connection.reuse:***

Specifies whether to force reuse of inbound connections for outbound requests. This custom property is only relevant for stream transports, such as Transmission Control Protocol (TCP) and Transport Layer Security (TLS). Disabling this property causes the container to create a separate connection for outbound requests, even if an existing connection is already established to the same peer address. The connection is automatically reused if the top Via header in the inbound request contains an alias parameter. (<http://www.ietf.org/internet-drafts/draft-ietf-sip-connect-reuse-07.txt>)

<b>Data type</b>	String
<b>Default</b>	False

**depfeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.hide.message.body:***

Specifies to hide message content in logs. Set the value of this property to true to remove the message body text from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

<b>Data type</b>	String
<b>Default</b>	False

**depfeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.hide.message.headers:***

Specifies to hide the specified message header field names in log files. The value of this property is a comma-separated list of header field names that you want removed from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

<b>Data type</b>	String
<b>Default</b>	None

***javax.sip.hide.request.uri:***

Specifies to hide request URIs in log files. Set the value of this property to true to remove request URIs from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

<b>Data type</b>	Boolean
<b>Default</b>	False

***javax.sip.OUTBOUND\_PROXY:***

Specifies the fixed address for routing all outbound SIP messages. The format is *address:port/transport*, such as 1.2.3.4:5065/tcp.

**Note:** Do not use this property if the container is fronted by an application server SIP proxy.

<b>Data type</b>	String
<b>Default</b>	null

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.PATH\_MTU:***

Specifies the maximum transmission unit, in bytes, for outbound User Datagram Protocol (UDP) requests. The SIP stack measures the size of a request before sending it out on the UDP channel. If the request is larger than the value specified for **PATH\_MTU-200** (1300 bytes by default), then the transport is switched from UDP to TCP before transmission. Increase this value to send larger requests over the UDP channel; however, messages might be truncated or dropped. See the RFC 3261-18.1.1 specification for details.

<b>Data type</b>	String
<b>Default</b>	1500

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.stat.report.interval:***

Specifies the amount of time, in milliseconds, for reporting dispatch and timer statistics to a system.out file. A value of zero indicates no report.

<b>Data type</b>	String
------------------	--------

**Default** 0

***javax.sip.trace.msg.in:***

Specifies whether to print incoming messages to a system.out file.

**Data type** String  
**Default** False

***javax.sip.trace.msg.out:***

Specifies whether to print outbound messages to a system.out file.

**Data type** String  
**Default** False

***javax.sip.transaction.invite.auto100:***

Specifies whether to automatically reply to invite requests with a 100 Trying response. Disabling this property might increase the number of invite retransmissions.

**Data type** String  
**Default** True

**depreat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.transaction.timer.a:***

Specifies, for UDP only, the amount of time, in milliseconds, before retransmitting invite requests for timer A for the RFC 3261 specification. This property is relevant for the invite client transaction.

**Data type** String  
**Default** javax.sip.transaction.timer.t1

**depreat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.transaction.timer.b:***

Specifies the amount of time, in milliseconds, for the invite client transaction timeout timer (timer B) for the RFC 3261 specification.

**Data type** String  
**Default** 64\*javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.transaction.timer.cancel:***

Specifies the amount of timer, in milliseconds, for the timer to keep the cancelled client transaction in the proceeding state before completing the cancelled transaction for the RFC 3261 9.1 specification. This property is relevant for the invite client transaction.

<b>Data type</b>	String
<b>Default</b>	64*javax.sip.transaction.timer.t1

***javax.sip.transaction.timer.d:***

Specifies the wait time, in milliseconds, before retransmission of the invite response for timer D for the RFC 3261 specification. This property is relevant for the invite client transaction.

<b>Data type</b>	String
<b>Default</b>	32000

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.transaction.timer.e:***

Specifies, for UDP only, the amount of time, in milliseconds, before the retransmission of the initial non-invite request for timer E for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

<b>Data type</b>	String
<b>Default</b>	javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.transaction.timer.f:***

Specifies the amount of time, in milliseconds, for the non-invite transaction timeout timer (timer F) for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

<b>Data type</b>	String
------------------	--------

**Default** 64\*javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.transaction.timer.g:***

Specifies the amount of time, in milliseconds, before retransmission of an initial invite response for timer G for the RFC 3261 specification. This property is relevant for the invite server transaction.

**Data type** String  
**Default** javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.transaction.timer.h:***

Specifies the amount of time, in milliseconds, to wait for an acknowledgement (ACK) receipt for timer H for the RFC 3261 specification. This property is relevant for the invite server transaction.

**Data type** String  
**Default** 64\*javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.transaction.timer.i:***

Specifies the amount of time in milliseconds to wait for an ACK retransmission for timer I for the RFC 3261 specification. This property is relevant for the invite server transaction.

**Data type** String  
**Default** javax.sip.transaction.timer.t4

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

### ***javax.sip.transaction.timer.invite.server:***

Specifies the amount of time, in milliseconds, for the timer to keep the invite server transaction in the complete state. This timer is not defined in the RFC specification.

To avoid creating a new server transaction when a client retransmits an invite request, keep the completed server transaction for a period of time before removing invite retransmissions. This timer is started when the transaction changes to the terminated state. When the timer completes, the transaction is removed.

<b>Data type</b>	String
<b>Default</b>	32000

### ***javax.sip.transaction.timer.j:***

Specifies the amount of time in milliseconds to wait for non-invite request retransmission for timer J for the RFC 3261 specification. This property is relevant for the non-invite server transaction.

<b>Data type</b>	String
<b>Default</b>	64*javax.sip.transaction.timer.t1

**deffeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

### ***javax.sip.transaction.timer.k:***

Specifies the amount of time, in milliseconds, to wait for non-INVITE response retransmissions for timer K for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

<b>Data type</b>	String
<b>Default</b>	javax.sip.transaction.timer.t4

**deffeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

### ***javax.sip.transaction.timer.non.invite.server:***

Specifies the amount of time, in milliseconds, for an Application Programming Interface (API) timer for the application to respond to a non-invite request. This property is relevant for non-invite server transactions.

This timer is not defined in the RFC specification. This property is needed to stop the transaction if the application does not generate a final response to the request. The timer starts when the request arrives in the stack and stops when a response is generated by the application. If no response is generated before the timer stops, then the transaction completes.

<b>Data type</b>	String
<b>Default</b>	34000

***javax.sip.transaction.timer.t1:***

Specifies the amount of time, in milliseconds, for a network round trip delay for timer T1 for the RFC 3261 specification. The value is used as a base for calculating some timers and is relevant for all types of transactions, such as client, server, invite, and non-invite transactions.

**Data type** String  
**Default** 500

**deprecat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.transaction.timer.t2:***

Specifies the maximum time in milliseconds before retransmitting non-invite requests and invite responses for timer T2 for the RFC 3261 specification.

**Data type** String  
**Default** 4000

**deprecat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***javax.sip.transaction.timer.t4:***

Specifies the maximum amount of time, in milliseconds, for a message to remain in the network. This value is used as a base for calculating other timers for timer T4 for the RFC 3261 specification.

**Data type** String  
**Default** 5000

**deprecat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***on.outgoing.message.replication:*** Specifies whether changes are buffered until a siplet issues a request.send() or response.send() call. If the value is set to true, then each change is buffered until a siplet issues a request.send() or response.send() call.

**Data type** Boolean  
**Default** false

***pws\_atr\_name:***

Specifies the LDAP attribute name that stores the user password.

<b>Data type</b>	String
<b>Default</b>	userpassword

***replicate.with.confirmed.dialog.only:***

Specifies whether to replicate the application session, even when no dialogs are confirmed. If the value is set to `false`, then the application session is replicated immediately after the session is created. Otherwise, the application session is only replicated when an associated dialog is confirmed.

<b>Data type</b>	String
<b>Default</b>	False

***sip.container.heartbeat.enabled:***

Specifies whether or not SIP network outage detection is enabled for the SIP container. SIP network outage detection allows the SIP proxy to send keepalive messages to the SIP container if the value of this property is set to `true`.

If the value is set to `false` for the SIP container, then this property has no effect on the SIP proxy. However, if the value is set to `true` for the SIP container, the value should also be set to `true` for the SIP proxy to ensure that keepalive messages are answered at the SIP container and not presented to the application.

<b>Data type</b>	String
<b>Default</b>	true

***sip.jsr289.parse.address:***

Specifies to use the SIP Servlet Specification 1.1, JSR 289 required format for `createRequest()` and `createAddress()` methods.

**Note:** The JSR 289 API requires that for any SIP URI that contains address parameters, you must enclose the SIP URI in angle brackets. The default behavior of the `sip.jsr289.parse.address` property is compliant with JSR 289 and correctly parses the address parameter as if it belongs to the SIP address. For example, when the property is set to `false`, the SIP address, `sip:fred@acme.com;param1=1`, is converted to `<sip:fred@acme.com;param1=1>`. When the property is set to `true`, the SIP address `sip:fred@acme.com;param1=1`, is converted to `<sip:fred@acme.com;>param1=1`.

<b>Data type</b>	String
<b>Default</b>	True

***SIP\_RFC3263\_nameserver:***

Specifies whether to allow a SIP URI to be resolved through Domain Name System (DNS) into the IP address, port, and transport protocol of the next hop.

The value of the property is a string containing one or two address and port tuples, where two tuples are separated by a space. The following examples specify a one address and port tuple or a two address and port tuple.

`dottedDecimalAddress@.port`

hostname.domain@port  
IPV6address@port

The following example values represent a single tuple.

- 1.2.3.4@53
- example.com@53
- a:b:c::d@53

The following example values represent two tuples separated by a space.

- 1.2.3.4@53 example.com@53
- a:b:c::d@53 9.32.211.14@53

<b>Data type</b>	String
<b>Default</b>	null

**defpeaf:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

***thread.message.queue.max.size:***

Specifies the maximum number of events allowed in the container threads queue. When this number is exceeded, the proxy server is notified that the container is overloaded and requests for new sessions are not accepted. Instead, the container returns an error message that indicates that the container is temporarily unavailable.

This value represents the total number of messages for all queues and reflects the state of the CPU. When the CPU approaches 100%, the maximum value for this custom property is reached quickly. Configure your system to limit the queue size and prevent the queue from reaching this threshold.

<b>Data type</b>	String
<b>Default</b>	1000

***weight.overload.watermark:***

Specifies the threshold value for the internal weight calculated by the container. When the container calculates the internal weight to be higher than the value specified, an overloaded container becomes available for service again.

This custom property represents a percentage of the maximum internal weight, such as 30 percent when the default value is set. When the high-water mark, or maximum threshold, is exceeded, the container waits until the weight drops below the maximum weight. This value cannot exceed 10.

<b>Data type</b>	String
<b>Default</b>	3

## Using DNS procedures to locate SIP servers

The Session Initiation Protocol (SIP) can use Domain Name Server (DNS) procedures for a client to resolve a SIP Uniform Resource Identifier (URI).

## About this task

WebSphere Application Server provides support for the RFC 3263 standard. This allows a SIP URI to be resolved through DNS into the IP address, port, and transport protocol of the next hop to contact.

**Note:** SIP does not support use of DNS procedures for a server to send a response to a back-up client if the primary client fails.

Complete these steps to configure WebSphere Application Server to support the RFC 3263 standard.

## Procedure

1. Start WebSphere Application Server.
2. From the administrative console, expand **Servers**, and click **Application servers > serverName**.
3. Under **General Properties**, check the **Enable locating SIP servers using DNS NAPTR records** checkbox, then fill in the **Primary DNS server name** and **Secondary DNS server name** fields.
4. Click **Apply** to save your changes.
5. Restart WebSphere Application Server.

## What to do next

You must configure your DNS server in order for RFC 3263 support to work for the SIP container. The following example is a BIND db file for configuring RFC 3263 support on a DNS server.

## SIP container settings

Use this page to configure the SIP container settings for Session Initiation Protocol (SIP).

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > server\_name > SIP container settings > SIP container**.

### **Maximum application sessions:**

Specifies the maximum number of SIP application sessions that the container manages. When the maximum is reached, no new SIP conversations are started. When the maximum is exceeded in a clustered environment, the server does not forward new dialogs until the number of application sessions no longer exceeds the maximum.

Application sessions are typically created by new incoming calls, but can also be created by other events. The application session count does not impact failover, but applies only to new sessions that are created as a result of incoming calls.

When application sessions are transferred from one application server to another due to failover, the active application server inherits the sessions created on the failed server. In addition, the servlet might create a new application session in the SIP container by calling `SipFactory.createApplicationSession()`.

New application sessions created for events other than starting SIP conversations are not controlled by this setting. But all new application sessions are included when computing the maximum number of application sessions allowed. Thus, all active application sessions, including those not related to starting SIP conversations, can cause the maximum to be exceeded.

<b>Data type</b>	Integer
<b>Default</b>	120000 (recommended)
<b>Range</b>	1 <= n <= java.lang.Integer.MAX_VALUE

### **Maximum messages per averaging period:**

Specifies the maximum amount of SIP messages processed per averaging period. The averaging period is the period of time during which the average number of messages received by the container is calculated.

This average is used to determine the load for the container and to determine if the number of messages is approaching the maximum. When the maximum is exceeded, the stand-alone server or the proxy server continues to handle all in-dialog messages. Other non-dialog requests are rejected. When a container is in an overloaded state, the proxy server returns a 503 error.

<b>Data type</b>	Integer
<b>Default</b>	5000 (recommended)
<b>Range</b>	1 <= n <= java.lang.Integer.MAX_VALUE

### **Maximum dispatch queue size:**

Specifies the size of the internal dispatch queue. When the maximum queue size threshold is reached, the container queue becomes overloaded and begins to drop requests for new sessions. In this case, the container does not report its overloaded state to the proxy server.

Configure your system to limit the queue size to prevent the queue from reaching this threshold. If the internal queue reaches the overloaded state, incoming UDP packets are dropped until the queue is no longer in an overloaded state. Limiting the queue size enables better recovery if the CPU is used by other processes or threads and prevents the container from reaching out-of-memory conditions. When the value is set to 0, the queue size is unlimited.

<b>Data type</b>	Integer
<b>Default</b>	3200 (recommended)
<b>Range</b>	0 <= n <= java.lang.Integer.MAX_VALUE

### ***Maximum response time:***

Specifies the maximum response time, in milliseconds, for an application. When the amount of time is exceeded, the container notifies the clustering framework that it is unavailable. You can disable this feature in the administrative console by deselecting the check box and specifying a value of 0.

Use the maximum SIP response time setting cautiously because the calculated response time does not match the behavior of all applications. For requests, such as INVITE requests, where the responses are generated as a result of a user interaction, the calculated response time is extensive. However, the extensive response time is not caused by a delay in the SIP container. Therefore, you should not calculate the response time as a load factor. The recommended applications for effective calculation of response time are applications that respond immediately without a user interaction. The subscribe and register applications are relevant examples.

<b>Data type</b>	Integer
<b>Default</b>	0
<b>Range</b>	1 <= n <= java.lang.Integer.MAX_VALUE

### ***Averaging period in milliseconds:***

Specifies the amount of time, in milliseconds, to use for calculating the maximum messages per averaging period. This setting is the sliding window during which the SIP container counts the number of messages sent to the container.

<b>Data type</b>	Integer
<b>Default</b>	1000 (recommended)
<b>Range</b>	1000 <= n <= java.lang.Integer.MAX_VALUE

### ***Statistic update rate:***

Specifies control over the interval for which the container calculates averages and publishes statistics to Performance Monitoring Infrastructure.

<b>Data type</b>	Integer
<b>Default</b>	10000 (recommended)
<b>Range</b>	1000 <= n <= java.lang.Integer.MAX_VALUE

### ***Locating SIP servers using DNS:***

Specifies whether to enable locating SIP servers using DNS (Directory Name Service).

A SIP Uniform Resource Identifier (URI) can be resolved through DNS into the Internet Protocol (IP) address, port, and transport protocol of the next hop.

The value for the **Primary DNS server name** or **Secondary DNS server name** fields is a string containing one address and port tuple. The following examples specify an address and port tuple.

**Note:** The container contacts the primary DNS server first; however, if the primary DNS server is unavailable, then the container contacts the secondary DNS server. If the secondary DNS server remains responsive, the container does not attempt to contact the primary DNS server.

dottedDecimalAddress@.port

hostname.domain@port

IPV6address@port

<b>Data type</b>	Boolean
<b>Default</b>	False

#### **Primary DNS server name**

Specifies an IP address and port tuple for the primary DNS server. If this server is not available, then the container sends a response to the secondary DNS server.

<b>Data type</b>	String
<b>Default</b>	empty string.

#### **Secondary DNS server name**

Specifies an IP address and port tuple for the secondary DNS server.

<b>Data type</b>	String
<b>Default</b>	empty string.

#### ***Thread pool:***

Specifies the thread pool to use for the SIP container.

If you do not choose a thread pool, the SIP container creates a new thread pool with maximum size of 15.

### **SIP stack settings**

Use this page to configure values for the Session Initiation Protocol (SIP) stack settings that are different from those specified in RFC 3261. The default values are the same as those specified for RFC 3261.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > server\_name > SIP container settings > SIP container > SIP stack**.

#### ***Automatically reply to INVITE with "100 Trying" response:***

Specifies whether to automatically reply to INVITE requests with a 100 Trying response. Disabling this setting might increase the number of INVITE retransmissions.

<b>Data type</b>	Boolean
<b>Default</b>	True

#### ***Hide message body:***

Specifies whether to hide message content in log files. Set the value to True to remove the message body text from SIP messages printed in the log files. This setting only affects the representation of the messages in log files.

<b>Data type</b>	Boolean
------------------	---------

**Default** False

**Maximum transmission unit:**

Specifies the maximum transmission unit, in bytes, for outbound User Datagram Protocol (UDP) requests. The SIP stack measures the size of a request before sending it out on the UDP channel. If the request is higher than the value specified for PATH\_MTU-200, 1300 bytes by default, then the transport is switched from UDP to TCP before transmission.

Increase this value to send larger requests over the UDP channel; however, messages might be truncated or discarded. See the RFC 3261-18.1.1 specification for details.

**Data type** Integer  
**Default** 1500

**SIP timers settings**

Use this page to set values for the Session Initiation Protocol (SIP) timers that are different from those specified in RFC 3261. SIP timers provide a mechanism for session expiration. The default values are the same as those specified for RFC 3261.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > server\_name > SIP container settings > SIP container > SIP stack > SIP timers**.

The following SIP timers can be configured from the administrative console.

**T1:**

Specifies the amount of time, in milliseconds, for a network round trip delay for timer T1 for the RFC 3261 specification. The value is used as a base for calculating some timers and is relevant for all types of transactions, such as client, server, invite, and non-invite transactions.

**Data type** Integer  
**Default** 500

**A** Specifies, for UDP only, the amount of time, in milliseconds, before retransmitting invite requests for timer A for the RFC 3261 specification. This setting is relevant for the invite client transaction.

**Data type** Integer  
**Default** T1

**B** Specifies the amount of time, in milliseconds, for the invite client transaction timeout timer (timer B) for the RFC 3261 specification.

**Data type** Integer  
**Default** T1\*64

**E** Specifies, for UDP only, the amount of time, in milliseconds, before the retransmission of the initial non-invite request for timer E for the RFC 3261 specification. This setting is relevant for the non-invite client transaction.

**Data type** Integer  
**Default** T1

F Specifies the amount of time, in milliseconds, for the non-invite transaction timeout timer (timer F) for the RFC 3261 specification. This setting is relevant for the non-invite client transaction.

**Data type** Integer  
**Default** T1\*64

G Specifies the amount of time, in milliseconds, before retransmission of an initial invite response for timer G for the RFC 3261 specification. This setting is relevant for the invite server transaction.

**Data type** Integer  
**Default** T1

H Specifies the amount of time, in milliseconds, to wait for an acknowledgement (ACK) receipt for timer H for the RFC 3261 specification. This setting is relevant for the invite server transaction.

**Data type** Integer  
**Default** T1\*64

J Specifies the amount of time, in milliseconds, to wait for non-invite request retransmission for timer J for the RFC 3261 specification. This setting is relevant for the non-invite server transaction.

**Data type** Integer  
**Default** T1\*64

#### **T2:**

Specifies the maximum amount of time, in milliseconds, before retransmitting non-invite requests and invite responses for timer T2 for the RFC 3261 specification.

**Data type** Integer  
**Default** 4000

#### **T4:**

Specifies the maximum amount of time, in milliseconds, for a message to remain in the network. This value is used as a base for calculating other timers for timer T4 for the RFC 3261 specification.

**Data type** Integer  
**Default** 5000

I Specifies the amount of time, in milliseconds, to wait for an ACK retransmission for timer I for the RFC 3261 specification. This setting is relevant for the invite server transaction.

**Data type** Integer  
**Default** T4

K Specifies the amount of time, in milliseconds, to wait for non-INVITE response retransmissions for timer K for the RFC 3261 specification. This setting is relevant for the non-invite client transaction.

**Data type** Integer  
**Default** T4

#### **D:**

Specifies the amount of time to wait, in milliseconds, before retransmission of the invite response for timer D for the RFC 3261 specification. This setting is relevant for the invite client transaction.

<b>Data type</b>	Integer
<b>Default</b>	32000

## Configuring SIP timers

You can configure SIP timers to set values for the Session Initiation Protocol (SIP) timers that are different from default values specified in RFC 3261. SIP timers provide a mechanism for session expiration. The default values are the same as those specified for RFC 3261.

### Before you begin

Ensure that clusters and stand-alone servers are created and federated.

### About this task

You can set values for the SIP timers from the administrative console.

**Note:** If you have already used the custom properties to specify a value for a SIP timer, the custom property value is the primary value. Therefore, the SIP timer value specified from the administrative console is not used.

### Procedure

1. From the administrative console, click **Servers > server\_name > SIP container > SIP stack > SIP timers**.
2. Specify a value for a timer by clicking the Use Custom Value check box beside the timer.
3. Specify a value for the timer in the Value column.
4. Click **OK**.
5. Restart the application server.

### Results

The container uses the times specified in the administrative console and not the RFC defaults.

#### **SIP timer summary:**

Request for Comments (RFC) 3261, "SIP: Session Initiation Protocol," specifies various timers that SIP uses.

Table 236 summarizes for each SIP timer the default value, the section of RFC 3261 that describes the timer, and the meaning of the timer.

*Table 236. Summary of SIP timers.*

*This table lists a summary of SIP timers.*

Timer	Default value	Section	Meaning
T1	500 ms	17.1.1.1	Round-trip time (RTT) estimate
T2	4 sec.	17.1.2.2	Maximum retransmission interval for non-INVITE requests and INVITE responses
T4	5 sec.	17.1.2.2	Maximum duration that a message can remain in the network
Timer A	initially T1	17.1.1.2	INVITE request retransmission interval, for UDP only

Table 236. Summary of SIP timers (continued).

This table lists a summary of SIP timers.

Timer	Default value	Section	Meaning
Timer B	64*T1	17.1.1.2	INVITE transaction timeout timer
Timer C	> 3 min.	16.6 bullet 11	Proxy INVITE transaction timeout
Timer D	> 32 sec. for UDP	17.1.1.2	Wait time for response retransmissions
	0 sec. for TCP and SCTP		
Timer E	initially T1	17.1.2.2	Non-INVITE request retransmission interval, UDP only
Timer F	64*T1	17.1.2.2	Non-INVITE transaction timeout timer
Timer G	initially T1	17.2.1	INVITE response retransmission interval
Timer H	64*T1	17.2.1	Wait time for ACK receipt
Timer I	T4 for UDP	17.2.1	Wait time for ACK retransmissions
	0 sec. for TCP and SCTP		
Timer J	64*T1 for UDP	17.2.2	Wait time for retransmissions of non-INVITE requests
	0 sec. for TCP and SCTP		
Timer K	T4 for UDP	17.1.2.2	Wait time for response retransmissions
	0 sec. for TCP and SCTP		

## Performing controlled failover of SIP applications

You can take an active application out of the loop via a controlled failover.

### Before you begin

SipContainerMBean is used to initiate a server quiesce through wsadmin (command line interface). This MBean is used to set the container's weight to 0, which prevents new messages from being routed to it.

WebSphere Application Server PMI is used to monitor the server's active sessions. The remaining active sessions can be watched by enabling a counter on the server being quiesced. The server can be shut down once the number of active sessions reaches an acceptable level. A script can be written to monitor active sessions and shut down the server when an acceptable threshold is achieved.

### About this task

#### Quiescing a single server

- On an ND machine, start the wsadmin utility:
  - Go to `<nd_installation_path>/bin`
  - Run the command: `./setupCmdLine.sh`
  - Run the command: `./wsadmin.sh`
  - Verify that received: `wsadmin>`
- Run the command: `set scBean [$AdminControl queryNames type=SipContainerMBean,process=<server name>,*]`
- Run the command: `$AdminControl invoke $scBean quiesce true`

#### From the admin console, command line or scripts

Use the following commands to stop application servers from the admin console, command line or scripts:

- **Stop:** Quiesces the application server. The sessions will failover to another server. It is important to manually quiesce the server on shutdown.
- **Immediate Stop:** Stops the server, but bypasses the normal server quiesce process that supports in-flight requests to complete before shutting down the entire server process. This shutdown mode is faster than the normal server stop processing, but some application clients can receive exceptions.
- **Terminate:** Deletes the application server process. Use this if immediate stop fails to stop the server.

## Replicating SIP sessions

You can set up a replication domain for SIP sessions if you want replication of session, and dialog state information to occur during typical Session Initiation Protocol (SIP) processing. The SIP container typically uses the Data Replication Service (DRS) to replicate all state information. Because DRS does not provide a way to confirm when data replication has completed, the only thing that can be quantified is when a piece of state information is queued for replication. Within this topic, references to replication of data only means that the data has been queued for replication.

### About this task

The SIP container replicates several different types of information. This data falls into two general categories:

- Internal SIP container state information associated with the dialog.
- Application state information associated with the various session objects.

Each of these categories includes a number of different data types, that are described below. Each data object is treated independently. Therefore, a change to an application session object, that causes a replication, does not result in the replication of any internal state information.

### Replication of internal state information

Internal state information can be defined as anything related to the state of a dialog being handled by the container. It includes things like cseq, dialog state (initial, early, confirmed, terminated), session expiration, local, remote party, etc. Internal state information is only replicated due to the existence of a dialog. Therefore, no internal SIP-related data will be replicated until the dialog with which it is associated is established. The types of SIP requests that can cause the creation of a dialog include:

- INVITE
- SUBSCRIBE
- REFER

Replication of internal state happens at well-defined, predictable points in the call flow. For example, a dialog is only established at the container when a 2xx response or a 1xx response with a “To” tag is received or sent due to one of the method types listed above. Events that can trigger an internal state replication include:

- Creation of a new SIP dialog
- Expiration of a session due to a session timeout
- The sending of a final response to a UAC
- Creation of an encoded URI
- Handling of any message that results in a change of the internal dialog state

It is important to note that transaction state is not replicated in the WebSphere Application Server 6.1 version of the SIP container, only dialog state. Not replicating transaction state reduces the load on all the servers in the replication domain, but can cause problems in failures that happen in the middle of a transaction (for example, loss of some dialog-related SIP messages).

An important difference between a B2BUA and a proxy application is the number of session objects created and replicated. In both cases only a single application session is created, but for the B2BUA, two session objects are created—one for the inbound leg and one for the outbound leg. For a proxy application, only a single session object is created.

### Replication of application state information

Application state information is treated differently from internal dialog state information because it does not rely on the existence of a dialog to be replicated. Application state refers to any data that is being maintained by the application through the use of JSR 116 data constructs. This includes:

- `javax.servlet.sip.SipApplicationSession`
- `javax.servlet.sip.SipSession`
- `javax.servlet.sip.ServletTimer`
- Any attribute set on the `SipSession` or the `SipApplicationSession`

Replication of internal state happens at well-defined, predictable points in the call flow, while replication of application state is less predictable because it is generally dependent on when an application creates, invalidates or modifies the session data and timers through JSR 116 APIs. This could be due to the processing of an inbound message, or to the expiration of a SIP timer. All of the following can cause the replication of application-related session data:

- Creation of an application session object
- Creation of a SIP session object
- Creation of a SIP session timer
- Modification of a session object through `setAttribute` or `removeAttribute`
- Invalidation of a SIP session object
- Expiration of a session timer
- Application code sending out a request \*

\*Causes replication of the `SipSession` and `SipApplicationSession` in order to synchronize the "last access timestamp" with the peer containers in the cluster. This is for the integrity of future calls to `SipSession.getLastAccessedTime()`, and `SipApplicationSession.getLastAccessedTime()`

Replication can occur for requests that do not establish a dialog if an application calls `request.getApplicationSession(true)` and if `addTimer()` and/or `addAttribute()` are called on the resulting application session object. This is needed so that a listener can be called when the timer expires.

### SIP failover and replication setup considerations

A SIP cluster that requires replication and failover can consist of many replication domains, each of which contain a set of SIP containers. There is no limit set on the number of containers in a cluster. For performance reasons, each replication domain should contain only two containers.

The replication domain should be set to the Entire Domain, which means state is replicated to all containers in the replication domain. The replication mode should be Both client and server.

The distributed session for a container needs to be set to Memory-to-memory replication. Any applications that require session replication must include the `<distributed />` tag in the `web.xml` and `sip.xml` files. Both SIP and HTTP will utilize the same replication topology

Make sure that your system is configured such that:

- Your system includes at least 2 controllers, and each controller has at least 2 servants for failover and recovery purposes.

- The total workload, which includes normal operation calls, failover calls, and recovery calls, must never exceed the maximum call rate.

To achieve the maximum number of calls per second, the following configuration settings are required:

- You are running on a z/OS Version 1 Release 10 system with High Performance FICON for System z (zHPF) enabled for fast I/O. A DS8000 DASD must also be running on this system.
- The log stream and the staging data set size definitions used when creating the log streams must be equal to or greater than 256 Megabytes (LS\_SIZE(64000) STG\_SIZE(64000)).

You can determine the maximum call rate by progressively increasing the call rates over a period of time and monitoring performance until tolerable timeout rates are achieved.

- The total amount of data propagated over all active calls does not exceed 2 GB.
- All nodes are at the Version 7.0.0.7 or later level before you enable SIP or Communications Enabled Applications (CEA) work on z/OS.
- Other services that require data persistence, such as transactions, and compensations are configured to use HFS file logging if you plan on using your system for SIP or CEA related work. After you configure your system for SIP or CEA related work, other services that require data persistence cannot use log streams.

You must also delete and re-create the log stream for a server if any of the following situations occur:

- All of the controllers within a cluster fail at the same time. In this situation, some of the data that is needed to perform the recovery is lost because of the multiple concurrent failures.
- A failure occurs during the recovery process. In this situation, the log stream associated with the failed sessions contains incomplete data.

### **SIP session replication topology**

- Each member replicates all state data to every peer in its replication domain.
- Each replication domain should ideally contain two servers.
- When a failure occurs, the core group coordinator tells the remaining core group members which replicated sessions to activate. These replicated sessions then become part of their active sessions.

Complete the following steps to set up a replication domain for SIP sessions.

### **Procedure**

1. In the administrative console, click **Environment > Replication domains > New**
2. Click **Number of replicas**, and then select **Entire domain**.
3. In the Container settings section, click **Session management**.
4. In the Additional Properties section, click **Distributed environment settings**, and then click **Memory-to-memory replication**.
5. Set **Replication mode** to **Both client and server**.
6. Save your changes.

### **Results**

Memory-to-memory replication is enabled for SIP sessions.

## **Configuring SIP application routers**

Use the Session Initiation Protocol (SIP) application router to select the order in which SIP applications are triggered. When configuring a SIP application router, you can either use the default application router or create a custom application router.

## About this task

The SIP container provides an application router component called the Default Application Router (DAR). The DAR component uses a configuration text file, similar to a Java properties file, that defines the order in which the application router sends SIP requests to applications.

**Restriction:** WebSphere Application Server has a default way of sorting the order of SIP applications invocation using the Startup behavior settings. The sorting order is based on the application weight. This weighting policy only applies if you do not specify a DAR configuration file, or if a custom application router has not been associated with the server or cluster.

You can either use the DAR or a custom application router to perform application routing, as described in the procedure.

Use the following procedure to select the best method to implement the SIP application router for your configuration.

### Procedure

- Use the DAR component with a DAR configuration file.
  1. In the administrative console, click **Environment > SIP application routers**. The table displays a list of available application routers, including the DAR component.
  2. Click the **DefaultSIPApplicationRouter** link.
  3. View the list of server and cluster targets that are associated with the application router in the **Targets** table.
  4. Targets may or may not be available. To change the target of an application router, go back to the SIP application routers panel, click on a router name, and check to see if a target is listed. If a target is listed, select a target and then click the **Move to Application Router** button. The drop-down menu lets you select another application router.
  5. For the **DefaultSIPApplicationRouter**, click a target link name to set the application routing configuration for the target.
  6. Click **Advanced application routing rules (DAR configuration)** to use a DAR configuration file, and click **Apply**.
  7. Click **Configure routing rules** to view or edit the routing rules.
  8. If you have an existing DAR configuration file, you can click the **Import...** button to upload the new DAR configuration file. The **File Import** window is displayed, which allows you to browse to the file and upload it; then click the **Import** button.
  9. Use the **New**, **Delete**, **Move up**, and **Move down** buttons on the **DAR Configuration File** page to create and modify routing rules.
  10. Click **Save** directly to the master configuration and then restart server or cluster to pick up the changes.
- Use the DAR component with manual application ordering.
  1. In the administrative console, click **Environment > SIP application routers**. The table displays a list of available application routers, including the DAR component.
  2. Click the **DefaultSIPApplicationRouter** link.
  3. View the list of server and cluster targets that are associated with the application router in the Targets table.
  4. Targets may or may not be available. To change the target of an application router, go back to the SIP application routers panel, click on a router name, and check to see if a target is listed. If a target is listed, select a target and then click the **Move to Application Router** button. The drop-down menu lets you select another application router.
  5. For the **DefaultSIPApplicationRouter**, click a target link name to set the application routing configuration for the target.

6. Click **Basic application startup order** to use the application order from the target; then click **Apply**.
7. Click **Configure application startup order** to view the application startup order weights for the applications on this target.
8. Enter a numerical value in the **Startup order weight** column for the application. The startup order weight determines the order in which the SIP application router sends SIP requests to applications. These values also determine the startup order of applications after a server restart. Applications with lower startup values start first.

**Restriction:** If there are two or more SIP applications bundled inside one enterprise archive (EAR) application file, the bundled SIP applications will have the same weight. If more complex routing rules are needed, a different application router method must be used.

9. Click **Update**.
10. Click **Save** directly to the master configuration and then restart server or cluster to pick up the changes.

**Attention:** The CEA samples package includes a wsadmin (Jython) script library that you can use to simplify the development and testing of scripts that automate configuration changes. For further information, see the wsadmin (Jython) scripting procedures for CEA information.

- Use a custom application router.
  1. In the administrative console, click **Environment > SIP application routers**. The table displays a list of available application routers, including the DAR component.
  2. Select a custom SIP application router from the list, or click **New** to create a new one. The Configuration tab shows the name of the application router and the provider name of the application router. The provider name of the application router must be set to the custom application router implementation fully qualified class name.
  3. Place the Java archive (JAR) file in the server class path. For example, place the JAR file in the *java\_home/lib/ext* directory, and ensure this directory is included in the class path for the server.

**gotcha:** Do not add this path to the **Servers > Server Types > Websphere application servers > server\_name > Sip Container > Java and Process Management > Process Definition > Java Virtual Machine > Classpath** entry, because this can cause conflicts.

4. Enter or edit the information in the required fields as needed. The required fields are identified with an asterisk (\*).
5. Click **Apply** and then click **Save** directly to the master configuration.
6. To change the target of an application router, click on a router name, and check to see if a target is listed. If a target is listed, select a target and then click the **Move to Application Router** button. The drop-down menu lets you select another application router.
7. Click **Save** directly to the master configuration and then restart server or cluster to pick up the changes.

**Attention:** The CEA samples package includes a wsadmin (Jython) script library that you can use to simplify the development and testing of scripts that automate configuration changes. For further information, see the wsadmin (Jython) scripting procedures for CEA information.

- Use custom properties to configure the SIP application router. You can use the following custom properties to configure a DAR or a custom application router. These custom properties override the administrative console settings.
  1. In the administrative console, click **Servers > Server Types > WebSphere application servers > server\_name**.
  2. Under **Container Settings**, expand **SIP Container Settings** and click **SIP container**.
  3. Under **Additional Properties**, click **Custom properties**, then click **New**.

4. For the DAR, use the **javax.servlet.sip.ar.dar.configuration** custom property. This property specifies the location of the DAR properties file that defines the order in which the application router sends SIP requests to applications as described in Appendix C of the JSR 289 specification.
5. For the custom application router, use the **javax.servlet.sip.ar.spi.SipApplicationRouterProvider** custom property. This property specifies the custom application router implementation fully qualified class name as described in section 15.4.2 of the JSR 289 specification. The custom application router implementation class defines the order in which the application router sends SIP requests to applications.
6. Click **Save** directly to the master configuration and then restart server or cluster to pick up the changes.

## Results

You have successfully configured a SIP application router.

### SIP application router collection

Use this page to create and delete SIP application routers. The Session Initiation Protocol (SIP) application router allows you to select the order in which SIP applications are run at an initial SIP request.

To view this administrative console page, click **Environment > SIP application routers**. The table displays a list of available application routers, including the default application router (DAR).

#### **New:**

Click **New** to create a new SIP application router.

On the Configuration tab, specify the following required fields. Click **Apply** to save the entry or **Reset** to clear.

- **SIP application router name** – Specify a logical name for the application router.
- **SIP application router provider name** – Specifies the provider name of the application router. This is defined in the custom application router jar file, which must be in the application server's classpath.

#### **Delete:**

To delete a listed application router, select it, then click **Delete**. The DefaultSIPApplicationRouter cannot be deleted.

#### **SIP Application Router Name:**

Specifies the SIP application router name that you entered on the Configuration tab or the Default SIP Application Router.

### SIP application router settings

Use this page to configure SIP application router container settings. The Session Initiation Protocol (SIP) application router allows you to select the order in which SIP applications are triggered. You can use the default application router (DAR) or specify a custom application router adhering to the SIP Servlet specification.

To view this administrative console page, click **Environment > SIP application routers**, then click *SIP\_application\_router\_name* from the list displayed.

#### **SIP application router name:**

Enter a logical name representing the application router. If you selected the default application router, this field cannot be edited.

### ***SIP application router provider name:***

Specifies the provider name of the application router. This is defined in the custom application router jar file, which must be in the application server's classpath. This field is not visible when you edit the DAR.

### ***Targets:***

Specifies a list of server and cluster targets that are associated with an application router. By default, all servers and clusters defined in the system are listed as targets of the DAR. Each target can only be associated with one application router. For the DAR, you can also set the order in which the applications are run on each target.

### ***Move to Application Router:***

Specifies the **Move to Application Router** button, which allows you to change the targets of an application router. Each application router can have a set of targets to choose from. Click this button to move the selected target to another application router.

### ***Target:***

Specifies the target associated with an application router. Click the target name to view more information about the target server, such as whether to use a DAR configuration file or to specify the application order.

### ***Full name:***

Specifies the full name of the target. This can be helpful to distinguish each target. For example, if you have multiple targets named "server1" on different nodes, you can tell them apart by looking at the **node=** part of the Full Name.

### ***Application routing order settings:***

Use this page to specify whether the Default SIP Application Router (DAR) must rely on the basic application startup order or advanced application routing rules (DAR configuration).

To view this administrative console page, click **Environment > SIP application routers > DefaultSIPApplicationRouter > target**.

#### *Basic application startup order:*

Specifies to use application startup order weights to determine the application routing order.

Click the link to go to the Startup order page where you can specify the application order weight for each application on the target server. Lower weighted values take precedence.

#### *Advanced application routing rules (DAR configuration):*

Specifies to use routing rules when determining the application routing order.

Click the link to go to the DAR configuration file rules page where you can edit, import, or view the rules to be used by the SIP application router for this target server.

### ***Application startup order settings:***

Use this page to define the order in which Session Initiation Protocol (SIP) requests are routed to applications.

To view this administrative console page, click **Environment > SIP application routers > DefaultSIPApplicationRouter > target > Configure application startup order**.

*Startup order weight:*

Specifies to manually order the installed applications using the Startup Weight column in the Application order table.

The Startup order weight determines the order in which the SIP application router sends SIP requests to applications. These values also determine the startup order of applications after a server restart. The lower values start first.

*Application name:*

Specifies the name of the SIP application whose startup order weight you can modify.

### ***SIP container custom properties:***

You can add any of the following custom properties to the configuration settings for a Session Initiation Protocol (SIP) container.

To specify custom properties for a specific SIP container, navigate to the custom properties page, and then specify a value for the custom property.

**Important:** The custom properties are supported as the primary method of configuration. Therefore, if a custom property is set and then you set the corresponding setting in the administrative console, the custom property value is used.

1. In the administrative console, expand **Servers > Server Types > WebSphere application servers > server\_name** to open the configuration tab for the server.
2. From **Container settings**, expand **SIP Container settings**, and click **SIP container**.
3. From **Additional properties**, select **Custom Properties > New**.
4. On the settings page, type the custom property to configure in the **Name** field, and then type the value of the custom property in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

The following list of SIP container custom properties is provided with the product. These properties are not shown on the settings page for the container.

You can define the following SIP container custom properties that are provided with the product. These properties are not shown on the settings page for the container.

- “auth.int.enable” on page 2592
- “com.ibm.sip.sm.lnm.size” on page 2592

- “thread.message.queue.max.size” on page 2603
- “weight.overload.watermark” on page 2603

*auth.int.enable:*

Specifies the **auth-int** quality of protection (QOP) for digest authentication. Digest authentication defines two types of QOP: **auth** and **auth-int**. By default, **auth** is used. When this custom property is set to True, the highest level of protection is used, which is the **auth-int** QOP.

<b>Data type</b>	String
<b>Default</b>	False

*com.ibm.sip.sm.lnm.size:*

Specifies the number of logical names in the application server. Each SIP object that can be replicated, such as a SIP session, is associated with a logical name. All objects with the same logical name are replicated to the same back-up container. The proxy can route messages to the correct container using the logical name found in the message. The value must be greater than 1.

<b>Data type</b>	String
<b>Default</b>	10

*com.ibm.websphere.sip.security.digest.ldap.cachecleanperiod:*

Specifies the clean Lightweight Directory Access Protocol (LDAP) cache period in minutes.

<b>Data type</b>	String
<b>Default</b>	120

*com.ibm.websphere.sip.security.tai.usercachecleanperiod:*

Specifies the clean security subject cache period in minutes.

<b>Data type</b>	String
<b>Default</b>	15

*com.ibm.ws.sip.key.set:*

Specifies the key to use for SIP flow token security. When a value is specified for this property, SIP flow token security is automatically enabled.

<b>Data type</b>	String
<b>Default</b>	There is no default value

*com.ibm.ws.sip.tai.DisableSIPBasicAuth:*

Specifies whether to allow basic authentication for SIP.

<b>Data type</b>	String
<b>Default</b>	False

*DigestPasswordServerClass:*

Specifies types of user registries that are supported, except LDAP. To configure DigestTAI without the LDAP user registry, complete the following steps.

1. Create a class that implements this interface: `com.ibm.ws.sip.security.digest.DigestPasswordServer`
2. Add the following property to the SIP container custom property:  
Default `LdapPasswordServer`
3. Ensure that all users declared by the impl class are declared in the user registry configured for the product security.

<b>Data type</b>	String
<b>Default</b>	impl

*enable.system.headers.modify:*

Specifies whether the application has access to headers that are otherwise restricted.

<b>Data type</b>	String
<b>Default</b>	False

*end.of.service.replication:* Specifies whether changes are buffered until the thread for a siplet is about to end. If the value is set to `true`, then each change is buffered until the thread for the siplet is about to end.

<b>Data type</b>	Boolean
<b>Default</b>	true

*immediate.replication:* Specifies whether each change is immediately sent to the Data Replication Service. When this property is set to `true`, when replication is issued from a non-SIP container thread, the replication is immediately performed on the calling thread. When this property is set to `false`, the changes are buffered, and replication does not occur until all changes are made.

Setting this property to `true` might have a negative impact on performance.

<b>Data type</b>	Boolean
<b>Default</b>	false

*javax.servlet.sip.ar.dar.configuration:*

Specifies the location of the default application router (DAR) properties file. The properties file defines the order in which the application router sends SIP requests to applications as described in Appendix C of the JSR 289 specification.

<b>Data type</b>	String
<b>Default</b>	Null

*javax.servlet.sip.ar.spi.SipApplicationRouterProvider:*

Specifies the custom application router implementation fully qualified class name as described in section 15.4.2 of the JSR 289 specification. The custom application router implementation class defines the order in which the application router sends SIP requests to applications.

<b>Data type</b>	String
<b>Default</b>	Null

*javax.sip.bind.retries:*

Specifies the amount of time, in milliseconds, between attempts to start the SIP channel if the SIP port is busy with another process during server startup.

<b>Data type</b>	String
<b>Default</b>	60

*javax.sip.bind.retry.delay:*

Specifies the delay, in milliseconds, between attempts to start the SIP channel if the SIP port is busy with another process during server startup.

<b>Data type</b>	String
<b>Default</b>	5000

*javax.sip.detect.pre.escaped.params:*

Specifies whether to prevent the container from re-escaping Uniform Resource Identifier (URI) parameters that were pre-escaped by the application.

Enabling this property provides the application with more control over escaping URI parameters, when calling the **javax.servlet.sip.SipFactory.createURI()** and the **javax.servlet.sip.SipURI.setParameter()** parameters.

By default, the container only escapes characters that it must encode according to the RFC 3261 25.1 specification. In some cases, however, escaping additional characters might be required. Due to a limitation in the JSR 116 (5.2.1) specification, the application cannot perform its own escaping. Because of this limitation, attempts by the application to encode URI parameters causes the container to re-encode the percent sign. If the value of this property is set to true, the container cannot re-encode the percent sign.

Setting the value to true is not in compliance with the JSR 116 (5.2.1) specification, but provides the application with greater control over URI parameter escaping. APAR PK37192 describes the problem and the workaround.

<b>Data type</b>	String
<b>Default</b>	False

*javax.sip.force.connection.reuse:*

Specifies whether to force reuse of inbound connections for outbound requests. This custom property is only relevant for stream transports, such as Transmission Control Protocol (TCP) and Transport Layer Security (TLS). Disabling this property causes the container to create a separate connection for outbound requests, even if an existing connection is already established to the same peer address. The connection is automatically reused if the top Via header in the inbound request contains an alias parameter. (<http://www.ietf.org/internet-drafts/draft-ietf-sip-connect-reuse-07.txt>)

<b>Data type</b>	String
<b>Default</b>	False

**depreat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.hide.message.body:*

Specifies to hide message content in logs. Set the value of this property to true to remove the message body text from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

<b>Data type</b>	String
<b>Default</b>	False

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.hide.message.headers:*

Specifies to hide the specified message header field names in log files. The value of this property is a comma-separated list of header field names that you want removed from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

<b>Data type</b>	String
<b>Default</b>	None

*javax.sip.hide.request.uri:*

Specifies to hide request URIs in log files. Set the value of this property to true to remove request URIs from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

<b>Data type</b>	Boolean
<b>Default</b>	False

*javax.sip.OUTBOUND\_PROXY:*

Specifies the fixed address for routing all outbound SIP messages. The format is *address:port/transport*, such as 1.2.3.4:5065/tcp.

**Note:** Do not use this property if the container is fronted by an application server SIP proxy.

<b>Data type</b>	String
<b>Default</b>	null

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.PATH\_MTU:*

Specifies the maximum transmission unit, in bytes, for outbound User Datagram Protocol (UDP) requests. The SIP stack measures the size of a request before sending it out on the UDP channel. If the request is larger than the value specified for **PATH\_MTU-200** (1300 bytes by default), then the transport is switched

from UDP to TCP before transmission. Increase this value to send larger requests over the UDP channel; however, messages might be truncated or dropped. See the RFC 3261-18.1.1 specification for details.

<b>Data type</b>	String
<b>Default</b>	1500

**deprecat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.stat.report.interval:*

Specifies the amount of time, in milliseconds, for reporting dispatch and timer statistics to a system.out file. A value of zero indicates no report.

<b>Data type</b>	String
<b>Default</b>	0

*javax.sip.trace.msg.in:*

Specifies whether to print incoming messages to a system.out file.

<b>Data type</b>	String
<b>Default</b>	False

*javax.sip.trace.msg.out:*

Specifies whether to print outbound messages to a system.out file.

<b>Data type</b>	String
<b>Default</b>	False

*javax.sip.transaction.invite.auto100:*

Specifies whether to automatically reply to invite requests with a 100 Trying response. Disabling this property might increase the number of invite retransmissions.

<b>Data type</b>	String
<b>Default</b>	True

**deprecat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.a:*

Specifies, for UDP only, the amount of time, in milliseconds, before retransmitting invite requests for timer A for the RFC 3261 specification. This property is relevant for the invite client transaction.

<b>Data type</b>	String
<b>Default</b>	javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.b:*

Specifies the amount of time, in milliseconds, for the invite client transaction timeout timer (timer B) for the RFC 3261 specification.

<b>Data type</b>	String
<b>Default</b>	64*javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.cancel:*

Specifies the amount of timer, in milliseconds, for the timer to keep the cancelled client transaction in the proceeding state before completing the cancelled transaction for the RFC 3261 9.1 specification. This property is relevant for the invite client transaction.

<b>Data type</b>	String
<b>Default</b>	64*javax.sip.transaction.timer.t1

*javax.sip.transaction.timer.d:*

Specifies the wait time, in milliseconds, before retransmission of the invite response for timer D for the RFC 3261 specification. This property is relevant for the invite client transaction.

<b>Data type</b>	String
<b>Default</b>	32000

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.e:*

Specifies, for UDP only, the amount of time, in milliseconds, before the retransmission of the initial non-invite request for timer E for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

<b>Data type</b>	String
<b>Default</b>	javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.f:*

Specifies the amount of time, in milliseconds, for the non-invite transaction timeout timer (timer F) for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

<b>Data type</b>	String
<b>Default</b>	64*javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.g:*

Specifies the amount of time, in milliseconds, before retransmission of an initial invite response for timer G for the RFC 3261 specification. This property is relevant for the invite server transaction.

<b>Data type</b>	String
<b>Default</b>	javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.h:*

Specifies the amount of time, in milliseconds, to wait for an acknowledgement (ACK) receipt for timer H for the RFC 3261 specification. This property is relevant for the invite server transaction.

<b>Data type</b>	String
<b>Default</b>	64*javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.i:*

Specifies the amount of time in milliseconds to wait for an ACK retransmission for timer I for the RFC 3261 specification. This property is relevant for the invite server transaction.

<b>Data type</b>	String
<b>Default</b>	javax.sip.transaction.timer.t4

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.invite.server:*

Specifies the amount of time, in milliseconds, for the timer to keep the invite server transaction in the complete state. This timer is not defined in the RFC specification.

To avoid creating a new server transaction when a client retransmits an invite request, keep the completed server transaction for a period of time before removing invite retransmissions. This timer is started when the transaction changes to the terminated state. When the timer completes, the transaction is removed.

<b>Data type</b>	String
<b>Default</b>	32000

*javax.sip.transaction.timer.j:*

Specifies the amount of time in milliseconds to wait for non-invite request retransmission for timer J for the RFC 3261 specification. This property is relevant for the non-invite server transaction.

<b>Data type</b>	String
<b>Default</b>	64*javax.sip.transaction.timer.t1

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.k:*

Specifies the amount of time, in milliseconds, to wait for non-INVITE response retransmissions for timer K for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

<b>Data type</b>	String
<b>Default</b>	javax.sip.transaction.timer.t4

**deffeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.non.invite.server:*

Specifies the amount of time, in milliseconds, for an Application Programming Interface (API) timer for the application to respond to a non-invite request. This property is relevant for non-invite server transactions.

This timer is not defined in the RFC specification. This property is needed to stop the transaction if the application does not generate a final response to the request. The timer starts when the request arrives in the stack and stops when a response is generated by the application. If no response is generated before the timer stops, then the transaction completes.

<b>Data type</b>	String
<b>Default</b>	34000

*javax.sip.transaction.timer.t1:*

Specifies the amount of time, in milliseconds, for a network round trip delay for timer T1 for the RFC 3261 specification. The value is used as a base for calculating some timers and is relevant for all types of transactions, such as client, server, invite, and non-invite transactions.

<b>Data type</b>	String
<b>Default</b>	500

**deffeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.t2:*

Specifies the maximum time in milliseconds before retransmitting non-invite requests and invite responses for timer T2 for the RFC 3261 specification.

<b>Data type</b>	String
<b>Default</b>	4000

**deffeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*javax.sip.transaction.timer.t4:*

Specifies the maximum amount of time, in milliseconds, for a message to remain in the network. This value is used as a base for calculating other timers for timer T4 for the RFC 3261 specification.

<b>Data type</b>	String
<b>Default</b>	5000

**defeat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*on.outgoing.message.replication:* Specifies whether changes are buffered until a siplet issues a request.send() or response.send() call. If the value is set to true, then each change is buffered until a siplet issues a request.send() or response.send() call.

<b>Data type</b>	Boolean
<b>Default</b>	false

*pws\_atr\_name:*

Specifies the LDAP attribute name that stores the user password.

<b>Data type</b>	String
<b>Default</b>	userpassword

*replicate.with.confirmed.dialog.only:*

Specifies whether to replicate the application session, even when no dialogs are confirmed. If the value is set to false, then the application session is replicated immediately after the session is created. Otherwise, the application session is only replicated when an associated dialog is confirmed.

<b>Data type</b>	String
<b>Default</b>	False

*sip.container.heartbeat.enabled:*

Specifies whether or not SIP network outage detection is enabled for the SIP container. SIP network outage detection allows the SIP proxy to send keepalive messages to the SIP container if the value of this property is set to true.

If the value is set to false for the SIP container, then this property has no effect on the SIP proxy. However, if the value is set to true for the SIP container, the value should also be set to true for the SIP proxy to ensure that keepalive messages are answered at the SIP container and not presented to the application.

<b>Data type</b>	String
<b>Default</b>	true

*sip.jsr289.parse.address:*

Specifies to use the SIP Servlet Specification 1.1, JSR 289 required format for `createRequest()` and `createAddress()` methods.

**Note:** The JSR 289 API requires that for any SIP URI that contains address parameters, you must enclose the SIP URI in angle brackets. The default behavior of the `sip.jsr289.parse.address` property is compliant with JSR 289 and correctly parses the address parameter as if it belongs to the SIP address. For example, when the property is set to `false`, the SIP address, `sip:fred@acme.com;param1=1`, is converted to `<sip:fred@acme.com;param1=1>`. When the property is set to `true`, the SIP address `sip:fred@acme.com;param1=1`, is converted to `<sip:fred@acme.com;>param1=1`.

<b>Data type</b>	String
<b>Default</b>	True

*SIP\_RFC3263\_nameserver:*

Specifies whether to allow a SIP URI to be resolved through Domain Name System (DNS) into the IP address, port, and transport protocol of the next hop.

The value of the property is a string containing one or two address and port tuples, where two tuples are separated by a space. The following examples specify a one address and port tuple or a two address and port tuple.

dottedDecimalAddress@.port  
hostname.domain@port  
IPV6address@port

The following example values represent a single tuple.

- 1.2.3.4@53
- example.com@53
- a:b:c::d@53

The following example values represent two tuples separated by a space.

- 1.2.3.4@53 example.com@53
- a:b:c::d@53 9.32.211.14@53

<b>Data type</b>	String
<b>Default</b>	null

**deprecat:** This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

**mixv:** If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

*thread.message.queue.max.size:*

Specifies the maximum number of events allowed in the container threads queue. When this number is exceeded, the proxy server is notified that the container is overloaded and requests for new sessions are not accepted. Instead, the container returns an error message that indicates that the container is temporarily unavailable.

This value represents the total number of messages for all queues and reflects the state of the CPU. When the CPU approaches 100%, the maximum value for this custom property is reached quickly. Configure your system to limit the queue size and prevent the queue from reaching this threshold.

**Data type** String  
**Default** 1000

*weight.overload.watermark:*

Specifies the threshold value for the internal weight calculated by the container. When the container calculates the internal weight to be higher than the value specified, an overloaded container becomes available for service again.

This custom property represents a percentage of the maximum internal weight, such as 30 percent when the default value is set. When the high-water mark, or maximum threshold, is exceeded, the container waits until the weight drops below the maximum weight. This value cannot exceed 10.

**Data type** String  
**Default** 3

**Default application router rule collection:**

Use this page to view or modify default application router (DAR) routing rules or import a new DAR configuration file. The DAR is a Session Initiation Protocol (SIP) application router that you can use to select the order in which SIP applications are triggered.

To view this administrative console page, click **Environment > SIP application routers > DefaultSIPApplicationRouter > target > Configure routing rules.**

The DAR configuration file contains the routing definitions for the application routing order of the DAR. You can upload a new DAR configuration file and view the definitions in the existing DAR configuration file. You can also use the New, Delete, Move up, and Move down buttons to edit rules individually. Use the **Method** menu list to filter the list of displayed rules by method name. Select **All Methods** to view all rules currently in the DAR configuration file.

*Table 237. Button descriptions. This table shows button descriptions.*

Button	Resulting action
<b>New</b>	Click to add a new DAR rule.
<b>Delete</b>	Click to delete the selected rules.
<b>Move Up / Move Down</b>	Click to move the selected rule up or down in the list of rules. Rules must remain grouped by the method name; rules only move up or down within the method group. For example, if you try to move up an INVITE method, but the previous method is an ACK method, then this INVITE method is already at the top of the INVITE method group, and cannot move any higher.
<b>Import</b>	Click to open the file import window. Browse to the new DAR configuration file.  <b>Attention:</b> Importing a new configuration file overwrites all existing rules.

*Method:*

Specifies the name of the SIP method used in the request.

*Application:*

Specifies the name of the application that the application router sends the SIP request to.

***Subscriber identifier:***

Specifies the identity of the subscriber that the DAR returns. The DAR can return any header in the SIP request. For example, if you specify `DAR:From`, the SIP URI is returned in the From header. The DAR can also return any string.

***Routing region:***

Specifies the routing region, which can be any of the following strings:

- ORIGINATING
- TERMINATING
- NEUTRAL

***Route modifier:***

Specifies the route modifier, which can be any of the following values:

- ROUTE
- ROUTE\_BACK
- NO\_ROUTE

## **Default application router rule settings**

Use this page to edit the details of an application router rule.

To view this administrative console page, click **Environment > SIP application routers > DefaultSIPApplicationRouter > target > Configure routing rules**. Select a routing rule to edit or click **New**.

Routing rules are used to determine how the default SIP application router routes SIP requests to the installed applications.

***Method:***

Specifies the name of the SIP method in the request.

Select a method from the existing method list, or specify a new method name.

***Application:***

Specifies the name of the application that the application router sends the request to.

***Subscriber identifier:***

Specifies the identity of the subscriber that the DAR returns. The DAR can return any header in the SIP request. For example, if you specify `DAR:From`, the SIP URI is returned in the From header. The DAR can also return any string.

Select a subscriber identifier from the list of existing identifiers, or specify a new subscriber identifier name.

***Routing region:***

Specifies the routing region, which can be any of the following strings:

- ORIGINATING
- TERMINATING

- NEUTRAL

**SIP URI:**

Specifies the SIP URI that indicates the route as returned by the application router. This value can be an empty string.

**Route modifier:**

Specifies the route modifier, which can be any of the following values:

- ROUTE
- ROUTE\_BACK
- NO\_ROUTE

**State info:**

Specifies the stateInfo object, which the application router uses internally. For more information about this value, see the SIP servlet specification.

## Configuring multihomed hosting

The SIP container can accept from the SIP proxy a list of outbound interfaces and expose it to any SIP application.

### Before you begin

Multihomed hosting is configured at the WebSphere SIP proxy after the multihomed environment is set up. The multihome topology may include setting up multiple networks (routers, switches, etc.), multiple load balancers (if more than one proxy server needs to be configured for each virtual IP), and multiple network cards on each of the available proxy servers. After you install the network cards and configure the loopback addresses, set up a separate SIP proxy channel chain in each SIP proxy for each available network interface.

**Attention:** You can only configure the SIP proxy server to support multiple interfaces. The SIP container does not support this capability.

### About this task

Multihoming allows you to have a single application communicate with different user agent clients (UAC) and user agent servers (UAS) on different networks.

The application queries the SIP container to determine the list of available outbound interfaces using standard procedures defined by JSR 289. This is done through a context attribute that is maintained in the container (through protocol exchanges with all the available SIP proxies). This attribute is `javax.servlet.sip.SipServlet.OUTBOUND_INTERFACES`, which is defined to be `javax.servlet.sip.outboundInterfaces`. This attribute contains all the available interfaces. The sample code in the Example section shows how to access the attribute from the application.

After the interfaces on each SIP proxy are configured, follow the steps in the procedure to control the routing of outbound messages. If more than one proxy is being used, it is important that each proxy be configured identically.

When an application does not specify an interface to use for sending outbound requests, the default interfaces are used by the proxy. It is recommended that you set the default interfaces for every protocol. See step 5 for more information.

The administrator can optionally set three SIP proxy custom properties that define the chain name that define the appropriate interface to use if the SIP application does not call the `setOutboundInterface` method. If these custom properties are not set and the `setOutboundInterface` method is not used, the interface that will be used for outbound requests cannot be definitively determined.

The following procedure applies to a topology that contains a single proxy setup for multihomed hosting with more than one network interface.

## Procedure

1. In the administrative console, expand **Servers > Server Types** and click **WebSphere proxy servers > proxy\_name**.
2. Under **Proxy Settings**, expand **SIP Proxy Server Settings** and click **SIP proxy server transports**.
3. On the Transport Chain panel, delete existing transport chain or chains that contain proxy host names that use an asterisk (\*).
4. Add new transport chain names and specify the IP address or host name associated with the interface that the chain is configured to use. Proxy multihomed configurations require you to configure a transport for each proxy interface. When using proxy servers with a load balancer, ensure a transport for TCP exists along with the desired transport type for SIP traffic. For example, when a proxy server uses two interfaces, then a minimum of six proxy transport chains are required. Each proxy interface will have a UDP transport chain (2) configured using the load balancer cluster alias IP address, TCP transport chain (2), and specific transport chain (2) of desired protocol (UDP, TLS, etc.) to run SIP traffic.
  - a. On the Transport chain panel, click **New**. The Create New Transport Chain wizard initializes. During the transport chain creation process, add a unique Transport chain name and select the proxy protocol template (UDP, TCP, or Secure) from the Transport chain template menu.
  - b. Click **Next**.
  - c. Select the **Use existing port** or **Create a new port** option. For new ports, provide the port name, host name, and port number. For the Host value, specify the IP address or specific host name. Do not use an asterisk (\*) for the Host value.
  - d. Click **Next** for Step 2.
  - e. Review the summary of actions and click **Finish** for Step 3.
  - f. At the top of the panel, click **Save** to save the changes to the master configuration and resynchronize with the nodes, if applicable.
5. Specify the default chain name to use on the proxy server. From the SIP proxy settings panel, custom properties can be set up to specify the appropriate default interface for each protocol. These interfaces are used to send outbound requests when an application does not specify which interface to use.
  - a. In the administrative console, expand **Servers > Server Types** and click **WebSphere proxy servers > proxy\_name**.
  - b. Under **Proxy Settings**, expand **SIP Proxy Server Settings** and click **SIP proxy settings > Custom properties**.
  - c. Enter the appropriate chain name previously configured in step 4 (not the interface or host name) to configure the transports section of the SIP proxy settings. There is one custom property for each transport type.

Custom Property Name	Description
<b>defaultUDPChainName</b>	The default UDP chain name to use when <code>setOutboundInterface</code> is not called.
<b>defaultTCPChainName</b>	The default TCP chain name to use when <code>setOutboundInterface</code> is not called.
<b>defaultTLSChainName</b>	The default TLS chain name to use when <code>setOutboundInterface</code> is not called.

6. Recycle the proxy server.

## Results

You have successfully configured SIP multihomed hosting, which enables your applications to route outbound SIP requests through more than a single outbound interface.

## Example

The following sample code demonstrates how to acquire the available outbound interfaces and set the appropriate outbound interface on the session object.

```
....
import javax.servlet.sip.SipServlet;
import javax.servlet.sip.SipSession;
....

protected void doInvite(SipServletRequest req1) throws ServletException, IOException
{
 ...
 // This block of code handles setting of the outbound interface.
 SipSession sipSession = req1.getSession();
 javax.servlet.ServletContext context = getServletContext();
 java.util.List list = (java.util.List)context.getAttribute(javax.servlet.sip.SipServlet.
OUTBOUND_INTERFACES);
 SipURI uri = getProtocolInterface ("udp", list);

 if (uri != null)
 {
 InetAddress inetSocketAddr = new InetAddress(uri.getHost(), uri.getPort());
 sipSession .setOutboundInterface(inetSocketAddr);
 }
 ...
}

// This method simply pulls out the first interface in the list for the specified protocol
private SipURI getProtocolInterface(String transport, List outboundInterfaceList)
{
 SipURI uri = null;
 Iterator iterator = outboundInterfaceList.iterator();

 while (iterator.hasNext())
 {
 SipURI tempUri = (SipURI)iterator.next();

 if (tempUri.getTransportParam().equals(transport) == true)
 {
 uri = tempUri;
 break;
 }
 }

 return (uri);
}
```

### ***Multihomed hosting:***

SIP can support the ability to route outbound SIP requests through more than a single interface with the multihomed host feature of JSR 289.

In a multihomed host environment, the SIP container has the ability to select a particular outbound interface for routing messages. The SIP container can accept from the SIP proxy a list of outbound interfaces and expose it to any SIP application. This functionality is for applications that require tighter control over the outgoing request flow.

The following two methods can be used to select the outbound interface to use when sending requests, as defined in section 14.2 of the JSR 289 specification:

- `setOutboundInterface(java.net.InetAddress address)`
- `setOutboundInterface(java.net.InetSocketAddress address)`

A SIP application can obtain a list of available SIP URIs it can send outbound requests on from the ServletContext attribute "javax.servlet.sip.outboundInterfaces," which is defined with the static string `javax.servlet.sip.SipServlet.OUTBOUND_INTERFACES`.

The application must set the interface on the Proxy, the ProxyBranch, or the SipSession objects before any outbound requests are sent. The interface is passed back in the attribute for outbound interfaces. The container then notifies the proxy which interface to send the outbound request on. Routing of non-request messages is controlled by other means, such as headers. For instance, a response message always flows through the same interface that the request arrived on.

Modifying the outbound routing of a request can affect all of the following SIP headers that are inserted into the outgoing SIP request, and subsequent responses in the dialog:

- Via header
- Contact headers
- Record-Route and Route headers
- Path header

Three SIP proxy custom properties specify the default chain names that define the appropriate interface to use for outbound requests. See the information on configuring multihomed hosting.

SIP with multihomed host is only supported in a distributed environment and must be configured at the WebSphere SIP proxy. A stand-alone SIP container does not support this capability.

## Configuring multiple proxy servers using a load balancer in a multihomed environment

You can configure multiple proxy servers with multiple network interfaces using a load balancer in a multihomed environment.

### Before you begin

Communications Enabled Applications (CEA) enables you to have multiple network interfaces on multiple proxy servers using a load balancer.

In a multihome environment, you need to define multiple virtual IP (VIP) alias addresses at the proxy server, and you need to define the proxy transport chains for each VIP alias address.

**Note:** Do not use an asterisk (\*) for the transport chain names. Instead, use host names and IP addresses for the transport chains.

### About this task

The following setup includes configuring a load balancer with two clusters, and two proxy servers with two VIP alias addresses defined. Ensure that the following steps are repeated for both proxy servers.

### Procedure

1. In the administrative console, expand **Servers > Server Types** and click **WebSphere proxy servers > proxy\_name**.
2. Under **Proxy Settings**, expand **SIP Proxy Server Settings** and click **SIP proxy settings**.

3. Under Load balancer health checking, set the Load balancer members for IP address 1 and IP address 2. The IP address of the load balancer is used to source the SIP health checks.
4. Under Container facing network interface, specify the User Datagram Protocol (UDP) interface. The UDP interface specifies the network interface for all UDP data that goes to and from the backend SIP containers.
5. Click **Custom properties** and set the default protocol chain name types for each protocol type (UDP, TCP, and TLS). Specify the default chain name to use on the proxy server. From the SIP proxy settings panel, custom properties can be set up to specify the appropriate default interface for each protocol. These interfaces are used to send outbound requests when an application does not specify which interface to use.
  - a. In the administrative console, expand **Servers > Server Types** and click **WebSphere proxy servers > proxy\_name**.
  - b. Under **Proxy Settings**, expand **SIP Proxy Server Settings** and click **SIP proxy settings > Custom properties**.
  - c. Enter the appropriate chain name to configure the transports section of the SIP proxy settings. There is one custom property for each transport type.

Custom Property Name	Description
<b>defaultUDPChainName</b>	The default UDP chain name to use when setOutboundInterface is not called.
<b>defaultTCPChainName</b>	The default TCP chain name to use when setOutboundInterface is not called.
<b>defaultTLSChainName</b>	The default TLS chain name to use when setOutboundInterface is not called.

6. In the administrative console, expand **Servers > Server Types** and click **WebSphere proxy servers > proxy\_name**.
7. Under **Proxy Settings**, expand **SIP Proxy Server Settings** and click **SIP proxy server transports**.
8. On the Transport Chain panel:
  - a. Add two TCP transport chains using the host name or IP address for each network interface.
  - b. Add two UDP transport chains using the host name or IP address for each network interface.
  - c. Add two UDP transport chains using the VIP alias addresses of the proxy servers so that the load balancer can communicate with the proxy servers. These two unique VIP alias addresses must be the same on both proxy servers.
9. Recycle the proxy server.

## Results

You have successfully configured multihomed network interfaces for two proxy servers using a load balancer.

---

## Chapter 25. Administering Startup beans

This page provides a starting point for finding information about startup beans.

Startup beans allow business logic to run when an application starts or stops.

---

### Using startup beans

There are two types of startup beans: application startup beans and Module startup beans.

#### About this task

**Note:** The capabilities provided with startup singleton session beans (EJB 3.1 specification) causes the WebSphere Application Server proprietary startup beans function to be deprecated.

A module startup bean is a session bean that is loaded when an EJB Jar file starts. Module startup beans enable Java Platform Enterprise Edition (Java EE) applications to run business logic automatically, whenever an EJB module starts or stops normally. An application startup bean is a session bean that is loaded when an application starts. Application startup beans enable Java EE applications to run business logic automatically, whenever an application starts or stops normally.

Startup beans are especially useful when used with asynchronous bean features. For example, a startup bean might create an alarm object that uses the Java Message Service (JMS) to periodically publish heartbeat messages on a well-known topic. This enables clients or other server applications to determine whether the application is available. Refer to the Enabling an application to wait for a messaging engine to start article if you are using the default JMS provider.

#### Procedure

1. For Application startup beans, use the home interface, `com.ibm.websphere.startupservice.AppStartUpHome`, to designate a bean as an Application startup bean. For Module startup beans, use the home interface, `com.ibm.websphere.startupservice.ModStartUpHome`, to designate a bean as a Module startup bean.
2. For Application startup beans, use the remote interface, `com.ibm.websphere.startupservice.AppStartUp`, to define `start()` and `stop()` methods on the bean. For Module startup beans, use the remote interface, `com.ibm.websphere.startupservice.ModStartUp`, to define `start()` and `stop()` methods on the bean.

The startup bean `start()` method is called when the module or application starts and contains business logic to be run at module or application start time.

The `start()` method returns a boolean value. **True** indicates that the business logic within the `start()` method ran successfully. Conversely, **False** indicates that the business logic within the `start()` method failed to run completely. A return value of `False` also indicates to the Application server that application startup is aborted.

The startup bean `stop()` methods are called when the module or application stops and contains business logic to be run at module or application stop time. Any exception thrown by a `stop()` method is logged only. No other action is taken.

The `start()` and `stop()` methods must never use the `TX_MANDATORY` transaction attribute. A global transaction does not exist on the thread when the `start()` or `stop()` methods are invoked. Any other `TX_*` attribute can be used. If `TX_MANDATORY` is used, an exception is logged, and the application start is aborted.

The `start()` and `stop()` methods on the remote interface use **Run-As** mode. **Run-As** mode specifies the credential information to be used by the security service to determine the permissions that a principal has on various resources. If security is on, the **Run-As** mode needs to be defined on all of the methods called. The identity of the bean without this setting is undefined.

There are no restrictions on what code the start() and stop() methods can run, since the full Application Server programming model is available to these methods.

3. Use an *optional* environment property integer, `wasStartupPriority`, to specify the start order of multiple startup beans in the same Java Archive (JAR) file. If the environment property is found and is the wrong type, application startup is aborted. If no priority value is specified, a default priority of 0 is used. It is recommended that you specify the priority property. Beans that have specified a priority are sorted using this property. Beans with numerically lower priorities are run first. Beans that have the same priority are run in an undefined order. All priorities must be positive integers. Beans are stopped in the opposite order to their start priority. The priority values for module startup beans and application startup beans are mutually exclusive. All modules will be started prior to the application being declared as "started" and therefore the start() methods for module startup beans within an application will be invoked prior to the start() methods for any application startup beans. Likewise, all application startup bean stop() methods for a specific Java Archive (JAR) file will be invoked prior to any module startup bean stop() methods for that JAR.
4. For module startup beans, the order in which EJB modules are started can be adjusted via the "Starting weight" value associated with each module
5. To control who can invoke startup bean methods via WebSphere Security do the following:
  - a. Define the method permissions for the Start() and Stop() methods as you would for any EJB module. (See "Defining method permissions for EJB modules".)
  - b. Ensure that the user that is mapped to the Security Role defined for the startup bean methods is the same user that is defined as the Server user ID within the User Registry.

## What to do next

View the startup beans service settings.

## Enabling startup beans in the administrative console

Enabling startup beans in the administrative console enables Java 2 Platform Enterprise Edition (J2EE) applications to run business logic automatically, whenever an application starts or stops normally.

### About this task

Use the following steps to enable startup beans in the administrative console.

### Procedure

1. Start the administrative console.
2. Select **Servers > Application Servers > *server\_name* > Container Services > Startup beans service**.
3. Select the **Enable service at server startup** check box.
4. Click **Apply** to save the configuration.

## What to do next

View the startup beans service settings.

## Startup beans service settings

Use this page to enable startup beans that control whether application-defined startup beans function on this server. Startup beans are session beans that run business logic through the invocation of start and stop methods when applications start and stop. If the startup beans service is disabled, then the automatic invocation of the start and stop methods does not occur for deployed startup beans when the parent application starts or stops. This service is disabled by default. Enable this service only when you want to use startup beans. Startup beans are especially useful when used with asynchronous beans.

**Note:** The capabilities provided with startup singleton session beans (EJB 3.1 specification) causes the WebSphere Application Server proprietary startup beans function to be deprecated.

To view this administrative console page, click **Servers > Server types > WebSphere application servers > *server\_name***. Under **Container Settings**, expand **Container Services** then click **Startup beans service**.

### Enable service at server startup

Specifies whether the server attempts to initiate the startup beans service.

**Default**  
**Range**

Cleared

**Selected**

When the application server starts, it attempts to initiate the startup bean service automatically.

**Cleared**

The server does not try to initiate the startup beans service. All startup beans do not start or stop with the application. If you use startup beans on this server, then the system administrator must start the startup beans service manually or select this property, and then restart the server.

---

## Chapter 26. Administering Transactions

This page provides a starting point for finding information about Java Transaction API (JTA) support. Applications running on the server can use transactions to coordinate multiple updates to resources as one unit of work, such that all or none of the updates are made permanent.

The product provides advanced transactional capabilities to help application developers avoid custom coding. It provides support for the many challenges related to integrating existing software assets with a Java EE environment. More introduction...

---

### Administering the transaction service

You can view or change settings for the transaction service and manage active and prepared transactions. You can configure transaction properties to enable peer recovery of failed application servers in a cluster. You can manage transaction logging to optimize the availability of application servers.

#### Procedure

- “Configuring transaction properties for an application server”
- “Configuring transaction properties for peer recovery” on page 2659
- “Managing active and prepared transactions” on page 2665
- “Displaying transaction recovery audit messages” on page 2670
- “Delaying the cancelling of transaction timeout alarms” on page 2671
- “Removing entries from the transaction partner log” on page 2671

### Configuring transaction properties for an application server

You can view or change settings for the transaction service. For example, you can change the location or default file size of the transaction log files, change transaction timeout properties, or change heuristic-related properties.

#### About this task

The transaction service is a server runtime component that can coordinate updates to multiple resource managers to ensure atomic updates of data. Transactions are started and ended by applications or the container in which the applications are deployed.

You might undertake this task when you want to move the transaction logs to a different storage device, or when you have to change the transaction service settings. You must restart the application server to make configuration changes take effect.

#### Procedure

1. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server\_name***. The properties of the application server, *server\_name*, are displayed in the content pane.
2. Click **[Container Settings] Container Services > Transaction Service**. The Transaction Service settings page is displayed.
3. Ensure that the Configuration tab is displayed.
4. Optional: To change the size of transaction log files, modify the **Transaction log directory** field to include a file size setting. Use one of the following formats, where *directory\_name* is the name of the transaction log directory and *file\_size* is the disk space allocation for the transaction log files, specified in kilobytes (*nK*) or megabytes (*nM*). The minimum transaction log file size that you can specify is 64K. If you specify a value that is less than 64K, or you do not specify a value for the file size, the default value of 1M is used.

```

;file_size <!-- This format keeps the default directory -->
directory_name;file_size
dir://directory_name/directory_name;file_size
/directory_name/directory_name;file_size

```

For a z/OS system, you might want to reduce the size of the transaction logs to ensure that they do not exceed the maximum amount of data space storage that is allocated for memory mappings. This is set through the MAXMMAPAREA parameter.

5. Optional: Increase the storage space that is used for memory mapping for transaction log files. You can modify the MAXMMAPAREA parameter, which specifies the maximum amount of data space storage, in pages, that can be allocated for memory mappings of the transaction log files. There are two transaction log files, which are named log1 and log2, and each file is allocated 1 MB. Therefore, each server needs 512 pages by default.

The following example shows how to calculate the value for the OMVS parameter, if you use the default size for log files:

```
MAXMMAPAREA = 512 x number_of_servers + (resources needed outside the application server)
```

where *number\_of\_servers* is the number of controllers that are running simultaneously, including application servers and the deployment manager, but not the node agent.

6. Optional: Disable MMAP functions. Set the com.ibm.ws.recoverylog.spi.NoMemoryMappedFiles property.

**Note:** With this option set, the behavior is the same as it was before z/OS Version 1.9. You do not need to adjust MAXMMAPAREA.

- a. From the administrative console, select **Servers > Server Types > WebSphere application servers > server\_name**.
- b. Click **[Server Infrastructure] Java and Process Management > Process Definition > Java Virtual Machine > Control > [Additional Properties] Custom Properties**.
- c. Click **New**. Enter the information for the com.ibm.ws.recoverylog.spi.NoMemoryMappedFiles property.

Name	Value
com.ibm.ws.recoverylog.spi.NoMemoryMappedFiles	true

- d. Click **OK**.
- e. Save your configuration and synchronize the changes.
7. Optional: Review or change the value of transaction timeout properties:

#### Total transaction lifetime timeout

The number of seconds to allow for a transaction that is started on this server, before the transaction service initiates timeout completion. If a transaction does not begin completion processing before this timeout occurs, it is rolled back. A value of 0 (zero) indicates that this timeout does not apply, and therefore the maximum transaction timeout is used instead. Application components can override the total transaction lifetime timeout for their transactions by setting their own timeout value.

#### Maximum transaction timeout

The number of seconds a transaction that is propagated into this application server can remain inactive before it is ended by the transaction service. This value also applies to transactions that are started in this server, if their associated applications do not set a transaction timeout and the total transaction lifetime timeout is set to 0 (zero).

This value must be equal to, or greater than, the total transaction lifetime timeout. A value of 0 (zero) indicates that this timeout does not apply. In this situation, transactions that are affected by this timeout never time out.

### **Client inactivity timeout**

The number of seconds after which a client is considered inactive and the transaction service ends any transactions associated with that client. A value of 0 (zero) indicates that there is no timeout limit.

8. Optional: Review or change heuristic-related properties:

### **Heuristic retry limit**

The number of times that the application server retries a completion signal, such as commit or rollback. Retries occur after a transient exception from a resource manager or remote partner, or if the configured asynchronous response timeout expires before all Web Services Atomic Transaction (WS-AT) partners have responded.

### **Heuristic retry wait**

The number of seconds that the application server waits before retrying a completion signal, such as commit or rollback, after a transient exception from a resource manager or remote partner.

### **Enable logging for heuristic reporting**

Select this option to enable the application server to log “about to commit one-phase resource” events from transactions that involve a one-phase commit resource and two-phase commit resources.

### **Heuristic completion direction**

Select the direction used to complete a transaction that has a heuristic outcome; either the application server commits or rolls back the transaction, or depends on manual completion by the administrator.

The heuristic completion direction property specifies how a transaction is completed in the following situations:

- The transaction manager reports a heuristic outcome for a last participant support (LPS) resource.
- The heuristic retry limit is exceeded during the recovery of a subordinate server in a distributed transaction.
- The transaction is imported from a Java EE Connector Architecture (JCA) provider.

This property applies only to transactions that are in the situations just described.

### **Accept heuristic hazard**

Select this option to specify that all applications on this server accept the possibility of a heuristic hazard occurring in a two-phase transaction that contains a one-phase resource. This setting configures last participant support (LPS) for the server. If you do not select this option, you must configure applications individually to accept the heuristic hazard.

9. Optional: To change the default WS-Transaction specification level to use for outbound requests that include a web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) coordination context, select the specification level from the **Default WS-Transaction specification level** list.
10. Review or change other configuration properties, to suit your requirements. For more information about the properties of the transaction service, see the topic about Transaction service settings.
11. Click **OK**, then save your changes to the master configuration.
12. Stop, then restart, the application server.

## **What to do next**

If you change the transaction log directory configuration property to an incorrect directory name, the application server restarts, but cannot open the transaction logs. Change the configuration property to a valid directory name, then restart the application server.

If you are running the application server as non-root, modify the permissions on the new transaction log location. To use peer recovery of transactions on a shared device with non-root users, make sure that your non-root users and groups have matching identification numbers across machines.

## Transaction service settings

Use this page to specify settings for the transaction service. The transaction service is a server runtime component that can coordinate updates to multiple resource managers to ensure atomic updates of data. Transactions are started and ended by applications or the container in which the applications are deployed.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > *server\_name* > [Container Settings] Container Services > Transaction Service**.

In the content pane, as well as the numerous configuration settings listed under the General Properties heading, under the Additional Properties heading you can click on the following link:

- **Custom properties** to display or change the custom properties of your WebSphere Application Server transaction service. For example, you would use this option to specify whether or not information messages are displayed on the administrative console and written to the `SystemOut.log` file upon transaction service recovery.

### **Transaction log directory:**

For the z/OS platform, specifies the location of the JTA Partner Log.

Set this property to change the transaction log file directory for an application server in one of the following situations:

- If the applications use distributed resources or XA transactions; for example, multiple databases and resources are accessed in a single transaction.
- If you configure the system for high availability of transactions. In this situation, the transaction log directory must be unique for each server in the cluster, and all servers in the cluster must be able to access the transaction log directory.

In a high availability (HA) environment, both the transaction log and the compensation log directory for each server in a cluster must be unique.

On z/OS, this log is used for recovery of XA resources. When the application that runs on the WebSphere product accesses XA resources, the WebSphere product stores information about the resource to enable XA transaction recovery. Use the following syntax:

*[location type URL tag] location\_specification*

- *location type URL tag* specifies the optional location type for the JTA Partner Log:
  - The default is `dir://`, which specifies that the JTA Partner Log location is in a fully qualified HFS directory specified by *location\_specification*.
- *location\_specification* specifies the location name for the JTA Partner Log:
  - To specify a logstream, use the syntax `logstream://HLQ`

If your application server installation followed the convention of configuring logstreams to the coupling facility (CF), the logstream is named according to the syntax `HLQ.server.X`, where HLQ is a user-defined value between 1-8 characters specified in the installation dialog. Use this HLQ value to specify the JTA Partner Log location.

**Note:** Set `AUTODELETE(NO)` for any logstreams.

- If the *location type URL tag* is `dir://`, use a fully qualified HFS directory for the *location\_specification*. The complete name of the directory must be unique in the WebSphere node.

The default is `dir://app_server_root/tranlog/server_name`.

To specify the size of transaction log files, include a file size setting. Use one of the following formats, where *directory\_name* is the name of the transaction log directory and *file\_size* is the new disk space allocation for the transaction log files, specified in KB (*nK*) or MB (*nM*). The minimum transaction log file size that you can specify is 64K. If you specify a value that is less than 64K, or you do not specify a value for the file size, the default value of 1M is used.

```
dir://directory_name/directory_name;file_sizeK
/directory_name/directory_name;file_sizeK
;file_sizeK <!-- This keeps the default directory -->
```

**Total transaction lifetime timeout:**

The default maximum time, in seconds, allowed for a transaction that is started on this server before the transaction service initiates timeout completion. Any transaction that does not begin completion processing before this timeout occurs is rolled back.

This timeout is used only if the application component does not set its own transaction timeout.

After the timeout occurs, transactions are allowed to continue running for a grace period of approximately four minutes. If the transaction is committed or rolled back during the grace period, the outcome of the transaction is always rolled back. If the transaction does not complete after the grace period, the controller abnormally ends the servant region in which the application component is running, with ABEND EC3 RSN=04130002 or 04130005.

**Note:** Only the total transaction lifetime timeout and the maximum transaction timeout have grace periods. You can disable the grace periods by using the `DISABLE_TRANSACTION_TIMEOUT_GRACE_PERIOD` custom property.

The upper limit of this timeout is constrained by the maximum transaction timeout. For example, if you set a value of 500 for the total transaction lifetime timeout, and a value of 300 for the maximum transaction timeout, transactions will time out after 300 seconds.

If you set this timeout to 0, the timeout does not apply and the value of the maximum transaction timeout is used instead.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	120
<b>Range</b>	0 to 2 147 040

**Asynchronous response timeout:**

Specifies the amount of time, in seconds, that the server waits for an inbound Web Services Atomic Transaction (WS-AT) protocol response before resending the previous WS-AT protocol message.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	30
<b>Range</b>	0 to 2 147 483 647

**Client inactivity timeout:**

Specifies the maximum duration, in seconds, between transactional requests from a remote client. Any period of client inactivity that exceeds this timeout results in the transaction being rolled back in this application server.

If you set this value to 0, there is no timeout limit.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	60
<b>Range</b>	0 to 2 147 483 647

**Maximum transaction timeout:**

Specifies, in seconds, the upper limit of the transaction timeout for transactions that run in this server. This value should be greater than or equal to the value specified for the total transaction timeout.

This timeout constrains the upper limit of all other transaction timeout periods.

*Table 238. Transaction timeout settings. The table shows how the different timeout settings apply to transactions running in the server.*

Timeout setting	Transactions affected
Maximum transaction timeout	All transactions running in this server that are not affected by the total transaction lifetime timeout or an application component timeout. These transactions include transactions imported from outside this server, such as those imported from a client.
Total transaction lifetime timeout	All transactions that originated in this server that are not affected by an application component timeout, in other words, the associated application component does not set its own timeout.
Application component timeout	<p>Transactions that are specific to an application component.</p> <p>You cannot set this transaction timeout using the administrative console.</p> <p>If the component is a container-managed bean, set this timeout in the deployment descriptor for the component. For example, you can use an assembly tool, such as the Rational Application Developer.</p> <p>If the component is a bean-managed bean, set this timeout programmatically by using the <code>UserTransaction.setTransactionTimeout</code> method.</p>

If you set a timeout to 0, that timeout does not apply, and is effectively disabled. If you set all timeouts to 0, transactions never time out.

For example, consider the following timeout values:

*Table 239. Example timeout values. The table lists different timeout settings and their values.*

Timeout setting	Value
Maximum transaction timeout	360
Total transaction lifetime timeout	240
Application component timeout	60

In this example, transactions that are specific to the application component time out after 60 seconds. Other local transactions time out after 240 seconds, and any transactions that are imported from outside this server time out after 360 seconds. If you then change the application component timeout to 500, application component transactions time out after 360 seconds, the value of the maximum transaction timeout. If you set the maximum transaction timeout to 0, application component transactions time out after 500 seconds. If you remove the application component timeout, application component transactions time out after 240 seconds.

To determine the occurrence of a timeout quickly, and to prevent further resource locking, the application server prevents further transactional work on the transactional path where the timeout condition has taken place. This applies equally to attempting to undertake work under the current transaction context and to attempting to perform work under a different transactional context.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	300
<b>Range</b>	0 to 2 147 040

***Heuristic retry limit:***

Specifies the number of times that the application server retries a completion signal, such as commit or rollback. Retries occur after a transient exception from a resource manager or remote partner, or if the configured asynchronous response timeout expires before all Web Services Atomic Transaction (WS-AT) partners have responded.

If the application server abandons the retries, the resource manager or remote partner is responsible for ensuring that the resource or partner branch of the transaction is completed appropriately. The application server raises (on behalf of the resource or partner) an exception that indicates a heuristic hazard. If a commit request was made, the transaction originator receives an exception on the commit operation; if the transaction is container-initiated, the container returns a remote exception or Enterprise JavaBeans (EJB) exception to the EJB client.

During recovery of a subordinate server in a distributed transaction, when the number of heuristic retries is exceeded, the heuristic completion direction property specifies how the transaction is completed.

<b>Data type</b>	Integer
<b>Default</b>	0
<b>Range</b>	0 to 2 147 483 647

A value of 0 (the default) means try again indefinitely.

***Heuristic retry wait:***

Specifies the number of seconds that the application server waits before retrying a completion signal, such as commit or rollback, after a transient exception from a resource manager or remote partner.

<b>Data type</b>	Integer
<b>Default</b>	0
<b>Range</b>	0 to 2 147 483 647

If you leave this value at 0, the application server still makes subsequent attempts to complete the transaction. It incrementally lengthens the wait time before each attempt, to improve system throughput.

***Heuristic completion direction:***

Specifies the direction that is used to complete a transaction that has a heuristic outcome; either the application server commits or rolls back the transaction, or depends on manual completion by the administrator.

The heuristic completion direction property specifies how a transaction is completed in the following situations:

- The transaction manager reports a heuristic outcome for a last participant support (LPS) resource.
- The heuristic retry limit is exceeded during the recovery of a subordinate server in a distributed transaction.
- The transaction is imported from a Java EE Connector Architecture (JCA) provider.

This property applies only to transactions that are in the situations just described.

<b>Data type</b>	Drop-down list
<b>Default</b>	ROLLBACK
<b>Range</b>	<b>COMMIT</b> The application server heuristically commits the transaction. <b>ROLLBACK</b> The application server heuristically rolls back the transaction. <b>MANUAL</b> The application server depends on an administrator to manually complete or roll back transactions with heuristic outcomes.

### ***Accept heuristic hazard:***

Specifies whether all applications on this server accept the possibility of a heuristic hazard occurring in a two-phase transaction that contains a one-phase resource. This setting configures last participant support (LPS) for the server. Last participant support is an extension to the transaction service that enables a single one-phase resource to participate in a two-phase transaction with one or more two-phase resources.

If the Accept heuristic hazard option is not selected, you must configure applications individually to accept the heuristic hazard. You can configure applications either when they are assembled, or following deployment by using the Last participant support extension pane.

<b>Data type</b>	Check box
<b>Default</b>	Cleared
<b>Range</b>	<b>Selected</b> All applications deployed on the server accept the increased risk of an heuristic outcome. <b>Cleared</b> Applications must be individually configured to accept the increased risk of an heuristic outcome.

### ***Enable file locking:***

Specifies whether the use of file locks is enabled when opening the transaction service recovery log.

If you enable this setting, a file lock will be obtained before accessing the transaction service recovery log files. File locking is used to ensure that, in a highly available WebSphere Application Server deployment, only one application server can access a particular transaction service recovery log at any one time. This setting has no effect in a standard deployment where you have not configured high availability support.

**Attention:** This setting requires a compatible network file system, such as Network File System (NFS) version 4, to operate correctly.

<b>Data type</b>	Check box
<b>Default</b>	Selected

### ***Enable transaction coordination authorization:***

Specifies whether the secure exchange of transaction service protocol messages is enabled.

This setting has no effect unless you enable WebSphere Application Server security on the server.

<b>Data type</b>	Check box
<b>Default</b>	Selected

***Default WS-Transaction specification level:***

Specifies the default WS-Transaction specification level to use for outbound requests that include a Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) coordination context.

You can choose from WS-Transaction 1.0, WS-Transaction 1.1 or WS-Transaction 1.2. For details of these specifications, see the topics about WS-AT support or WS-BA support in the application server.

The default WS-Transaction specification level is used if a level cannot be determined from the provider policy (the WS-Transaction WS-Policy assertion). This could be, for example, if the policy assertion is not available either from the WSDL of the target web service or from the WS-Transaction policy type of the client, or if the policy assertion is available but more than one specification level is applicable.

<b>Data type</b>	Drop-down list
<b>Default</b>	1.0

***External WS-Transaction HTTP(S) URL prefix:***

Select or specify the external WS-Transaction HTTP(S) URL prefix.

Select or specify one of these fields if you are using an intermediary node, such as an HTTP server or Proxy Server for WebSphere, to send requests that comply with the Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) protocols.

If WebSphere Application Server security is enabled and transaction coordination authorization is enabled, the HTTPS prefix is used. Otherwise, the HTTP prefix is used.

If the intermediary node is not a Proxy Server, the prefix must be unique for each server.

If you are using a Proxy Server, prefixes can be the same for each server in a cluster, because the Proxy Server determines dynamically which server to forward the request to.

***Select prefix:***

Select this option to select the external endpoint URL information to use for WS-AT and WS-BA service endpoints from the list.

<b>Data type</b>	Drop-down list
<b>Default</b>	None

***Specify custom prefix:***

Select this option to specify the external endpoint URL information to use for WS-AT and WS-BA service endpoints in the field.

Use one of the following formats for the prefix, where *host\_name* and *port* represent the intermediary node that is an HTTP or HTTPS proxy for the server.

http://host\_name:port  
https://host\_name:port

<b>Data type</b>	String
<b>Default</b>	None

### ***Manual transactions:***

Specifies the number of transactions that await manual completion by an administrator.

If there are transactions awaiting manual completion, you can click the **Review** link to display a list of those transactions on the Transactions needing manual completion panel.

<b>Data type</b>	Integer
<b>Default</b>	0

### ***Retry transactions:***

Specifies the number of transactions with some resources being retried.

If there are transactions with resources being retried, you can click the **Review** link to display a list of those transactions on the Transactions retrying resources panel.

<b>Data type</b>	Integer
<b>Default</b>	0

### ***Heuristic transactions:***

Specifies the number of transactions that have completed heuristically.

If there are transactions that have completed heuristically, you can click the **Review** link to display a list of those transactions on the Transactions with heuristic outcome panel.

<b>Data type</b>	Integer
<b>Default</b>	0

### ***Imported prepared transactions:***

Specifies the number of transactions that are imported and prepared but not yet committed.

If there are transactions that have been imported and prepared but not yet committed, you can click the **Review** link to display a list of those transactions on the Transactions imported and prepared panel.

<b>Data type</b>	Integer
<b>Default</b>	0

### ***Transactions needing manual completion:***

Use this page to review transactions that need manual completion.

It is unusual for transactions to require manual completion. A transaction needs manual completion in the following circumstances:

1. An application was exploiting the last participant support to coordinate a single one-phase capable resource and one or more two-phase capable resources.
2. A failure occurred during the commit of the one-phase capable resource.
3. The transaction service heuristic completion direction is set to **Manual**, in the transaction service settings.

An administrator reviewing transactions in this state can review the outcome of any one-phase resources, by using facilities provided by the specific resource manager, then use this page to complete the transaction accordingly.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > [Content pane] server\_name > [Container Settings] Container Services > Transaction Service > Runtime > Manual transactions - Review**.

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, select the check boxes next to the transactions that you want to act on, then use the buttons provided.

#### **Local ID**

The local identifier of the transaction.

#### **Global ID**

The global identifier of the transaction.

#### **Buttons**

##### **Commit**

Heuristically commit the selected transactions.

##### **Rollback**

Heuristically roll back the selected transactions.

#### ***Transactions retrying resources:***

Use this page to review transactions with resources being retried.

If the transaction manager has prepared resources, but has lost contact with the resource managers before committing them or aborting them, then the transaction manager retries the commit or rollback requests to the affected resource managers. The number of times and frequency that the transaction manager retries such commit or rollback requests is configured on the **Heuristic retry limit** and **Heuristic retry wait** properties of the transaction service settings.

An administrator can use this page to make the transaction service abandon the retries of one or more transactions. If a resource manager cannot be contacted, WebSphere Application Server relegates that resource manager to an in-doubt (prepared) state. The administrator then needs to use mechanisms specific to the resource manager to resolve the in-doubt status.

WebSphere Application Server for z/OS can relegate the resource manager to an in-doubt (prepared) state *only if* the RRS transaction context is available.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > [Content pane] server\_name > [Container Settings] Container Services > Transaction Service > Runtime > Retry transactions - Review**.

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, select the check boxes next to the transactions that you want to act on, then use the buttons provided.

**Local ID**

The local identifier of the transaction.

**Status**

The status of the transaction, shown as an integer value. The values correspond to the following status:

- 0 - active
- 1 - marked for rollback
- 2 - prepared
- 3 - committed
- 4 - rolled back
- 5 - unknown
- 6 - none
- 7 - preparing
- 8 - committing
- 9 - rolling back

**Global ID**

The global identifier of the transaction.

**Buttons**

**Finish** Stop retrying resources for the selected transactions.

***Transactions with heuristic outcome:***

Use this page to review transactions that completed with a heuristic outcome.

The page is provided for information purposes only. After you have reviewed the information in this page, then the only action required is to remove the transactions from the list. If you do not remove a transaction from the list, it is kept in the list for three days or until the server is shut down, whichever occurs first.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers** [Content pane] *server\_name* [Container Settings] **Container Services > Transaction Service > Runtime > Heuristic transactions - Review.**

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, select the check boxes next to the transactions that you want to act on, then use the buttons provided.

**Local ID**

The local identifier of the transaction.

**Heuristic outcome**

The outcome of the transaction.

**Global ID**

The global identifier of the transaction.

**Buttons**

**Clear** Remove the selected transactions from the list.

***Transactions imported and prepared:***

Use this page to review transactions that have been imported and prepared but not yet committed.

Under normal circumstances no administrative action is required for any of the transactions listed on this page. This page lists those transactions that are in a prepared state, but are being directed by an external transaction manager (for example, another WebSphere application server) from a transaction context that has been propagated.

Under aberrant circumstances, however, an administrator can configure WebSphere Application Server to resolve the transactions listed on this page independent of the external transaction manager. (This step might be necessary if, for example, the external transaction manager has become unavailable for an unacceptable period of time.)

WebSphere Application Server for z/OS can resolve the transactions according to the selections made on this page *only if* the RRS transaction context is available.

**Note:** If the completion direction (commit or rollback) chosen administratively differs from the eventual direction of the external transaction manager, then the overall outcome of the transaction is not atomic and data corruption can result.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers** [Content pane] *server\_name* > **[Container Settings] Container Services > Transaction Service > Runtime > Imported prepared transactions - Review**.

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, select the check boxes next to the transactions that you want to act on, then use the buttons provided.

#### **Local ID**

The local identifier of the transaction.

#### **Global ID**

The global identifier of the transaction.

#### **Buttons**

##### **Commit**

Heuristically commit the selected transactions.

##### **Rollback**

Heuristically roll back the selected transactions.

#### ***Transaction resources:***

Use this page to review resources used by a transaction.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers** [Content pane] *server\_name* > **[Container Settings] Container Services > Transaction Service > Runtime > *transaction\_type* local\_ID**.

Where:

- *transaction\_type* is one of:
  - **Manual transactions - Review**
  - **Retry transactions - Review**
  - **Heuristic transactions - Review**
  - **Imported prepared transactions - Review**
- *local\_ID* is the local ID of the transaction (as an active link in the list of transactions).

The details displayed depend on the resource provider.

## Transaction service custom properties

WebSphere Application Server allows you to configure a number of custom properties for transaction services.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log, SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Transaction service custom properties can be specified in the administrative console. To use any of these custom properties click on **Servers > Server Types > WebSphere application servers > server\_name > [Container Settings] Container Services > Transaction Service > [Additional Properties] Custom Properties**.

**Note:** In z/OS ensure that all relevant log streams are set to AUTODELETE(NO).

You can define the following transaction service custom properties:

- DELAY\_CANCELLING\_ALARMS
- DISABLE\_OUTBOUND\_CASCADE\_SUPPORT
- DISABLE\_RECOVERY\_AUDIT\_LOGGING
- DISABLE\_TRANSACTION\_TIMEOUT\_GRACE\_PERIOD
- DISABLE\_WSTX\_RMFAIL\_LOGGING
- REMOVE\_PARTNER\_LOG\_ENTRY
- RLS\_LOGSTREAM\_COMPRESS\_INTERVAL

**DELAY\_CANCELLING\_ALARMS:** If the before completion stage of a transaction process is likely to include processes that could either take a long time to complete or could fail, then you might want the transaction to time out.

By default, transaction timeout alarms are cancelled prior to the before completion phase of the transaction begins. The DELAY\_CANCELLING\_ALARMS custom property allows the before completion phase of the transaction to be encompassed within the transaction timeout period. To do this, set the custom property on the application server.

*Table 240. DELAY\_CANCELLING\_ALARMS custom properties. The table includes the data type, acceptable values, and default for the property.*

Data type	Boolean
Acceptable values	TRUE, FALSE
Default	FALSE

**DISABLE\_OUTBOUND\_CASCADE\_SUPPORT:** Specifies whether or not the transaction manager is to disable the support that allows initiating cascaded transactions and be able to let other WebSphere Application Servers on z/OS, who also support RRS cascaded transaction processing, be part of a cascaded family.

Set this value to true if you do not want outbound cascaded support. Setting this value to true will prompt the server to default to standard JTS transaction propagation.

*Table 241. DISABLE\_OUTBOUND\_CASCADE\_SUPPORT custom properties. The table includes the data type, acceptable values, and default for the property.*

Data type	Boolean
-----------	---------

Table 241. *DISABLE\_OUTBOUND\_CASCADE\_SUPPORT* custom properties (continued). The table includes the data type, acceptable values, and default for the property.

Acceptable values	TRUE, FALSE
Default	FALSE

**DISABLE\_RECOVERY\_AUDIT\_LOGGING:** You can control whether information messages are displayed on the administrative console and written to the SystemOut.log file upon transaction service recovery. To do this, set the `DISABLE_RECOVERY_AUDIT_LOGGING` custom property for the transaction service for the server.

On z/OS® information messages do not appear by default, either on the administrative console or in the SystemOut.log file during the recovery of transaction services. If you want these messages displayed you can use the `DISABLE_RECOVERY_AUDIT_LOGGING` custom property.

**Note:** On z/OS, if you choose to turn on transaction recovery audit messages, other audit messages (such as those relating to servant recovery and XA resource recovery) are also displayed in the console and the SystemOut.log file.

Table 242. *DISABLE\_RECOVERY\_AUDIT\_LOGGING* custom properties. The table includes the data type, acceptable values, and default for the property.

Data type	Boolean
Acceptable values	TRUE, FALSE
Default	TRUE

**DISABLE\_TRANSACTION\_TIMEOUT\_GRACE\_PERIOD:** Specifies whether there is a delay between a transaction timeout and the abnormal ending of the servant region that was running the transaction.

If you set this value to false, a global transaction that times out is marked rollback-only. The transaction server gives the associated application an additional period of time, approximately four minutes, to complete. If the application completes in this time, the transaction is rolled back. If the application does not complete in this time, the application and associated servant region are ended abnormally, with an ABENDEC3 or ABENDSEC3 error.

Set this value to true to remove the delay, and abnormally end the application and servant region immediately.

Table 243. *DISABLE\_TRANSACTION\_TIMEOUT\_GRACE\_PERIOD* custom properties. The table includes the data type, acceptable values, and default for the property.

Data type	Boolean
Acceptable values	TRUE, FALSE
Default	FALSE

**DISABLE\_WSTX\_RMFAIL\_LOGGING:** Specifies whether an RMFAIL message is sent to the error log file when a WS-AT participant fails to send a response within the asynchronous response timeout period, causing an XAER\_RMFAIL transaction exception to occur.

If you set this value to false, an RMFAIL message is sent to the error log file when a WS-AT participant fails to send a response within the asynchronous response timeout period.

Set this value to true if you do not want an RMFAIL message sent to the error log file when a WS-AT participant fails to send a response within the asynchronous response timeout period.

Table 244. *DISABLE\_WSTX\_RMFAIL\_LOGGING* custom properties. The table includes the data type, acceptable values, and default for the property.

Data type	Boolean
Acceptable values	TRUE, FALSE
Default	FALSE

**REMOVE\_PARTNER\_LOG\_ENTRY:** You can remove entries from the transaction partner log file. To do this, set the REMOVE\_PARTNER\_LOG\_ENTRY custom property for the transaction service on the server that owns the partner log.

As part of the transaction recovery process, the partner log is checked to establish which resources are needed. If you want to remove certain entries from the partner log, such as a resource that no longer exists, set this custom property on the application server that owns the transaction partner log containing the entries you want to remove.

The REMOVE\_PARTNER\_LOG\_ENTRY custom property is effective only when both of the following situations apply.

- The application server is started in recovery mode.
- The application server has no transactions that currently require recovery. You can establish this by checking the SystemOut.log file.

Table 245. *REMOVE\_PARTNER\_LOG\_ENTRY* custom properties. The table includes the data type, acceptable values, and default for the property.

Data type	Integer
Acceptable values	(one or more comma-delimited integer recovery ID)
Default	(null)

**RLS\_LOGSTREAM\_COMPRESS\_INTERVAL:** Specifies, in seconds, the interval at which the recovery log service attempts to compress any log streams application components are using. The Transaction Service (XA partner log) and the Compensation Service components can be configured to use the recovery log service.

The log stream is checked for compression once per interval. This operation can cause unnecessary CPU usage if the log stream is not being used.

**Note:**

- If you do not use a log stream for the compensation service, set this property to a value that is higher than the default value.
- If your recovery log service uses log streams, do not set this property to too high a value. If the recovery log service log streams become full before the compression interval expires, transactions might start to fail until the log streams are compressed.
- If none of your components are configured to use a log stream, you set this property to 0 (zero) to disable this function.

Table 246. *RLS\_LOGSTREAM\_COMPRESS\_INTERVAL* custom properties. The table includes the data type, acceptable values, and default for the property.

Data type	Integer
Acceptable values	0 - 2,147,483,647 (0 disables the function)
Default	30 seconds

## Configuring transaction properties for peer recovery

Peer recovery for the transaction service enables servers in a cluster to complete outstanding work for a failed cluster member. Follow the steps in this topic to configure the transaction properties that are required for peer recovery of failed application servers in a cluster.

### Before you begin

To enable transaction peer recovery between servers, you must have a common configuration of the resource providers between the participating server members. This means that peer recovery processing can only take place between members of the same server cluster. Although a cluster can contain servers that are at different versions of WebSphere Application Server, you must enable and configure high availability only if all servers in the cluster are at Version 6 or later.

### About this task

Peer recovery of transactions is in addition to the support for Peer restart and recovery, which enables you to restart on a peer system in the sysplex. For more information about configuring peer restart and recovery, see [Setting up peer restart and recovery](#).

Configuring the transaction properties that are required for peer recovery is part of the overall task for configuring a cluster to use high availability support.

### Procedure

1. On z/OS platforms, configure the Resource Access Control Facility (RACF) to allow the application servers to call the ATRSRV macro.

The ATRSRV macro allows a server to commit and back out transactions for other servers. This process differs from peer restart and recovery support, where the other server is started on another system. The ATRSRV macro is provided by MVS Resource Recovery Services (RRS).

The user ID that the application server controller region runs under must have ALTER access to the MVSADMIN.RRS.COMMANDS.*gname.sysname* resource in the FACILITY class, where *gname* is the RRS logging group (usually the SYSPLEX name), and *sysname* is the system name. To allow access to all logging groups and systems, use wildcards in the resource name, for example MVSADMIN.RRS.COMMANDS.\*.

**Note:** Because the controller region runs as an authorized address space, it implicitly has ALTER access to this resource class, unless the RACF configuration explicitly restricts access. By explicitly allowing access to this resource, you are not relying on the authorized state of the controller region.

For more information about the ATRSRV macro and setting the appropriate RACF permissions, see Chapter 8 of *MVS Programming: Resource Recovery*, SA22-7616-02.

2. Configure the transaction log directory setting for each server in the cluster. You can configure the location of the transaction log directory by using either the administrative console or commands. The configuration is stored in the `serverindex.xml` node-level configuration file.

Each server in the cluster must be able to access the log directories of other servers in the same cluster. For this reason, do not leave this setting unset. If you do not set a directory, the application server assumes a default location within the appropriate profile directory, which might not be accessible to other servers in the cluster.

Each server in the cluster must also have a unique transaction log directory, to avoid attempts by multiple servers to access the same log file. For example, you could use the name of each server as part of the log directory name for that server.

The storage mechanism that is used to host recovery log files (for example, you can use IBM Network attached storage (NAS) and shared SCSI drives, but not simple network share) and access to that

mechanism (for example, through a local area network (LAN)), must support the file-based force operation that is used by the recovery log service to force data to disk.

In addition, configure the mechanism by which the remote log files are accessed, to exploit any fault tolerance in the underlying file system. For example, by using the Network File System (NFS) and hard-mounting the remote directory containing the log files (by using the `-o hard` option of the NFS mount command), the NFS client will try again with a failed operation until the NFS server becomes available again.

For more information about configuring transaction log directories, see “Configuring transaction properties for an application server” on page 2643.

**Note:** If you have migrated from a previous version of WebSphere Application Server, be aware that previous versions stored the recovery log configuration in the `server.xml` server-level configuration file. If you run existing scripting that configures the original recovery log settings, or migrate Version 5 application servers to a later version of WebSphere Application Server, the original transaction log directory configuration in the `server.xml` file is updated. The administrative console detects this condition and prompts you to save the configuration when you view the transaction service panel. This save operation saves the changed configuration to the `serverindex.xml` file, and resets the older fields to null. Change your existing scripting to target the `serverindex.xml` file at the earliest opportunity. New scripting should also target the `serverindex.xml` file.

3. Enable the high availability function for the cluster, by completing the following steps on the cluster configuration panel of the WebSphere Application Server administrative console:
  - a. In the administrative console, click **Servers > Clusters > WebSphere application server clusters > *cluster\_name***.
  - b. Select the **Enable failover of transaction log recovery** option.
  - c. Click **OK**.

For more information about enabling the high availability function for a cluster, see Server cluster settings.

4. Decide which kind of transaction peer recovery to use by referring to How to choose between automated and manual transaction peer recovery.
5. Complete one of the following actions, depending on the configuration that you require.
  - If you want to use automated peer recovery, follow the steps in “Configuring automated peer recovery for the transaction service” on page 2663.
  - If you want to use manual peer recovery, configure a policy for the transaction service, as described in “Configuring manual peer recovery for the transaction service.”

## What to do next

You must also configure the compensation log location. Each server must have a unique compensation log directory and the compensation logs must be accessible, in a similar way to the transaction logs.

## Configuring manual peer recovery for the transaction service

Manual peer recovery processing is not the default setting; you must enable it through configuration. Administrator intervention is then required to trigger any peer recovery processing.

## About this task

Complete this task if you want to use manual peer recovery for the transaction service. A scenario where you might want to use manual peer recovery is when your file system does not provide the required level of file locking support, and no constraints are in place to ensure that overloading or network partitioning does not occur. For more information, see the topic about how to choose between automated and manual transaction peer recovery.

After you configure manual peer recovery, your intervention is required only when a server fails and cannot be restarted; in this case, use the administrative console to specify which peer server performs recovery processing for the failed server.

Manual peer recovery configuration is provided by a group of policies known as *static policies*, where one policy definition is provided for each application server. Individual definitions are required to define server-specific configuration within the policy, which in this case is the identity of the server that initiates a peer recovery process.

## Procedure

1. Create the required static policy definitions.
  - a. In the navigation pane of the administrative console, click **Servers > Core groups > Core group settings**. All the members of a cluster are in a single core group, which by default is the DefaultCoreGroup core group. Click the core group that contains your cluster. The Core groups configuration panel is displayed.
  - b. Under **Additional Properties**, click **Policies**. The current set of policies is displayed. You can identify the current policy that applies to transactional high availability (HA) by the match criteria type = WAS\_TRANSACTION. The default policy has a policy type of One of N policy. If this policy exists, you do not have to remove it, because it is overridden by the static policy that you are creating.
  - c. Click **New** to create a new policy.
  - d. Select **Static policy** and click **Next**.
  - e. Provide a name for the policy. This value is a free-form text string that is used only as a label in the administrative console. However, to assist readability in the administrative console, use a name that associates the policy with a particular server, for example, TM-SERVER1 policy.
  - f. Enter a description if required, and click **OK**.
  - g. Set values for the **Is alive timer** and the **Quorum** options, if required.
  - h. Under **Additional Properties**, click **Match criteria** to open an empty match criteria panel.
  - i. Click **New** to create a new match criterion. Match criteria are key-value pairs that are used to define the scope of a policy.
  - j. Enter type in the **Name** field and WAS\_TRANSACTION in the **Value** field. Click **OK**. This match criterion is used to associate the policy with the transaction service.
  - k. Click **New** to create a second new match criterion.
  - l. Enter GN\_PS in the **Name** field and *cell\_name\node\_name\server\_name* in the **Value** field, where *cell\_name*, *node\_name* and *server\_name* are the names of your cell, node and server. For example, dmgrCell\apnode1\server1. Click **OK**. This match criterion is used to associate the policy with a particular server.
  - m. Return to the configuration page for the new policy, and under **Additional Properties**, click **Static group servers**. The Static group servers panel is displayed. This panel lists all the servers in the core group and classifies them as either core group servers or static group servers.
  - n. From the **Core group servers** list, select the server that is associated with the policy and click **Add >>** to move it to the **Static group servers** list. The static group servers list is the set of servers that attempts to own the recovery logs at the same time. Adding an incorrect server to this list can compromise data integrity. For normal operation, follow these rules to guarantee data integrity:
    - Add only one server to the list of static group servers. Adding two servers causes recovery log contention, because both servers attempt to own the associated recovery logs. The exception to this rule is adding a second server as part of manual peer recovery initiation. For more information, see “Managing manual peer recovery of the transaction service” on page 2662.
    - Add only the server that is associated with the policy to the list. Adding a different server prevents the home server from owning its recovery logs, and stops the home server from starting correctly.

2. Repeat the procedure in step 1 for each server in the cluster.
3. Save your changes to the master configuration, ensuring that you select the **Synchronize changes with Nodes** check box.
4. Stop and restart the cluster members for the changes to take effect.

## Results

Manual transaction peer recovery is configured for all the servers in the cluster. Automatic transaction peer recovery can no longer occur.

## What to do next

If a server fails, follow the instructions in “Managing manual peer recovery of the transaction service,” to trigger recovery processing.

## Managing manual peer recovery of the transaction service

After you configure manual peer recovery, you trigger a recovery process by using the administrative console; peer recovery can no longer take place automatically. This requirement applies to transaction peer recovery processing only; standard recovery processing of server recovery logs, driven when the server starts, still occurs automatically.

## Before you begin

Before you initiate the peer recovery process, verify that the problem server has failed and cannot restart. To ensure data integrity, you must initiate a manual peer recovery process only for servers that are not running.

## About this task

You usually direct a peer recovery process if an application server becomes unavailable for some reason, for example, a machine failure. The choice of peer server, within the cluster, is arbitrary.

## Procedure

1. In the administrative console click **Servers > Core groups > Core group settings**.
2. Click the core group that contains the failed server. The Core groups configuration panel is displayed.
3. Under **Additional Properties**, click **Policies**.
4. Click the static policy that is associated with the failed server. The Configuration settings for this policy are displayed.
5. Under **Additional Properties**, click **Static group servers**. The General Properties panel is displayed.
6. During normal running, the static group servers list must contain only the server that is associated with the policy. However, if you determine that the server failed, you can add a second server to undertake the peer recovery processing. From the Core group servers list, select the server on which you want to initiate the peer recovery process. Ensure that you select an application server, rather than a system server such as the node agent or domain manager. Click **Add >>** to add the server to the static group servers list. Do not add more than one server.
7. Save your changes to the master configuration, ensuring that you select the **Synchronize changes with Nodes** check box. This step causes a recovery process for the failed server to begin on the peer server.
8. When recovery processing is complete, you must reverse the configuration changes that you made before restarting the failed server. Return to the Static group servers list, select the peer server that you added previously and click **Remove <<**. Click **OK**.
9. Save your changes to the master configuration, ensuring that you select the **Synchronize changes with Nodes** check box.

## Results

The server that you selected performed transaction peer recovery, completing any outstanding work for the failed server.

## What to do next

Verify that you have reversed the configuration changes that you made, then restart the failed server if required.

## Configuring automated peer recovery for the transaction service

Configure automated peer recovery to enable cluster members to automatically complete outstanding work for a failed cluster member. After you have configured automated peer recovery, recovery processing occurs without any intervention on your part.

## Before you begin

Make sure that you understand the infrastructure requirements for automatic peer recovery. For more information, see the topics about how to choose between automated and manual transaction peer recovery and “Disabling file locking” on page 2664.

## About this task

Automated peer recovery processing is the default setting when high availability is enabled. Follow the steps in this topic to ensure that your system is configured correctly. If you configured manual peer recovery and want to return to automated peer recovery, you must reconfigure the system back to the default settings.

## Procedure

1. Verify that high availability is enabled, and that the location of the transaction recovery log is specified, as described in “Configuring transaction properties for peer recovery” on page 2659.
2. Remove any high availability (HA) policies with a policy type of Static. Such policies might exist if you previously configured the system for manual peer recovery.
  - a. In the navigation pane of the administrative console, click **Servers > Core groups > Core group settings**. All the members of a cluster are in a single core group, which by default is the DefaultCoreGroup core group. Click the core group that contains your cluster. The Core groups configuration panel is displayed.
  - b. Under **Additional Properties**, click **Policies**. The current set of policies is displayed.
  - c. Select any policies with a **Policy type** of Static, and a **Match criteria** that includes type = WAS\_TRANSACTIONS. Click **Delete**.
3. Check to see if the required One-of-N transaction HA policy already exists. This policy has a **Policy type** of One of N, and a **Match criteria** that includes type = WAS\_TRANSACTIONS. If this policy already exists, you do not have to take any further action. If the policy does not already exist, use the following steps to create it.
  - a. Click **New** to create a new policy.
  - b. Select **One of N policy** and click **Next**.
  - c. Provide a name for the policy. This value is a free-form text string that is used only as a label in the administrative console, however to assist readability in the administrative console, use a name that associates the policy with the required behavior, for example, Clustered TM policy.
  - d. Enter a description, if required.
  - e. Select the **Failback** check box to ensure that a failed server reclaims its recovery log when it restarts, and click **OK**.

- f. Set values for the **Is alive timer**, **Quorum**, and **Preferred servers only** options, if required. See the contextual help for more information.
- g. Under **Additional Properties**, click **Match criteria** to open an empty Match criteria panel.
- h. Click **New** to create a new match criterion.
- i. Enter type in the **Name** field and WAS\_TRANSACTION in the **Value** field. Click **OK**.
- j. Save your changes to the master configuration, ensuring that you select the **Synchronize changes with Nodes** check box.
- k. Stop and restart the cluster members for the changes to take effect.

## Results

Automated transaction peer recovery is configured for all the servers in the cluster. If a server fails, another server in the cluster will complete any outstanding work for the failed server.

### *Disabling file locking:*

If you use Network File System Version 3 (NFSv3) for storing transaction recovery logs, and you want to use automated peer recovery, you must first disable file locking.

### Before you begin

To complete this task you must first configure your system to prevent system overloading and network partitioning, as described in the topic about how to choose between automated and manual transaction peer recovery. These situations can lead to the initiation of a peer recovery process for an active server.

**Attention:** If you do not take this precautionary step, data corruption can occur.

The following list contains some actions that you can take to prevent system overloading and network partitioning:

- Modify the core group heartbeat settings to change the amount of time after which WebSphere Application Server considers a server failed. For more information, see the topic about the high availability manager.
- Ensure that your network is safe from network partitioning by, for example, installing backup network adapters.
- Modify the workload management throttling so that the server cannot be overloaded.

### About this task

WebSphere Application Server obtains an exclusive lock on the physical recovery log files whenever it is instructed to undertake recovery processing, and releases this lock when it is instructed to pass ownership of the logs to another server. Access to a recovery log is performed only when the exclusive lock is held.

NFSv3 supports exclusive file locks, but holds them on behalf of a failed host until that host can restart. In this context, the host is the physical machine running the application server that requests the lock and it is the restart of the host, not the application server, that eventually triggers the locks to release. See the topic about how to choose between automated and manual transaction peer recovery for more information.

To provide a more appropriate failover behavior, you can either use manual failover, and configure the system as described in “Configuring manual peer recovery for the transaction service” on page 2660, or you can disable the use of exclusive file locking.

### Procedure

1. In the administrative console, click **Servers > Server Types > WebSphere application servers > server\_name > [Container Settings] Container Services > Transaction Service**.

2. Clear the **Enable file locking** check box.
3. Click **Apply** or **OK**.
4. Save your change to the master configuration.
5. Repeat the previous steps for every server in the cluster.
6. Restart the servers in the cluster for the changes to take effect.

## Results

Exclusive file locking is disabled for all the servers in the cluster.

## What to do next

Having taken steps to mitigate the risk to recovery log integrity when locking is disabled, you can tune the heartbeating parameters of the WebSphere Application Server high availability (HA) framework to change the conditions under which a server is considered failed. By considering the characteristics of applications, network, and peak workloads, determine an acceptable period of time after which the likelihood of an incorrectly diagnosed server failure is acceptably small.

A trade-off exists between reducing the risk of an incorrect diagnosis of server failure and increasing the time for automated failover and peer recovery to occur. By default, a server is considered failed after 20 heartbeats, with a 10-second frequency, are missed. These defaults are custom properties of the core group that you can modify.

## Managing active and prepared transactions

Use this task to manage active and prepared transactions that might need administrator action.

### About this task

Under normal circumstances, every effort is made to finish a transaction. However, due to RRS and native contexts finishing, finishing the transaction might not be possible. In this case, the transaction is marked `rollback_only` so that it rolls back at the next available window. In other situations, you might have to finish a transaction manually. For example, you might want to finish a transaction that has become stuck polling a resource manager that you know will not become available again within the required timeframe.

**Note:** If you choose to complete a transaction on an application server, it is recorded as having completed in the transaction service logs for that server, so will not be eligible for recovery during server start up. If you complete a transaction, you are responsible for cleaning up any in-doubt transactions on the resource managers affected.

You can use the administrative console to display a snapshot of all the transactions in an application server that are in the following states:

#### Manual transactions

Transactions awaiting administrative completion. For each transaction, the local id or global id is displayed. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to commit or roll back transactions in this state.

#### Retry transactions

Transactions with some resources being retried. For each transaction, the local id or global id is displayed, and whether the transaction is committing or rolling back. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to finish (stop retrying) transactions in this state.

## Heuristic transactions

Transactions that have completed heuristically. For each transaction, the local id or global id and the heuristic outcome is displayed. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to clear the transaction from the list.

## Imported prepared transactions

Transactions that have been imported and prepared but not yet committed. For each transaction, the local id or global id is displayed. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to commit or roll back transactions in this state.

To manage the active and prepared transactions for an application server, use the administrative console to complete the following steps:

## Procedure

1. Display the Transaction Service runtime page for application server:
  - a. In the navigation pane, click **Servers > Server Types > WebSphere application servers**.
  - b. In the content pane, click the name of the application server.
  - c. In the content pane, click the **Runtime** tab.
  - d. Under Additional Properties, click **Transaction Service**.

The page displays values for the runtime properties of the transaction service, including the number of transactions in the active and prepared states.

2. To display a snapshot of the transactions in a specific state, click **Review** in the field label.
3. Optional: To display information about the resources associated with a transaction, click the name of the transaction.
4. Optional: To act on a transaction, select the check box provided on the entry for the transaction, then click one of the buttons provided. Alternatively, to act on all transactions, select the check box in the header of the transactions table, then click a button.

## Managing active and prepared transactions by using wsadmin scripting

You can use wsadmin scripting to manage active and prepared transactions that might need administrator action.

### Before you begin

Before you start this task, the wsadmin scripting client must be running.

### About this task

In normal circumstances, every effort is made to finish a transaction. However, because of Resource Recovery Services (RRS) and native contexts finishing, it might not be possible to finish the transaction. In this case, the transaction is marked `rollback_only` so that it rolls back at the next available window. In other situations, you might have to finish a transaction manually. For example, you might want to finish a transaction that is stuck polling a resource manager that you know will not become available again in the required time frame.

**Note:** If you choose to complete a transaction on an application server, it is recorded as having completed in the transaction service logs for that server, so it is not eligible for recovery during server start up. If you complete a transaction, you are responsible for cleaning up any in-doubt transactions on the resource managers affected.

For more information about the TransactionService and Transaction MBeans, see the application programming interface (API) documentation.

## Procedure

- You can use the TransactionService Managed Bean (MBean) to list transactions in various states by invoking one of the following methods:

### **listOfTransactions**

Lists all non-completed transactions. Never attempt to alter the state of active transactions (for example, by using commit or rollback).

### **listManualTransactions**

Lists transactions awaiting administrative completion. You can commit or roll back transactions in this state.

### **listRetryTransactions**

Lists transactions with some resources being retried. You can finish (stop retrying) transactions in this state.

### **listHeuristicTransactions**

Lists transactions that have completed heuristically. You can clear these transactions from the list.

### **listImportedPreparedTransactions**

Lists transactions that have been imported and prepared but not yet committed. You can commit or roll back transactions in this state.

Each entry in the returned list contains the following attributes:

- **Local Transaction Identifier**
  - **Status**, which can be interpreted by calling `getPrintableStatus` on the Transaction MBean.
  - **Global Transaction Identifier**
  - **Heuristic Outcome**, which can take one of the following values:
    - 8 (HEURISTIC\_COMMIT)
    - 9 (HEURISTIC\_ROLLBACK)
    - 10 (HEURISTIC\_MIXED)
    - 11 (HEURISTIC\_HAZARD)
- You can use the TransactionService MBean to gather more information about the properties of the transaction service, by obtaining the following attributes:

### **transactionLogDirectory**

The directory for this server where the transaction service stores log files for recovery.

### **totalTranLifetimeTimeout**

The default maximum time, in seconds, allowed for a transaction that is started on this server before the transaction service initiates timeout completion. Any transaction that does not begin completion processing before this timeout occurs is rolled back. This value applies only to container-managed transaction (CMT) beans.

### **asyncResponseTimeout**

The time, in seconds, that the server waits for an inbound Web Services Atomic Transaction (WS-AT) protocol response before resending the previous WS-AT protocol message.

### **enableFileLocking**

Specifies whether the use of file locks is enabled when opening the transaction service recovery log.

### **enableProtocolSecurity**

Specifies whether the secure exchange of transaction service protocol messages is enabled.

**clientInactivityTimeout**

The maximum duration, in seconds, between transactional requests from a remote client. Any period of client inactivity that exceeds this timeout results in the transaction being rolled back in this application server.

**heuristicRetryLimit**

The number of times that the application server retries a completion signal, such as commit or rollback. Retries occur after a transient exception from a resource manager or remote partner, or if the configured asynchronous response timeout expires before all Web Services Atomic Transaction (WS-AT) partners have responded.

**heuristicRetryWait**

The number of seconds that the application server waits before retrying a completion signal, such as commit or rollback, after a transient exception from a resource manager or remote partner.

**propagatedOrBMTTranLifetimeTimeout**

The upper limit of the transaction timeout, in seconds, for transactions that run in this server. This value must be greater than or equal to the total transaction timeout.

**LPSHeuristicCompletion**

The action to use to complete a transaction that has an heuristic outcome. Either the application server commits or rolls back the transaction, or the administrator must complete the transaction manually.

- You can use the Transaction MBean to commit, roll back, or finish a transaction, or remove a transaction from the list of heuristically completed transactions, depending on the state of the transaction, by invoking one of the following methods:

**commit**

Heuristically commits the transaction.

**rollback**

Heuristically rolls back the transaction.

**finish** Stops retrying resources for the transaction.

**removeHeuristic**

Clears the transaction from the list.

- You can use the Transaction MBean to gather more information about a transaction, by invoking the following methods:

**getPrintableStatus**

Return the transaction status.

**getGlobalTranName**

Get the global identifier for the transaction.

**listResources**

List the resources for the transaction.

**Example**

The following script is an example of how to use the TransactionService and Transaction MBeans to work with manual transactions. Run the script only against an application server, and not against the deployment manager or node agent.

Example Jacl script:

```
get the TransactionService MBean
set servicembean [$AdminControl queryNames type=TransactionService,*]

get the Transaction MBean
set mbean [$AdminControl queryNames type=Transaction,*]

set input 0
```

```

while {$input >= 0} {
 # invoke the listManualTransactions method
 set tranManualList [$AdminControl invoke $servicembean listManualTransactions]

 if {[length $tranManualList] > 0} {
 puts "----Manual Transaction details-----"
 set index 0
 foreach tran $tranManualList {
 puts " Index= $index tran= $tran"
 incr index
 }
 puts "----End of Manual Transactions -----"
 puts "Select index of transaction to commit/rollback:"
 set input [gets stdin]
 if {$input < 0} {
 puts "No index selected, exiting."
 } else {
 set tran [lindex $tranManualList $input]
 set commaPos [expr [string first "," $tran]-1]
 set localTID [string range $tran 0 $commaPos]
 puts "Enter c to commit or r to rollback Transaction $localTID"
 set input [gets stdin]
 if {$input=="c"} {
 puts "Committing transaction=$localTID"
 $AdminControl invoke $mbean commit $localTID
 }
 if {$input=="r"} {
 puts "Rolling back transaction=$localTID"
 $AdminControl invoke $mbean rollback $localTID
 }
 }
 } else {
 puts "No Manual transactions found, exiting"
 set input -1
 }
 puts " "
}

```

### Example Jython script:

```

import sys
def wsadminToList(inStr):
 outList=[]
 if (len(inStr)>0 and inStr[0]=='[' and inStr[-1]==']'):
 tmpList = inStr[1:-1].split(" ")
 else:
 tmpList = inStr.split("\n") #splits for Windows or Linux
 for item in tmpList:
 item = item.rstrip(); #removes any Windows "\r"
 if (len(item)>0):
 outList.append(item)
 return outList
#endDef

servicembean = AdminControl.queryNames("type=TransactionService,*")
mbean = AdminControl.queryNames("type=Transaction,*")
input = 0

while (input >= 0):
 tranList = wsadminToList(AdminControl.invoke(servicembean, "listManualTransactions"))

 tranLength = len(tranList)
 if (tranLength > 0):
 print "----Manual Transaction details-----"
 index = 0
 for tran in tranList:
 print " Index=" , index , " tran=" , tran
 index = index+1
 #endFor
 print "----End of Manual Transactions -----"
 print "Select index of transaction to commit/rollback:"
 input = sys.stdin.readline().strip()
 if (input == ""):
 print "No index selected, exiting."
 input = -1
 else:
 tran = tranList[int(input)]

```

```

 commaPos = (tran.find(",") -1)
 localTID = tran[0:commaPos+1]
 print "Enter c to commit or r to rollback transaction ", localTID
 input = sys.stdin.readline().strip()
 if (input == "c"):
 print "Committing transaction=", localTID
 AdminControl.invoke(mbean, "commit", localTID)
 #endif
 elif (input == "r"):
 print "Rolling back transaction=", localTID
 AdminControl.invoke(mbean, "rollback", localTID)
 #endif
 else:
 input = -1
 #endelse
 #endElse
else:
 print "No transactions found, exiting"
 input = -1
#endElse
print " "

#endWhile

```

## Displaying transaction recovery audit messages

You can choose whether information messages are displayed on the administrative console and written to the SystemOut.log file upon transaction service recovery. To do this, set the DISABLE\_RECOVERY\_AUDIT\_LOGGING custom property for the transaction service for the server.

### About this task

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log , SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

On z/OS information messages do not appear by default, either on the administrative console or in the SystemOut.log file during the recovery of transaction services. If you want these messages displayed you can use the DISABLE\_RECOVERY\_AUDIT\_LOGGING custom property.

**Note:** On z/OS, if you choose to turn on transaction recovery audit messages, other audit messages (such as those relating to servant recovery and XA resource recovery) are also displayed in the console and the SystemOut.log file.

### Procedure

1. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server\_name* > [Container Settings] Container Services > Transaction Service > [Additional Properties] Custom Properties**.
2. Click **New**.
3. Enter the values required, depending on the operating system:
  - To display the information messages, type DISABLE\_RECOVERY\_AUDIT\_LOGGING in the **Name** field, and FALSE in the **Value** field.
4. Click **Apply** or **OK**.
5. Save your changes to the master configuration.
6. Restart the server in recovery mode.

## Delaying the cancelling of transaction timeout alarms

If the before completion stage of a transaction process is likely to include processes that could either take a long time to complete or could fail, then you might want the transaction to time out.

### About this task

By default, transaction timeout alarms are cancelled prior to the before completion phase of the transaction begins. The `DELAY_CANCELLING_ALARMS` custom property allows the before completion phase of the transaction to be encompassed within the transaction timeout period. To do this, set the custom property on the application server.

### Procedure

1. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server\_name* > [Container Settings] Container Services > Transaction Service > [Additional Properties] Custom Properties.**
2. Click **New**.
3. Type `DELAY_CANCELLING_ALARMS` in the **Name** field, and `TRUE` in the **Value** field.
4. Click **Apply** or **OK**.
5. Save your changes to the master configuration.
6. Restart the server in recovery mode.

## Removing entries from the transaction partner log

You can remove entries from the transaction partner log file. To do this, set the `REMOVE_PARTNER_LOG_ENTRY` custom property for the transaction service on the server that owns the partner log.

### About this task

As part of the transaction recovery process, the partner log is checked to establish which resources are needed. If you want to remove certain entries from the partner log, such as a resource that no longer exists, set this custom property on the application server that owns the transaction partner log containing the entries you want to remove.

The `REMOVE_PARTNER_LOG_ENTRY` custom property is effective only when both of the following situations apply.

- The application server is started in recovery mode.
- The application server has no transactions that currently require recovery. You can establish this by checking the `SystemOut.log` file.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log`, `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

### Procedure

1. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server\_name* > [Container Settings] Container Services > Transaction Service > [Additional Properties] Custom Properties.**
2. Click **New**.

3. Type REMOVE\_PARTNER\_LOG\_ENTRY in the **Name** field, and in the **Value** field, type one or more comma-delimited integer recovery IDs to be removed.
4. Click **Apply** or **OK**.
5. Save your changes to the master configuration.
6. Restart the server in recovery mode.

---

## Chapter 27. Administering web applications

This page provides a starting point for finding information about web applications, which are comprised of one or more related files that you can manage as a unit, including:

- HTML files
- Servlets can support dynamic web page content, provide database access, serve multiple clients at one time, and filter data.
- Java ServerPages (JSP) files enable the separation of the HTML code from the business logic in web pages.

IBM extensions to the JSP specification make it easy for HTML authors to add the power of Java technology to web pages, without being experts in Java programming. More introduction...

---

### Deploying JavaServer Pages and JavaServer Faces files

#### JSP class loading settings

You can configure a JavaServer Pages (JSP) class to be loaded by either the JSP engine's class loader or by the web module's class loader.

By default, a JSP class is loaded by a unique instance of the JSP engine's class loader. The JSP engine's class loader enables reloading at runtime of a JSP class when the JSP source or one of its dependents is modified. This allows you to reload a single JSP class when necessary, without affecting any other loaded JSP classes.

JSP classes are loaded by the web module's class loader under either of the following scenarios.

1. The JSP engine configuration parameter `useFullPackageNames` is set to `true`, and the JSP file is configured as a servlet in the `web.xml` file using the `<servlet-class>` scenario in the table below.
2. The JSP engine configuration parameters `useFullPackageNames` and `disableJspRuntimeCompilation` are both set to `true`. In this case, you do not need to configure a JSP file as a servlet in the `web.xml` file.

#### Configuring JSP files as Servlets

You can configure a JSP file as a servlet in the `web.xml` file. There are two ways to do this. They are described in the table below.

Before you configure a JSP file as a servlet, consider the following.

1. Reloading capability - If runtime reloading of JavaServer Pages files is desired, requests for JavaServer Pages files must be handled by the JSP engine. The `<servlet-class>` scenario in the table below disables runtime JSP file reloading, while the `<jsp-file>` scenario is compatible with reloading.
2. Reducing the number of class loaders - If you do not require runtime reloading of modified JSP pages and you want to reduce the number of class loader instances, then you can use the `<servlet-class>` scenario in the table below. Similarly, scenario 2 in section 1 above can be used without having to configure a JSP file as a servlet.

Table 247. Example: Configure a JSP file as a servlet in the `web.xml` file.. Configure a JSP file as a servlet

Scenario	Example	compatible with runtime reloading	multiple class loaders used?	useFullPackageNames
----------	---------	-----------------------------------	------------------------------	---------------------

Table 247. Example: Configure a JSP file as a servlet in the web.xml file. (continued). Configure a JSP file as a servlet

<jsp-file>	<servlet> <servlet-name>jspOne</servlet-name> <jsp-file>jspOne.jsp</jsp-file> </servlet>	Yes	Yes	Can be true or false
<servlet-class>	<servlet> <servlet-name>jspTwo</servlet-name> <servlet-class>_ibmjsp.jspTwo</servlet-class> </servlet>	No	No	Must be true

The JSP batch compiler tool helps you configure JavaServer Pages files as servlets. When useFullPackageNames is true, the JSP batch compiler generates <servlet> and <servlet-mapping> elements for each JSP file that it successfully translates and compiles. The elements are written to a web.xml fragment file named generated\_web.xml which is located in the binaries WEB-INF directory of a web module processed by the JSP file batch compiler (this directory is located within the deployed application's ear file). You can copy and paste all or some of these elements into the web.xml file to configure JavaServer Pages files as servlets.

Take note of the location of the web.xml that is used by the application server. The application specific configuration is obtained from either the application binaries (the application's ear file) or from the configuration repository. If an application is deployed into WebSphere Application Server with the flag Use Binary Configuration set to true, then the WEB-INF/web.xml file is looked for in a web module's binaries directory, not in the configuration repository. Below are examples of these two locations.

- An example of a configuration repository directory is {WAS\_ROOT}/profiles/profilename/config/cells/cellname/applications/enterpriseappname/deployments/deploynedname/webmodulename
- An example of an application binaries directory is: {WAS\_ROOT}/profiles/profilename/installedApps/nodename/EnterpriseAppName/WebModuleName/

If the JSP batch compiler is executed on a pre-deployed application then the web.xml file is in the web module's WEB-INF directory.

## JavaServer Pages (JSP) runtime reloading settings

JavaServer Pages files can be translated and compiled at run time when the JSP file or its dependencies are modified. This is known as JSP reloading.

**Note:** Use an assembly tool, such as Rational Application Developer, to modify IBM extension and binding files. You can convert extension and binding files within modules from XMI to XML using the IBM Bindings and Extensions Conversion Tool for Multi-Platforms.

JSP reloading is enabled through the **reloadEnabled** JSP engine parameter in the WEB-INF/ibm-web-ext.xmi or WEB-INF/ibm-web-ext.xml file.

### ibm-web-ext.xmi example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadEnabled" value="true"/>
```

### ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
 xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
 version="1.0">
```

```

<jsp-attribute name="trackDependencies" value="true" />
<jsp-attribute name="disableJspRuntimeCompilation" value="true" />
<jsp-attribute name="reloadEnabled" value="true"/>

<reload-interval value="5"/>
<auto-encode-requests value="false"/>
<auto-encode-responses value="false"/>
<enable-directory-browsing value="false"/>
<enable-file-serving value="false"/>
<pre-compile-jsp value="false"/>
<enable-reloading value="true"/>
<enable-serving-servlets-by-class-name value="false" />
</web-ext>

```

**Note:** For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named `ibm-*-ext.xmi` or `ibm-*-bnd.xmi` where `*` is the type of extension or binding file such as `app`, `application`, `ejb-jar`, or `web`. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be `.xmi`.
- For an application or module that uses Java EE 5 or later, the file extension must be `.xml`. If `.xmi` files are included with the application or module, the product ignores the `.xmi` files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the `.xmi` file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the `.xmi` file extensions.

The following table contains suggested reload settings for production and development environments.

*Table 248. Suggested reload settings for production and development environments.. Reload settings*

Configuration Attribute	Settings	
	Production Environment	Development Environment
<code>reloadEnabled</code>	false	true
<code>reloadInterval</code>	n/a (ignored if <code>reloadEnabled</code> is false)	approximately 5 seconds
<code>trackDependencies</code>	n/a (ignored if <code>reloadEnabled</code> is false)	true Alternatively, set this to false to improve response time if dependencies are not changing
<code>disableJspRuntimeCompilation</code>	true - Alternatively, set this to false if JSP files are not pre-compiled and therefore need to be compiled on the first request.	false

The default for the **reloadEnabled** parameter is true. If the **reloadEnabled** parameter is set to true, a JSP file is reloaded at run time if the JSP file and its class file do not have the same timestamp. In addition, if **trackDependencies** is set to true then the JSP file is reloaded if the timestamp of any of its dependencies has changed since the JSP class file was last generated. If the **reloadEnabled** parameter is set to false, a JSP file is still compiled if necessary on the first request to it unless the parameter **disableJspRuntimeCompilation** is true. For example, when **disableJspRuntimeCompilation** is false and **reloadEnabled** is false, a JSP file is compiled on the first request if the class file is outdated. It would not compile on subsequent requests, even if the JSP source file is modified or the class file is deleted,, unless **reloadEnabled** is true.

## Reload interval

The reload interval is set through the **reloadInterval** JSP engine parameter.

### ibm-web-ext.xmi example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadInterval" value="5"/>
```

### ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
 xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
 version="1.0">

 <jsp-attribute name="trackDependencies" value="true" />
 <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
 <jsp-attribute name="reloadInterval" value="5"/>

 <reload-interval value="5"/>
 <auto-encode-requests value="false"/>
 <auto-encode-responses value="false"/>
 <enable-directory-browsing value="false"/>
 <enable-file-serving value="false"/>
 <pre-compile-jsp value="false"/>
 <enable-reloading value="true"/>
 <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If reloading is enabled, the **reloadInterval** parameter value determines the delay between checks to see if a JSP file is outdated. For example, if **reloadInterval** is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than five seconds prior to the current request for the JSP file. Once the **reloadInterval** is exceeded, reload checking is performed and the reload interval timer is reset to 0 for that JSP file. The larger the **reloadInterval**, the less frequently the JSP engine checks for the need to reload a JSP file.

## Dependency tracking

Dependency tracking is set through the **trackDependencies** JSP engine parameter.

### ibm-web-ext.xml example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="trackDependencies" value="true"/>
```

### ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
 xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
 version="1.0">

 <jsp-attribute name="trackDependencies" value="true" />
 <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
 <jsp-attribute name="reloadInterval" value="5"/>

 <reload-interval value="5"/>
 <auto-encode-requests value="false"/>
 <auto-encode-responses value="false"/>
 <enable-directory-browsing value="false"/>
 <enable-file-serving value="false"/>
 <pre-compile-jsp value="false"/>
 <enable-reloading value="true"/>
 <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If reloading is enabled, the **trackDependencies** parameter value determines whether the JSP engine tracks modifications to the requested JSP file dependencies as well as to the JSP file itself. The three types of dependencies tracked by the JSP engine are:

- files statically included in the JSP file
- tag files that are referenced in the JSP file (excluding tag files that are in JAR files)
- TLDs that are referenced in the JSP file (excluding TLDs that are in JAR files)

Dependency tracking information is always included in the generated class file even if **trackDependencies** is false. The information is not used by the JSP engine or batch compiler unless the **trackDependencies** parameter is true. This means that you can enable dependency tracking without having to recompile JSP files.

For example, the `toplevel.jsp` file statically includes the `footer.jspf` file. When the `toplevel.jsp` file is compiled, the path to the `footer.jspf` file and its timestamp are stored in the `toplevel.jsp`'s class file. As a result, the `footer.jspf` file is modified and the `toplevel.jsp` file is requested. Now that the reload interval for the `toplevel.jsp` file has been exceeded, the JSP engine compares the timestamp stored in the class file with the `footer.jspf` file timestamp on disk. Because the timestamps are different, the `toplevel.jsp` file is compiled, picking up the modification to the `footer.jspf` file. In order for dependency tracking to work, the **trackDependencies** value must be set to true at the time a JSP file is requested at run time or is processed by the batch compiler.

## Disabling compilation

Disabling of run time compilation of JavaServer Pages is set via the `disableJspRuntimeCompilation` JSP engine parameter.

### ibm-web-ext.xmi example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="disableJspRuntimeCompilation" value="true"/>
```

### ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
 xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
 version="1.0">

 <jsp-attribute name="trackDependencies" value="true" />
 <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
 <jsp-attribute name="reloadInterval" value="5"/>

 <reload-interval value="5"/>
 <auto-encode-requests value="false"/>
 <auto-encode-responses value="false"/>
 <enable-directory-browsing value="false"/>
 <enable-file-serving value="false"/>
 <pre-compile-jsp value="false"/>
 <enable-reloading value="true"/>
 <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If the **disableJspRuntimeCompilation** parameter is set to true, the JSP engine at run time does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order for the class files to be loaded. With this option set to true, an application can be installed without JSP source, but must have precompiled class files. There is a web container custom property of the same name that can be used to determine the behavior of all web modules installed in a server. If both the web container custom property and the JSP engine option are set, the JSP engine option takes precedence. Setting the **disableJspRuntimeCompilation** parameter to true automatically sets **reloadEnabled** to false.

## Reload processing sequence

The processing sequence pertaining to JSP file reloading when **trackDependencies** is false is shown in Figure 1.

Figure 40. Reload processing sequence when **trackDependencies** is false.

When **trackDependencies** is true, the JSP engine does additional file system processing to determine if any of a JSP file's dependencies have changed since the JSP file was last translated and compiled. Figure 2 shows the additional processes that are performed on the 'No' path of flow chart labeled "is JSP class file outdated?". You can see that the path taken when `disableJspRuntimeCompilation` is true is the most efficient path.

Figure 41. Additional reload processing performed when `trackDependencies` is true.

## JSP and JSF option settings

Use this panel to configure the class reloading of web modules such as JavaServer Pages (JSP) files and to select a JSF implementation to use with this application.

To view this administrative console panel, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > JSP and JSF options**. This panel is the same as the **Provide JSP reloading options for web modules** panel on the application installation and update wizards.

The following note applies to the files with a `.xmi` extension in this topic:

**Note:** For IBM extension and binding files, the `.xmi` or `.xml` file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named `ibm-*-ext.xmi` or `ibm-*-bnd.xmi` where `*` is the type of extension or binding file such as `app`, `application`, `ejb-jar`, or `web`. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be `.xmi`.
- For an application or module that uses Java EE 5 or later, the file extension must be `.xml`. If `.xmi` files are included with the application or module, the product ignores the `.xmi` files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the `.xmi` file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the `.xmi` extensions.

### Web module

Specifies the name of a web module in the installed or deployed application.

## URI

Specifies the location of the module that is relative to the root of the application (EAR file).

## JSP enable class reloading

Specifies whether to enable class reloading when JSP files are updated.

A web container reloads JSP files only when the IBM extension reloadEnabled in the jspAttributes of the `ibm-web-ext.xml` file is set to true.

Java Platform, Enterprise Edition 5 (Java EE 5) applications IBM extension files are in `.xml` file format. For applications versions earlier than Java EE 5, they are in the `.xmi` file format.

## JSP reload interval in seconds

Specifies the number of seconds to scan the application file system for updated JSP files. The default is the value of the reloading interval attribute in the IBM extension (META-INF/ibm-web-ext.xml) file of the web module.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). The default reload interval is 5. To disable reloading, specify zero (0). The range is from 0 to 2147483647.

The reloading interval attribute takes effect only if class reloading is enabled.

Java EE 5 applications IBM extension files are in `.xml` file format. For applications versions earlier than Java EE 5, they are in the `.xmi` file format.

## Sun Reference Implementation 1.2

Select this option to use the Sun Reference Implementation 1.2 JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration parameter, `com.ibm.ws.jsf.JSF_IMPL_CHECK`, to true to automatically mark the JSP files to recompile at application startup.

## MyFaces 2.0

Select this option to use the MyFaces JSF implementation. This is the default JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration parameter, `com.ibm.ws.jsf.JSF_IMPL_CHECK`, to true to automatically mark the JSP files to recompile at application startup.

In a mixed-version cell, a V7 node uses MyFaces 1.2 if the MyFaces selection is toggled, while a V8 node uses MyFaces 2.0. For WebSphere Application Server versions before V7 (for example, V6.1 and earlier), this toggle is ineffective because JSF implementation switching was not supported before V7.

## JSP run time compilation settings

By default, the JavaServer Pages (JSP) engine translates a requested JSP file, compiles the `.java` file, and loads the compiled servlet into the run time environment. You can change the JSP engine default behavior by indicating that a JSP file must not be translated or compiled at run time, even when a `.class` file does not exist.

If run time compilation is disabled, you must precompile the JSP files, which provides the following advantages:

- Reduces compilation related disk operations.
- Minimizes disk storage requirements necessary for handling temporary .java files generated during a run time compilation.
- Allows you to not include the JSP source files in the application.
- Allows verification that a JSP file compiled successfully before deploying and installing the application in the product

You can disable run time JSP file compilation on a global or an individual web application basis:

- To disable the translation and compilation of JSP files for all Web applications, in the administrative console, click **Servers > Server Types > WebSphere application servers > server\_name**. Then, in the Container Settings section, click **Web container settings > Web container > Custom properties**.

If the `disableJspRuntimeCompilation` property appears in the list of defined custom properties, but is set to `false`, click the property name, and then set the property to `true`.

If this property is not included in the list of defined custom properties, click **New**, and then specify `disableJspRuntimeCompilation` in the **Name** field and `true` in the **Value** field.

Valid settings for this property are `true` or `false`. When this property is set to `true`, translation and compilation of the JSP files is disabled at run time for all web applications.

- To disable the translation and compilation of JSP files for a specific web application, set the JSP engine initialization parameter `disableJspRuntimeCompilation` to `true`. This setting, if enabled, determines the run time behavior of the JSP engine and overrides the web container custom property setting.

Set this parameter through the **JavaServer Pages attribute assembly settings** page when assembling applications.

Valid values for this setting are `true` or `false`. If this parameter is set to `true`, then, for that specific web application, translation and compilation of the JSP files is disabled at run time, and the JSP engine only loads precompiled files.

- If neither the web container custom property nor the JSP parameter is set, the first request for a JSP file results in the translation and compilation of the JSP file when the `.class` file does not exist or is outdated. Subsequent requests for the file also result in translations and compilations, but only if the following conditions are met:
  - Translations are required because the `.class` file is outdated.
  - Reloading is enabled for the web module.
  - Reload interval is exceeded.

If you disable run time compilation and a request arrives for a JSP file that does not have a matching `.class` file, the JSP engine returns the following 404 error to the browser:

```
Error 404: SRVE0200E: Servlet [org.apache.jsp._jsp1]: Could not find required servlet class - _jsp1.class
```

In this case, an exception is written to the joblog (SYSPRINT) file if the `ras_trace_outputLocation` property in the `was.env` file is set to `SYSPRINT`, or to `CTRACE` if `ras_trace_outputLocation` is set to `BUFFER`.

If a JSP file has a matching `.class` file but that file is out of date, the JSP engine still loads the `.class` file into memory.

## Provide options to compile JavaServer Pages settings

Use this page to specify options to be used by the JavaServer Pages (JSP) compiler.

This administrative console page is a step in the application installation and update wizards. To view this page, you must select **Precompile JavaServer Pages files** on the **Select installations options** page. Thus, to view this page, click **Applications > New Application > New Enterprise Application > application\_path > Next > Detailed - Show me all installation options and parameters > Next > Next or Continue > Precompile JavaServer Pages files > Next > Step: Provide options to compile JSPs**.

You can specify the JSP compiler options on this page only when installing or updating an application that contains web modules. After the application is installed, you must edit the JSP engine configuration parameters of a web module `WEB-INF/ibm-web-ext.xmi` file to change its JSP compiler options.

**Note:** For IBM extension and binding files, the `.xmi` or `.xml` file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named `ibm-*-ext.xmi` or `ibm-*-bnd.xmi` where `*` is the type of extension or binding file such as `app`, `application`, `ejb-jar`, or `web`. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be `.xmi`.
- For an application or module that uses Java EE 5 or later, the file extension must be `.xml`. If `.xmi` files are included with the application or module, the product ignores the `.xmi` files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the `.xmi` file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the `.xmi` file extensions.

## Web module

Specifies the name of a module within the application.

## URI

Specifies the location of the module relative to the root of the application (EAR file).

## JSP class path

Specifies a temporary class path for the JSP compiler to use when compiling JSP files during application installation. This class path is not saved when the application installation is complete and is not used when the application is running. This class path is used only to identify resources outside of the application which are necessary for JSP compilation and which will be identified by other means (such as shared libraries) after the application is installed. In network deployment configurations, this class path is specific to the deployment manager machine.

To specify that multiple web modules use the same class path:

1. In the list of web modules, select the **Select** check box beside each web module that you want to use a particular class path.
2. Expand **Apply Multiple Mappings**.
3. Specify the desired class path.
4. Click **Apply**.

## Use full package names

Specifies whether the JSP engine generates and loads JSP classes using full package names.

When full package names are used, precompiled JSP class files can be configured as servlets in the `web.xml` file, without having to use the `jsp-file` attribute. When full package names are not used, all JSP classes are generated in the same package, which has the benefit of smaller file-system paths.

When the options `useFullPackageNames` and `disableJspRuntimeCompilation` are both `true`, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

This option is the same as the `useFullPackageNames` JSP engine parameter.

## JDK source level

Specifies the source level at which the Java compiler compiles JSP Java sources. Valid values are 13, 14, and 15. The default value is 13 for pre-Java EE 5 web modules, which specifies source level 1.3 and 15 for Java EE 5 and later web modules.

## Disable JSP runtime compilation

Specifies whether a JSP file should never be translated or compiled at run time, even when a `.class` file does not exist.

When this option is set to `true`, the JSP engine does not translate and compile JSP files at run time; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load class files. You can install an application without JSP source, but the application must have precompiled class files.

For a single web application class loader to load all JSP classes, this compiler option and the **Use full package names** option both must be set to `true`.

This option is the same as the `disableJspRuntimeCompilation` JSP engine parameter.

## Deploying web applications using RRD

### Task overview: Assembling applications using remote request dispatcher

Remote request dispatcher (RRD) is a pluggable extension to the web container which allows application frameworks, servlets and JavaServer Pages (JSP) to include content from outside the currently executing resource's Java Virtual Machine (JVM) as part of the response sent to the client.

### Before you begin

You must have WebSphere Application Server, Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, Remote request dispatcher considerations for details.

### Procedure

1. Install enterprise application files with the console.
2. Configure the sending of include requests between the application and remote resources.
  - Configure web applications to dispatch remote includes.
  - Configure web applications to service remote includes.
3. Optional: Modify your application to locate resources located in two different contexts using the servlet programming model.

The Servlet Programming Model for including resources remotely does not require you to use any non-Java Platform, Enterprise Edition (Java EE) Servlet Application Programming Interfaces (APIs). The remote request dispatcher (RRD) component follows the same rules to obtain a `ServletContext` and a remote resource. By using JavaServer Pages standard tag library (JSTL), your application is further removed from obtaining a `ServletContext` object or `RequestDispatcher` that is required in the framework example in the following step because the JSTL custom tag does this implicitly. Study the following example of a sample JavaServer Pages application to learn how to locate resources that are in two different contexts, investments and banking.

```
<HEAD>
<%@ page
language="java"
contentType="text/html; charset=ISO-8859-1"
pageEncoding="ISO-8859-1"
isELIgnored="false"
%>
<%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" %>
</HEAD>
<BODY>
```

```
<%--
```

Programming example using JavaServer Pages and JavaServer Pages Standard Tag Library (JSTL). JSTL provides a custom tag to import contents (in servlet and JSP terms include) in the scope of the same request from outside of the current web module context by specifying a context parameter.

JSTL restriction: The web module that is imported must run inside of the same JVM as the calling resource if imported URL is not fully qualified.

RRD extends this functionality by permitting the web module to be located within the scope of the current WebSphere Application Server core group versus the scope of the JVM.

```
--%>
```

```
<hr size="5"/>
```

```
<%-- Include resource investmentSummary.jsp located in the web application with context root of /investments. --%>
```

```
<c:import url="investmentSummary.jsp" context="/investments"/>
```

```
<hr size="5"/>
```

```
<%-- Include resource accountSummary.jsp located in the web application with context root of /banking. --%>
```

```
<c:import url="accountSummary.jsp" context="/banking"/>
```

```
<hr size="5"/>
```

```
</BODY>
```

```
</HTML>
```

#### 4. Optional: Modify your application to locate resources located in two different contexts using the framework programming model.

The Framework Programming Model for including resources remotely does not require you to use any non- Java Platform, Enterprise Edition (Java EE) Servlet Application Programming Interfaces (APIs). When a request is initiated for a ServletContext name that is not presently running inside of the current web container, the remote request dispatcher (RRD) component returns a ServletContext object that can locate a resource that exists anywhere inside a WebSphere Application Server WebSphere Application Server, Network Deployment environment provided that the resource exists and RRD is enabled for that ServletContext object. Study the following sample framework snippet that demonstrates how to locate resources located in two different contexts, investments and banking.

```
/*
```

Programming example using a generic framework. Servlet Specification provides an API to obtain a servlet context in the scope of the same request different from the current web module context by specifying a context parameter.

Servlet Specification restriction: The web module that obtain must run inside of the same JVM as the calling resource.

RRD extends this functionality by permitting the web module to be located within the scope of the current WebSphere Application Server core group versus the scope of the JVM.

```
*/
```

```
protected void frameworkCall (ServletContext context, HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException{
```

```
 PrintWriter writer = response.getWriter();
```

```
 writer.write("<HTML>");
 writer.write("<HEAD>");
 writer.write("</HEAD>");
 writer.write("<BODY>");
 writer.write("<hr size=\"5\"/>");
```

```
 //Include resource investmentSummary.jsp located in web application
 //with context root of /investments.
 RequestDispatcher rd = getRequestDispatcher (context, "/investments", "/investmentSummary.jsp");
 rd.include(request, response);
```

```
 writer.write("<hr size=\"5\"/>");
```

```
 //Include resource accountSummary.jsp located in web application
 //with context root of /banking.
 rd = getRequestDispatcher (context, "/banking", "/accountSummary.jsp");
 rd.include(request, response);
```

```

writer.write("</BODY>");
writer.write("</HTML>");
}
private RequestDispatcher getRequestDispatcher (ServletContext context, String contextName, String resource) {
return context.getContext(contextName).getRequestDispatcher(resource);
}

```

## Results

After enabling at least one enterprise application to dispatch remote includes and at least one enterprise application to service remote includes, RRD is now enabled.

## What to do next

Restart the modified applications if already installed or start newly installed applications to enable RRD on each application.

### ***Remote request dispatcher:***

Remote Request Dispatcher (RRD) is a pluggable extension to the web container for application frameworks, servlets, and JavaServer Pages to include content from outside of the current Java virtual machine (JVM) for the resource, as part of the response sent to the client.

Remote request dispatcher is an extensible infrastructure for other components and stack products to add custom extensions like generators and handlers, to the RRD extension. The remote request dispatcher extension enhances the standard Java Platform, Enterprise Edition (Java EE) `javax.servlet.RequestDispatcher` implementation to be aware of locating remote resources using web services to communicate between machines within a WebSphere Application Server, Network Deployment (ND) core group. The remote request dispatcher extension reports any errors that occur on the remote server back to the originating server. It can also use SSL for secure communications and WS-Security security context propagation between servers. See the `rrdSecurity.props` file topic for more information.

RRD portlet support carries forward the remote request dispatcher concept to portlets and enhances the portlet container for invocation of portlets outside of the current JVM resource.

By using the RRD extension, you can share request load across multiple machines and JVMs by including remote servers within the cell. If RRD resource is memory or processor intensive, the calling resource is not affected as much as a standard `RequestDispatcher` running within the same JVM. RRD solves this problem by separating resources into a different JVM.

## Capabilities

- Requests on remote server are treated as include requests. Filters and request listeners are started as if the dispatch type is INCLUDE.
- Serializable request attributes and query parameters are sent to remote server.
- Security context is sent to a remote server through LTPA tokens.
- Servlet parameters and `OutputStream`  
Request parameters are passed to remote server.
- Response headers that are set by the remotely included resource are ignored similar to includes on a local server. Internal headers such as `Set-Cookie` can still be set and are propagated back.
- All original request headers are passed to remote server
  - Similar to the plug-in for WebSphere Application Server.
  - Method calls return the state as if they are on local server. For example, `getServer` returns the local server name or `isSecure` returns whether the request to the 'local' server has been secure.
- Cookies and sessions
  - Cookies are passed to the remote server as part of headers.

- Sessions in local and remote servers use the same cookie or session ID for a given client which is similar to includes in the same server. If a session exists on a remote server, the session cookie contains the information for both the servers to maintain the affinity to the remote server.
- Exceptions
  - If there is an exception on the remote server, the server returns an RRD-specific web services fault which wraps the original exception created by the application.
  - Attempt to recreate the original exception on the local server if the exception class exists on both servers. If the original exception cannot be recreated, an RRD-specific ServletException is constructed and used instead.
  - The exception is recreated by the local server for error handling purposes.
- Dynamic cache

When dynamic cache is enabled, caching is performed on the local and remote machine.
- Security

You can use SSL to encrypt RRD messages between application servers. SSL is enabled by default, however, you must also pass security context needs through RRD to ensure that the security state is available in the remote machine. RRD uses WS-Security to pass this information, but this security context propagation is disabled by default. See the rrdSecurity.props file topic for additional information.

---

## Administering web applications

### Modifying the default web container configuration

A web container handles requests for servlets, JavaServer Pages (JSP) files, and other types of files that include server-side code. The web container creates servlet instances, loads and unloads servlets, creates and manages request and response objects, and performs other servlet management tasks. The web server plug-ins, provided by the product, help supported web servers to pass servlet requests to web containers.

#### About this task

If the property to start servlets during application server startup is enabled, part of its startup process calls the Servlet.init method on its servlets when you start the web container. Therefore, when the web container starts and calls the init method, other components such as Naming and Work Load Management might not be fully started yet. As a result, application server related calls may not work because all of the application server components might not be ready yet. Once the application server is 'ready for e-business', it is completely ready. If application server related calls fail during Servlet.init method, you can either:

- Start the servlet manually when the server is ready for e-business instead of starting the servlet upon startup or
- You can choose not to make application server related calls in the servlet's init method.

The web container is created initially with default properties values suitable for simple web applications. However, these values might not be appropriate for more complex web applications.

Your application is considered complex if it requires any of the following features:

- Additional virtual host aliases
- Servlet caching
- Persistent HTTP session support
- Session tracking support with URL rewriting
- Special web container transport chain settings
- Asynchronous or remote dispatching
- No request or response pooling

Make the following configuration changes if you have a complex application:

## Procedure

1. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server\_name***. Then under web container settings, click on one of the following:
  - a. **Web container**, if your web application requires a virtual host, other than the default\_host, or requires servlet caching.
  - b. **Web container transport chains**, if you need to reconfigure your HTTP connections.
2. If your application requires global settings for internal servlets for web application archive (WAR) files packaged by third-party tools, in the administrative console, click **Servers > Server Types > WebSphere application servers > *server\_name* > Web Container Settings > Web container**. Then under Additional Properties, click **Custom properties** and enter the appropriate custom property.
3. If your application uses transaction class mappings to classify workload, in the administrative console, click **Resources > Asynchronous Beans > Work managers > *workmanager\_name***. Then enter the name of the transaction class mapping file in the Default transaction class field.

## Web container settings

Use this page to configure the web container settings.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > *server\_name* > Web Container Settings > Web container**.

### ***Default virtual host:***

Specifies a virtual host that enables a single host machine to resemble multiple host machines. Resources associated with one virtual host cannot share data with resources associated with another virtual host, even if the virtual hosts share the same physical machine.

Select a virtual host option:

#### **default\_host**

The product provides a default virtual host with some common aliases such as the machine IP address, short host name, and fully qualified host name. The alias comprises the first part of the path for accessing a resource such as a servlet. For example, it is localhost:9080 in the request `http://localhost:9080/myServlet`.

#### **admin\_host**

This virtual host option is another name for the application server; also known as *server1* in the base installation. This process supports the use of the administrative console.

#### **proxy\_host**

The virtual host called proxy\_host, includes default port definitions, port 80 and 443, which are typically initialized as part of the proxy server initialization. Use this proxy host as appropriate with routing rules associated with the proxy server.

### ***Enable servlet caching:***

Specifies that if a servlet is started once and it generates output to be cached, a cache entry is created containing not only the output, but also side effects of the invocation. These side effects can include calls to other servlets or JavaServer Pages (JSP) files, as well as metadata about the entry, including timeout and entry priority information.

Portlet fragment caching requires that servlet caching is enabled. Therefore, enabling portlet fragment caching automatically enables servlet caching. Disabling servlet caching automatically disables portlet fragment caching.

### ***Disable servlet request and response pooling:***

Specifies to disable the pooling of servlet request and servlet response objects that are pooled by the web container. When you disable pooling of servlet request and servlet response objects, new servlet request and servlet response objects are created for each request.

When you disable pooling of servlet request and servlet response objects, new servlet request and servlet response objects are created for each request, which can negatively affect performance, but provides protection from any unforeseen pooling bugs.

***Number of timeout threads:***

Specifies the number of threads that are available to handle asynchronous servlet timeout operations per server.

The default of two might be too low if you have many applications using asynchronous servlets that often have timeouts.

***Default timeout:***

Specifies the default asynchronous servlet timeout for the server.

The default of 30 seconds can be lowered if responses are not being received quickly enough and there is a viable fall back in the error case. You can raise the value if too many timeouts are being received and the longer timeout produces responses in an acceptable manner to the client. The units are in millisecond, so multiply the number by 1000 to convert to seconds. To configure at a higher granularity, you must use the AsyncContext setTimeout method programmatically.

***Use thread pool to start Runnable objects:***

Select this option to use the same thread pool where the request originates. This option does not propagate any context from the original request.

***Use a work manager to start Runnable objects:***

Select this option to use an Asynchronous Beans work manager to start the runnable. This option is the default selection. The work manager option propagates any context that is configured for the selected work manager. This option also requires selecting the JNDI name of the work manager that you will use.

Considerations when using a work manager:

- The context that is propagated is configurable under Resources > Asynchronous Beans > Work managers. You can also create new work managers on the same panel.
- The WebSphere Application Server default Work Manger is used unless you specify otherwise. This might not be desirable as other components might be using the work manager and effectively decreasing the number of threads that are available at one time.
- To make changes to the work manager settings, it is recommended that you create a work manager so changes to defaults do not affect other components.
- If you have a work manager configured to throw exceptions when the work queue is full, then an exception of type IllegalStateException is thrown to the caller of start(Runnable) and the caller is responsible for handling the exception.

## **Programmatic session cookie configuration collection**

Use this page to secure cookies by prohibiting programmatic configuration.

To view this administrative console page at the web container level, click **Security > Global security > Programmatic session cookie configuration**.

**Cookie domain:**

Specifies the domain where the cookie is used. Use the asterisk (\*) symbol as a wild card, for example, \*.ibm.com.

**Cookie name:**

Specifies an alphanumeric name for the cookie, for example, **JSESSIONID**. Use the asterisk (\*) symbol as a wild card.

**Cookie path:**

Specifies the directory in the domain where the cookie is valid; for example, **/path\_name**. Use the asterisk (\*) symbol as a wild card.

**Web container custom properties**

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console. The following is a list of some of the available web container custom properties.

To specify web container custom properties:

1. In the administrative console click **Servers > Server Types > WebSphere application servers > server\_name > Web Container Settings > Web container**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the name of the custom property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

The following is a list of custom properties provided with the Application Server. The topics, JavaServer Pages specific web container custom properties and HTTP transport custom properties, are listed in a separate topic.

You can use the Custom properties page to define the following properties for use by the Java virtual machine.

- “BodyContentBuffSize” on page 2691
- com.ibm.ws.jsf.disablealternatefacesconfigsearch
- “com.ibm.ws.jsp.enableDefaultIsELIgnoredInTag” on page 2691
- “com.ibm.ws.jsp.getWriterOnEmptyBuffer” on page 2691
- “com.ibm.ws.jsp.limitBuffer” on page 2692
- “com.ibm.ws.jsp.throwExceptionForAddELResolver” on page 2692
- “com.ibm.ws.jsp.zosFileLockRetrying” on page 2692
- “com.ibm.ws.jsp.zosReCompile” on page 2692
- “com.ibm.ws.webcontainer.assumeFiltersSuccessOnSecurityError” on page 2693
- “com.ibm.ws.webcontainer.channelwritetype” on page 2693
- “com.ibm.ws.webcontainer.checkEDRinGetRealPath” on page 2693
- “com.ibm.ws.webcontainer.copyattributeskeyset” on page 2694
- “com.ibm.ws.webcontainer.disableSetCharacterEncodingAfterParametersRead” on page 2694

- “com.ibm.ws.webcontainer.disableSystemAppGlobalListenerLoading” on page 2694
- “com.ibm.ws.webcontainer.disablexPoweredBy” on page 2694
- “com.ibm.ws.webcontainer.disallowAllFileServing” on page 2695
- “com.ibm.ws.webcontainer.disallowservletsbyclassname” on page 2695
- “com.ibm.ws.webcontainer.discernUnavailableServlet” on page 2695
- “com.ibm.ws.webcontainer.dispatcherRethrowSER” on page 2695
- “com.ibm.ws.webcontainer.dispatcherRethrowSErError” on page 2696
- “com.ibm.ws.webcontainer.divertrecursiveexceptiontoerrorlog” on page 2696
- “com.ibm.ws.webcontainer.donotservebyclassname” on page 2696
- “com.ibm.ws.webcontainer.enabledefaultservletrequestpathelements” on page 2696
- “com.ibm.ws.webcontainer.enableJspMappingOverride” on page 2697
- “com.ibm.ws.webcontainer.enableMultiReadOfPostData” on page 2697
- “com.ibm.ws.webcontainer.extractHostHeaderPort and trusthostheaderport” on page 2697
- “com.ibm.ws.webcontainer.fileWrapperEvents” on page 2698
- “com.ibm.ws.webcontainer.FileWrapperEventsLessDetail” on page 2698
- “com.ibm.ws.webcontainer.finishresponseonclose” on page 2698
- “com.ibm.ws.webcontainer.ForceDifferentCookiePaths” on page 2698
- “com.ibm.ws.webcontainer.HTTPOnlyCookies” on page 2699
- “com.ibm.ws.webcontainer.ignoreinjectionfailure” on page 2699
- “com.ibm.ws.webcontainer.ignoreInvalidQueryString” on page 2699
- “com.ibm.ws.webcontainer.IgnoreSessiononStaticFileRequest” on page 2700
- “com.ibm.ws.webcontainer.invokeFilterInitAtStartup” on page 2700
- “com.ibm.ws.webcontainer.invokeFiltersCompatibility” on page 2700
- “com.ibm.ws.webcontainer.invokerequestlistenerforfilter” on page 2700
- “com.ibm.ws.webcontainer.KeepUnreadPostDataAfterResponseSentToClient” on page 2701
- “com.ibm.ws.webcontainer.logServletContainerInitializerClassloadingErrors” on page 2701
- “com.ibm.ws.webcontainer.mapFiltersToAsterisk” on page 2701
- “com.ibm.ws.webcontainer.normalizerequesturi” on page 2701
- “com.ibm.ws.webcontainer.parseUTF8PostData” on page 2701
- “com.ibm.ws.webcontainer.provideQStringToWelcomeFile” on page 2702
- “com.ibm.ws.webcontainer.SendResponseToClientAsPartOfSendRedirect” on page 2702
- “com.ibm.ws.webcontainer.SendResponseToClientWhenResponseIsComplete” on page 2702
- “com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot” on page 2702
- “com.ibm.ws.webcontainer.ServletDestroyWaitTime” on page 2703
- “com.ibm.ws.webcontainer.setUnencodedHTMLinsendError” on page 2703
- “com.ibm.ws.webcontainer.suppressheadersinrequest” on page 2703
- “com.ibm.ws.webcontainer.suppressHtmlRecursiveErrorOutput” on page 2703
- “com.ibm.ws.webcontainer.suppressLastZeroBytePackage” on page 2704
- “com.ibm.ws.webcontainer.suppressServletExceptionLogging” on page 2704
- “com.ibm.ws.webcontainer.throwMissingJspException” on page 2704
- “com.ibm.ws.webcontainer.webgroupvhostnotfound” on page 2704
- “com.ibm.ws.webcontainer.xPoweredBy” on page 2705
- “com.ibm.wsspi.jsp.convertAttrValueToString” on page 2705
- “com.ibm.wsspi.jsp.disableEICache” on page 2705
- “com.ibm.wsspi.jsp.disableResourceInjection” on page 2705

- “com.ibm.wsspi.jsp.disableTldSearch” on page 2705
- “com.ibm.wsspi.jsp.enabledoublequotesdecoding” on page 2706
- “DecodeUriAsUTF8” on page 2706
- “enableInProcessConnections” on page 2706
- “fileServingEnabled, directoryBrowsingEnabled, and serveServletsByClassnameEnabled” on page 2706
- “ForceSessionIdLengthCheck” on page 2707
- “ForceSessionInvalidationMultiple” on page 2707
- “httpsIndicatorHeader” on page 2708
- “HttpSessionIdReuse” on page 2708
- “listeners” on page 2708
- “MutualAuthCBindCheck” on page 2708
- “prependSlashToResource” on page 2709
- “trusted” on page 2709
- “UseOracleBLOB” on page 2709

**BodyContentBuffSize:** The size of the body content buffer for a JavaServer Pages (JSP) file can affect the performance of some applications. By default, the body content buffer size is 512 bytes. However, you can use the BodyContentBuffSize custom property to set a different buffer value.

Data type	Integer
-----------	---------

**com.ibm.ws.jsf.disablealternatefacesconfigsearch:** Disables MyFaces searching for META-INF/\*.faces-config.xml for all web applications on a server.

Name	Value
com.ibm.ws.jsf.disablealternatefacesconfigsearchg	false

**com.ibm.ws.jsp.enableDefaultIsELIgnoredInTag:** Typically Expression Language (EL) expressions in tag files get evaluated before the tag files a JavaServer Page (JSP) is compiled. However, under certain conditions these EL expressions in a tag file do not get evaluated if the <el-ignored> attribute is set to true.

To ensure that EL expressions are always evaluated, set the com.ibm.ws.jsp.enableDefaultIsELIgnoredInTag custom property to true. The default value for this property is false.

Name	Value
com.ibm.ws.jsp.enableDefaultIsELIgnoredInTag	true

**com.ibm.ws.jsp.getWriterOnEmptyBuffer:** The dynamic cache service uses flushes to determine when one cacheable web fragment, such as a JSP include or a c:import, ends and the next web fragment begins. If you set the com.ibm.wsspi.jsp.usecdatatrims custom property to true for your JSP engine, all of the white space and extra lines in the generated Java code are stripped out. In this situation, there might not be any content to write before the first flush. If the generated Java code contains text or other code before the first flush then normal dynamic cache service processing occurs.

If you set the com.ibm.wsspi.jsp.usecdatatrims custom property to true, and are using the dynamic cache service, you must also set the com.ibm.ws.jsp.getWriterOnEmptyBuffer custom property to true. This custom property requires the JSP Engine to call the flush function when it reaches the end of the first cacheable web fragments even if there is not any data to flush. The default value for this property is false.

Name	Value
com.ibm.ws.jsp.getWriterOnEmptyBuffer	true

**com.ibm.ws.jsp.limitBuffer:** The body content buffer size of the tag bodies for a JavaServer Pages (JSP) file are reused to optimize performance. If the size of a tag body increases beyond the default body content buffer size, the buffer is resized to accommodate the tag body. However, the buffer is not reset to the default size after serving a request. As a result, the heap memory that is used by org.apache.jasper.runtime.BodyContentImpl implementation might increase over time. You can configure the body content buffer size by setting an integer value for the BodyContentBuffSize custom property. For more information, see “BodyContentBuffSize” on page 2691.

Use the com.ibm.ws.jsp.limitBuffer custom property to deallocate large body content buffer sizes and create a buffer with the default buffer size.

Default	false
---------	-------

**com.ibm.ws.jsp.throwExceptionForAddELResolver:** Set the com.ibm.ws.jsp.throwExceptionForAddELResolver property to true if you do not want to allow an ELResolver to be registered from a servlet or a filter after the application has received a request from the client. When this property is set to true, an IllegalStateException is thrown as specified by the JSP (Java Server Pages) specification for addELResolver() method of the JspApplicationContext interface.

The default value for this property is false.

Name	Value
com.ibm.ws.jsp.throwExceptionForAddELResolver	true

**com.ibm.ws.jsp.zosFileLockRetrying:** Use the com.ibm.ws.jsp.zosFileLockRetrying property to specify, in seconds, the amount of time during which a thread continues to try to obtain a lock on a JSP.

A JSP file is locked before the start of the compile process, and unlocked after the compile process completes. If a thread fails to lock a JSP, the thread continues to try to obtain the file lock for that JSP for up to 240 seconds. If the thread cannot obtain the lock during this time interval, an error message is issued. The thread does not make any additional attempts to obtain a lock for the JSP.

Data type	Integer
Default	240

**gotcha:** This custom property was added to the product in Fix Pack 7.0.03.

**com.ibm.ws.jsp.zosReCompile:** Use the com.ibm.ws.jsp.zosReCompile property to specify how many times a thread should attempt to lock a JSP.

After a thread obtains the lock for a JSP, the thread determines whether the JSP is already compiled. If the JSP is not compiled, the thread tries to compile the JSP.

If after the specified number of tries, the thread cannot compile the JSP, an error message is issued. The thread does not make any additional attempts to compile the JSP.

Data type	Integer
Default	5

**gotcha:** This custom property was added to the product in Fix Pack 7.0.0.3.

**com.ibm.ws.webcontainer.assumefiltersuccessonsecurityerror:** When a request is received for a static file which does not exist, the web container calls defined servlet filters. If the filters do not successfully complete, a 404 error code is set. In a situation where application security is enabled, a security check is performed as part of filter invocation. Typically if the security check fails the web container considers the filters to have failed and still sets a 404 error code instead of the 401 error code that indicates the failure of a security check. The 404 error code enables the requester to access the static file without logging on.

If you are running on Version 7.0.0.5, or later, you can set the `com.ibm.ws.webcontainer.assumefiltersuccessonsecurityerror` custom property to `true`, to prevent the 401 error code from being replaced with a 404 error code, and ensure that a user must enter a valid user ID and password before they can access a static file. The default value for this property is `false`.

Name	Value
<code>com.ibm.ws.webcontainer.assumefiltersuccessonsecurityerror</code>	<code>true</code>

**com.ibm.ws.webcontainer.channelwritetype:**

By default, the web container uses asynchronous writes to write response data in chunks up to the response buffer size. For larger responses that are greater than the response buffer size, the web container continues to buffer response data into memory while waiting for an asynchronous write of a response data chunk to complete. This process can result in part of a large response held in memory, which can lead to high memory usage and potentially an out of memory error. An application server hang might also occur when a server is simultaneously processing more requests than web container-defined threads.

If the `com.ibm.ws.webcontainer.channelwritetype` property is set to `sync`, synchronous writing is used, otherwise asynchronous writing is used by default. With synchronous writing, response data are written synchronously in chunks of up to the value of `responsebuffersize` and no response data are buffered into memory while waiting for a synchronous write of a response data chunk to complete. As a result, the approximate maximum amount of response data that is held in memory is equal to the `responsebuffersize` multiplied by the number of web container threads. The maximum number of requests that can be processed simultaneously by the web container is limited by the number of web container threads. Additional requests are queued, waiting for a request that is in process to complete.

The `responsebuffersize` web container custom property defines the maximum amount of response data written by the web container in a single chunk, and is 32k by default. As a result, it is used to change the number of writes needed by the web container to send complete response data. However, if an application flushes response data, any response data held by the web container is immediately written irrespective of the `responsebuffersize`.

Use the following name-value pair to write chunks of data using synchronous writes.

Name	Value
<code>com.ibm.ws.webcontainer.channelwritetype</code>	<code>sync</code>

| **com.ibm.ws.webcontainer.checkEDRinGetRealPath:** The `ServletContext.getRealPath()` Java Servlet API does not return the correct path for a requested resource when the resource exists in an `extendedDocumentRoot` path and does not exist in the installed application path. If you want the `ServletContext.getRealPath()` Java Servlet API to look for the requested resource in the `extendedDocumentRoot` path if the resource is not found in the installed application path, set the `com.ibm.ws.webcontainer.checkEDRinGetRealPath` custom property to `true`.

When this property is set to true, and the requested resource is also not found in the extendedDocumentRoot path, a null value is returned.

Name	Default value
com.ibm.ws.webcontainer.checkEDRinGetRealPath	false

**com.ibm.ws.webcontainer.copyattributeskeyset:** This custom property addresses a situation where the request.getAttributeNames method returns a list of values. If a servlet modifies the list using the request.removeAttribute method, subsequent calls to the nextElement method causes a java.util.ConcurrentModificationException exception. To enable a servlet to modify the list, set the com.ibm.ws.webcontainer.copyattributeskeyset custom property to true. When you set this custom property to true, a copy of the list of attributes is returned, which enables the servlet to modify the list without resulting in a java.util.ConcurrentModificationException exception when the nextElement method is called.

Name	Default value
com.ibm.ws.webcontainer.copyattributeskeyset	false

**com.ibm.ws.webcontainer.disableSetCharacterEncodingAfterParametersRead:** The web container processes a setCharacterEncoding(String) method of the ServletRequest API even if it is called after the post data is parsed. According to the Java Servlet Specification, the web container should ignore a setCharacterEncoding(String) method if the method is called after the data is parsed.

If you want the web container to ignore a setCharacterEncoding(String) method if the method is called after the data is parsed, add the com.ibm.ws.webcontainer.disableSetCharacterEncodingAfterParametersRead custom property to your web container configuration settings and set this property to true.

The default value for this property is false.

Name	Value
com.ibm.ws.webcontainer.disableSetCharacterEncodingAfterParametersRead	false

**com.ibm.ws.webcontainer.disableSystemAppGlobalListenerLoading:**

If a system application is the first to start, and the application attempts to load a global listener in a shared library that is associated with the server classloader, the application does not load that listener and prevents the listener from being loaded or invoked by a later non-system application. Set the com.ibm.ws.webcontainer.disableSystemAppGlobalListenerLoading custom property to true to prevent system applications from loading global listeners. When this property is set to true, the system application does not attempt to load the global listeners and later non-system applications can load them from a shared library associated with a server class loader.

Name	Value
com.ibm.ws.webcontainer.disableSystemAppGlobalListenerLoading	true

**com.ibm.ws.webcontainer.disableXPoweredBy:**

**Note:** When you configure server security, you can turn off the X-Powered-By header if you do not want to reveal which server you are running. Use this custom property to disable the X-Powered-By header, which prevents the header from being sent on the HTTP response. The default value is false. However, set to true, if you want to disable this header.

Name	Value
com.ibm.ws.webcontainer.disablePoweredBy	false

***com.ibm.ws.webcontainer.disallowAllFileServing:***

Use the com.ibm.ws.webcontainer.disallowAllFileServing custom property to disable file serving on all applications on a specific application server.

You can enable file serving on a global level across a given application server by using the fileServingEnabled custom property. However, the fileServingEnabled property is overridden by the specific deployment information of each application. Therefore, the current fileServingEnabled custom property only applies as a backup in case an application does not define the fileServingEnabled setting itself.

To globally override this setting on a specific application server to prevent the application server from serving static files regardless of their individual deployment settings, set the com.ibm.ws.webcontainer.disallowAllFileServing web container custom property to true using the following name-value pair.

Name	Value
com.ibm.ws.webcontainer.disallowAllFileServing	true

***com.ibm.ws.webcontainer.disallowserveservletsbyclassname:***

When the serveServletsByClassnameEnabled property is enabled, it is possible to access servlets directly, resulting in a possible security exposure. Define the following custom property to disallow the use of the serveServletsByClassnameEnabled property across the entire application server level.

Name	Value
com.ibm.ws.webcontainer.disallowserveservletsbyclassname	true

***com.ibm.ws.webcontainer.discernUnavailableServlet:*** Typically, when the web container receives an UnavailableException, it cannot determine whether the exception was issued from a servlet or a dispatched resource. Therefore, the web container automatically marks the servlet unavailable even if it is the dispatched resource that is unavailable.

If you are running on Version 7.0.0.5 or later, and have set the com.ibm.ws.webcontainer.discernUnavailableServlet custom property to true, any UnavailableException that is issued from a dispatched resource is placed in a wrapper. This wrapper enables the web container to determine whether the exception was issued from the servlet or a dispatched resource. If the exception is not issued by the servlet, the web container does not mark the servlet unavailable.

The default value for the com.ibm.ws.webcontainer.discernUnavailableServlet custom property is false.

Name	Value
com.ibm.ws.webcontainer.discernUnavailableServlet	true

***com.ibm.ws.webcontainer.dispatcherRethrowSER:*** Typically, the RequestDispatcher does not propagate exceptions thrown from dispatched servlets, including JavaServer Pages, back to the servlet doing the dispatching. If you want the RequestDispatcher to throw exceptions back to the servlet doing the dispatching, add the com.ibm.ws.webcontainer.dispatcherRethrowSER custom property to the settings for the web container, and set the property to true. The default value for this property is false.

Name	Value
com.ibm.ws.webcontainer.dispatcherRethrowSER	true

**Note:** The `com.ibm.ws.webcontainer.dispatcherRethrowSER` custom property supersedes the `com.ibm.ws.webcontainer.dispatcherRethrowSER` custom property. When you enable the `com.ibm.ws.webcontainer.dispatcherRethrowSER` custom property by setting its value to `true`, the `com.ibm.ws.webcontainer.dispatcherRethrowSER` custom property is also set to `true`.

***com.ibm.ws.webcontainer.dispatcherRethrowSEError:*** When a JavaServer Page (JSP) file contains a compilation error, the runtime error is caught and handled directly by the container. Exceptions are not propagated and addressed by the dispatched JSP resource. With the `com.ibm.ws.webcontainer.dispatcherRethrowSEError` custom property, exceptions are propagated back to the dispatched JSP resource.

By default, this custom property value is set to `false`.

Name	Value
com.ibm.ws.webcontainer.dispatcherRethrowSEError	true

**Note:** The `com.ibm.ws.webcontainer.dispatcherRethrowSEError` custom property supersedes the `com.ibm.ws.webcontainer.dispatcherRethrowSER` custom property. When you enable the `com.ibm.ws.webcontainer.dispatcherRethrowSEError` custom property by setting its value to `true`, the `com.ibm.ws.webcontainer.dispatcherRethrowSER` custom property is also set to `true`.

***com.ibm.ws.webcontainer.divertrecursiveexceptiontoerrorlog:***

When a recursive error occurs in an application, the exception message is logged by the trace audit method, which directs the message to the system console. If you need the message to be logged in the error log instead, add the `com.ibm.ws.webcontainer.divertrecursiveexceptiontoerrorlog` custom property to the web container configuration settings, and set the property to `true`. When the `com.ibm.ws.webcontainer.divertrecursiveexceptiontoerrorlog` property is set to `true`, exception messages are sent to the error log instead of to the system console.

Name	Value
com.ibm.ws.webcontainer.divertrecursiveexceptiontoerrorlog	true

***com.ibm.ws.webcontainer.donotservebyclassname:***

The `com.ibm.ws.webcontainer.donotservebyclassname` custom property specifies a list of classes that cannot be served by the class name.

Name	Value
com.ibm.ws.webcontainer.donotservebyclassname	A semi-colon delimited list of classes to be completely disallowed from being served by class name.

***com.ibm.ws.webcontainer.enabledefaultservletrequestpathelements:*** To correctly map a request to a default servlet, you must determine the proper servlet path and `PathInfo` values. The following table shows the affects on the Servlet Path and `PathInfo` values when you set the `com.ibm.ws.webcontainer.enabledefaultservletrequestpathelements` custom property to a `true` or `false` value.

Table 249. Servlet Path and PathInfo values. Values for Servlet Path and PathInfo

Value	Servlet Path value	PathInfo value
true	Set to the contents of the URI after the Context Path	Set to a null value
false (Default)	Set to an empty string	Set based on the contents of the URI after the Context Path

**com.ibm.ws.webcontainer.enableJspMappingOverride:** When a url-pattern is defined in the jsp-property-group of the web.xml, file, it is typically mapped to, and handled by the JavaServer Page (JSP) engine. If you have applications that must override this mapping so that they can handle and serve the JSP content themselves, set the com.ibm.ws.webcontainer.enableJspMappingOverride property to true.

The default value for this property is false.

Name	Value
com.ibm.ws.webcontainer.enableJspMappingOverride	true

**com.ibm.ws.webcontainer.enableMultiReadOfPostData:** Set the com.ibm.ws.webcontainer.enableMultiReadOfPostData custom property to true if you want to enable multiple reads of post data. When this property is set to true, the post data can be read multiple times as either an InputStream or Reader, and as parameters.

When the web container is enabled for multiple reads of post data, you can set up an application to complete the following actions if you want that application to re-read post data from the beginning using either an InputStream or Reader:

1. Obtain the InputStream or Reader
2. Read the data
3. Close the InputStream or Reader

If either the first or third action does not occur, the next read of the post data is not reset to the beginning of that data.

The web container automatically completes this sequence if an application re-reads the post data as parameters.

The default value for this property is false.

Name	Value
com.ibm.ws.webcontainer.enableMultiReadOfPostData	true

**com.ibm.ws.webcontainer.extractHostHeaderPort and trusthostheaderport:** The getServerPort method relies on the getVirtualPort method of the channel, which returns a port number in the following order:

1. Port number from the request URL
2. Port number from the request host header

This order is compliant with HTTP/1.1 RFC but not with the Java Servlet Specification Version 2.4 API, which requires the port number from the host header to be returned first, if any, or the request URL. The correct returned URL for the above example is: http://ProxyServer:8888. The web container was modified to return a port number from the host header, if any, or the URL port that accepted the client

connection. You must set the `truststheaderport` and the `com.ibm.ws.webcontainer.extractHostHeaderPort` custom property to true to return the port number from the request host header first. For example, set these properties in the `web.xml` file using:

```
truststheaderport = true
com.ibm.ws.webcontainer.extractHostHeaderPort = true
```

Or you can set these properties as web container custom properties in the administrative console using the following two sets of name-value pairs:

Name	Value
<code>com.ibm.ws.webcontainer.extractHostHeaderPort</code>	true
<code>truststheaderport</code>	true

***com.ibm.ws.webcontainer.fileWrapperEvents:***

In WebSphere Application Server Version 5.1 processing of static files is performed by `SimpleFileServlet` which generates both SMF and PMI data. In Version 6.0.1 and later, static files are handled by a file wrapper that does not generate SMF and PMI data for static files. If you need to generate SMF and PMI data when serving static files, add the `com.ibm.ws.webcontainer.fileWrapperEvents` custom property to your web container configuration settings, and set the property to true.

Name	Value
<code>com.ibm.ws.webcontainer.fileWrapperEvents</code>	true

***com.ibm.ws.webcontainer.FileWrapperEventsLessDetail:*** Starting with Version 6.1, the SMF type 120 record displays the name of the static resource instead of `FileServletWrapper` in the name field of a static file report. If you migrated from an earlier version of the product, and want your SMF type 120 record to display `FileServletWrapper` in the name field of a static file report, add the `com.ibm.ws.webcontainer.FileWrapperEventsLessDetail` custom property to your web container settings and set it to true. The default value for this property is false.

Name	Value
<code>com.ibm.ws.webcontainer.FileWrapperEventsLessDetail</code>	false

***com.ibm.ws.webcontainer.finishresponseonclose:***

Use the `com.ibm.ws.webcontainer.finishresponseonclose` custom property to indicate that you want the web container to close a connection when a servlet calls `close()` on a writer or output stream.

Typically, when a servlet calls `close()` on a writer or output stream, the web container sends the data that has been written to the writer or output stream to the client, and then waits for the servlet `service()` method to finish before it closes the connection. This delay might be interpreted as a response completion delay, especially if a servlet `service()` method does not complete until sometime after the writer or output stream is closed.

Name	Value
<code>com.ibm.ws.webcontainer.finishresponseonclose</code>	true

***com.ibm.ws.webcontainer.ForceDifferentCookiePaths:***

**Note:** When you configure an application to use a cookie to track the session, the default path for the cookie is set to the context root of the application. Therefore, the cookie is only sent to requests

that are made to this application. To change the default path to be "/" (forward slash), such that the cookie is sent to requests for any application in this domain, set the ForceDifferentCookiePaths session manager custom property.

Name	Value
com.ibm.ws.webcontainer.ForceDifferentCookiePaths	false

**com.ibm.ws.webcontainer.HTTPOnlyCookies:** The com.ibm.ws.webcontainer.HTTPOnlyCookies custom property provides a level of defense against a client-side script accessing a protected cookie and acquiring its content. By using this custom property you can prevent Java scripts that run in a browser from accessing all cookies or a particular list of cookies of your choosing. The HTTPOnly attribute is added to each cookie specified in this custom property and enables protection from client-side script access.

**gotcha:** Specifying com.ibm.ws.webcontainer.HTTPOnlyCookies with no operands means that the HTTPOnly attribute will NOT be added to any cookie, and any client-side Java script running in a browser can access the content of any cookies.

The following examples illustrate setting this custom property.

```
com.ibm.ws.webcontainer.HTTPOnlyCookies = *
com.ibm.ws.webcontainer.HTTPOnlyCookies = cookieName1, Account3Cookie, JsessionID
```

**Note:** Cookie names used in specifying com.ibm.ws.webcontainer.HTTPOnlyCookies are case-insensitive.

Name	Value
com.ibm.ws.webcontainer.HTTPOnlyCookies	<p>* (An asterisk value means that all cookies are given the HTTPOnly attribute.)</p> <p>or</p> <p>A comma delimited list of the specific cookies that are given the HTTPOnly attribute. The HTTPOnly attribute is only given to cookies that are on this list.</p>

**com.ibm.ws.webcontainer.ignoreinjectionfailure:** If a resource or Enterprise JavaBeans (EJB) injection fails during the servlet initialization process, an error message is written to the server log files. However, the error message is not propagated to the client. In addition, the servlet is put into service and it is not reinitialized until its application is restarted. During this time, if a request is received that references the resource, which previously failed to inject, a NullPointerException exception results. Similarly, this problem can occur during the filter and listener initialization processes.

The com.ibm.ws.webcontainer.ignoreinjectionfailure custom property enables you to specify whether to propagate these error messages and whether to put a servlet into service. By default, the custom property has a default value of false, which retains the previously described behavior. To enable the propagation of these injection exceptions to the client and to not put the servlet into service, you must leave this custom property set to false.

Name	Value
com.ibm.ws.webcontainer.ignoreinjectionfailure	true

**com.ibm.ws.webcontainer.ignoreInvalidQueryString:** When the web container encounters an encoding character in a query string pair that is not valid, it throws an IllegalArgumentException exception and, by default, ignores the entire query string. In applications where every field in the query string is an essential resource, it might not be desirable to ignore the entire query string. If you set the com.ibm.ws.webcontainer.ignoreInvalidQueryString custom property to true, the web container ignores query string pairs that are not valid and continues to process valid query string pairs.

Name	Value
com.ibm.ws.webcontainer.ignoreInvalidQueryString	false

**com.ibm.ws.webcontainer.IgnoreSessiononStaticFileRequest:** The web container accesses a session for the static file requests involving filters. This action can result in a performance degradation, for example, when running with database session persistence. If you set the `com.ibm.ws.webcontainer.IgnoreSessiononStaticFileRequest` custom property to `true`, the web container cannot access a session for the static files requests involving filters. The default value for this property is `false`.

Name	Value
com.ibm.ws.webcontainer.IgnoreSessiononStaticFileRequest	true

**com.ibm.ws.webcontainer.invokeFilterInitAtStartup:** The `com.ibm.ws.webcontainer.invokeFilterInitAtStartup` custom property enables the web container to invoke the `init` method and initialize a filter during the startup process for an application. The default value for this property is `false`.

Name	Value
com.ibm.ws.webcontainer.invokeFilterInitAtStartup	true

**com.ibm.ws.webcontainer.invokeFiltersCompatibility:**

You might need to use a custom servlet filter with web applications to map files from a one URI to another URI that points to a particular resource. For example, you might map URIs that start with `my_company` to the `my_company/external` directory. Without enabling the `com.ibm.ws.webcontainer.invokeFiltersCompatibility` custom property, the web container does not call any custom servlet filters.

With this custom property, the web container calls custom servlet filters before looking for welcome files. Also, if the web container cannot find a resource, it calls the custom servlet filters before creating a `FileNotFoundException` exception. This change enables the web container to verify whether the custom servlet filters modify the path to a resource.

Name	Value
com.ibm.ws.webcontainer.invokeFiltersCompatibility	true

**com.ibm.ws.webcontainer.invokeRequestListenerForFilter:** If a web application has defined the listener in the web deployment descriptor xml file, then you must set the `com.ibm.ws.webcontainer.invokeRequestListenerForFilter` custom property to `true` to have `ServletRequestListener` invoked when a request is about to enter the filter for that web application.

According to the Java Servlet Specification, a `ServletRequestListener` should be invoked if a request is about to enter the filter for a web application that has defined the listener in the web deployment descriptor xml file.

The default value is `false`.

Name	Value
com.ibm.ws.webcontainer.invokeRequestListenerForFilter	true

**com.ibm.ws.webcontainer.KeepUnreadPostDataAfterResponseSentToClient:** This property indicates whether post data is available to read after the client response is completed, following either the completion of a forward request completes, or a return from a sendRedirect. If this property is set to true, post data is available to read after the client response is completed either after a forward request completes, which is the default behavior, or on a return from a sendRedirect, which occurs when the com.ibm.ws.webcontainer.SendResponseToClientAsPartOfSendRedirect custom property is set to true. However, setting this property to true requires unread post data to be held in memory until the target resource completes, and increases memory usage.

The default value is false.

**com.ibm.ws.webcontainer.logServletContainerInitializerClassloadingErrors:**

**Note:** When examining the classes of an application to see if they match any of the criteria that is specified by the HandlesTypes annotation of a ServletContainerInitializer, the container might run into class loading problems if one or more of the optional application JAR files are missing. Because the container does not decide whether these types of class loading failures prevent the application from working correctly, it ignores the failures and provides a configuration option that logs them.

The default value for the com.ibm.ws.webcontainer.logServletContainerInitializerClassloadingErrors custom property is false. Changing the value to true turns on logging.

Name	Value
com.ibm.ws.webcontainer.logServletContainerInitializerClassloadingErrors	false

**com.ibm.ws.webcontainer.mapFiltersToAsterisk:**

When processing a request, the web container recognizes servlet mappings to "\*" as the same as servlet mappings to "/\*". To provide the same behavior with filter mapping, set the com.ibm.ws.webcontainer.mapFiltersToAsterisk custom property to true. Setting the com.ibm.ws.webcontainer.mapFiltersToAsterisk custom property to true causes the web container to recognize filter mappings to "\*" as a filter mapping to "/\*". This custom property is not case-sensitive.

Name	Value
com.ibm.ws.webcontainer.mapFiltersToAsterisk	true

**com.ibm.ws.webcontainer.normalizerequesturi:** Typically, request URI 404 errors do not occur if a request URI is submitted from a browser, because most modern browsers automatically normalizes a request URI before calling WebSphere Application Server. Therefore, by default, the web container does not normalize a request URI before trying to resolve that URI to an application and servlet mapping.

A request URI, that includes ./ or ././ as part of an application context, that has not been normalized, might fail with a 404 error. Similarly, a request URI, that includes ./ or ././ as part of a servlet path, that has not been normalized, fails to match a servlet mapping, which also results in a 404 error, even though the URI is normalized before resolving the URI to a JavaServer Pages (JSP) or static file.

You can set the com.ibm.ws.webcontainer.normalizerequesturi custom property to true and the web container normalizes these types of request URIs.

Name	Value
com.ibm.ws.webcontainer.normalizerequesturi	true

**com.ibm.ws.webcontainer.parseUTF8PostData:**

If the web container attempts to process a request that includes UTF-8 post data that is not URL encoded, the target resource accesses the post data as parameters. However, the UTF-8 data is not decoded correctly and the result data might be lost.

To resolve this issue, set the `com.ibm.ws.webcontainer.parseUTF8PostData` custom property to true. When the web container processes parameters, it detects UTF-8 post data that is not URL encoded and includes the data in the parameter values.

By default, the value for this custom property is false. To use the function, you must set the value to true.

Name	Value
<code>com.ibm.ws.webcontainer.parseUTF8PostData</code>	true

***com.ibm.ws.webcontainer.provideQueryStringToWelcomeFile:*** Typically, when a request is initially sent to the context root of the application, the request is forwarded to a welcome file. If a query string is included in an initial request, it is unavailable to the welcome file if you included the `request.getQueryString()` attribute in the welcome file. However, the query string is available to the welcome file if you included the `javax.servlet.forward.query_string` attribute in the welcome file.

If you must use the `request.getQueryString()` attribute, instead of the `javax.servlet.forward.query_string` attribute, to make the query string available to the welcome file, add the `com.ibm.ws.webcontainer.provideQueryStringToWelcomeFile` custom property to your web container configuration and set the property to true. The default value for this property is false.

Name	Value
<code>com.ibm.ws.webcontainer.provideQueryStringToWelcomeFile</code>	true

***com.ibm.ws.webcontainer.SendResponseToClientAsPartOfSendRedirect:*** This property indicates whether a response is completed as part of a `sendRedirect` request. If this property is set to true, a response is completed as part of a `sendRedirect` request, and any post data associated with the request is not available for a read on return from `sendRedirect`.

The default value is false.

***com.ibm.ws.webcontainer.SendResponseToClientWhenResponselsComplete:*** This property indicates whether a response is completed on return from a forward request.

If this property is set to false, a response is not completed on return from a forward request. Instead, it is delayed until the target resource completes. Post data is available for a read after the forward completes.

The default value is true.

***com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot:*** Typically, the first time the web container handles a request for a static welcome page that is not a JavaServer Pages (JSP) file, the web container does not search the `ExtendedDocumentRoot` for the welcome file unless the request for that welcome file is fully-qualified. If the request is fully-qualified, the web container serves the welcome file, and the context root of the application displays the welcome file. If the request for the static welcome file is not fully-qualified, the web container returns a 404 error, which indicates that the web container did not find the welcome file.

After the web container successfully serves a welcome file, the web container creates a mapping for that welcome file. The web container then uses this mapping to handle future requests for the welcome file, thereby eliminating the need for subsequent requests to be fully-qualified.

If you want the web container to always search an application defined `ExtendedDocumentRoot` for a welcome file, even if the request is not fully-qualified, you can add the `com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot` custom property to your web container settings, and set this property to `true`.

The default value for this property is `false`.

Name	Value
<code>com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot</code>	<code>false</code>

***com.ibm.ws.webcontainer.ServletDestroyWaitTime:*** By default, when an application is stopped the web container waits up to 60 seconds for each active request for a resource of that application to complete. You can now define the `com.ibm.ws.webcontainer.ServletDestroyWaitTime` web container custom property to control the amount of time that the web container waits for an active request to complete when the owning application is stopped.

Set the `com.ibm.ws.webcontainer.ServletDestroyWaitTime` custom property to an integer value, which specifies the number of seconds to wait for a request to complete. The default value is 60 seconds.

Name	Value
<code>com.ibm.ws.webcontainer.ServletDestroyWaitTime</code>	<code>integer</code>

***com.ibm.ws.webcontainer.setUnencodedHTMLinsendError:*** Typically, the web container encodes the specified error messages before formatting them, to prevent Cross-Site Scripting (XSS) attacks on the client if the application does not sanitize these messages. However the Java Servlet Specification for the `sendError(int, String)` method, indicates that the server should create the response to look like an HTML-formatted server error page.

If you do not want the web container to encode the specified error messages before formatting them, add the `com.ibm.ws.webcontainer.setUnencodedHTMLinsendError` custom property to your web container configuration settings, and set the property to `true`.

The default value for this property is `false`.

Name	Value
<code>com.ibm.ws.webcontainer.setUnencodedHTMLinsendError</code>	<code>true</code>

***com.ibm.ws.webcontainer.suppressheadersinrequest:*** The `com.ibm.ws.webcontainer.suppressheadersinrequest` custom property can be used to suppress the inclusion of request headers that start with special characters, such as "\$" or "\_". Some applications do not handle request headers that start with special characters.

Name	Value
<code>com.ibm.ws.webcontainer.suppressheadersinrequest</code>	Delimited list of header prefixes to be suppressed.  Example: <code>\$WS,_WS</code>

***com.ibm.ws.webcontainer.suppressHtmlRecursiveErrorOutput:***

During a recursive error that an application-specified error page cannot handle, the stack trace and error message are output as an HTML page. This information includes class names and program information that the application developer does not want expose to the user.

You can set the `com.ibm.ws.webcontainer.suppressHtmlRecursiveErrorOutput` web container custom property to suppress the HTML output of the error text, without changing the internal logging of the message. Set the custom property `com.ibm.ws.webcontainer.suppressHtmlRecursiveErrorOutput` to `true` to disable the HTML output of the error message to the user and present the user with blank page with a 500 error code.

Name	Value
<code>com.ibm.ws.webcontainer.suppressHtmlRecursiveErrorOutput</code>	<code>true</code>

***com.ibm.ws.webcontainer.suppressLastZeroBytePackage:*** Typically, the last zero byte chunk is used to indicate, to a client, the end of the response data in a chunked encoded transmission. Some applications use this last zero to determine when the response data is completely received, and they can start processing it. If an error occurs in the application after the response headers are sent, the last chunk of data is still sent to the client. The client might not realize that an error has occurred, and attempt to process incomplete data.

If you set the `com.ibm.ws.webcontainer.suppressLastZeroBytePackage` custom property to `true`, if an error occurs in the application after the response headers are sent, the last chunk of data is not sent to the client. The default value for this property is `false`.

Name	Value
<code>com.ibm.ws.webcontainer.suppressLastZeroBytePackage</code>	<code>true</code>

***com.ibm.ws.webcontainer.suppressServletExceptionLogging:***

If a servlet creates an exception, it is logged to the system console. If you do not want the web container to log servlet- created exceptions, add the `com.ibm.ws.webcontainer.suppressServletExceptionLogging` custom property to the web container configuration settings, and set the property to `true`.

Name	Value
<code>com.ibm.ws.webcontainer.suppressServletExceptionLogging</code>	<code>true</code>

***com.ibm.ws.webcontainer.throwMissingJspException:***

Set the `com.ibm.ws.webcontainer.throwMissingJspException` custom property to `true` to create a `FileNotFoundException` when a resource that is included by a JSP file is missing. If this property is not set to `true`, an error page displays.

Name	Value
<code>com.ibm.ws.webcontainer.throwMissingJspException</code>	<code>true</code>

***com.ibm.ws.webcontainer.webgroupvhostnotfound:*** Error message SRVE0017W states "Web Group not found: {0}", and error message SRVE0255 states "A WebGroup/Virtual Host to handle {0} has not been defined". These messages might be returned when the application that is called to process the request serviced by IBM WebSphere Application Server is not found. You can use the `com.ibm.ws.webcontainer.webgroupvhostnotfound` custom property to change the text of these messages to text that is more suitable for your environment.

Name	Value
<code>com.ibm.ws.webcontainer.webgroupvhostnotfound</code>	String Example: Application not found.

***com.ibm.ws.webcontainer.xPoweredBy:***

**Note:** This custom property enables you to configure the value of the X-Powered-By header, which supplies the implementation information of the server. The default value is Servlet/3.0.

Name	Value
com.ibm.ws.webcontainer.xPoweredBy	Servlet/3.0

***com.ibm.wsspi.jsp.convertAttrValueToString:***

Set the com.ibm.wsspi.jsp.convertAttrValueToString web container custom property to true to convert start and end attributes of the repeat tag to strings before they are used.

Name	Value
com.ibm.wsspi.jsp.convertAttrValueToString	true

***com.ibm.wsspi.jsp.disableElCache:***

Set the com.ibm.wsspi.jsp.disableElCache web container custom property to true to disable the commons-el expression cache if you are experiencing out of memory conditions because the hash maps are held by the expression evaluator.

Name	Value
com.ibm.wsspi.jsp.disableElCache	true

***com.ibm.wsspi.jsp.disableResourceInjection:*** The resource injection feature accesses resources in applications differently than it did in earlier versions of the product, and causes the compiled method output to be larger than it was previously. If you have large JSP files that in earlier releases pushed the 65535 byte limit in the translated service method, they might now exceed this limit, causing the compile to fail.

If you encounter this situation, you can either break a large JSP file into smaller JSP files, and use <jsp:include> statements to combine them after they are compiled, or you can add the com.ibm.wsspi.jsp.disableResourceInjection custom property to your web container settings to disable the resource injection function during the JSP translation process. When the com.ibm.wsspi.jsp.disableResourceInjection custom property is set to true, the resource injection function is disabled for all applications.

If you only want to disable the resource injection function for specific applications, you can add the disableResourceInjection JSP attribute to the ibm-web-ext.xml files for those specific applications.

The default value for the com.ibm.wsspi.jsp.disableResourceInjection custom property is false.

Name	Value
com.ibm.wsspi.jsp.disableResourceInjection	true

***com.ibm.wsspi.jsp.disableTldSearch:*** The *com.ibm.wsspi.jsp.disableTldSearch* custom property can be used to improve application startup time. By default, when an application starts, the JSP engine searches the application installation directories for the taglib descriptor (TLD) files. This search process might increase the startup time for large applications with many files and directories. To disable this search process, use the following name-value pair:

Name	Value
com.ibm.wsspi.jsp.disableTldSearch	true

***com.ibm.wsspi.jsp.enabledoublequotesdecoding:***

Set the com.ibm.wsspi.jsp.enabledoublequotesdecoding web container custom property to decode an encoded double quote character if it is embedded in a script function within a JavaServer Pages (JSP) file.

The JSP Container does not decode an encoded double quote character during the translation of a JSP file. Instead, there is a dependency on the browser to decode it. However, when an encoded double quote character exists inside a script function of a tag, the browser cannot decode it. Thus, when this custom property is not set, the encoded double quote character causes the script function to malfunction.

When you set this custom property, the value affects all of your deployed applications. If you want to affect an individual application, set the enableDoubleQuotesDecoding JSP attribute to true within the `ibm-web-ext.xml` file in your application.

Name	Value
com.ibm.wsspi.jsp.enabledoublequotesdecoding	true

***DecodeUriAsUTF8:***

The UTF-8 encoded URL feature, which provides UTF-8 encoded Uniform Resource Locators (URLs) to support the double-byte characters in URLs is enabled by default. You can prevent the web container from explicitly decoding URLs in UTF-8 and have them use the ISO-8859 standard as per the current HTTP specification by using the following name-value pair.

Name	Value
DecodeUriAsUTF8	false

***enableInProcessConnections:***

Use the enableInProcessConnections custom property to reduce response times and to reduce the number of threads that are used to service a request, which reduces the potential for a deadlock. There is an optimized communication path between a web services client application and a web container that are located in the same application server process. Requests from the web services client that are normally sent to the web container using a network connection are delivered directly to the web container using an optimized local path. The local path is available because the web services client application and the web container are running in the same process. This optimized communication path is disabled by default. Before enabling this property, make sure that wild cards are not specified for the web container ports. Use specific ports for the web container when the optimized communication path is enabled. To enable the optimized communication path, use the following name-value pair:

Name	Value
enableInProcessConnections	true

Refer to the [Web services client to web container optimized communication](#) article for additional information.

***fileServingEnabled, directoryBrowsingEnabled, and serveServletsByClassnameEnabled:***

fileServingEnabled, directoryBrowsingEnabled, and similar properties are global settings for internal servlets. Web application archive (WAR) files that are packaged using third-party tools cannot specify

behavior for the services that are exposed by the web container internal servlets. You can globally enable and disable internal servlets for all web applications at the web container level by creating name-value pairs.

Name	Default
fileServingEnabled	true
directoryBrowsingEnabled	false
serveServletsByClassnameEnabled	false

Settings that are defined in an assembly tool take precedence over the global settings that are set through the custom properties at the web container level.

Web application deployment extensions continue to hold configuration information for the services that are provided by the internal servlets, and take precedence over the global settings that are set through the custom properties at the web container level.

**ForceSessionIdLengthCheck:** Newly-generated session IDs are, by default, 23 characters in length, unless you use the `HttpSessionIdLength` custom property to specify a different maximum length for your session IDs.

When an incoming request has a session ID that is longer than the expected session ID length, and whose prefix is identical to a pre-existing session ID, the longer ID is used to return a new session. If the length of the session ID on the incoming request is larger than the maximum length specified for your system, such that it exceeds the width of the ID column in the session table column that is used in database persistence, an SQL0302 error occurs.

To prevent the occurrence of these SQL0302 errors, you can add the `ForceSessionIdLengthCheck` custom property to your web container custom properties and set it to `true`. When this custom property is set to `true`, the length of a session ID cannot exceed 23 characters. If an incoming request has a session ID that is longer than 23 characters, the first 23 characters are used to return a new session.

Name	Value
ForceSessionIdLengthCheck	true

### **ForceSessionInvalidationMultiple:**

The `ForceSessionInvalidationMultiple` custom property indicates whether the session manager should wait indefinitely for a request to complete before attempting to invalidate the session, or attempt to invalidate a session after the specified time limit has elapsed. The default value for this property is 1.

- If you specify 0 (zero) for this custom property, the session manager waits indefinitely until a request is complete before attempting to invalidate the session.

If your requests normally are not bound by a response time limit, specify 0 for this property.

- If you specify a positive integer, such as 1, 2, or 3 for this custom property, even if a session is not known to have completed, the session manager attempts to invalidate the session if the indicated time period since the last access occurred has elapsed. This time period is the result of multiplying the value specified for this property and the value specified for the `Session Timeout` property. For example, if you specify 2 minutes for the `Session Timeout` property and 2 for the `ForceSessionInvalidationMultiple` property, the session manager attempts to invalidate the session after 4 minutes.

If you want to invalidate your sessions after a certain amount of time has elapsed, specify the appropriate positive integer for this property.

Name	Value
ForceSessionInvalidationMultiple	1

### ***httpsIndicatorHeader:***

The custom property *httpsIndicatorHeader* manages HTTPS requests that are forwarded to an application server from an SSL offloader that is used in front of WebSphere Application Server. When an HTTPS request is received by an SSL offloader it is redirected over HTTP to an application server using WebSphere Application Server. The SSL offloader adds a header indicating the original request was over HTTP. The *httpsIndicatorHeader* property specifies the header name added by the SSL box. The application server checks this indicator to determine if SSL is required. If it determines the request is SSL over HTTP, an HTTPS scheme is chosen.

Name	Value
httpsIndicatorHeader	<i>Request header key name</i>

### ***HttpSessionIdReuse:***

The custom property *HttpSessionIdReuse* determines whether the session manager can use the session ID sent from a browser to preserve session data across web applications that are running in an environment that is not configured for session persistence. In a multi-JVM environment, that is not configured for session persistence, setting this property to `true` enables the session manager to use the same session information for all of a user requests, even if the web applications that are handling these requests are governed by different JVM files. The default value for this property is `false`.

**Note:** The use of the *HttpSessionIdReuse* property as a web container custom property is deprecated. You can now define it as a session management custom property.

To enable the session manager to use the session ID sent from a browser to preserve session data across web applications that are running in an environment that is not configured for session persistence, use the following name-value pair:

Name	Value
HttpSessionIdReuse	true

### ***listeners:***

The servlet specification supports applications registering listeners for servlet-related events on an individual application basis through the `web.xml` descriptor. However, using the *listeners* custom property, a server can listen to servlet events across web applications. To implement global listening, a listener is registered at the web container level and is propagated to all of the installed and new web applications. This global behavior of internal servlet listeners is controlled by the *listeners* custom property by using the following name-value pair format.

Name	Value
listeners	<i>listener_class</i>

The value for this property is a string, specifying a comma-separated list of listener classes. The listener that is supplied must implement standard listener classes from the Java Servlet API or IBM listener extension classes.

### ***MutualAuthCBindCheck:***

This property is only valid on the z/OS platform. Use the *MutualAuthCBindCheck* property to specify whether a client certificate should be resolved to a SAF principal.

Use the `MutualAuthCBindCheck` property to specify whether a client certificate should be resolved to a SAF principal. If this property is set to `true`, all SSL connections from a browser must have a client certificate, and the user ID associated with that client certificate must have RACF CONTROL authority for `CB.BIND.servername`. Regardless whether client certificate authentication is being used in an SSL connection, if these conditions are not met, the connection is closed. Issue the following RACF command to give the user ID associated with that client certificate RACF CONTROL authority:

```
PERMIT CB.BIND.<optional SAF profile prefix>.clustername CLASS(CBIND) ID(clientCertUserid) ACCESS(CONTROL)
```

Data type	String
Value	true or false
Default	false

**Important:** You can use HTTP transports on a V5.1 node in a mixed WebSphere Application Server environment. Refer to the HTTP transport custom properties topic for a description of these properties. However, you must use HTTP transport channels, instead of HTTP transports, to handle your HTTP requests on all of your other nodes. Refer to the HTTP transport channel custom properties topic for a description of the custom properties that you can specify for an HTTP transport channel.

***prependSlashToResource:***

WebSphere Application Server 5.x supports Uniform Resource Locators (URLs) without leading front slashes (/) and to preserve compatibility, You can set the custom property, `prependSlashToResource` to `true`. To ignore the specification and consider URLs without the leading front slash, use the following name-value pair.

Name	Value
<code>prependSlashToResource</code>	<code>true</code>

**trusted:** The **trusted** custom property enables the application server to use inbound private headers from the web server plug-in. These inbound private headers notify the application server about the connection to the web server. When you set the custom property to **true**, the application server uses the asserted information on the client certificates. These client certificates are used by the end user to connect to the web server and establish the client information, which is treated as the certificate for the end user. Then, the application server uses the certificate information for authentication purposes when client certificate authentication is used or when the application code accesses the `javax.net.ssl.peer_certificates` certificates. Because this information is asserted, it is insecure and potentially vulnerable to an attacker that is able to connect directly to the application server and bypass the web server.

The default value for this property is `true`.

**Important:** If you allow direct connections to the application server and use client certificates, you must set this custom property to **false**.

Name	Value
<code>trusted</code>	<code>true</code>

***UseOracleBLOB:***

The *UseOracleBLOB* custom property creates the HTTP session database table using the Binary Large Object (BLOB) data type for the medium column. This property increases performance of persistent sessions when Oracle databases are used. Due to an Oracle restriction, BLOB support requires use of the `oci` database driver for Oracle for more than 4000 bytes of data. You must also ensure that a new

sessions table is created before the server is restarted by dropping your old sessions table or by changing the datasource definition to reference a database that does not contain a sessions table.

**Note:** The use of the *UseOracleBLOB* property as a web container custom property is deprecated. You can now define it as a session management custom property.

To create a sessions table using the BLOB data type, use the following name-value pair:

Name	Value
UseOracleBLOB	true

## Web module deployment settings

Use this page to configure an instance of web module deployment.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Manage Modules > *Web\_module\_instance***.

### **URI:**

Specifies the relative location of the module within the application enterprise archive (EAR) file.

### **Alternate deployment descriptor:**

Specifies the alternate deployment descriptor for the module as defined in the application deployment descriptor according to the Java Platform, Enterprise Edition (Java EE) specification.

### **Starting weight:**

Specifies the order that modules are started. Lower weighted modules are started before higher weighted modules.

If the application deployment descriptor specifies the `<initialize-in-order>true</initialize-in-order>` element, the default starting weights reflect the order that is specified in the deployment descriptor. Otherwise, the defaults are determined based on module type (RAR modules start before EJB modules, which start before web modules).

### **Class loader order:**

Specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The standard for development kit class loaders and product class loaders is `Classes loaded with parent class loader first`. By specifying `Classes loaded with application class loader first`, your application can override classes contained in the parent class loader, but this action can potentially result in `ClassCastException` or `LinkageErrors` if you have mixed use of overridden classes and non-overridden classes.

The options are `Classes loaded with parent class loader first` and `Classes loaded with local class loader first (parent last)`. The default is to search in the parent class loader before searching in the application class loader to load a class.

#### **Data type**

String

#### **Default**

Classes loaded with parent class loader first

## Context root for web modules settings

Use this page to specify the context root for web modules during or after installation of an application onto a WebSphere Application Server deployment target.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Context root for web modules**. This page is the same as the Context root for web modules page on the application installation and update wizards.

***Web Module:***

Specifies the name of a web module in the application that you are installing or that you are viewing after installation.

***URI:***

Specifies the location of the module relative to the root of the application EAR file.

***Context Root:***

Specifies the context root of the web application (WAR).

A context root for each web module is defined in the application deployment descriptor during application assembly. Use this field to assign a different context root to a web module. The context root is combined with the defined servlet mapping (from the WAR file) to compose the full URL that users type to access the servlet. For example, if the context root is `/gettingstarted` and the servlet mapping is `MySession`, then the URL is `http://host:port/gettingstarted/MySession`.

## **Environment entries for web modules settings**

Use this page to configure the environment entries of Web modules such as servlets and JavaServer Pages (JSP) files.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Environment entries for web modules**. This page is the same as the Environment entries for web modules page on the application installation and update wizards.

***Module:***

Specifies the name of a web module.

***URI:***

Specifies the location of the module relative to the root of the application (EAR file).

***Name:***

Specifies the name of the environment entry that you are editing or viewing. The environment entry is the `env-entry` property in the web module.

***Type:***

Specifies a data type for the environment entry defined by the `env-entry` property in the web module.

***Description:***

Specifies information on the environment entry.

***Value:***

Specifies an editable value for the environment entry defined by the `env-entry` property in the web module.

The lookup name is displayed in the **Value** column if the lookup name is configured in the application metadata. The lookup name is not editable. If you do not specify a value on this page, the lookup name is used for the value.

## Web container advanced settings

Use this page to support web container advanced settings. This support includes Network QoS and transaction class mapping

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > server name > Web container > z/OS additional settings**.

### **Network quality of service:**

Specifies the parameter that will be used to classify outbound data that is delivered in response to HTTP and HTTPS requests.

The classification parameters are used to construct an ApplicationData parameter for the TCP/IP network service, which is called Quality of Service (QoS). The ApplicationData parameter is used in a QoS PolicyRule statement.

You can specify at most one classification parameter. If you do not specify a classification parameter, the response data will not be classified to the network agent.

Parameter	Description
<b>HOST</b>	<p>Indicates that the Host value from the Host header, not including the port, is to be used to construct an ApplicationData parameter. If you specify this parameter, WebSphere Application Server for z/OS classifies the outbound response data by using the HOST value.</p> <p>In the request: http://www.mycompany.com/mywebap/myservlet</p> <p>www.mycompany.com represents the host value.</p>
<b>URI</b>	<p>Indicates that the part of the Universal Resource Locator that specifies the path to a resource is to be used to construct an ApplicationData parameter. If you specify this parameter, WebSphere Application Server for z/OS classifies the outbound response data by using the URI value. The path must be specified exactly as it is entered in a browser because the check for this path is case sensitive.</p> <p>In the request: http://www.mycompany.com/mywebap/myservlet</p> <p>/mywebap/myservlet represents the URI value.</p>
<b>HOSTURI</b>	<p>Indicates that the HOST and URI, concatenated together, are to be used to construct an ApplicationData parameter. If you specify this parameter, WebSphere Application Server for z/OS classifies the outbound response using the concatenated HOST and URI value.</p> <p>In the request: Get request: http://www.mycompany.com/mywebap/myservlet</p> <p>www.mycompany.com/mywebap/myservlet represents the concatenated HOST and URI value.</p>

**TCLASS** Indicates that a valid Workload Management (WLM) transaction class is to be used to construct an ApplicationData parameter. If you specify this parameter, you must specify the fully qualified name of the transaction class mapping file on the Transaction Class Mapping property.

**Attention:** Transaction class mapping file support is deprecated and is not available for WebSphere Application Server Version 8. Transaction class mapping file support is available for WebSphere Application Server versions 7.x and 6.1.

### ***Transaction class mapping:***

Specifies the fully qualified name of the file that contains the rules for classifying the Workload Management Transaction Class for HTTP or HTTPS requests. The file name is class sensitive.

**depfact:** Transaction class mapping file support is deprecated and is not available for WebSphere Application Server Version 8. Transaction class mapping file support is available for WebSphere Application Server versions 7.x and 6.1. You should use a workload classification document instead of a transaction class mapping file to classify work requests in a z/OS environment.

For example, if `tclass.conf` is the name of your transaction class mapping file, you would specify the following for the value on this property:

```
/mydir/tclass.conf
```

where *mydir* is the fully qualified directory where the `tclass.conf` file is located.

#### **For example**

```
/mydir/tclass.conf
```

## **Web container inbound transport channel settings**

Use this page to view and configure a web container inbound channel transport. This type of channel transport handles inbound web container requests from a remote client.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > server\_name > Web Container Settings > Web container > Web container transport chains > transport\_chain > Web container inbound channel (transport\_channel\_name)**.

### ***Transport Channel Name:***

Specifies the name of the web container inbound transport channel.

The name field cannot contain the following characters: # \ / , : ; " \* ? < > | = + & % ' .

This name must be unique across all channels in a WebSphere Application Server environment. For example, a web container inbound transport channel and a TCP transport channel cannot have the same name if they reside within the same system.

**Data type** String

### ***Discrimination weight:***

Specifies the priority this channel has in relation to the other channels in this transport chain. This property is only used when port sharing is enabled and the transport chain includes multiple channels to which it might forward data. The channel in the chain with the lowest discrimination weight is the first one given the opportunity to look at incoming data and determine whether or not it owns that data.

**Data type** Positive integer

Default

0

### **Write buffer size:**

Specifies the amount of content in bytes to buffer unless the servlet explicitly calls flush/close on the response/writer output stream.

**Data type**

bytes

**Default**

32768 bytes

## **Web container troubleshooting tips**

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log, SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

If you are having problems starting a web module, or accessing resources within a particular web module:

- View the logs for the application server which hosts the problem web modules, and look for messages in the JVM output file which indicate that the web module has started successfully. You should see messages similar to the following:

```
WebContainer A SRVE0161I: IBM WebSphere Application Server - Web Container.
Copyright IBM Corp. 1998-2002
```

```
WebContainer A SRVE0169I: Loading Web Module: [module_name]
```

```
ApplicationMg A WSVR0221I: Application started: [application_name]
```

```
HttpTransport A SRVE0171I: Transport http is listening on port [port_number]
```

```
[server_name] open for e-business in [profile_root]/logs/[server_name]/SystemOut.log
```

- For specific problems that can cause servlets, HTML files, and JavaServer Pages (JSP) files not to be served, refer to the topic, web resource (JSP file, servlet, HTML file, image) does not display .

If application server related calls fail during Servlet.init method, you can either:

- Initialize the servlet manually by making a single request to that servlet in your browser when the server is ready for e-business instead of starting the servlet upon startup or
- You can choose not to make application server related calls in the servlet's init method.

If the property to start servlets during application server startup is enabled, part of its startup process calls the Servlet.init method on its servlets when you start the web container. Therefore, when the web container is starts and calls the init method, other components such as Naming and Work Load Management may not be fully started yet. As a result, application server related calls may not work since all of the application server components may not be ready yet. Once the application server is 'ready for e-business', it is completely ready.

If none of these steps fixes your problem, check to see if the problem has been identified and documented by looking at the available online support (hints and tips, tech notes, and fixes). If you do not find your problem listed there contact IBM support.

For current information available from IBM Support on known problems and their resolution, refer to the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

## Disabling servlet pooling: Best practices and considerations

This topic provides usage examples of when you may want to disable servlet pooling. You may want to disable request and response pooling if your application is creating threads inside of the application or if you are concerned about the web container reusing request and response objects.

### Disabling request and response pooling

- Application is creating threads inside of the application.

The Servlet 2.4 specification states the following:

**SRV.4.10 Lifetime of the Request Object** Each request object is valid only within the scope of a servlet's service method, or within the scope of a filter's doFilter method. Containers commonly recycle request objects in order to avoid the performance overhead of request object creation. The developer must be aware that maintaining references to request objects outside the scope described above is not recommended as it may have indeterminate results.

**SRV.5.6 Lifetime of the Response Object** Each response object is valid only within the scope of a servlet's service method, or within the scope of a filter's doFilter method. Containers commonly recycle response objects in order to avoid the performance overhead of response object creation. The developer must be aware that maintaining references to response objects outside the scope described above may lead to non-deterministic behavior.

- If you are concerned about the web container reuse of reusing request and response objects. Since these objects are reused, there is the potential for two requests in two separate applications to have access to the same request or response object as described in the Thread Safety section of Servlet 2.4.

**SRV.2.3.3.3 Thread Safety** Implementations of the request and response objects are not guaranteed to be thread safe. This means that they should only be used within the scope of the request handling thread.

References to the request and response objects should not be given to objects executing in other threads as the resulting behavior may be nondeterministic. If the thread created by the application uses the container-managed objects, such as the request or response object, those objects must be accessed only within the servlet's service life cycle and such thread itself should have a life cycle within the life cycle of the servlet's service method because accessing those objects after the service method ends may cause undeterministic problems. Be aware that the request and response objects are not thread safe. If those objects were accessed in the multiple threads, the access should be synchronized or be done through the wrapper to add the thread safety, for instance, synchronizing the call of the methods to access the request attribute, or using a local output stream for the response object within a thread.

It is important to note that disabling pooling prevents the web container from recycling the servlet request and servlet response objects for subsequent requests. This creates additional overhead as a result of an increase in request and response object creation and the subsequent garbage collection of these discarded objects.

## JavaServer Pages specific web container custom properties

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. You can define a new property to configure a setting beyond what is available in the administrative console. This topic includes a list of the available JavaServer Pages custom properties. The JavaServer Pages custom properties are case-sensitive.

You can use the following JSP file-specific web container custom properties:

- "com.ibm.ws.jsp.getParameterreturnemptystring" on page 2716
- "com.ibm.ws.jsp.jdksourcelevel" on page 2716
- "com.ibm.wsspi.jsp.allowjspoutputelementmismatch" on page 2716

- “com.ibm.wsspi.jsp.allowtaglibprefixusebeforedefinition”
- “com.ibm.wsspi.jsp.allowtaglibprefixredefinition” on page 2717
- “com.ibm.wsspi.jsp.allowunmatchedendtag” on page 2717
- “com.ibm.wsspi.jsp.evalquotedandescapedexpression” on page 2717
- “com.ibm.wsspi.jsp.modifyPageContextVariable” on page 2718
- “com.ibm.wsspi.jsp.recompilejsponrestart” on page 2718
- “com.ibm.wsspi.jsp.usecdatatrims” on page 2718
- “com.ibm.wsspi.jsp.usescrriptvardupinit” on page 2719
- “com.ibm.wsspi.jsp.usestringcast” on page 2719
- com.ibm.wsspi.jsp.reusepropertygroupconfigoninclude

***com.ibm.ws.jsp.getparameterreturnemptystring:***

This property is for returning an empty string for actions not set in a JSP file. If a JSP file contains an action and that property has not been set, the JSP engine returns null on WebSphere Application Server Versions 6.0 and 6.1. However, in WebSphere Application Server Version 5.1 an empty string is returned. This custom property was added to provide backwards compatibility. When it is set to true, the value returned on a call to `jsp:getProperty` is an empty string instead of null for Versions 6.0 and 6.1.

**Name** com.ibm.ws.jsp.getparameterreturnemptystring

**Value** true

***com.ibm.ws.jsp.jdksourcelevel:***

This property is for setting the JDK source level through the administrative console. A JSP engine parameter can be configured for different levels of JDK. However, setting a JSP parameter requires that you set the `jdksourcelevel` JSP attribute in the web extension file for each web module. However, you can use the `com.ibm.ws.jsp.jdksourcelevel` custom property to set the JSP attribute globally using the web container custom property. If this attribute is also defined in the web extension file, the property defined in the web extension file supersedes the custom property for that particular application. This custom property is not case-sensitive. The default value is 16.

**Name** com.ibm.ws.jsp.jdksourcelevel

**Value** 13, 14, 15, or 16

***com.ibm.wsspi.jsp.allowjspoutputelementmismatch:***

CTS requirements in previous releases were not applicable to the product, therefore the JSP container supported multiple occurrences of properties in the `jsp:output` element. In the current release, CTS compliance requires that the JSP container strictly enforces rules about multiple occurrences of properties in the `jsp:output` element. You can use the `com.ibm.wsspi.jsp.allowjspoutputelementmismatch` custom property to relax the enforcement of the rule for compatibility with earlier versions.

**Name** com.ibm.wsspi.jsp.allowjspoutputelementmismatch

**Value** true

***com.ibm.wsspi.jsp.allowtaglibprefixusebeforedefinition:***

CTS compliance requires that a tag library directive that defines a prefix must occur before that prefix is used in a custom tag. This rule was not enforced in previous releases because CTS requirements were not required. However, you can use the `com.ibm.wsspi.jsp.allowtaglibprefixusebeforedefinition` custom property to relax the enforcement of the rule for compatibility with earlier versions.

**Name** com.ibm.wsspi.jsp.allowtaglibprefixusebeforedefinition

**Value** true

***com.ibm.wsspi.jsp.allowtaglibprefixredefinition:***

CTS compliance requires that if a tag library prefix is already defined with a different URI within a JSP, the product must create a translation error. This rule was not enforced in previous releases because CTS requirements were not required. However, you can use the `com.ibm.wsspi.jsp.allowtaglibprefixredefinition` custom property to relax the enforcement of the rule for compatibility with earlier versions.

**Name** `com.ibm.wsspi.jsp.allowtaglibprefixredefinition`

**Value** true

***com.ibm.wsspi.jsp.allowunmatchedendtag:***

In Version 5 of the product, improper termination of end tags was ignored whereas in Version 6, a translation exception is created. This change of behavior in Version 6 causes problems to users who are migrating their applications, which had improperly terminated end tags, to Version 6. In Version 6, to facilitate migration, a web container property, `com.ibm.wsspi.jsp.allowunmatchedendtag`, and a JSPAttribute, `allowUnmatchedEndTag`, are provided. You can enable these properties provides the Version 5 behavior.

**Name** `com.ibm.wsspi.jsp.allowunmatchedendtag`

**Value** true

***com.ibm.wsspi.jsp.evalquotedandescapedexpression:***

This property is for compiling functions that contain an expression. The JSP translation code was modified to handle escape characters and quotations properly when determining whether to evaluate an expression or to treat it as a literal string. To apply this behavior globally across all web applications, add the following name-value pair as a web container custom property.

**Name** `com.ibm.wsspi.jsp.evalquotedandescapedexpression`

**Value** true

To enable this new behavior for a single application, you must also add the `evalquotedandescapedexpression` JSP attribute to the `ibm-web-ext.xmi` or `ibm-web-ext.xml` file of the failing application and set the value to `true`.

The following example code shows the attribute in an XMI format:

```
<jspAttributes xmi:id="JSPAttribute_1" name="evalquotedandescapedexpression" value="true"/>
```

**Note:** The attribute ID value must be unique.

The following example code shows the attribute in the `ibm-web-ext.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
 xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
 version="1.0">
 <jsp-attribute name="evalquotedandescapedexpression" value="true" />

 <reload-interval value="3"/>
 <auto-encode-requests value="true"/>
 <auto-encode-responses value="true"/>
 <enable-directory-browsing value="true"/>
 <enable-file-serving value="true"/>
 <pre-compile-jsp value="true"/>
```

```
<enable-reloading value="true"/>
<enable-serving-servlets-by-class-name value="true" />

</web-ext>
```

**Note:** Use an assembly tool, such as Rational Application Developer, to modify IBM extension and binding files. You can convert extension and binding files within modules from XMI to XML using the IBM Bindings and Extensions Conversion Tool for Multi-Platforms.

**Note:** For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named `ibm-*-ext.xmi` or `ibm-*-bnd.xmi` where `*` is the type of extension or binding file such as `app`, `application`, `ejb-jar`, or `web`. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be `.xmi`.
- For an application or module that uses Java EE 5 or later, the file extension must be `.xml`. If `.xmi` files are included with the application or module, the product ignores the `.xmi` files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the `.xmi` file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the `.xmi` file extensions.

#### ***com.ibm.wsspi.jsp.modifyPageContextVariable:***

During the translation phase of a tag file that is compiled, the JSP container implicitly uses the `pageContext` variable for the `PageContext` object. The use of the `pageContext` variable as an implicit variable name in tag files does not comply with the JSP Specification.

If compilation errors occur for applications that use a local `pageContext` variable in their tag file, set the `com.ibm.wsspi.jsp.modifyPageContextVariable` custom property to `true` to remove the use of the `pageContext` variable name in the generated Java code for tag files.

**Name** `com.ibm.wsspi.jsp.modifyPageContextVariable`

**Value** `true`

#### ***com.ibm.wsspi.jsp.recompilejsponrestart:***

This property forces JSP files that were compiled at run time to be recompiled every time the application is restarted. This property is helpful if you switch the underlying JSF implementation. This property is best used on development environments.

**Name** `com.ibm.wsspi.jsp.recompilejsponrestart`

**Value** `true`

#### ***com.ibm.wsspi.jsp.usecdatatrim:***

You can use the `com.ibm.wsspi.jsp.usecdatatrim` custom property to trim the text before creating CDATA section which eliminates the extra white spaces added. **Users Affected:** WebSphere Application Server Version 6.0 users who are migrating their applications from Version 5 to Version 6 and whose JSPs use nesting tags in separate lines. **Problem Description:** JSP files that use nesting tags have extra lines in the code generated for this section. In Version 6, you could eliminate the extra spaces by appending all the lines into one using: `"`. The extra line is added in the Java code generated because the text is not trimmed

before creating the CDATA section. Therefore, a switch is provided to enable the trimming of the text before creating the CDATA section. You can set the JSP attribute, `useCDATATrim`, at the web module level or set the `com.ibm.wsspi.jsp.usecdatatrim` web container property at the web container level using the following name-value pair.

**Name** `com.ibm.wsspi.jsp.usecdatatrim`

***com.ibm.wsspi.jsp.uscriptvardupinit:***

The code generated for a JSP file assumed that the same tag variables to be declared two or more times in an If-Else condition, even if the variable had a page scope. The `com.ibm.wsspi.jsp.uscriptvardupinit` custom property enables this feature for all the applications deployed on a particular server. If the compatibility feature is required only for a specific application, enable the `useScriptVarDuplNit` JSP attribute. If both the options are set, then the JSP attribute takes preference over the web container custom property.

**Name** `com.ibm.wsspi.jsp.uscriptvardupinit`

**Value** `true`

***com.ibm.wsspi.jsp.usestringcast:***

The `com.ibm.wsspi.jsp.usestringcast` property explicitly adds a String cast to the relative path before inclusion when you migrate Version 5.1 applications. In Version 6.0.x, the generated Java source for the JSP file did not add the "implicit" cast, for return types of type String when the `request.getAttribute` method is called. When a JSP file includes a resource whose relative path does not evaluate to a String, then the include fails as the include takes only a String as a relative path of the resource. You can set the `com.ibm.wsspi.jsp.usestringcast` custom property, which would affect all the deployed applications or you can set the property as a JSPAttribute, `useStringCast`, in the extensions file, which affects only the application for which the property is set.

**Name** `com.ibm.wsspi.jsp.usestringcast`

**Value** `true`

***com.ibm.wsspi.jsp.reusepropertygroupconfigoninclude:***

**Note:** Most properties that are defined in a JSP property group apply to an entire translation unit, for example, the requested JSP file that is matched by its URL pattern and all the files it includes using the include directive. The exceptions are the page-encoding and is-xml properties, which apply separately to each JSP file that is matched by its URL pattern. To revert the behavior to a setting before WebSphere Application Server Version 8.0, set the custom property to `true` to apply the two property values to the entire translation unit.

**Name** `com.ibm.wsspi.jsp.reusepropertygroupconfigoninclude`

**Value** `false`

## Configuring JSP engine parameters

Learn about how to add, change or delete JSP engine configuration parameters.

### About this task

The following note applies to the file references with a `.xmi` extension in this topic:

**Note:** For IBM extension and binding files, the `.xmi` or `.xml` file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or

module. An IBM extension or binding file is named `ibm-*-ext.xmi` or `ibm-*-bnd.xmi` where `*` is the type of extension or binding file such as `app`, `application`, `ejb-jar`, or `web`. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be `.xmi`.
- For an application or module that uses Java EE 5 or later, the file extension must be `.xml`. If `.xmi` files are included with the application or module, the product ignores the `.xmi` files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the `.xmi` file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the `.xmi` file extensions.

WebSphere Application Server does not support the modification of deployment descriptor extension parameters through the Administrative Console or through administrative scripting.

**Note:** Use an assembly tool, such as Rational Application Developer, to modify IBM extension and binding files. You can convert extension and binding files within modules from XMI to XML using the IBM Bindings and Extensions Conversion Tool for Multi-Platforms.

To add, change or delete JSP engine configuration parameters, complete the following steps:

## Procedure

1. Open the `WEB-INF/ibm-web-ext.xmi` or `WEB-INF/ibm-web-ext.xml` file.

JSP engine configuration parameters are stored in a web module's configuration directory or in a web module's binaries directory in the `WEB-INF/ibm-web-ext.xmi` or `WEB-INF/ibm-web-ext.xml` file. Open the `WEB-INF/ibm-web-ext.xmi` or `WEB-INF/ibm-web-ext.xml` file from:

- The configuration directory, as in the following example: `{WAS_ROOT}/profiles/profilename/config/cells/cellname/applications/enterpriseappname/deployments/deployedname/webmodulename`
- The binaries directory if an application was deployed into WebSphere Application Server with the flag "Use Binary Configuration" set to true. An example of a binaries directory is: `{WAS_ROOT}/profiles/profilename/installedApps/nodename/EnterpriseAppName/WebModuleName/`

2. Edit the `WEB-INF/ibm-web-ext.xmi` or `WEB-INF/ibm-web-ext.xml` file.

- To add configuration parameters to the `WEB-INF/ibm-web-ext.xmi` file, use the following format:  
`xmi:id="JSPAttribute_6" name="parametername" value="parametervalue"/>`
- To add configuration parameters to the `WEB-INF/ibm-web-ext.xml` file, use the following format:  
`<jsp-attribute name="parametername" value="parametervalue"/>`
- To delete configuration parameters, either delete the line from the file, or enclose the statement with `<!-- -->` tags.

3. Save the file.

4. Restart the Enterprise Application. It is not necessary to restart the server for parameter changes to take effect. However, some JSP engine configuration parameters affect the Java source code that is generated for a JSP. If such a parameter is changed, then you must retranslate the JSP files in the web module to regenerate Java source. You can use the batch compiler to retranslate all JSP files in a web module. The batch compiler uses the JSP engine configuration parameters that you have set in the `ibm-web-ext.xmi` or `ibm-web-ext.xml` file, unless you specifically override them. The topic, JSP engine configuration parameters, identifies the parameters that affect the generated Java source.

## Example

The following is a sample of the WEB-INF/ibm-web-ext.xml file. The lines in bold text are JSP engine configuration parameters.

```
<?xml version="1.0" encoding="UTF-8"?>
<webappext:WebAppExtension xmi:version="2.0" xmlns:xmi=http://www.omg.org/XMI
 xmlns:webappext="webappext.xmi" xmlns:webapplication="webapplication.xmi" xmi:id="WebAppExtension_1"
 reloadInterval="9" reloadingEnabled="true" defaultErrorPage="error.jsp" additionalClassPath=""
 fileServingEnabled="true" directoryBrowsingEnabled="false" serveServletsByClassnameEnabled="true"
 autoRequestEncoding="true" autoResponseEncoding="false"
 <webApp href="WEB-INF/web.xml#WebApp_1"/>
 <jspAttributes xmi:id="JSPAttribute_1" name="useThreadTagPool" value="true"/>
 <jspAttributes xmi:id="JSPAttribute_2" name="verbose" value="false"/>
 <jspAttributes xmi:id="JSPAttribute_3" name="deprecation" value="false"/>
 <jspAttributes xmi:id="JSPAttribute_4" name="reloadEnabled" value="true"/>
 <jspAttributes xmi:id="JSPAttribute_5" name="reloadInterval" value="5"/>
 <jspAttributes xmi:id="JSPAttribute_6" name="keepgenerated" value="true"/>
 <!--<jspAttributes xmi:id="JSPAttribute_7" name="trackDependencies" value="true"/> -->
</webappext:WebAppExtension>
```

The following is a sample of the WEB-INF/ibm-web-ext.xml file. The lines in bold text are JSP engine configuration parameters.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
 xmlns="http://websphere.ibm.com/xml/ns/javaee"

**Attention:** The integer **n** in **JSPAttribute\_n** has to be unique within the file.

## JSP engine

The WebSphere Application Server JavaServer Pages (JSP) engine is the implementation of the JavaServer Pages Specification.

WebSphere Application Server Version 8.0 supports the JSP 2.1 specification.

The JSP engine

- Validates JSP source, both classic and XML styles
- Translates JSP source to Java classes
- Compiles Java classes, reporting any errors
- Generates Java classes for any tag files that are used by the JSP

- Interfaces with the web container to load JSP class files
- Supports JSP batch compilation, JSP compilation during application installation, and JSP compilation during the build process of customer applications, through an Ant task.
- Loads class files, and manage life-cycle (reloading, unloading as necessary)
- Supports debugging of JavaServer Pages files through support for JSR 45 (Debugging Support for Other Languages)

## **JSP engine configuration parameters**

In WebSphere Application Server, you can configure the JavaServer Pages (JSP) engine configuration parameters for optimal performance in a production server environment and for the needs of developers in a development environment.

The JSP engine parameters are case sensitive. If the value specified for a parameter is comprised of two or more words separated by spaces, you must add quotation marks around the value. Some parameters affect the Java source that is generated for a JSP or tag file. These parameters are identified by the statement "This parameter requires regeneration of Java source." This statement indicates that if the configuration parameter is modified, the new value for the parameter does not have any effect until the JSP files are retranslated and the Java sources are recompiled.

**Note:** Use an assembly tool, such as Rational Application Developer, to modify IBM extension and binding files. You can convert extension and binding files within modules from XMI to XML using the IBM Bindings and Extensions Conversion Tool for Multi-Platforms.

### ***compileWithAssert:***

Specifies whether the generated Java classes should contain support for the Developer Kit, Java Technology Edition 1.4 Assertion facility. The effect of setting this parameter to true is that the `-source 1.4` option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

### ***classdebuginfo:***

Indicates whether the compiler includes debugging information in the generated class file. When you set this parameter to true, the `-g` option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

### ***convertAttrValueToString:***

Specifies whether to convert start and end attributes of the repeat tag to strings before they are used. The default for this parameter is `false`. This parameter requires regeneration of Java source.

### ***deprecation:***

Specifies whether the compiler generates deprecation warnings when compiling the generated Java source. When you set this parameter to true, the `-deprecation` option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

### ***disableEICache:***

Set the `com.ibm.wsspi.jsp.disableEICache` web container custom property to true to disable the commons-el expression cache if you are experiencing out of memory conditions because the hash maps are held by the expression evaluator. The default for this parameter is `false`.

### ***disableJspRuntimeCompilation:***

If this option is set to true, the JSP engine at runtime does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load class files. When this option is set to true, you can install an application without JSP source, but the application must have precompiled class files. There is a web container custom property with the same name that is used to determine the behavior of all web modules installed in a server. If both the web container custom property and the JSP engine option are set, the JSP engine option takes precedence. The default for this parameter is false.

***disableTldSearch:***

Set this option is set to true to prevent the JSP engine from searching the application installation directories for the taglib descriptor (TLD) files when an application starts. If this option is set to false, when an application starts, the JSP engine searches the application installation directories for the TLD files. The default for this parameter is false.

There is a web container custom property, `com.ibm.wsspi.jsp.disableTldSearch`, that can be used to specify whether, when an application starts, the JSP engines in all web modules installed in a server do not search the application installation directories for the TLD files. If conflicting values are set for the web container custom property and the JSP engine option, the setting for the JSP engine option takes precedence.

**Note:** This option is only available in version levels 7.0.0.3, and higher.

***evalQuotedAndEscapedExpression:***

Set this option to true to handle escape characters and quotations properly when determining whether to evaluate an expression.

During the translation phase of a JSP compile, expressions are evaluated by the JSP engine. Characters, such as the escape character (\) or nested quotations, single or double, causes the JSP file translation to fail. For example, when you use functions that contain an expression such as

```
<input type="text" value="{fn:substring('1234567', 0,4)}/>
```

Because of the double quote directly before the `fn:substring` statement, the JSP file fails to compile because the translator did not add the function mapper to the generated Java class. Also, if a dollar sign (\$) was escaped using the backslash (\\$), the translator still attempts to evaluate the expression instead of treating it as a literal string. To handle escape characters and quotations properly, you must set `evalQuotedAndEscapedExpression` to true in the `ibm-web-ext.xmi` or `ibm-web-ext.xml` file of the failing application.

The following code sample shows an entry in the `ibm-web-ext.xmi` file:

```
<jspAttributes xmi:id="JSPAttribute_1"
name="evalQuotedAndEscapedExpression" value="true"/>
```

The following code sample shows an entry in the `ibm-web-ext.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
 xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
 version="1.0">
 <file-serving-attribute name="extendedDocumentRoot" value="true" />
 <jsp-attribute name="evalQuotedAndEscapedExpression" value="true" />
 <jsp-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
 <jsp-attribute name="extendedDocumentRoot" value="{MY_CUSTOM_VARIABLE}" />

 <reload-interval value="3"/>
 <auto-encode-requests value="false"/>
```

```

<auto-encode-responses value="false"/>
<enable-directory-browsing value="false"/>
<enable-file-serving value="true"/>
<pre-compile-jsp value="false"/>
<enable-reloading value="true"/>
<enable-serving-servlets-by-class-name value="false" />
</web-ext>

```

To apply this behavior globally across all web applications, you can set the `com.ibm.wsspi.jsp.evalQuotedAndEscapedExpression` web container custom property to true.

### **extendedDocumentRoot:**

Use the extended document root facility when applications require access to files outside of the application web application archive (WAR) directory. This facility enables you to configure an application with one or more directory paths from which you can serve static files and JSP files. You can use this attribute when an application requires access to files that exist outside of the web application archive (WAR) directory. For example, if several applications require access to a set of common files, you can place the common files in a directory to which you can link each application as an extended document root directory.

To configure an application with an extended document root, add an `extendedDocumentRoot` attribute as a file-serving attribute to the `ibm-web-ext.xml` or `ibm-web-ext.xmi` file for the application. The value of this attribute is a comma-delimited list of directories that serve as the root directory location for the static files.

The following entry is an example within the `ibm-web-ext.xmi` file:

```
<fileServingAttributes xmi:id="FileServingAttribute_1" name="extendedDocumentRoot" value="/opt/extDocRootDir"/>
```

The following examples are based on the previous entry in the `ibm-web-ext.xmi` file with the attribute set to the `/opt/extDocRootDir` value:

- A request for the `http://localhost:9080/context_root/sample.html` resource requires that the `sample.html` file is located in the `/opt/extDocRootDir/sample.html` directory structure.
- A request for the `http://localhost:9080/context_root/myDir/sample.gif` resource requires that the `sample.gif` file is located in the `/opt/extDocRootDir/myDir/sample.gif` directory structure.

The following entry is an example within the `ibm-web-ext.xml` file:

```

<?xml version="1.0" encoding="UTF-8"?>
<web-ext
 xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
 version="1.0">
 <file-serving-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
 <jsp-attribute name="evalQuotedAndEscapedExpression" value="true" />
 <jsp-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
 <jsp-attribute name="extendedDocumentRoot" value="{MY_CUSTOM_VARIABLE}" />
 <reload-interval value="3"/>
 <auto-encode-requests value="false"/>
 <auto-encode-responses value="false"/>
 <enable-directory-browsing value="false"/>
 <enable-file-serving value="true"/>
 <pre-compile-jsp value="false"/>
 <enable-reloading value="true"/>
 <enable-serving-servlets-by-class-name value="false" />
</web-ext>

```

**Important:** To serve static files from an extended document root directory, you must enable file serving.

To configure an application with an extended document root from which JSP files are served, add an `extendedDocumentRoot` attribute as a JSP attribute to the `ibm-web-ext.xmi` or `ibm-web-ext.xml` file. The value of this attribute is a comma-delimited list of directories that serve as the root directory location for the JSP files.

The following entry is an example within the `ibm-web-ext.xmi` file:

```
<jspAttributes xmi:id="JSPAttribute_1" name="extendedDocumentRoot" value="/opt/extDocRootDir"/>
```

The following example shows the entry within the `ibm-web-ext.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
 xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
 version="1.0">
 <file-serving-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
 <jsp-attribute name="evalQuotedAndEscapedExpression" value="true" />
 <jsp-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
 <jsp-attribute name="extendedDocumentRoot" value="{MY_CUSTOM_VARIABLE}" />
 <reload-interval value="3"/>
 <auto-encode-requests value="false"/>
 <auto-encode-responses value="false"/>
 <enable-directory-browsing value="false"/>
 <enable-file-serving value="true"/>
 <pre-compile-jsp value="false"/>
 <enable-reloading value="true"/>
 <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

You can also use an `extendedDocumentRoot` attribute to define a WebSphere variable on multiple nodes to the appropriate directory.

#### **ibm-web-ext.xmi example:**

```
<jspAttributes xmi:id="JSPAttribute_2" name="extendedDocumentRoot"
 value="{MY_CUSTOM_VARIABLE}" />
```

#### **ibm-web-ext.xml example:**

```
<jsp-attribute name="extendedDocumentRoot"
 value="{MY_CUSTOM_VARIABLE}" />
```

where `MY_CUSTOM_VARIABLE` is the WebSphere variable that you want to define on multiple nodes.

The following example shows a `ibm-web-ext.xmi` file that defines an extended document root both as a file-serving attribute and a JSP attribute:

```
<?xml version="1.0" encoding="UTF-8"?>
<com.ibm.ejs.models.base.extensions.webappext:WebAppExtension xmi:version="2.0"
 xmlns:xmi="http://www.omg.org/XMI"
 xmlns:com.ibm.ejs.models.base.extensions.webappext="webappext.xmi" xmi:id="WebAppExtension_1"
 reloadInterval="3"
 reloadingEnabled="true"
 fileServingEnabled="true">
 <webApp href="WEB-INF/web.xml#WebApp_ID"/>
 <fileServingAttributes xmi:id="FileServingAttribute_1" name="extendedDocumentRoot"
 value="/opt/extDocRootDir"/>
 <jspAttributes xmi:id="JSPAttribute_1" name="extendedDocumentRoot"
 value="/opt/extDocRootDir"/>
</com.ibm.ejs.models.base.extensions.webappext:WebAppExtension>
```

The following example shows a `ibm-web-ext.xml` file that defines an extended document root both as a file-serving attribute and a JSP attribute:

```

<?xml version="1.0" encoding="UTF-8"?>
<web-ext
 xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
 version="1.0">
 <file-serving-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
 <jsp-attribute name="evalQuotedAndEscapedExpression" value="true" />
 <jsp-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
 <jsp-attribute name="extendedDocumentRoot" value="{MY_CUSTOM_VARIABLE}" />

 <reload-interval value="3"/>
 <auto-encode-requests value="false"/>
 <auto-encode-responses value="false"/>
 <enable-directory-browsing value="false"/>
 <enable-file-serving value="true"/>
 <pre-compile-jsp value="false"/>
 <enable-reloading value="true"/>
 <enable-serving-servlets-by-class-name value="false" />
</web-ext>

```

If the request is a valid partial request for a welcome file, a 404 error is returned. If the JSP file is located inside a JAR file and the reloadEnabled attribute value is true, the time stamp of the JAR file is used for isOutDated checks for recompile purposes. The default for this parameter is null.

**Note:** For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-\*-ext.xmi or ibm-\*-bnd.xmi where \* is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The ibm-webservices-ext.xmi, ibm-webservices-bnd.xmi, ibm-webservicesclient-bnd.xmi, ibm-webservicesclient-ext.xmi, and ibm-portlet-ext.xmi files continue to use the .xmi file extensions.

### ***ieClassId:***

Indicates the Java plug-in COM class ID for Internet Explorer.

The <jsp:plugin> tags use this value. The default classid is clsid:8AD9C840-044E-11D1-B3E9-00805F499D93

### ***javaEncoding:***

Specifies the encoding that is used when the .java file is generated, and when it is compiled by the Java compiler. Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible. When javaEncoding is set, the encoding is passed to the Java compiler through the -encoding argument. Note that encoding is not supported by Jikes. The default is UTF-8. This parameter requires regeneration of Java source.

### ***jdkSourceLevel:***

This JSP engine parameter was introduced in WebSphere Application Server version 6.1 to support JDK 5. Use this parameter instead of the `compileWithAssert` parameter, although `compileWithAssert` still works in version 6.1.

The default value for this parameter is 16. This parameter requires regeneration of Java source. The following are `jdkSourceLevel` parameter values:

- **13** - This value will disable all new language features of JDK 1.4, JDK 5.0 and JDK 6.0.
- **14** - This value will enable the use of the assertion facility and will disable all new language features of JDK 5.0 and JDK 6.0.
- **15** - This value will enable the use of the assertion facility and will disable all new language features of JDK 6.0.
- **16** - This value will enable the use of the new features of JDK 6.0.

#### ***jsp.file.extensions:***

For JSP files with extensions other than the four standard extensions, `*.jsp`, `*.jspx`, `*.jsw`, and `*.jsv`, you can configure these extensions using this parameter. These extensions are added to the standard extensions.

The preferred method for doing this is to create a `<jsp-property-group>` in `web.xml`, and add a `<url-pattern>` tag for each extension.

The JSP engine can handle a list of file extensions that is separated by a colon or semi-colon. For example, `*.ext1;*.ext2:*.extn`

#### ***keepgenerated:***

Indicates that the Java files generated by the JSP compiler during the translation phase of the processing are retained. The default for this parameter is `false`. This parameter requires regeneration of Java source.

#### ***keepGeneratedclassfiles:***

Indicates that the class files generated by the JSP compiler during the translation phase of the processing are retained. The default for this parameter is `true`. This parameter requires regeneration of Java source.

#### ***modifyPageContextVariable:***

During the translation phase of a tag file that is compiled, the JSP container implicitly uses the `pageContext` variable for the `PageContext` object. The use of the `pageContext` variable as an implicit variable name in tag files does not comply with the JSP Specification. If compilation errors occur for applications that use a local `pageContext` variable in their tag file, set the `modifyPageContextVariable` attribute to `true` to remove the use of the `pageContext` variable name in the generated Java code for tag files.

#### ***recompileJspOnRestart:***

Determines whether a JSP file is retranslated and recompiled after application startup for the first time the file is requested. If `recompileJspOnRestart` is `false`, a JSP file is still compiled, if necessary, on the first request to that JSP file unless the parameter `disableJspRuntimeCompilation` is `true`. The default for this parameter is `false`.

#### ***reloadEnabled:***

Determines whether or not a JSP file is translated and compiled at runtime if the JSP file or its dependencies (see `trackDependencies`) are modified.

If `reloadEnabled` is false, a JSP file is still compiled, if necessary, on the first request to it unless the parameter `disableJspRuntimeCompilation` is true. The default for this parameter is `false`.

If this JSP engine parameter is not specified, the equivalent web container parameter for web module class reloading is used. However, for an application whose deployment descriptor is at the Servlet 2.2 level, the default is true. This is done for the support of applications being migrated from WebSphere Application Server Version 4.x.

#### ***reloadInterval:***

If reloading is enabled, `reloadInterval` determines the delay between checks to see if a JSP file is outdated.

For example, if `reloadInterval` is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than 5 seconds prior to the current request for the JSP file. The larger the `reloadInterval`, the less frequently the JSP engine checks for the need to reload a JSP file. If this JSP engine parameter is not specified, the equivalent web container parameter for web module class reloading is used. However, for an application whose deployment descriptor is at the Servlet 2.2 level, the default is 5 seconds. This is done for the support of applications being migrated from WebSphere Application Server Version 4.x.

#### ***reusePropertyGroupConfigOnInclude:***

**Note:** Most properties that are defined in a JSP attribute group apply to an entire translation unit, for example, the requested JSP file that is matched by its URL pattern and all the files it includes using the `include` directive. The exceptions are the `page-encoding` and `is-xml` properties, which apply separately to each JSP file that is matched by its URL pattern. To revert the behavior to a setting prior to WebSphere Application Server Version 8.0, set the attribute to `true` to apply the two property values to the entire translation unit.

#### ***scratchdir:***

Specifies the directory where the generated class files are created.

The system property `com.ibm.websphere.servlet.temp.dir` is used to set the `scratchdir` option on a server-wide basis. The JSP engine `scratchdir` parameter takes precedence over the system property `com.ibm.websphere.servlet.temp.dir`. The default for this parameter is `profile_root/temp`. This parameter requires regeneration of Java source.

**gotcha:** Do not specify a directory path that places the JSP temporary directory at the same level or underneath the configuration temporary directory. The default location for the configuration temporary directory is `profile_home/config/temp`.

For example, if you change the location of the JSP temporary directory to also be `profile_home/config/temp`. or if you place the JSP temporary directory underneath the configuration temporary directory at `profile_home/config/temp/temp`, processing errors occur.

#### ***trackDependencies:***

If reloading is enabled, `trackDependencies` determines whether the JSP engine tracks modifications to the requested JavaServer Pages files dependencies as well as to the JSP file itself.

The dependencies tracked by the JSP engine are :

1. files statically included in the JSP file
2. tag files referenced in the JSP file (excluding tag files that are in JARs)
3. TLD files referenced in the JSP file (excluding TLDs that are in JARs)

The default is false.

### ***useFullPackageNames:***

If `useFullPackageNames` is true, the JSP engine generates and loads JSP classes using full package names.

The default is to generate all JSP classes in the same package. (For more information, refer to the Packages and directories for generated .java and .class files topic). The JSP engine's class loader knows how to load JSP classes when they are all in the same package.

The default method of generating all JSP classes in the same package has the benefit of generating smaller file-system paths. Full package names has the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without the use of the `jsp-file` attribute, resulting in a single class loader, the web application's class loader, that is used to load all such JSP classes. Similarly, when the JSP engine's configuration attributes `useFullPackageNames` and `disableJspRuntimeCompilation` are both true, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

When `useFullPackageNames` is set to true, the batch compiler generates a `generated_web.xml` file in the web module's `WEB-INF` directory. This file contains servlet configuration information for each JSP file that was successfully translated and compiled. The information can optionally be copied into the web module `web.xml` file so that the JSP files are loaded as servlets by the web container. Note that if a JSP file is configured as a servlet in this way, no reloading of the JSP file is done at runtime if the JSP file is modified. This is because the JSP file is treated as a regular servlet and requests for it do not pass through the JSP engine. This parameter requires regeneration of Java source.

### ***useImplicitTagLibs:***

The JSP engine implicitly recognizes `tsx` and `jsx` as tag library prefixes for tag libraries supplied by the JSP engine. If `tsx` or `jsx` are used as prefixes for a customer's tag library, the customer's tag library overrides the implicit tag library. However, the implicit tag library is still cached by the JSP engine. Explicitly setting this parameter to false tells the engine not to cache the implicit tag library, and save resources. The default for this parameter is true.

The default URL for the `tsx` tags is `http://websphere.ibm.com/tags/tsx`. The default URI for the `jsx` tags is `http://websphere.ibm.com/tags/jsx`.

You might need to define the `tsx` or `jsx` tag library prefix with a different URI than its default URI. Also, you might need to define the same library prefix with a different URI. In these two situations, you can set the `com.ibm.wsspi.jsp.allowtaglibprefixredefinition` custom property to avoid translation errors. For more information, see the documentation about JavaServer Pages custom properties.

### ***useInMemory:***

Specifies that the JSP engine translate and compile Java code in the system memory.

When this option is not set, the JSP engine must perform the following steps:

1. Write the translated Java file to the file system
2. Load the Java file from the file system
3. Compile the code into a class file
4. Write the class to the file system
5. Load the class file into a classloader.

**Note:** No .class file or .java file will be written to the system disk. For debugging or creating a JAR file from precompiled JSP code, you will need to disable this option.

***useJikes:***

Specifies whether Jikes is used for compiling Java sources.

NOTE: Jikes is not shipped with WebSphere Application Server. The default for this parameter is false. This parameter requires regeneration of Java source.

***usePageTagPool:***

\*Enables or disables the reuse of custom tag handlers on an individual JavaServer Pages basis. The default for this parameter is false. This parameter requires regeneration of Java source.

***useThreadTagPool:***

When thread-level tag handler pooling is used, tag handlers may be reused among separate occurrences of a custom action across all JSP pages in a single web module across separate requests. The default for this parameter is false. This parameter requires regeneration of Java source.

Enabling custom tag handler reuse might reveal problems in the tag handler code with regard to the tag's ability to be reused. A custom tag handler should always do two things:

- The release method of the tag handler should reset its state and release any private resources that it might have used. The JSP engine ensures the release method is called before the tag handler is garbage collected.
- In the doEndTag method, all instance states associated with this instance must be reset.

***verbose:***

Indicates that the compiler generates verbose output when compiling the generated Java source code. The effect of setting this parameter to true is that the -verbose option is passed to the Java compiler. The default for this parameter is false. This parameter requires regeneration of Java source.

\*Enabling custom tag handler reuse might reveal problems in the tag handler code with regard to the tag's ability to be reused. A custom tag handler should always do two things:

- The release method of the tag handler should reset its state and release any private resources that it might have used. The JSP engine ensures the release method is called before the tag handler is garbage collected.
- In the doEndTag method, all instance states associated with this instance must be reset.

**CAUTION:**

**When using page or thread tag pooling, the doEndTag method is not called in the case of an exception, and if there is service state that must be cleared, then the TryCatchFinally interface should be implemented.**

## **JavaServer Pages troubleshooting tips**

Use these tips to troubleshoot problems with JavaServer Pages.

### **JavaServer Pages source code shown by the web server**

If you share the document root of the WebSphere Application Server with the web server document root, a security exposure can result as the web server might display the JavaServer Pages (JSP) source file as plain text.

#### **Problem**

You can use the WebSphere Web server plug-in set of rules to determine whether a given request

will be handled by the WebSphere Application Server. When an incoming request fails to match those rules, the web server plug-in returns control to the web server so that the web server can fulfill the request. In this case, the unknown host header causes the web server plug-in to return control to the web server because the rules do not indicate that the WebSphere Application Server should handle it. Therefore, the web server looks for the request in the web server document root. Since the JSP source file is stored in the document root of the web server, the web server finds the file and displays it as plain text.

### Suggested solution

Move the WebSphere Application Server JSP source file outside of the web server document root. Then, when this request comes in with the unknown host header, the plug-in returns control to the web server and the JSP source file is not found in the document root. Therefore, the web server returns a 404 File Not Found error rather than the JSP source file.

### Problems displaying double-byte character set (DBCS) characters when using the @include directive

JavaServer Pages files that use the @include directive might experience problems when displaying double-byte character set (DBCS) characters. Some applications that are migrated to WebSphere Application Server Version 6.0 and above might need to be modified to comply with the JSP 2.0 specification as a result of backwards compatibility issues. The JSP 2.0 specification requires that each statically included resource must set a page encoding or content type because the character encoding for each file is determined separately, even if one file includes another using the include directive.

### Problems using the JavaServer Pages (JSP) engine

If you are having difficulty using the JavaServer Pages (JSP) engine, try these steps:

1. Determine whether other resources such as .html files or servlets are being requested and displayed correctly. If they are not, the problem probably lies at a deeper level, such as with the HTTP server.
2. If other resources are being displayed correctly, determine whether the JSP processor has started normally:
  - Browse the logs of the server hosting the JSP files you are trying to access. The following messages indicate that the JSP processor has started normally:

```
Extension Processor [class com.ibm.ws.jsp.webcontainerext.JSPExtensionProcessor]
was initialized successfully.
Extension Processor [class com.ibm.ws.jsp.webcontainerext.JSPExtensionProcessor]
has been associated with patterns [*.jsp *.jspx *.jsw *.jst].
```

If the JSP processor fails to load, you will see a message such as

```
No Extension Processor found for handling JSPs.
JSP Processor not defined. Skipping : jspfilename.
```

in the server log files.

3. If the JSP engine has started normally, the problem may be with the JSP file itself.
  - The JSP may have invalid JSP syntax and could not be processed by the JSP Processor. Examine the server log files of the target application for invalid JSP directive syntax messages. Errors similar to the following in a browser indicate this kind of problem:

```
Message: /filename.jsp(2,1)JSPG0076E: Missing required attribute page for jsp
element jsp:include
```

This example indicates that line 2, column 1 of the named JavaServer Pages file is missing a mandatory attribute for the jsp:include action. Similar messages are displayed for other syntax errors.

- Examine the target application server's SystemErr.log files for problems with invalid Java syntax. Errors similar to Message: Unable to compile class for JSP in a browser indicate this kind of problem.

The error message output from the Javac compiler will be found in the SystemErr.log file. It might look like:

```
JSPG0091E: An error occurred at line: 2 in the file: /myJsp.jsp
JSPG0093E: Generated servlet error: c:\WASROOT\temp\ ...
test.war_myJsp.java:16: myInt is already defined in com.ibm.ws.jsp20._myJsp
int myInt = 122; String myString = "number is 122"; static int myStaticInt=22;
int myInt=121;
 ^ 1 error
```

Correct the error in the JSP file and retry the file.

- Examine the log files for the target application for problems with invalid Java syntax. Errors similar to Message: Unable to compile class for JSP in a browser indicate this kind of problem.

The error message output from the Javac compiler will be found in the server log files. It might look like:

```
JSPG0091E: An error occurred at line: 2 in the file: /myJsp.jsp
JSPG0093E: Generated servlet error: c:\WASROOT\temp\ ...
test.war_myJsp.java:16: myInt is already defined in com.ibm.ws.jsp20._myJsp
int myInt = 122; String myString = "number is 122"; static int myStaticInt=22;
int myInt=121;
 ^ 1 error
```

Correct the error in the JSP file and retry the file.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log, SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

## JavaServer Pages fail to compile when using precompile

**Symptom** JavaServer Pages fail to compile during deployment through the administrative console when precompile is selected.

```
SystemErr R com.ibm.websphere.management.exception.AdminException:
ADMA0021E: Error in compiling jsps - xyz.war (rc=1)
```

**Problem** JavaServer Pages fail to compile during deployment through the administrative console when precompile is selected when there is a dependency on another Java archive (JAR) file that is not available on any class path.

**Suggested solution** You may use wsadmin scripting to precompile JSP files during enterprise application deployment. However if you want to use the administrative console, then compile all JSP files before packaging the application.

1. Add the dependent JAR to the deployment manager in a cell environment.
  - a. Click **System Administration > Deployment manager > Java and Process Management > Process Definition > Java Virtual Machine** in the console navigation.
  - b. Add fully qualified dependent JAR in class path field.
  - c. Click OK.
  - d. Restart deployment manager.

## JSPG0089E: Mismatch found between page directive encoding Shift\_JIS and xml prolog encoding UTF-8

<b>Symptom</b>	The following error appears: JSP Processing Error  HTTP Error Code: 500  Error Message: /test.jsp(2,1) /test.jsp(2,1) JSPG0089E: Mismatch found between page directive encoding Shift_JIS and xml prolog encoding UTF-8
<b>Problem</b>	The pageEncoding attribute in the jsp:directive.page element is not UTF-8.
<b>Suggested solution</b>	JavaServer Pages must specify a prolog that matches the encoding specified in the page directive. For example, <pre>&lt;?xml version="1.0" encoding="Shift_JIS"?&gt; &lt;jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.0"&gt; &lt;jsp:directive.page language="java" contentType="text/html";   charset=Shift_JIS" pageEncoding="Shift_JIS"/&gt; &lt;jsp:text&gt;XXXXXjsp:text&gt;XXXXX&gt; &lt;/jsp:root&gt;</pre> For additional information, see section JSP.4.1, Page Character Encoding, in the JavaServer Pages specification and section 4.3.3 and appendix F.1 of the Extensible Markup Language (XML) specification

If none of these steps solves the problem, check to see if the problem is identified and documented using the links in the topic, [Diagnosing and fixing problems: Resources for learning](#). If you do not see a problem that resembles yours, or if the information provided does not solve your problem, contact IBM support for further assistance.

For current information available from IBM Support on known problems and their resolution, see the [IBM Support page](#). The IBM Support page contains documents that can save you time gathering information needed to resolve this problem.

## Administering RRD applications

### Configuring web applications to dispatch remote includes

You can configure web modules in an application as remote request dispatcher clients to dispatch include requests to resources across web modules that are in different Java virtual machines in a managed node environment through the standard request dispatcher.

#### Before you begin

You must have WebSphere Application Server, Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, "Remote request dispatcher considerations" on page 2737 for details.

#### About this task

You can also configure this property when you install the application installation. See [Installing enterprise application files with the console](#)

#### Procedure

1. In the administrative console, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Request dispatcher properties**.
2. Select **Allow dispatching includes to remote resources**.

## Results

Web modules included in this application are enabled as remote request dispatcher clients that can dispatch remote includes.

## What to do next

You must enable remote request dispatcher on both the remote server and local server to use remote request dispatcher. If you have not yet enabled remote request dispatcher on the remote server that includes the resource that you want to include, see article, “Configuring web applications to service remote includes.”

## Configuring web applications to service remote includes

You can configure web modules in an application as remote request dispatcher servers that are remotely included by other web applications.

## Before you begin

You must have WebSphere Application Server, Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, Remote request dispatcher considerations, for details.

## About this task

The purpose of this task is to specify whether an application can service an include request from another application. You can also configure this property when you install the application installation. Some statement about the process used to arrive here. See article, Installing enterprise application files with the console, for more information.

## Procedure

1. In the administrative console, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Request dispatcher properties**.
2. Select **Allow servicing includes from remote resources**.

## Results

Web modules included in this application are enabled as remote request dispatcher servers that are resolved to service remote includes from another application.

## What to do next

You must enable remote request dispatcher on both the remote server and local server to use remote request dispatcher. If you have not yet enabled remote request dispatcher on the local server to include a remote resource, see article, Configuring web applications to dispatch remote includes, for more information.

## Configuring remote request dispatcher caching

The creation and handling of the remote request dispatcher (RRD) message and the transfer of this data across a network creates substantial overhead. To improve performance, the local machine can receive the cache rules of the remote server and know when to cache the response locally to prevent the RRD call altogether.

## About this task

Unsupported rules are cached remotely. However, remote request dispatcher does not support the entire set of rules of the `cachespec.xml` file for local caching. The following rules for the `cachespec.xml` file are supported for local caching.

### parameters

Retrieves the named parameter value.

### cookie

Retrieves the named cookie value.

### header

Retrieves the named request header.

### locale

Retrieves the request locale.

### requestType

Retrieves the HTTP request method from the request.

Complete the following steps to enable RRD dynamic cache support.

## Procedure

1. Enable servlet caching on the local server Refer to the Configuring servlet caching article for more information.
2. Construct and install an application with a valid `cachespec.xml` file policy with RRD supported rules. See the article, Configuring cacheable objects with the `cachespec.xml` file, for additional information.
3. Enable servlet caching on the remote server. Refer to the Configuring servlet caching article for more information.
4. Restart WebSphere Application Server. Refer to the Managing application servers article for more information.

## Results

To verify that dynamic cache is enabled locally, you can enable RRD trace and verify that there is a CACHE HIT printed out for multiple requests to a resource that has an appropriate cache policy. You also have the option to use CacheMonior instead of turning on tracing. If the CacheMonitor on the remote machine is not receiving cache hits, then the response is cached locally. The local CacheMonitor will not receive hits because RRD uses its own custom cache.

## Remote request dispatcher

Remote Request Dispatcher (RRD) is a pluggable extension to the web container for application frameworks, servlets, and JavaServer Pages to include content from outside of the current Java virtual machine (JVM) for the resource, as part of the response sent to the client.

Remote request dispatcher is an extensible infrastructure for other components and stack products to add custom extensions like generators and handlers, to the RRD extension. The remote request dispatcher extension enhances the standard Java Platform, Enterprise Edition (Java EE) `javax.servlet.RequestDispatcher` implementation to be aware of locating remote resources using web services to communicate between machines within a WebSphere Application Server, Network Deployment (ND) core group. The remote request dispatcher extension reports any errors that occur on the remote server back to the originating server. It can also use SSL for secure communications and WS-Security security context propagation between servers. See the `rrdSecurity.props` file topic for more information.

RRD portlet support carries forward the remote request dispatcher concept to portlets and enhances the portlet container for invocation of portlets outside of the current JVM resource.

By using the RRD extension, you can share request load across multiple machines and JVMs by including remote servers within the cell. If RRD resource is memory or processor intensive, the calling resource is not affected as much as a standard RequestDispatcher running within the same JVM. RRD solves this problem by separating resources into a different JVM.

## Capabilities

- Requests on remote server are treated as include requests. Filters and request listeners are started as if the dispatch type is INCLUDE.
- Serializable request attributes and query parameters are sent to remote server.
- Security context is sent to a remote server through LTPA tokens.
- Servlet parameters and OutputStream  
Request parameters are passed to remote server.
- Response headers that are set by the remotely included resource are ignored similar to includes on a local server. Internal headers such as Set-Cookie can still be set and are propagated back.
- All original request headers are passed to remote server
  - Similar to the plug-in for WebSphere Application Server.
  - Method calls return the state as if they are on local server. For example, `getServer` returns the local server name or `isSecure` returns whether the request to the 'local' server has been secure.
- Cookies and sessions
  - Cookies are passed to the remote server as part of headers.
  - Sessions in local and remote servers use the same cookie or session ID for a given client which is similar to includes in the same server. If a session exists on a remote server, the session cookie contains the information for both the servers to maintain the affinity to the remote server.
- Exceptions
  - If there is an exception on the remote server, the server returns an RRD-specific web services fault which wraps the original exception created by the application.
  - Attempt to recreate the original exception on the local server if the exception class exists on both servers. If the original exception cannot be recreated, an RRD-specific `ServletException` is constructed and used instead.
  - The exception is recreated by the local server for error handling purposes.
- Dynamic cache  
When dynamic cache is enabled, caching is performed on the local and remote machine.
- Security  
You can use SSL to encrypt RRD messages between application servers. SSL is enabled by default, however, you must also pass security context needs through RRD to ensure that the security state is available in the remote machine. RRD uses WS-Security to pass this information, but this security context propagation is disabled by default. See the `rrdSecurity.props` file topic for additional information.

## Remote dispatcher property settings

Use this page to configure the sending of include requests between the application and remote resources.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Request dispatcher properties**.

### ***Allow dispatching includes to remote resources:***

Specifies whether an application can dispatch include requests to resources across web modules that are in different Java virtual machines in a managed node environment through the standard request dispatcher.

**Data type** Boolean

**Default** false

***Allow servicing includes from remote resources:***

Specifies whether an application can service an include request from another application.

**Data type** Boolean  
**Default** false

***Asynchronous request dispatching type:***

Changes the behavior of the servlet request dispatcher to support cross-JVM dispatching and asynchronous dispatching.

**Disabled** Specifies that asynchronous request dispatching is not supported for this application  
**Server side** Specifies that the response content is aggregated on the server  
**Client side** Specifies that the response content is aggregated on the client/browser

**Remote request dispatcher considerations**

This topic presents some considerations of which you need to be aware when using remote request dispatcher.

- If an application expects parameters in certain encoding, the application should set character encoding, as in a normal include, before the remote request dispatch (RRD) occurs.
  - ServletInputStream data of local server is not available to remote server. The local server parses POST data prior to sending the RRD request to the remote server and include parameters as request parameters. Multipart form data is inaccessible to remote server. An UnsupportedOperationException is created if the remote server attempts to obtain inputstream from the request.
  - No access to original request reference on the remote server.
  - Request and response wrappers created in the local server are not available in remote server. This cannot be done due to ServletRequestWrappers and WebSphere internal ServletRequest objects not implementing Serializable.
- Request attributes need to be serializable.
  - Class definition of attributes need to be available in both local and remote servers.
  - Request attributes are propagated to the remote server and back to the local server.
- HTTP Sessions
  - You cannot have cross session access between different web applications when web applications are remote.
  - When all web applications are in a local server, an application can share sessions across web applications by storing the session in a table that is accessible to multiple web applications. This is not possible with RRD and not recommended in local case either.
  - Servlet Programming Model: You cannot access sessions in different Web applications.
  - Normal programming model in local case as well as remote case.
  - In local mode, application can cache away reference and share the session across the web applications, which is not feasible in RRD case.
  - A session object that is stored as request attribute is not available on remote server as the Session class does not implement Serializable.
- Thread local variables that are set on the local server are not available on the remote server.

- Not all methods defined on ServletContext object are available for the RRD ServletContext object. See the SPI documentation for com.ibm.wsspi.rrd.context.RemoteServletContext for details.
- The remote server does not have access to output of local server when using RRD.
- Cookies and ServletRequestWrappers

If customer application wrappers the HttpServletRequest.getCookies method and returns additional cookies or removes cookies, the modified cookies are not sent to the remote server because javax.servlet.http.Cookie does not implement Serializable. Cookies from the original request headers are sent to the remote server.

## Asynchronous request dispatching settings

### Asynchronous request dispatching settings

Use this page to enable the asynchronous request dispatcher (ARD), which enables servlets and JSP pages to make standard include calls concurrently on separate threads.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > *server\_name* > Web Container Settings > Web container > Asynchronous request dispatching**.

Additionally, the initiation and the insertion of the include contents can be separated so that the include has more time to execute before it needs to be written to the response. ARD requires aggregation of the include contents with the original response. The application server can aggregate the contents in memory or the client browser can aggregate the contents through AJAX. Aggregation type is configurable at the application level.

#### ***Allow Asynchronous Request Dispatching:***

Enables applications installed on this server to use asynchronous request dispatching.

#### ***Asynchronous include timeout:***

Specifies the default timeout in milliseconds to complete asynchronous includes.

<b>Data type</b>	Integer
<b>Units</b>	Milliseconds
<b>Default</b>	60000
<b>Range</b>	

#### ***Maximum expired requests per minute:***

Specifies the maximum percentage of expired response versus total response in one minute before switching to synchronous requests.

<b>Data type</b>	Integer
<b>Units</b>	Percentage
<b>Default</b>	15
<b>Range</b>	

#### ***Maximum memory size of results store:***

Specifies the maximum size of store for client side requests.

<b>Data type</b>	Integer
<b>Units</b>	Megabytes

Default  
Range

100

---

## Asynchronous request dispatching settings

### Asynchronous request dispatching settings

Use this page to enable the asynchronous request dispatcher (ARD), which enables servlets and JSP pages to make standard include calls concurrently on separate threads.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > *server\_name* > Web Container Settings > Web container > Asynchronous request dispatching**.

Additionally, the initiation and the insertion of the include contents can be separated so that the include has more time to execute before it needs to be written to the response. ARD requires aggregation of the include contents with the original response. The application server can aggregate the contents in memory or the client browser can aggregate the contents through AJAX. ## Administering RRD applications

### Configuring web applications to dispatch remote includes

You can configure web modules in an application as remote request dispatcher clients to dispatch include requests to resources across web modules that are in different Java virtual machines in a managed node environment through the standard request dispatcher.

#### Before you begin

You must have WebSphere Application Server, Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, “Remote request dispatcher considerations” on page 2737 for details.

#### About this task

You can also configure this property when you install the application installation. See Installing enterprise application files with the console

#### Procedure

1. In the administrative console, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Request dispatcher properties**.
2. Select **Allow dispatching includes to remote resources**.

#### Results

Web modules included in this application are enabled as remote request dispatcher clients that can dispatch remote includes.

#### What to do next

You must enable remote request dispatcher on both the remote server and local server to use remote request dispatcher. If you have not yet enabled remote request dispatcher on the remote server that includes the resource that you want to include, see article, “Configuring web applications to service remote includes” on page 2734.

### Configuring web applications to service remote includes

You can configure web modules in an application as remote request dispatcher servers that are remotely included by other web applications.

#### Before you begin

You must have WebSphere Application Server, Network Deployment installed to use remote request dispatcher function. You should also familiarize yourself the limitations of remote request dispatcher. See article, Remote request dispatcher considerations, for details.

#### About this task

The purpose of this task is to specify whether an application can service an include request from another application. You can also configure this property when you install the application installation. Some statement about the process used to arrive here. See article, Installing enterprise application files with the console, for more information.

## Procedure

1. In the administrative console, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Request dispatcher properties**.
2. Select **Allow servicing includes from remote resources**.

## Results

Web modules included in this application are enabled as remote request dispatcher servers that are resolved to service remote includes from another application.

## What to do next

You must enable remote request dispatcher on both the remote server and local server to use remote request dispatcher. If you have not yet enabled remote request dispatcher on the local server to include a remote resource, see article, [Configuring web applications to dispatch remote includes](#), for more information.

## Configuring remote request dispatcher caching

The creation and handling of the remote request dispatcher (RRD) message and the transfer of this data across a network creates substantial overhead. To improve performance, the local machine can receive the cache rules of the remote server and know when to cache the response locally to prevent the RRD call altogether.

## About this task

Unsupported rules are cached remotely. However, remote request dispatcher does not support the entire set of rules of the `cachespec.xml` file for local caching. The following rules for the `cachespec.xml` file are supported for local caching.

### parameters

Retrieves the named parameter value.

### cookie

Retrieves the named cookie value.

### header

Retrieves the named request header.

### locale

Retrieves the request locale.

### requestType

Retrieves the HTTP request method from the request.

Complete the following steps to enable RRD dynamic cache support.

## Procedure

1. Enable servlet caching on the local server Refer to the [Configuring servlet caching](#) article for more information.
2. Construct and install an application with a valid `cachespec.xml` file policy with RRD supported rules. See the article, [Configuring cacheable objects with the cachespec.xml file](#), for additional information.
3. Enable servlet caching on the remote server. Refer to the [Configuring servlet caching](#) article for more information.
4. Restart WebSphere Application Server. Refer to the [Managing application servers](#) article for more information.

## Results

To verify that dynamic cache is enabled locally, you can enable RRD trace and verify that there is a CACHE HIT printed out for multiple requests to a resource that has an appropriate cache policy. You also have the option to use CacheMonitor instead of turning on tracing. If the CacheMonitor on the remote machine is not receiving cache hits, then the response is cached locally. The local CacheMonitor will not receive hits because RRD uses its own custom cache.

## Remote request dispatcher

Remote Request Dispatcher (RRD) is a pluggable extension to the web container for application frameworks, servlets, and JavaServer Pages to include content from outside of the current Java virtual machine (JVM) for the resource, as part of the response sent to the client.

Remote request dispatcher is an extensible infrastructure for other components and stack products to add custom extensions like generators and handlers, to the RRD extension. The remote request dispatcher extension enhances the standard Java Platform, Enterprise Edition (Java EE) `javax.servlet.RequestDispatcher` implementation to be aware of locating remote resources using web services to communicate between machines within a WebSphere Application Server, Network Deployment (ND) core group. The remote request dispatcher extension reports any errors that occur on the remote server back to the originating server. It can also use SSL for secure communications and WS-Security security context propagation between servers. See the `rrdSecurity.props` file topic for more information.

RRD portlet support carries forward the remote request dispatcher concept to portlets and enhances the portlet container for invocation of portlets outside of the current JVM resource.

By using the RRD extension, you can share request load across multiple machines and JVMs by including remote servers within the cell. If RRD resource is memory or processor intensive, the calling resource is not affected as much as a standard `RequestDispatcher` running within the same JVM. RRD solves this problem by separating resources into a different JVM.

## Capabilities

- Requests on remote server are treated as include requests. Filters and request listeners are started as if the dispatch type is INCLUDE.
- Serializable request attributes and query parameters are sent to remote server.
- Security context is sent to a remote server through LTPA tokens.
- Servlet parameters and `OutputStream`  
Request parameters are passed to remote server.
- Response headers that are set by the remotely included resource are ignored similar to includes on a local server. Internal headers such as `Set-Cookie` can still be set and are propagated back.
- All original request headers are passed to remote server
  - Similar to the plug-in for WebSphere Application Server.
  - Method calls return the state as if they are on local server. For example, `getServer` returns the local server name or `isSecure` returns whether the request to the 'local' server has been secure.
- Cookies and sessions
  - Cookies are passed to the remote server as part of headers.
  - Sessions in local and remote servers use the same cookie or session ID for a given client which is similar to includes in the same server. If a session exists on a remote server, the session cookie contains the information for both the servers to maintain the affinity to the remote server.
- Exceptions
  - If there is an exception on the remote server, the server returns an RRD-specific web services fault which wraps the original exception created by the application.

- Attempt to recreate the original exception on the local server if the exception class exists on both servers. If the original exception cannot be recreated, an RRD-specific ServletException is constructed and used instead.
- The exception is recreated by the local server for error handling purposes.
- Dynamic cache
 

When dynamic cache is enabled, caching is performed on the local and remote machine.
- Security
 

You can use SSL to encrypt RRD messages between application servers. SSL is enabled by default, however, you must also pass security context needs through RRD to ensure that the security state is available in the remote machine. RRD uses WS-Security to pass this information, but this security context propagation is disabled by default. See the `rrdSecurity.props` file topic for additional information.

## Remote dispatcher property settings

Use this page to configure the sending of include requests between the application and remote resources.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Request dispatcher properties**.

### Allow dispatching includes to remote resources

Specifies whether an application can dispatch include requests to resources across web modules that are in different Java virtual machines in a managed node environment through the standard request dispatcher.

<b>Data type</b>	Boolean
<b>Default</b>	false

### Allow servicing includes from remote resources

Specifies whether an application can service an include request from another application.

<b>Data type</b>	Boolean
<b>Default</b>	false

### Asynchronous request dispatching type

Changes the behavior of the servlet request dispatcher to support cross-JVM dispatching and asynchronous dispatching.

<b>Disabled</b>	Specifies that asynchronous request dispatching is not supported for this application
<b>Server side</b>	Specifies that the response content is aggregated on the server
<b>Client side</b>	Specifies that the response content is aggregated on the client/browser

## Remote request dispatcher considerations

This topic presents some considerations of which you need to be aware when using remote request dispatcher.

- If an application expects parameters in certain encoding, the application should set character encoding, as in a normal include, before the remote request dispatch (RRD) occurs.
  - ServletInputStream data of local server is not available to remote server. The local server parses POST data prior to sending the RRD request to the remote server and include parameters as request parameters. Multipart form data is inaccessible to remote server. An UnsupportedOperationException is created if the remote server attempts to obtain inputStream from the request.
  - No access to original request reference on the remote server.

- Request and response wrappers created in the local server are not available in remote server. This cannot be done due to ServletRequestWrappers and WebSphere internal ServletRequest objects not implementing Serializable.
- Request attributes need to be serializable.
  - Class definition of attributes need to be available in both local and remote servers.
  - Request attributes are propagated to the remote server and back to the local server.
- HTTP Sessions
  - You cannot have cross session access between different web applications when web applications are remote.
  - When all web applications are in a local server, an application can share sessions across web applications by storing the session in a table that is accessible to multiple web applications. This is not possible with RRD and not recommended in local case either.
  - Servlet Programming Model: You cannot access sessions in different Web applications.
  - Normal programming model in local case as well as remote case.
  - In local mode, application can cache away reference and share the session across the web applications, which is not feasible in RRD case.
  - A session object that is stored as request attribute is not available on remote server as the Session class does not implement Serializable.
- Thread local variables that are set on the local server are not available on the remote server.
- Not all methods defined on ServletContext object are available for the RRD ServletContext object. See the SPI documentation for com.ibm.wsspi.rrd.context.RemoteServletContext for details.
- The remote server does not have access to output of local server when using RRD.
- Cookies and ServletRequestWrappers
 

If customer application wrappers the HttpServletRequest.getCookies method and returns additional cookies or removes cookies, the modified cookies are not sent to the remote server because javax.servlet.http.Cookie does not implement Serializable. Cookies from the original request headers are sent to the remote server.

---

## Configuring HTTP sessions

### Configuring session management by level

When you configure session management at the web container level, all applications and the respective web modules in the web container normally inherit that configuration, setting up a basic default configuration for the applications and web modules below it. However, you can set up different configurations individually for specific applications and web modules that vary from the web container default. These different configurations override the default for these applications and web modules only.

#### About this task

An enterprise application can contain web modules, and so can an OSGi application. At the web container level and at the application level, the process for configuring HTTP sessions is the same whether the web module is part of an enterprise application or an OSGi application. For enterprise applications only, you can also configure HTTP sessions at the web module level.

**Note:** When you overwrite the default session management settings at the application level, all the web modules below the application inherit the new setting unless they too are set to overwrite these settings.

**Note:** Session management configuration is a post-deployment configuration and is tied to existing targets. If you change the target mapping after you configure session management, you must return to the session management configuration page in the administrative console or use wsadmin

scripting and apply the changes. Apply the changes to module targets if session management is configured for a web module. Apply the changes to all targets if session management is configured for an application level.

## Procedure

1. Open the administrative console.
2. Change the configuration for the web container, enterprise application, or web module level. The following substeps explain how to access the configuration panels for each of these levels.
  - Complete the following substeps for the web container level:
    - a. Click **Servers > Server Types > WebSphere application servers > *server\_name***.
    - b. Under **Container Settings**, expand **Web Container Settings** and click **Web container**.
    - c. Under **Additional Properties**, click **Session management**.
  - Complete the following substeps for the application level:

If the application is an enterprise application:

    - a. Click **Applications > Application Types > WebSphere enterprise applications > *application\_name***.
    - b. Under **Web Module Properties**, click **Session management**.

If the application is an OSGi application:

    - a. Click **Applications > Application Types > Business-level applications > *application\_name* > *eba\_asset\_name***.
    - b. Under **Additional Properties**, click **Session management**.
  - Complete the following substeps for the web module level, if the application is an enterprise application:
    - a. Click **Applications > Application Types > WebSphere enterprise applications > *application\_name***.
    - b. Under **Modules**, click **Manage Modules > *module\_name***.
    - c. Under **Additional Properties**, click **Session Management**.
3. Manage sessions by configuring session tracking, session timeouts and serializing access.
4. If you are working at the web module or application level and want these settings to override the inherited Session Management settings, under **General Properties** select **Override session management**.
5. Click **Apply** and **Save**.

## Session management settings

Use this page to manage HTTP session support. This support includes specifying a session tracking mechanism, setting maximum in-memory session count, controlling overflow, and configuring session timeout.

To view this administrative console page at the web container level, click **Servers > Server Types > WebSphere application servers > *server\_name* > Session management** .

### Important:

You can override the session management settings at the application level.

### ***Session tracking mechanism:***

Table 250. HTTP session tracking mechanism. This table describes mechanisms for HTTP session management.

Mechanism	Function	Default
Enable SSL ID Tracking	<p>Specifies that session tracking uses Secure Sockets Layer (SSL) information as a session ID. Enabling SSL tracking takes precedence over cookie-based session tracking and URL rewriting.</p> <p>There are two parameters available if you enable SSL ID tracking: SSLV3Timeout and Secure Authentication Service (SAS). SSLV3Timeout specifies the time interval after which SSL sessions are renegotiated. This parameter is a high setting and modification does not provide any significant impact on performance. The SAS parameter establishes an SSL connection only if it goes out of the Java Virtual Machine (JVM) to another JVM. If all the beans are co-located within the same JVM, the SSL used by SAS does not hinder performance.</p> <p>These parameters are set by editing the <code>sas.server.properties</code> and <code>sas.client.props</code> files, located in the <code>product_installation_root\properties</code> directory, where <code>product_installation_root</code> is the directory where WebSphere Application Server is installed.</p> <p><b>Important:</b> SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.</p>	9600 seconds
Enable cookies	<p>Specifies that session tracking uses cookies to carry session IDs. If cookies are enabled, session tracking recognizes session IDs that arrive as cookies and tries to use cookies for sending session IDs. If cookies are not enabled, session tracking uses Uniform Resource Identifier (URL) rewriting instead of cookies (if URL rewriting is enabled).</p> <p>Enabling cookies takes precedence over URL rewriting. Click <b>Enable cookies</b> to change these settings. Application level session management settings override the server level session management settings. Because session management is defined at the application level, enabling cookies for the administration console is handled in the <code>deployment.xml</code> file.</p>	

Table 250. HTTP session tracking mechanism (continued). This table describes mechanisms for HTTP session management.

Mechanism	Function	Default
Enable URL rewriting	Specifies that the session management facility uses rewritten URLs to carry the session IDs. If URL rewriting is enabled, the session management facility recognizes session IDs that arrive in the URL if the encodeURL method is called in the servlet. This option is only available when <b>Enable URL rewriting</b> is selected. This option specifies that the session ID is added to a URL when the URL requires a switch from HTTP to HTTPS or from HTTPS to HTTP. If rewriting is enabled, the session ID is required to go between HTTP and HTTPS.	
Enable protocol switch rewriting		

**Maximum in-memory session count:**

Specifies the maximum number of sessions to maintain in memory for each web module.

The meaning differs depending on whether you are using in-memory or distributed sessions. For in-memory sessions, this value specifies the number of sessions in the base session table for a web module. Use the Allow overflow property to specify whether to limit sessions to this number for the entire session management facility or to allow additional sessions to be stored in secondary tables. For distributed sessions, this value specifies the size of the memory cache for each web module's sessions. When the session cache has reached its maximum size and a new session is requested, the session management facility removes the least recently used session from the cache to make room for the new one.

**Note:** Do not set this value to a number less than the maximum thread pool size for your server.

**Allow overflow:**

Specifies that the number of sessions in memory can exceed the value specified by the Max in-memory session count property. This option is valid only in non-distributed sessions mode.

**Session timeout:**

Specifies how long a session can go unused before it is no longer valid. Specify either Set timeout or No timeout. Specify the value in minutes greater than or equal to two.

The value specified in a web module deployment descriptor file takes precedence over the administrative console settings. However, the value of this setting is used as a default when the session timeout is not specified in a web module deployment descriptor. To preserve performance, the invalidation timer is not accurate to the second. When the write frequency is time-based, ensure that this value is least twice as large as the write interval.

**Security integration:**

Specifies that when security integration is enabled, the session management facility associates the identity of users with their HTTP sessions. Session security (security integration) is enabled by default.

### **Serialize session access:**

Specifies that concurrent session access in a given server is not permitted.

Table 251. *Serialize session access. This table describes mechanisms for serialize session access.*

<b>Mechanism</b>	<b>Function</b>
Maximum wait time	Specifies the maximum amount of time a servlet request waits on an HTTP session before starting. This parameter is optional and expressed in seconds. The default is five seconds. Under normal conditions, a servlet request waits for access to an HTTP session and is notified by the request that currently owns the given HTTP session when the request finishes.
Allow access on timeout	Specifies whether the servlet starts normally or aborts in the event of a timeout. The servlet starts normally when this box is checked. If this box is not checked, the servlet execution aborts and error logs are generated.

### **Session recovery support**

For session recovery support, WebSphere Application Server provides distributed session support in the form of database sessions and memory-to-memory replication. You can use session recovery support when the user's session data must be maintained across a server restart or when the user's session data is too valuable to lose through an unexpected server failure.

All the attributes set in a session must implement `java.io.Serializable` if the session requires external storage. In general, consider making all objects held by a session serialized, even if immediate plans do not call for session recovery support. If the website grows, and session recovery support becomes necessary, the transition occurs transparently to the application if the sessions only hold serialized objects. If not, a switch to session recovery support requires coding changes to make the session contents serialized.

### **Distributed environment settings**

Use this page to specify a type for saving a session in a distributed environment.

To view this administrative console page at the web container level, click **Servers > Server Types > WebSphere application servers > *server\_name* > Session management > Distributed environment settings**.

Note that the distributed environment settings can be overridden at the application level.

#### ***Distributed sessions:***

Specifies the type of distributed environment to be used for saving sessions.

<b>None</b>	Specifies that the session management facility discards the session data when the server shuts down.
<b>Database</b>	Specifies that the session management facility stores session information in the data source specified by the data source connection settings. Click <b>Database</b> to change these data source settings.
<b>Memory-to-memory replication</b>	Specifies that the session management facility stores the session information in a data source in memory. The session information is copied to other session management facilities for failure recovery. Click <b>Memory-to-memory replication</b> to change these data source settings.

# Configuring session tracking

## About this task

Review the Session tracking options to plan your approach to session management. To configure session tracking, complete the following:

### Procedure

1. Go to the appropriate level of Session Management.
2. Specify the session tracking mechanism that you want to pass the session ID between the browser and the servlet:
  - To track sessions with cookies, click **Enable Cookies**.  
To change the cookie settings, click **Modify**.
  - To track sessions with URL rewriting, click **Enable URL Rewriting**.  
If you want to enable protocol switch rewriting, click **Enable protocol switch rewriting**.
  - To track sessions with SSL information, click **Enable SSL ID tracking**.

**Note:** Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can reconfigure session tracking to use cookies or modify the application to use URL rewriting.

3. Click **Apply**.
4. Click **Save**.
5. Define the “Distributed environment settings” on page 2748 to specify how to save a session in a distributed environment.

### Session tracking options

HTTP session support also involves session tracking. You can use cookies, URL rewriting, or Secure Sockets Layer (SSL) information for session tracking.

the following tracking methods are available:

- Session tracking with cookies
- Session tracking with URL rewriting
- Session tracking with Secure Sockets Layer (SSL) information

**Session tracking with cookies:** Tracking sessions with cookies is the default. No special programming is required to track sessions with cookies.

**Session tracking with URL rewriting:** An application that uses URL rewriting to track sessions must adhere to certain programming guidelines. The application developer needs to do the following:

- Program servlets to encode URLs
- Supply a servlet or JavaServer Pages (JSP) file as an entry point to the application

Using URL rewriting also requires that you enable URL rewriting in the session management facility.

**Note:** In certain cases, clients cannot accept cookies. Therefore, you cannot use cookies as a session tracking mechanism. Applications can use URL rewriting as a substitute.

### Program session servlets to encode URLs

Depending on whether the servlet is returning URLs to the browser or redirecting them, include either the `encodeURL` method or the `encodeRedirectURL` method in the servlet code. Examples demonstrating what to replace in your current servlet code follow.

## Rewrite URLs to return to the browser

Suppose you currently have this statement:

```
out.println("catalog<a>");
```

Change the servlet to call the `encodeURL` method before sending the URL to the output stream:

```
out.println("<a href=\"\"");
out.println(response.encodeURL ("/store/catalog"));
out.println(">catalog");
```

## Rewrite URLs to redirect

Suppose you currently have the following statement:

```
response.sendRedirect ("http://myhost/store/catalog");
```

Change the servlet to call the `encodeRedirectURL` method before sending the URL to the output stream:

```
response.sendRedirect (response.encodeRedirectURL ("http://myhost/store/catalog"));
```

The `encodeURL` method and `encodeRedirectURL` method are part of the `HttpServletResponse` object. These calls check to see if URL rewriting is configured before encoding the URL. If it is not configured, the calls return the original URL.

You can also configure session support to enable protocol switch rewriting. When this option is enabled, the product encodes the URL with the session ID for switching between HTTP and HTTPS protocols.

**gotcha:** If you want to encode a URL, you must enable the `AlwaysEncodeURL` custom property and set the value to true.

Session management properties, like the session management configuration, can be configured at the server, application, or web module level. The following steps are for setting the custom properties for session management at the server level.

1. In the administrative console click **Servers > Server Types > WebSphere application servers > server\_name > Session management**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

## Supply a servlet or JSP file as an entry point

The entry point to an application, such as the initial screen presented, may not require the use of sessions. However, if the application in general requires session support (meaning some part of it, such as a servlet, requires session support), then after a session is created, all URLs are encoded to perpetuate the session ID for the servlet (or other application component) requiring the session support.

The following example shows how you can embed Java code within a JSP file:

```
<%
response.encodeURL ("/store/catalog");
%>
```

## ***Session tracking with SSL information (Deprecated):***

**Note:** Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or URL rewriting.

No special programming is required to track sessions with Secure Sockets Layer (SSL) information.

To use SSL information, turn on **Enable SSL ID tracking** in the session management property page. Because the SSL session ID is negotiated between the web browser and HTTP server, this ID cannot survive an HTTP server failure. However, the failure of an application server does not affect the SSL session ID if an external HTTP server is present between WebSphere Application Server and the browser.

SSL tracking is supported for the IBM HTTP Server and iPlanet Web Servers only. You can control the lifetime of an SSL session ID by configuring options in the web server. For example, in the IBM HTTP Server, set the configuration variable SSLV3TIMEOUT to provide an adequate lifetime for the SSL session ID. An interval that is too short can cause a premature termination of a session. Also, some web browsers might have their own timers that affect the lifetime of the SSL session ID. These web browsers may not leave the SSL session ID active long enough to serve as a useful mechanism for session tracking. The internal HTTP Server of WebSphere Application Server also supports SSL tracking.

When using the SSL session ID as the session tracking mechanism in a cloned environment, use either cookies or URL rewriting to maintain session affinity. The cookie or rewritten URL contains session affinity information that enables the web server to properly route a session back to the same server for each request.

### **Serializing access to session data**

The Servlet API supports concurrent access to a session in a given server instance. WebSphere Application Server provides an option to prevent the concurrent access to a session in a given server instance so that concurrent modification of a session does not occur in a given server instance.

### **About this task**

Preventing concurrent access to a session is achieved by synchronizing the requests based on session. When this feature is turned on, a session is obtained for the request before invoking the servlet and requests are synchronized by locking the session for the servlet initiation time. Note that synchronization is based on the memory copy of session. So this feature cannot serialize requests across servers based on session when session affinity fails.

You can also use the serializing access to session data feature to synchronize session objects inside of servlets or JavaServer pages. Applications cannot synchronize session objects inside of their servlets or JavaServer Pages because a deadlock with the session manager may occur. The deadlock occurs because the session manager does not expect the use of more than one locking mechanism. You can ensure that only one request can access the session at a time through the use of the configuration option, Allow serial access.

Use this feature only when concurrent modification of the same session data is possible and is not desirable by the application. This feature has overhead of serializing the requests based on a session.

Do the following to synchronize session access:

### **Procedure**

1. Select the level of Session Management on which you want to serialize session access.
2. Under Serialize Session access, click **Allow serial access**.
3. In the Maximum wait time box, type the amount of time, in milliseconds, a servlet waits on a session before continuing execution. The default is 120000 milliseconds or two minutes.

4. Select **Allow access on timeout** if you want the servlet to gain access to the session and continue normal execution even if the session is still locked by another servlet. If you do not select this box, the servlet execution will abort when the session request times out.
5. Click **Apply**.
6. Click **Save**.

## Cookie settings

Use this page to configure cookie settings for session management.

To view this administrative console page, click **Servers > Server types > WebSphere application servers > server\_name > Session management > Enable cookies**.

### ***Cookie name:***

Specifies a unique name for the session management cookie. The servlet specification requires the name JSESSIONID. However, for flexibility, you can configure this value.

### ***Restrict cookies to HTTPS sessions:***

Specifies that the session cookies include the secure field. Enabling this feature restricts the exchange of cookies to HTTPS sessions only.

### ***Set cookies as HTTP only to help prevent cross-site scripting attacks:***

Specifies that session cookies include the HTTP only field. When checked, browsers that support the HTTP only attribute do not enable cookies to be accessed by client-side scripts. For security cookies, see the global security settings for web single sign-on (SSO).

### ***Cookie domain:***

Specifies the domain field of a session tracking cookie. This value controls whether a browser sends a cookie to particular servers. For example, if you specify a particular domain, session cookies are sent to hosts in that domain. The default domain is the server.

### ***Cookie maximum age:***

Specifies the amount of time that the cookie lives on the client browser. Specify that the cookie lives only as long as the current browser session, or to a maximum age. If you choose the maximum age option, specify the age in seconds. This value corresponds to the Time to Live (TTL) value described in the Cookie specification.

Default is the current browser session which is equivalent to setting the value to -1.

### ***Cookie path:***

Specifies that a cookie is sent to the URL designated in the path. Specify any string representing a path on the server. A slash (/) indicates root directory. Specify a value to restrict the paths to which the cookie is sent. By restricting paths, you prevent the cookie from going to certain URLs on the server. If you specify the root directory, the cookie is sent no matter which path on the given server is accessed.

Set the cookie path to match the context root for each application. This setting restricts the cookie from being sent to other applications and results in having different cookies created when accessing multiple applications.

## Session management custom properties

You can specify additional settings for session management through setting custom properties.

Session management properties, like the session management configuration, can be configured at the server, application, or web module level. The following steps are for setting the custom properties for session management at the server level.

1. In the administrative console click **Servers > Server Types > WebSphere application servers > *server\_name* > Session management**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

You can use the custom properties page to define the following session management properties:

- “AlwaysEncodeURL”
- “CloneSeparator”
- “CloneSeparatorChange” on page 2754
- “DebugSessionCrossover” on page 2754
- “ForceSessionInvalidationMultiple” on page 2754
- “HideSessionValues” on page 2754
- “HttpSessionCloneId” on page 2754
- “HttpSessionEnableUnmanagedServerReplication” on page 2755
- “HttpSessionIdLength” on page 2755
- “HttpSessionIdReuse” on page 2755
- “HttpSessionReaperPollInterval” on page 2755
- “NoAdditionalSessionInfo” on page 2756
- “NoAffinitySwitchBack” on page 2756
- “OptimizeCacheIdIncrements” on page 2756
- “SecurityUserIgnoreCase” on page 2756
- “Servlet21SessionCompatibility” on page 2757
- “SessionIdentifierMaxLength” on page 2757
- “SessionRewriteIdentifier” on page 2757
- “SessionTableName” on page 2757
- “UseInvalidatedId” on page 2757
- “UseOracleBLOB” on page 2757
- “UsingApplicationSessionsAndInvalidateAll” on page 2757
- “UsingCustomSchemaName” on page 2758

#### ***AlwaysEncodeURL:***

The Servlet 2.5 specification specifies to not encode the URL on a `response.encodeURL` call if it is not necessary. To support backward compatibility when URL encoding is enabled, set the *AlwaysEncodeURL* custom property to `true` to call the `encodeURL` method. The URL is always encoded, even if the browser supports cookies.

#### ***CloneSeparator:***

Use this property to specify a different character as the clone separator in session cookies. The value specified for this custom property must be a single character.

This property was set as a web container custom property in version 6.1 but must now be set as a session management custom property.

**bprac:** This property should only be used as a means to provide more flexibility if you have a situation where you cannot use either a colon (:), or a plus sign (+) as the clone separator in session cookies. You should understand the clone character requirements of other products running on your system before using this property to change the clone separator character.

The fact that any character can be specified as the value for this custom property does not imply that the character you specify will function correctly. This fact also does not imply that IBM is responsible for fixing any problem that might arise from using an alternative character.

#### ***CloneSeparatorChange:***

Use this property to maintain session affinity. The clone ID of the server is appended to session identifier separated by colon. On some Wireless Application Protocol (WAP) devices, a colon is not allowed. Set this property to true to change clone separator to a plus sign (+).

#### ***DebugSessionCrossover:***

The *DebugSessionCrossover* custom property enables code to perform additional checks to verify that only the session associated with the request is accessed or referenced. Messages are logged if any discrepancies are detected.

Set this property to true to enable session data crossover detection.

See article, HTTP session problems, for additional information.

#### ***ForceSessionInvalidationMultiple:***

The *ForceSessionInvalidationMultiple* custom property indicates whether the session manager should wait indefinitely for a request to complete before attempting to invalidate the session, or should attempt to invalidate a session after the specified time limit has elapsed. The default value for this property is 1.

- If you specify 0 (zero) for this custom property, the session manager waits indefinitely until a request is complete before attempting to invalidate the session.

If your requests normally are not bound by a response time limit, specify 0 for this property.

- If you specify a positive integer, such as 1, 2, or 3, for this custom property, even if a session is not known to have completed, the session manager attempts to invalidate the session, if the indicated time period since the last access occurred has elapsed. This time period is the result of multiplying the value specified for this property and the value specified for the Session Timeout property. For example, if you specify 2 minutes for the Session Timeout property and 2 for the *ForceSessionInvalidationMultiple* property, the session manager attempts to invalidate the session after 4 minutes.

If you want to invalidate your sessions after a certain amount of time has elapsed, specify the appropriate positive integer for this property.

#### ***HideSessionValues:***

The *HideSessionValues* custom property prevents the logging of session attribute values in session manager traces.

Applications store these session attribute values. However, you might not want to see these values in application server traces. Set this property to true if you do not want to see these values in application server traces.

#### ***HttpSessionCloneld:***

Use this property to change the clone ID of the cluster member. Within a cluster, this ID must be unique to maintain session affinity. When set, this name overwrites the default name generated by WebSphere Application Server.

Default clone ID length: 40

#### ***HttpSessionEnableUnmanagedServerReplication:***

Set this custom property to `true` if you want to enable servant failover by replicating session data to a controller managed data space. The default value is `false`.

#### ***HttpSessionIdLength:***

Use this property to configure the session identifier length. Do not use an extremely low value; using a low value results in reduced number of combinations possible, thereby increasing risk of guessing the session identifier. In a cluster, all cluster members should be configured with same ID length. Allowed range: 8 to 128. Default length: 23.

#### ***HttpSessionIdReuse:***

The custom property *HttpSessionIdReuse* determines whether the session manager can use the session ID sent from a browser to preserve session data across web applications that are running in an environment that is not configured for session persistence.

In a multi-JVM environment that is not configured for session persistence setting this property to `true` enables the session manager to use the same session information for all of a user's requests even if the web applications that are handling these requests are governed by different JVMs. The default value for this property is `false`. Set this property to `true` if you want to enable the session manager to use the session ID sent from a browser to preserve session data across web applications that are running in an environment that is not configured for session persistence.

In a z/OS system that includes multiple servants, on rare occasions two requests come in at approximately the same time, and are routed to two separate servants. However, because the two requests come in at approximately the same time, they both request a new session with the same session ID. If the *HttpSessionIdReuse* property is set to `true` when this situation occurs, the following error message is logged for one of the servants, and the servant where the message is logged does not get a session:

```
ExtendedMessage: BB000220E: SessionContext:createSession - call to
establishAffinity for id id_number failed with rc 4
```

#### ***HttpSessionReaperPollInterval:***

Use this property to specify, in seconds, a wake-up interval for the process that removes invalid sessions. The value specified for this property overrides the default installation value, which is between 30 and 360 seconds, and ensures that the reaper process runs at a specific interval.

If the maximum inactive interval is less than 2 minutes, the reaper poll interval may be as short as 30 seconds.

If the maximum inactive interval is more than 15 minutes, the reaper poll interval can be as long as 6 minutes.

Because the default timeout and maximum inactive interval is 30 minutes, the reaper interval is usually between 5 and 6 minutes.

For example, you might want to use this property if you want the installation timed out sessions invalidated more frequently than 5 to 6 minutes. Specifying `HttpSessionReaperPollInterval=120` ensures that sessions are invalidated within 2 minutes of timing out.

The minimum value for this property is 30 seconds. If a value less than the minimum is entered, the specified property is ignored and an appropriate value is automatically determined and used. The maximum inactive interval is the session timeout. The default is based on maximum inactive interval set in session management.

***NoAdditionalSessionInfo:***

Set this value to "true" to force removal of information that is not needed in session identifiers.

***NoAffinitySwitchBack:***

Set this property to "true" to maintain affinity to the new member even after original one comes back up. When a cluster member fails, its requests routed to a different cluster member, and sessions are activated in that other member. Thus, session affinity is maintained to the new member, and when failed cluster member comes back up, the requests for sessions that were created in the original cluster member are routed back to it. Allowed values are true or false, with the default being false.

Set this property to **true** when you have distributed sessions configured with time-based write. Note that this property has no affect on the behavior when distributed sessions is not enabled.

***OptimizeCacheIdIncrements:***

Set the *OptimizeCacheIdIncrements* custom property to true to make the session manager assess whether the in-memory session for a web module is older than the copy in persistent store. Setting this property resolves the continually increasing cache ID.

If HTTP session management is configured to use session persistence and the user's browser session is moving back and forth across multiple web applications you might see extra persistent store activity as the in-memory sessions for a web module are refreshed from the persistent store. As a result, the cache IDs are continually increasing and the in-memory session attributes are overwritten by those of the persistent copy. Set this property to true if you want to prevent the cache IDs from continually increasing.

If the configuration is a cluster, ensure that the system times of each cluster member is identical as possible.

***SecurityUserIgnoreCase:***

Set this property to true if you want the session security identity and the client security identity to be considered a match even if their cases are different.

When a user configures session security integration, the session manager compares the security identity of th session owner with the security identity of the client request. Because the matching criteria is case sensitive, if these two identities do not exactly match, an `UnauthorizedSessionRequestException` is sent back to the client.

If you have situations where you want the session security identity and the client security identity to be considered a match even if their cases are different, add the `SecurityUserIgnoreCase` custom property to your Web container configuration settings, and set the property to true. When this property is set to true, an `UnauthorizedSessionRequestException` does not occur if the session security identity and the client security identity are identical except for their cases. For example, when this property is set to true, the session security identity `USER1` matches the client security identities `User1` and `user1`.

### ***Servlet21SessionCompatibility:***

Set this custom property to true to enable global session behavior. In Servlet 2.2 and later, sessions are scoped at the Web module level. The default is **false**.

**Note:** This property is deprecated. The `IBMApplicationSession` method replaces the function of the `Servlet21SessionCompatibility` custom property.

### ***SessionIdentifierMaxLength:***

Use this value to set maximum length that a session identifier can grow.

In a cluster, because of fail-over when a request goes to new cluster member, session management appends a new clone ID to the existing clone ID. In a large cluster, if for some reason servers are failing more often, then it is possible that the session identifier length can be more than expected reducing room for URL. This property helps to find out the condition and take appropriate action to address servers fail-over. When this is specified, message is logged when specified maximum length is reached. Allowed value: integer.

### ***SessionRewriteIdentifier:***

Use this property to change the key used with URL rewriting. Default key: `jsessionid`.

### ***SessionTableName:***

Use this custom property to set the database table name. Allowed value: String. The default value is `SESSIONS`.

Some applications may rely on method `ejbCreate(...)` to have created the entity bean in the database. For such a requirement, setting the JVM property `com.ibm.websphere.ejbcontainer.allowEarlyInsert` to **true** overrides the default behavior.

### ***UseInvalidatedId:***

Set this custom property to true to reuse the incoming ID if the session with that ID was recently invalidated. This is a performance optimization because it prevents checking the persistent store. The default value is **true**.

### ***UseOracleBLOB:***

The `UseOracleBLOB` custom property creates the HTTP session database table using the Binary Large Object (BLOB) data type for the medium column. This property increases performance of persistent sessions when Oracle databases are used. Due to an Oracle restriction, BLOB support requires use of the Oracle Call Interface (OCI) database driver for more than 4000 bytes of data. You must also ensure that a new sessions table is created before the server is restarted by dropping your old sessions table or by changing the datasource definition to reference a database that does not contain a sessions table.

To create a sessions table using the BLOB data type, use the following name-value pair:

Name	Value
UseOracleBLOB	true

### ***UsingApplicationSessionsAndInvalidateAll:***

When the `invalidateAllSet` method is called, not all `IBMApplicationSessions` objects are checked. If you are using both the `IBMApplicationSessions` object and the `invalidateAll` call, use the following name-value pair:

Name	Value
<code>UsingApplicationSessionsAndInvalidateAll</code>	<code>true</code>

### ***UsingCustomSchemaName:***

Use this property to ensure that the session manager successfully detects the sessions table on subsequent server startups.

Set this custom property to `true` if you are using DB2 for sessions persistence and the `customSchema` property is not set to the default value in the DB2 JDBC driver.

The default value is `false`.

## **Configuring session tracking for Wireless Application Protocol (WAP) devices**

Applications that run in a web container use sessions to keep track of individual users. Because most Wireless Application Protocol (WAP) devices do not support cookies, you can configure WAP devices to use URL rewriting to track sessions.

### **About this task**

On most WAP devices, the maximum URL length is 128 characters. With URL rewriting, a session identifier is added to the URL itself, effectively decreasing the space available for the actual URL and the number of parameters that can be sent on a request.

To reduce the length of session identifier, you can configure key (`jsessionid`), session ID length and clone ID. To make these configuration changes, complete the following steps.

### **Procedure**

1. Open the administrative console.
2. Click **Servers > Server Types > WebSphere application servers > *server\_name* > Web Container Settings > Web container**.
3. Under Additional Properties, click **Custom properties**.
4. Add the appropriate properties from the following list:
  - `HttpSessionIdLength`
  - `SessionRewriteIdentifier`
  - `HttpSessionCloneId`
  - `CloneSeparatorChange`
  - `NoAdditionalSessionInfo`
  - `SessionIdentifierMaxLength`
5. Click **Apply** and **Save**.

## **Configuring for database session persistence**

You can configure a database to collect session data for database session persistence.

### **About this task**

To configure the session management facility for database session persistence, complete the following steps.

## Procedure

1. Create and configure a JDBC provider.
2. Create a data source pointing to a database.

Use the JDBC provider that you defined: **Resources > JDBC > JDBC Providers > *JDBC\_provider* > Data Sources > New**. The data source should be non-JTA, for example, non-XA enabled. Note the JNDI name of the data source.

Point to the z/OS DB2 database containing the DB2 table for session persistence.

Example configuration for session persistence:

Name	Sessions
JNDI Name	jdbc/sessions
Container managed persistence	Selected
Component-managed Authentication Alias	CELL/jaasalias
Container-managed Authentication Alias	CELL/jaasalias

3. Verify that the correct database is listed under **Resources > JDBC Providers > *JDBC\_provider* > Data Sources > *datasource\_name***. If necessary, contact your database administrator to verify the correct database name.

For example:

Database Name	LOC1 (specify your system)
---------------	----------------------------

4. Create a DB2 table in the z/OS DB2 database that will be used for session persistence.
5. Configure the DB2 table for session persistence.
6. Go to the appropriate level of Session Management.
7. Under Additional Properties, click **Distributed Environment Settings**
8. Select and click **Database**.
9. Specify the Data Source JNDI name from a previous step. The database user ID and password are case-sensitive.
10. Specify the database user ID and password that is used to access the database and for table creation. When you created your data source, you might have specified a Container Managed Authentication Alias or a Component Managed Authentication Alias; however, these two settings are not used by the session manager for session persistence. The session manager uses the `userid` and password specified in this step for session persistence.
11. Optional: Append the schema name in the session User ID field if you want to have more than one instance of the session table.  

The session manager uses the schema name to qualify the session table name for all database operations. If only the `userid` is specified without the schema name, the schema name defaults to NULL and therefore a table name with NULL as the schema name, for example, NULL.SESSIONS, is created. You can create multiple session tables with different schema names, other than NULL, and access them separately by modifying the user name to contain the appropriate schema name.
12. Switch to a multirow schema.
13. Click **OK**.
14. If you want to change the tuning parameters, click **Custom Tuning Parameters** under Additional properties.
15. Click **Apply**.
16. Click **Save**.

## Switching to a multi-row schema

The multi-row schema configuration supports storing an unlimited amount of data that is only bounded by the database capacities in an application. The application can read individual fields instead of the whole record, which can help to improve performance by avoiding unnecessary Java object serialization. Configure the session management facility to store each attribute in a session object in its own row in the database by using the multi-row schema configuration.

### About this task

The only practical limit that remains is the size of the session attribute object. The multi-row schema potentially has performance benefits in certain usage scenarios, such as when larger amounts of data are stored in the session but only small amounts are specifically accessed during a given servlet processing of an HTTP request. In such a scenario, avoiding unneeded Java object serialization is beneficial to performance.

In addition to allowing larger session records, using multi-row schema can yield performance benefits. However, it requires a little work to switch from single-row to multi-row schema, as shown in the following table.

By default, a single session maps to a single row in the database table used to hold sessions. With this setup, there are hard limits to the amount of user-defined, application-specific data that WebSphere Application Server can access.

Consider configuring direct single-row usage to one database and multi-row usage to another database while you verify which option suits your application needs. Do this in code by switching the data source used; then monitor performance.

Table 252. Choosing a single-row or multi-row schema configuration. Single-row or multi-row schema configuration

Programming issue	Application scenario
Reasons to use single-row	<ul style="list-style-type: none"><li>You can read or write all values with just one record read and write.</li><li>This takes up less space in a database because you are guaranteed that each session is only one record long.</li></ul>
Reasons <b>not</b> to use single-row	2-megabyte limit of stored data per session.
Reasons to use multi-row	<ul style="list-style-type: none"><li>The application can store an unlimited amount of data; that is, you are limited only by the size of the database and a 2-megabyte-per-record limit.</li><li>The application can read individual fields instead of the whole record. When large amounts of data are stored in the session but only small amounts are specifically accessed during servlet processing of an HTTP request, multi-row sessions can improve performance by avoiding unneeded Java object serialization.</li></ul>
Reasons <b>not</b> to use multi-row	If data is small in size, you probably do not want the extra overhead of multiple row reads when you can store everything in one row.

In the case of multi-row usage, design your application data objects not to have references to each other, to prevent circular references. For example, suppose you are storing two objects A and B in the session using `HttpSession.put(..)` method, and A contains a reference to B. In the multi-row case, because objects are stored in different rows of the database, when objects A and B are retrieved later, the object graph between A and B is different than stored. A and B behave as independent objects.

## Procedure

1. Modify the Session Management facility properties to switch from single to multi-row schema.
2. Manually drop the table.
  - a. Determine which data source configuration Session Management is using.
  - b. In the data source configuration, look up the database name.
  - c. Use the database facilities to connect to the database.
  - d. Drop the SESSIONS table.
3. Recreate the database table or delete all the rows in the database table that the product uses to maintain HttpSession objects.

See the *DB2 UDB for OS/390 and z/OS V7 Administration Guide* for a description of how to drop a DB2 database table.

Creating a DB2 table for session persistence describes how to create a new DB2 database table.

## Creating a DB2 table for session persistence

Session data is collected and stored in a DB2 table. If you are using DB2 for session persistence, you must create and define a DB2 table that is associated with the application server.

### About this task

To create a DB2 table for collecting session data, do the following:

## Procedure

1. Have your DB2 Administrator create a DB2 database table for storing your session data. (For more information about creating DB2 databases see the *DB2 UDB for OS/390 and z/OS V7 Administration Guide*.)

The table space in which the database table is created must be defined with row level locking (LOCKSIZE ROW). It should also have a page size that is large enough for the objects that are stored in the table during a session. Following is an example of a table space definition with row level locking specified and a buffer pool page size of 32K:

```
CREATE DATABASE database_name
 STOGROUP SYSDEFLT
 CCSID EBCDIC;

CREATE TABLESPACE tablespace_name IN database_name
 USING STOGROUP group_name
 PRIQTY 512
 SECQTY 1024
 LOCKSIZE ROW
 BUFFERPOOL BP32K;
```

The Session Manager uses the DB2 table defined within this table space to process the session data. This table must have the following format:

```
CREATE TABLE database_name.table_name (
 ID VARCHAR(95) NOT NULL ,
 PROPID VARCHAR(95) NOT NULL ,
 APPNAME VARCHAR(64) ,
 LISTENERCNT SMALLINT ,
 LASTACCESS DECIMAL(19,0),
 CREATIONTIME DECIMAL(19,0),
 MAXINACTIVETIME INTEGER ,
 USERNAME VARCHAR(256) ,
 SMALL VARCHAR(3122) FOR BIT DATA ,
 MEDIUM VARCHAR(28869) FOR BIT DATA ,
 LARGE BLOB(2097152),
 SESSROW ROWID NOT NULL GENERATED ALWAYS
)
IN database_name.tablespace_name;
```

**Note:** The length attributes specified for VARCHAR in this example are not necessarily the values your DB2 Administrator should use for the DB2 table he is creating. See the DB2 SQL Reference for the version of DB2 that you are using for guidance in determining appropriate values for these length attributes for your installation.

A unique index must be created on the ID, PROPID, and APPNAME columns of this table. The following is an example of the index definition:

```
CREATE UNIQUE INDEX database_name.index_name ON
 database_name.table_name
 (ID ASC,
 PROPID ASC,
 APPNAME ASC);
```

**Note:**

- a. At run time, the Session Manager accesses the target table using the identity of the J2EE server in which the owning web application is deployed. Any Web container that is configured to use persistent sessions must have both read and update access to the subject database table.
- b. HTTP session processing uses the index defined using the CREATE INDEX statement to avoid database deadlocks. In some situations, such as when a relatively small table size is defined for the database, DB2 may decide not to use this index. When the index isn't used, database deadlocks can occur. If this situation occurs, see the DB2 Administration Guide for the version of DB2 you are using for recommendations on how to calculate the space required for an index, and adjust the size of the tables you are using accordingly.
- c. It might be necessary to tune DB2 in order to make efficient use of the sessions database table and to avoid deadlocks when accessing it. Your DB2 Administrator should refer to the DB2 Administration Guide for specific information about tuning the version of DB2 that you are using.

You must define a large object (LOB) table space and also define an auxiliary table within that table space. The following is an example of the LOB table space definition:

```
CREATE LOB TABLESPACE LOB_tablespace_name IN database_name
 BUFFERPOOL BP32K
 USING STOGROUP group_name
 PRIQTY 512
 SECQTY 1024
 LOCKSIZE LOB;
```

```
CREATE AUX TABLE database_name.aux_table_name
 IN database_name.LOB_tablespace_name
 STORES database_name.table_name
 COLUMN LARGE;
```

An index must be created for this auxiliary table. The following is an example of the index definition:

```
CREATE INDEX database_name.aux_index_name ON
 database_name.aux_table_name;
```

2. Have your DB2 Administrator grant the z/OS userID, under which the server region is running, the appropriate access to this DB2 table. For example, issue the following command to grant z/OS userID CBASRU1, under which the server region is running, access to the table SESSIONS contained in the database SESSDB:

```
GRANT ALL ON SESSDB.SESSIONS TO CBASRU1;
```

3. Configure DB2 table for session persistence.

## Configuring a table for session persistence

To configure a table for collecting session data, you must add the name of the table to the web container configuration properties.

## About this task

If you are using database for session persistence, you must create and define a database table to the application server to collect session data.

To configure a table for collecting session data, use the administrative console to add the name of this table to the web container's configuration properties:

### Procedure

1. Open the administrative console.
2. Click **Servers > Server Types > WebSphere application servers**.
3. Select a server from the list of application servers.
4. Under Additional Properties, click **Web Container**.
5. Under Additional Properties, click **Custom properties**.
6. Click **SessionTableName** to configure the DB2 table, or click **New** to create a new property.
7. Specify 'SessionTableName' in the Name field if you are creating a new property. In the **Value** field, enter the name of the session table. The value must have the form, *schema\_name.table\_name*. For example, if the schema name is DB2ADMIN and the table name is SESSIONS, enter DB2ADMIN.SESSIONS for **Value**. Optionally, you can update the description of this table in the **Description** field. For example, you might enter "Table name for HTTP session data."
8. Click **Apply > Save**.

### Results

When the product is restarted, the session management facility creates the new SESSIONS table in the specified tablespace.

## Creating a table for session persistence

You can use a database table to collect and store session data. If you are using a database table for session persistence, you must create and define a database table that is associated with the application server.

## About this task

Whenever the session manager is set for database persistence, the session manager creates a table for its use. If you want to expand the column size limits to make it more appropriate for your website, you can create the table externally. If the external table is specified as the target table in the session manager database persistence configuration, then during the session manager start up, the external table is used. In most cases it is better to let the session manager create the table during startup.

To create a table for collecting session data, do the following:

### Procedure

1. Have your administrator create a database table for storing your session data using one of the following data definition language (DDL): For DB2:

```
CREATE TABLE <SchemaName>.sessions (
 ID VARCHAR(128) NOT NULL ,
 PROPID VARCHAR(128) NOT NULL ,
 APPNAME VARCHAR(128) NOT NULL ,
 LISTENERCNT SMALLINT ,
 LASTACCESS BIGINT ,
 CREATIONTIME BIGINT ,
 MAXINACTIVETIME INTEGER ,
 USERNAME VARCHAR(256) ,
```

```

SMALL VARCHAR(3122) FOR BIT DATA ,
MEDIUM LONG VARCHAR FOR BIT DATA ,
LARGE BLOB(2M)
)

```

For Oracle:

```

CREATE TABLE SESSIONS (
 ID VARCHAR(128) NOT NULL ,
 PROPID VARCHAR(128) NOT NULL ,
 APPNAME VARCHAR(128) NOT NULL,
 LISTENERCNT SMALLINT ,
 LASTACCESS INTEGER,
 CREATIONTIME INTEGER,
 MAXINACTIVETIME INTEGER ,
 USERNAME VARCHAR(256) ,
 SMALL RAW(2000),
 MEDIUM LONG RAW ,
 LARGE RAW(1)
)

```

If the web container custom property UseOracleBLOB is set to true then:

```

CREATE TABLE SESSIONS (
 ID VARCHAR(128) NOT NULL ,
 PROPID VARCHAR(128) NOT NULL ,
 APPNAME VARCHAR(128) NOT NULL,
 LISTENERCNT SMALLINT ,
 LASTACCESS INTEGER,
 CREATIONTIME INTEGER,
 MAXINACTIVETIME INTEGER ,
 USERNAME VARCHAR(256) ,
 SMALL RAW(2000),
 MEDIUM BLOB,
 LARGE RAW(1)
)

```

**Attention:**

- a. At run time, the session manager accesses the target table using the identity of the Java Platform, Enterprise Edition (Java EE) server in which the owning web application is deployed. Any web container that is configured to use persistent sessions must have both read and update access to the subject database table.
  - b. HTTP session processing uses the index defined using the CREATE INDEX statement to avoid database deadlocks. In some situations, such as when a relatively small table size is defined for the database, DB2 may decide not to use this index. When the index is not used, database deadlocks can occur. If database deadlocks occur, see the DB2 Administration Guide for the version of DB2 you are using for recommendations on how to calculate the space required for an index and adjust the size of the tables that you are using accordingly.
  - c. It might be necessary to tune DB2 to make efficient use of the sessions database table and to avoid deadlocks when accessing it. Your DB2 administrator should refer to the DB2 Administration Guide for specific information about tuning the version of DB2 that you are using.
  - d. During run time, the session manager may create an entry in the database for each web module of the application. This row of data is used internally for session management purposes, such as in session invalidation. Do not be concerned with this entry. It can be overlooked.
2. Configure a table for session persistence.

**Database settings**

Use this page to specify the settings for database session support.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > *server\_name* > Session management > Distributed environment settings > Database.**

### ***Datasource JNDI name:***

Specifies the datasource description.

The JNDI name of the non-XA enabled datasource from which session management obtains database connections. For example, if the JNDI name of the datasource is "jdbc/sessions", specify "jdbc/sessions." The datasource represents a pool of database connections and a configuration for that pool (such as the pool size). The datasource must already exist as a configured resource in the environment.

### ***Use multi row schema:***

Specifies that each session data attribute is placed in a separate row in the database, allowing larger amounts of data to be stored for each session. This action can yield better performance when session attributes are very large and few changes are required to the session attributes. If use multi row schema is not enabled, instances of application data can be placed in the same row.

## **Configuring memory-to-memory replication for the peer-to-peer mode (default memory-to-memory replication)**

You can use the peer-to-peer configuration to attain session affinity using a combination of servers that are configured as both client and server. The peer-to-peer configuration contains a single replica by default.

### **About this task**

To configure the session management facility for memory-to-memory session replication for peer-to-peer functions (both client and server function, or both mode) with a single replica, complete the following steps:

### **Procedure**

1. Create an application cluster. This cluster is used to deploy the application.
  - a. Go to the Server Cluster page. Click **Servers > Server Types > Clusters > Clusters**.
  - b. Click **New**.
  - c. Type a cluster name for this application cluster.
  - d. Define a replication domain. Select the **Create a replication domain for this cluster** check box.
  - e. Click **Next**.
  - f. Define each cluster member server. Type a cluster member name.
  - g. Click **Apply**. Repeat steps **f** through **g** for each server created in this cluster.
  - h. Click **Next** and review the summary of changes.
  - i. Click **Finish** to complete the configuration.

You have now created a cluster that contains the deployed application and the replication domain.

2. Enable memory-to-memory session replication for each server.
  - a. Go to the appropriate level of session management for the web container level. Click **Servers > Server Types > WebSphere application servers > server\_name > Web Container Settings > Web container > Session management**.
  - b. Click **Distributed environment settings** under Additional Properties.
  - c. Click **Memory-to-memory replication**.
  - d. Select the **Replication domain** that you want to use for the replication of sessions.
  - e. Select the both client and server **Replication mode**. You must configure all session managers connected to a replication domain to have the same topology. If one session manager instance in a domain is configured to use the client/server topology, then the rest of the session manager instances in that domain must be a combination of servers configured as "Client only" and "Server only". If one session manager instance is configured to use the peer-to-peer topology, then all session manager instances must be configured as "Both client and server".

- f. Click **OK** on the Memory-to-memory replication page.
- g. Optional: If you want to change the tuning parameters, click **Custom tuning parameters**. Click **OK**. Click **Save**.

**Note:** Using the default tuning parameter custom settings, which specifies time based write interval of 10 seconds, may result in data loss when an application server in your cluster fails. However, this is just a small opportunity for lost data when compared to the significant improvement in performance.

- h. Click **OK** the Distributed environment settings page.
- i. Click **OK** the Session management page.
- j. Repeat **a** through **i** for each server.

## Memory-to-memory replication settings

Use this page to configure memory-to-memory sessions for failure recovery.

To view the Memory-to-memory sessions page, click **Servers > Server Types > WebSphere application servers > server\_name > Session management > Distributed environment settings > Memory-to-memory replication**.

The memory-to-memory replication settings can be overridden at the application level.

### **Replication domain:**

Specifies the replication domain in which HTTP sessions are replicated.

### **Replication mode:**

Specifies the mode that is used for replication. The mode specifies whether data is only sent (client), only received (server), or both. Select client if sessions need to be replicated. Select server if sessions need to be stored. Select both client and server if sessions need to be replicated and stored. The default is both.

## Configuring memory-to-memory replication for the client/server mode

You can use the client/server configuration to attain session affinity using a combination of servers that are configured as client only and server only.

### **About this task**

To configure the session management facility for memory-to-memory replication using the clients/server mode, complete the following steps:

### **Procedure**

1. Create an application cluster. This cluster is used to deploy the application.
  - a. Go to the Server Cluster page. Click **Servers > Clusters**.
  - b. Click **New**.
  - c. Type a cluster name for this application cluster.
  - d. Click **Next**.
  - e. Define each cluster member server. Type a cluster member name.
  - f. Click **Apply**. Complete steps **e** and **f** for each server created in this cluster.
  - g. Click **Next** and review the summary of changes.
  - h. Click **Finish** to complete the configuration.

Do not create a replication domain for the application cluster. You have now created a cluster that contains the deployed application.

2. Enable memory-to-memory session replication for each cluster member server in the application cluster.
  - a. Go to the appropriate level of session management for the web container level. Click **Servers > Server Types > WebSphere application servers > server\_name > Web Container Settings > Web container > Session management**
  - b. Click **Distributed environment settings** under Additional Properties.
  - c. Click **Memory-to-memory replication**.
  - d. Select the **Replication domain** that you want to use for the replication of sessions.
  - e. Select the Client only **Replication mode**. You must configure all session managers connected to a replication domain to have the same topology. If one session manager instance in a domain is configured to use the client/server topology, then the rest of the session manager instances in that domain must be a combination of servers configured as Client only and Server only. If one session manager instance is configured to use the peer-to-peer topology, then all session manager instances must be configured as Both client and server. Alternatively, if one DRS Instance is configured in the client only mode then all DRS Instances in the domain must be configured in either the client only or the server only modes.
  - f. Click **OK** on the Memory-to-memory replication page.
  - g. Optional: If you want to change the tuning parameters, click **Custom tuning parameters**. Click **OK**. Click **Save**.
 

**Note:** Using the default tuning parameter custom settings, which specifies time based write interval of 10 seconds, may result in data loss when an application server in your cluster fails. However, this is just a small opportunity for lost data when compared to the significant improvement in performance.
  - h. Click **OK** the Distributed environment settings page.
  - i. Click **OK** the Session management page.
  - j. Repeat **a** through **i** for each server.

3. Enable memory-to-memory session replication for each cluster member server in the replication cluster.
  - a. Go to the appropriate level of session management for the web container level. Click **Servers > Application Servers > server\_name > Container Settings > Web Container Settings > Session management**
  - b. Click **Distributed Environment Settings** under Additional Properties.
  - c. Click **Memory-to-memory replication**.
  - d. Select the **Replication domain** that you want to use for the replication of sessions.
  - e. Select the Server only **Replication mode**. You must configure all session managers connected to a replication domain to have the same topology. If one session manager instance in a domain is configured to use the client/server topology, then the rest of the session manager instances in that domain must be a combination of servers configured as Client only and Server only. If one session manager instance is configured to use the peer-to-peer topology, then all session manager instances must be configured as Both client and server. Alternatively, if one DRS Instance is configured in the client only mode then all DRS Instances in the domain must be configured in either the client only or the server only modes.
  - f. Click **OK** on the Memory-to-memory replication page.
  - g. Optional: If you want to change the tuning parameters, click **Custom tuning parameters**. Click **OK**. Click **Save**.
 

**Note:** Using the default tuning parameter custom settings, which specifies time based write interval of 10 seconds, may result in data loss when an application server in your cluster fails. However, this is just a small opportunity for lost data when compared to the significant improvement in performance.

- h. Click **OK** the Distributed environment settings page.
- i. Click **OK** the Session management page.
- j. Repeat **a** through **i** for each server.

## Configuring write contents

In session management, you can configure which session data is written to the database or to another WebSphere instance, depending on whether you are using database persistent sessions or memory to memory replication. You can either write only session data properties that have been updated through `setAttribute` method and `removeAttribute` method calls or you can write all session data properties.

### About this task

This flexibility allows for fewer code changes for the JavaServer Pages (JSP) writer when the application will be operating in a clustered environment. The following options are available in Session Management for tuning what is written back:

- Write changed (the default) - Write only session data properties that have been updated through `setAttribute` method and `removeAttribute` method calls.
- Write all - Write all session data properties.

The **Write all** setting might benefit servlet and JSP writers who change Java objects' states that reside as attributes in `HttpSession` and do not call `HttpSession.setAttribute` method.

However, the use of **Write all** could result in more data being written back than is necessary. If this situation applies to you, consider combining the use of **Write all** with **Time-based write** to boost performance overall. As always, be sure to evaluate the advantages and disadvantages for your installation.

With either Write Contents setting, when a session is first created, complete session information is written, including all of the objects bound to the session.

*Table 253. Single-row or multi-row schemas. When using database session persistence, in subsequent session requests, what is written to the database depends on whether a single-row or multi-row schema has been set for the session database, as shown in the following table.*

Write Contents setting	Behavior with single-row schema	Behavior with multirow schema
Write changed	If any session attribute is updated, all objects bound to the session are written.	Only the session data modified through <code>setAttribute</code> method or <code>removeAttribute</code> method calls is written.
Write all	All bound session attributes are written.	All session attributes that currently reside in the cache are written. If the session has never left the cache, all session attributes are written.

### Procedure

1. Go to the appropriate level of Session Management. See the *Administering applications and their environment* PDF for more information.
2. Click Distributed environment settings
3. Click Custom tuning parameters.
4. Click Custom settings.
5. Select the appropriate write contents setting.
6. Click **OK**.

## Configuring write frequency

In the session management facility, you can configure the frequency for writing session data to the database or to a WebSphere instance, depending on whether you use database distributed sessions or memory-to-memory replication. You can write session data using the end of service servlet, manual update or time based update options.

### About this task

This flexibility enables you to weigh session performance gains against varying degrees of failover support. The following options are available in the Session Management facility for tuning write frequency:

- **End of service servlet**- Write session data at the end of the servlet service method call.
- **Manual update**- Write session data only when the servlet calls the `IBMSession.sync` method.
- **Time based** (the default) - Write session data at periodic intervals, in seconds (called the *write interval*).

When a session is first created, session information is always written at the end of the service call.

If you are using the time based write option, when a server shuts down, the server typically attempts to write the latest session data, that is in the session cache, to the persistent store, as part of the shutdown process.

Using the time based write or manual update options can result in the loss of data in failover scenarios because the backup copy of the session in the persistent store, such as a database, or another JVM, might not be in sync with the session in the session cache.

### Procedure

1. Go to the appropriate level of Session Management. See the *Administering applications and their environment* PDF for more information.
2. Click Distributed environment settings
3. Click Custom tuning parameters.
4. Click Custom settings.
5. Select the method of write frequency that you want to use.
6. Click **OK**.

---

## Chapter 28. Administering web services

This page provides a starting point for finding information about web services.

Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a very flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

---

### Planning to use web services

You can plan to develop and implement web services based on a variety of Java programming models.

#### Before you begin

Read the web services scenario overview information to learn about the story of a fictional online garden supply retailer named Plants by WebSphere and how this retailer incorporated the web services concept. You can also review the Samples section of the Information Center for web services samples. These samples demonstrate enterprise beans and JavaBeans components that are available as web services.

The JAX-WS Web services samples demonstrate the simple message exchange patterns using both synchronous and asynchronous invocation of web services in SOAP 1.1 and SOAP 1.2 environments. The samples are composed with web service standards such as WS-Addressing (WS-A) , WS-Reliable Messaging (WS-RM), and WS-Secure Conversation (WS-SC), which you can use to complete a broad range of interoperability tests. The samples demonstrate the use of JavaBeans artifacts and static service endpoints and proxy-based clients. Additionally, a sample is provided that demonstrates Message Transmission Optimization Mechanism (MTOM).

#### About this task

**best-practices:** IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new web services applications and clients.

You must re-write existing JAX-RPC applications if you want to take advantage of the features of the JAX-WS programming model.

Web services reflect the service-oriented architecture approach to programming. This approach is based on the idea of building applications by discovering and implementing network-available services, or by invoking the available applications to accomplish a task. Web services deliver interoperability, for example, web services applications provide a way for components created in different programming languages to work together as if they were created using the same language. Web services rely on existing transport technologies, such as HTTP, and standard data encoding techniques, such as Extensible Markup Language (XML), for invoking the implementation.

#### Procedure

1. Identify your goals and design web services to fit your e-business solution. Consider what you want to accomplish by using web services. Decide how web services fit into your current topology, applications and programming model. Determine how the Web services process requests on the server and how the clients manage and use the web service.

2. Design your web services for reliability, availability, manageability and security. For example, you want your web services to process a transaction in a reasonable time at all hours of the day and provide users with optimal security, such as authentication for buyers. Planning to use web services to work with WebSphere Application Server helps to meet these requirements.
3. Review the standards used in developing and deploying web services onto WebSphere Application Server. Development and deployment are based on a variety of Java programming models.
4. Decide what development and implementation tools to use. You can use a variety of manual development and implementation tasks. Whether you have an existing web service to implement or you want to develop your own from a JavaBeans implementation or from an Enterprise JavaBeans (EJB) module, you can choose different tasks respective to your resources. You can also use assembly tools to complete development and implementation tasks.
5. Install the application server. For detailed information on installing the application server, read about installing your application serving environment.
6. Review web services samples.

## Results

You have a design plan for implementing web services applications into your business architecture.

---

## Deploying web services

### Deploying web services applications onto application servers

After assembling the artifacts required to enable the web module for web services into an enterprise archive (EAR) file, you can deploy the EAR file into the application server.

#### Before you begin

To deploy Java-based web services, you need an enterprise application, also known as an EAR file that is configured and enabled for web services.

A Java API for XML-Based Web Services (JAX-WS) application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications.

For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

**Note:** In a mixed node cell, you can only target a JAX-WS enabled enterprise beans module to a server using WebSphere Application Server Version 7.0 and later. However, you can target a JAX-WS enabled web application archives (WAR) module to a server using either WebSphere Application Server Version 7.0 and later or WebSphere Application Server Version 6.1 Feature Pack for Web Services

You can use the `wsdeploy` command with JAX-RPC applications to add WebSphere product-specific deployment classes to a web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

To install or deploy a JAX-WS application, you only need to install the JAX-WS enabled EAR file. If your web services application contains only JAX-WS endpoints, you do not need to run the `wsdeploy` command, as this command is used to process only JAX-RPC endpoints.

Ensure that you have installed the HTTP or Java Message Service (JMS) router module that was generated with the `endptEnabler` command onto the same target as your web services enterprise bean JAR files. These HTTP or JMS router modules are included in your web services application and they need to use the runtime libraries of the application server.

## About this task

This task is one of the steps in developing and implementing web services.

You can use either the administrative console or the `wsadmin` scripting tool to deploy an EAR file. If you are installing an containing web services by using the `wsadmin` command, specify the **-deployws** option for JAX-RPC applications. If you are installing an application containing web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. For more information about installing applications using the administrative console, see the installing enterprise application files with the console information.

If your JAX-RPC web services application was previously deployed with the `wsdeploy` command, it is not necessary to specify web services deployment during installation.

The following actions deploy the EAR file with the `wsadmin` command:

## Procedure

1. Start `install_root/bin/wsadmin` from a command prompt.
2. Deploy the EAR file.
  - For JAX-WS web service applications, enter the `$AdminApp install EARfile "-usedefaultbindings"` command at the `wsadmin` prompt.
  - For JAX-RPC web service applications, enter the `$AdminApp install EARfile "-usedefaultbindings -deployws"` command at the `wsadmin` prompt.

## Results

You have a web service installed onto your application server.

**Note:** While installing web services applications that contain a large number of enterprise beans onto the application server, you might receive out of memory errors. If you receive out of memory errors, increase the heap size of your Java Virtual Machine (JVM). If you are installing the application server in a network deployment environment, you might need to increase the heap size of the JVM in the application servers in which you are installing the application, and in the deployment manager profile, `dmgr`. Read about tuning the IBM virtual machine for Java documentation to learn more about tuning the application server environment.

## What to do next

You can confirm that the web services application was deployed by entering the web service endpoint URL in a browser, then viewing an informative page. The information page contains the following information:

```
{http://webservice.pli.tc.wssvt.ibm.com}RetireWebServices
Hello! This is an Axis2 web service!
```

The first line of this information is variable, depending on your web service. The URI in the brackets is the namespace and the string that follows, in this example `RetireWebServices`, is the name of the port used to access the web service.

The next step you might want to consider is to apply security to your web service.

## Provide options to perform the web services deployment settings

Use this page to specify options for web services deployment.

This administrative console page is a step in the application installation and update wizards.

To view this page, you must select **Deploy web services** on the **Select installation options** page.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **New application** > *application\_path* .
2. Select the option to **Show all installation options and parameters** .
3. Click **Next** to get to the **Step: Select installation options** page.
4. Select **Deploy web service**.
5. Click **Next** to get to the **Step: Provide options to perform the web services deployment** page.

You can specify the web services deployment options on this page only when installing or updating an application that uses web services.

The wsdeploy command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the wsdeploy command. If your web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

The options that you specify set parameter values for the wsdeploy command. The wsdeploy command adds product-specific deployment classes to a web services-compatible enterprise archive (EAR) file or an application client Java archive (JAR) file. These classes include:

- Stubs
- Serializers and deserializers
- Implementations of service interfaces

The wsdeploy command is run during installation after you click **Finish** on the **Summary** page of the wizard.

### **Deploy web services option - Classpath:**

Specifies entries to add to the CLASSPATH when the generated classes are compiled.

To specify the class paths of multiple entries, you need to separate the entries with a semicolon on Windows platforms and on Linux, Unix, and z/OS platforms, you need to use a colon to separate the entries. This is the same separator that is used with the CLASSPATH environment variable.

This option is the same as the wsdeploy command parameter `-cp class_path`.

<b>Data type</b>	String
<b>Default</b>	null

### **Deploy web services option - Extension Directories:**

Specifies a directory that contains zipped or Java archive (JAR) files. All zipped and JAR files in this directory are added to the CLASSPATH used to compile the generated files.

This option is the same as the wsdeploy command parameter `-jardir directory`.

<b>Data type</b>	String
<b>Default</b>	null

## wsdeploy command

Use the `wsdeploy` command to add WebSphere product-specific deployment classes to a web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

The `wsdeploy` command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the `wsdeploy` command. If your web services application contains only JAX-WS endpoints, you do not need to run the `wsdeploy` command, as this command is used to process only JAX-RPC endpoints.

The deployment classes that are added by the `wsdeploy` tool to a web services-compatible EAR file or a JAR file include:

- Stubs
- Serializers and deserializers
- Implementations of service interfaces

This deployment step must be performed at least once, and can be performed more often. Deployment can be performed separately using the `wsdeploy` command, assembly tools, or when the application is installed. When using the `wsadmin` command for installation, specify the **-deployws** option.

The `wsdeploy` command operates as noted in the following list:

- Each module in the enterprise application or JAR file is examined.
- If the module contains web services implementations, indicated by the presence of the `webservices.xml` deployment descriptor, the associated Web Services Description Language (WSDL) files are located and the `WSDL2Java` command is run with the `role deploy-server` option.
- If the module contains web services clients, indicated by the presence of the client deployment descriptor, the associated WSDL files are located and the `WSDL2Java` command is run with the `role deploy-client` option.
- The files generated by the `WSDL2Java` command are compiled and repackaged.

See the `WSDL2Java` command for JAX-RPC applications command information to learn more about the files that are generated for deployment.

When the generated files are compiled, they can reference application-specific classes outside the EAR or JAR file, if the EAR or JAR file is not self-contained. In this case, use either the `-jardir` or `-cp` option to specify additional JAR or zip files to be added to CLASSPATH variable when the generated files are compiled.

## wsdeploy command syntax

The command syntax is noted in the following example:

```
wsdeploy Input_filename Output_filename [options]
```

### Required options:

- ***Input\_filename***  
Specifies the path to the EAR or JAR file to deploy.
- ***Output\_filename***  
Specifies the path of the deployed EAR or JAR file. If *output\_filename* already exists, it is silently overwritten. The *output\_filename* can be the same as the *input\_filename*.

### Other options:

- **-jardir** *directory*  
Specifies a directory that contains JAR or zip files. All JAR and zip files in this directory are added to the CLASSPATH used to compile the generated files. This option can be specified zero or more times.
- **-cp** *entries*  
Specifies entries to add to the CLASSPATH when the generated classes are compiled. Multiple entries are separated the same as they are in the CLASSPATH environment variable.
- **-codegen**  
Specifies to generate but not compile deployment code. This option implicitly specifies the -keep option.
- **-debug**  
Includes debugging information when compiling, that is, use javac -g to compile.
- **-help**  
Displays a help message and exit.
- **-ignoreerrors**  
Do not stop deployment if validation or compilation errors are encountered.
- **-keep**  
Do not delete working directories containing generated classes. A message is displayed indicating the name of the working directory that is retained.
- **-novalidate**  
Do not validate the web services deployment descriptors in the input file.
- **-trace**  
Displays processing information, including the names of the generated files.
- **-compliancelevel** *level*  
Sets the JDK level for compiler compliance. Valid values include: 1.4, 5.0, 6.0 (default) and 7.0. This flag is optional.

**Example** The following example illustrates how the options are used with the wsdeploy command:

```
wsdeploy x.ear x_deployed.ear -trace -keep
Processing web service module x_client.jar.
Keeping directory: f:\temp\Base53383.tmp for module: x_client.jar.
Parsing XML file:f:\temp\Base53383.tmp\WarDeploy.wsdl
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java.
Done processing module x_client.jar.
```

## Messages

- Flag *-f* is not valid.  
Option *f* was not recognized as a valid option.
- Flag *-c* is ambiguous.  
Options can be abbreviated, but the abbreviation must be unique. In this case, the wsdeploy command cannot determine which option was intended.
- Flag *-c* is missing parameter *-p*.  
A required parameter for an option is omitted.
- Missing *p* parameter.  
A required option is omitted.

## JAX-WS application deployment model

The administration function of the product is enhanced to support installing and deploying Java Application Programming Interface (API) for XML Web Services (JAX-WS) applications like any other WebSphere Application Server applications.

A JAX-WS application is packaged as a web application archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. The JAX-WS application deployment model is similar to the Java API for XML Remote Protocol Call (JAX-RPC) web services application model. The main difference between them is that JAX-RPC web services application requires you to add additional bindings and deployment descriptors for application deployment. A JAX-WS application does not require additional bindings and deployment descriptors for deployment. You can deploy your JAX-WS applications as you would deploy any other WebSphere Application Server application.

JAX-WS web services is a rewrite of JAX-RPC web services. The table compares the web services stack for both JAX-WS and JAX-RPC web services.

JAX-RPC web services	JAX-WS web services
Bindings are proprietary	Bindings are based on the open source Java API for XML Bindings (JAXB)
Parsing is proprietary	Parsing is based on the open source Java Specification Request (JSR) 173
No Java annotations support	Support for Java annotations such as @WebService, @WebMethod, @WebParam, @WebResult, and @SOAPBinding
<p>During deployment, some deployment descriptor files are created in a JAX-RPC based service and client.</p> <p>The following files are created on the services side, when it is an EJB based web service and EJB based module:</p> <ul style="list-style-type: none"> <li>• webservices.xml</li> <li>• &lt;name_of_service&gt;_mapping.xml</li> <li>• ibm-webservices-bnd.xmi</li> <li>• ibm-webservices-ext.xmi</li> </ul> <p>When the service is a JavaBeans-based or web module-based service, the following files and deployment descriptors are required:</p> <ul style="list-style-type: none"> <li>• webservices.xml</li> <li>• &lt;name_of_service&gt;_mapping.xml</li> <li>• In the web.xml file, there is no additional content</li> <li>• ibm-webservices-bnd.xmi</li> <li>• ibm-webservices-ext.xmi</li> </ul> <p>The web.xml exists in both EJB and JavaBeans based services. However, there is no additional content added to the file during deployment of a Web service application or module.</p>	<p>For JAX-WS web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.</p>

**Note:** Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations. In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre-Java EE 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatibility with the feature pack from previous releases, you must configure either the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a web application archive (WAR) file or EJB module or define the Java virtual machine custom property,

com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations information.

## Using a third-party JAX-WS web services engine

In certain situations you might need to set up a third-party JAX-WS web services engine. For example, you must set up a third-party JAX-WS web services engine if you need to deploy applications that use a single runtime across various application servers such as WebSphere Application Server, JBoss, and WebLogic, or if you want to build JAX-WS web services applications using third party JAX-WS run-times such as CXF, Axis2, and Metro.

### Before you begin

Use of a third-party JAX-WS runtime has limitations. It also requires mandatory configuration changes, and in some cases, it requires manual intervention to resolve issues that occur during deployment and when you run the application. These limitations and issues vary based on the third-party JAX-WS runtime you decide to use. You should understand the limitations for the third-party JAX-WS runtime you are preparing to use before you configure your system to use that implementation.

The following limitations exist regardless of which third-party JAX-WS implementation you use:

- The WebSphere Application Server runtime restricts usage of application modules that use both the JAX-WS implementation provided with WebSphere Application Server, and an external JAX-WS implementation in the same application EAR file. You must use either the JAX-WS implementation provided with WebSphere Application Server or the external implementation in a single application EAR file. This limitation ensures that the runtime WebSphere Application Server does not conflict with the external third-party JAX-WS implementation.
- You must remove any conflicting JAR files from your application library before you deploy an application that uses an external JAX-WS implementation. Most of the external third-party JAX-WS runtimes include some JAR file libraries that are already installed on WebSphere Application Server. This situation causes conflicts in your application library.
- After an application that uses a third-party JAX-WS runtime is deployed on WebSphere Application Server, it is not recognized as a service client or provider. Therefore, you cannot attach application level policy sets to these applications. You must rely on external runtimes support quality of service. Following is a list of WebSphere Application Server features that are not available if you decide to deploy and run application that uses third-party JAX-WS implementations:
  - WS-Security, WS-RM, and WS-Transactions policy sets
  - WSDM
  - JNDI lookup to retrieve JAX-WS Service or Port Instance.

**gotcha:** Even though IBM supports the enablement of third party JAX-WS runtimes to run on WebSphere Application Server, and ensures the successful deployment of applications that use such runtimes, IBM does not provide support for resolving JAR file conflict problems, or any problem that a stack trace indicates is in the third party code.

### About this task

When you deploy an application EAR file with a third-party JAX-WS implementation on WebSphere Application Server, the WebSphere Application Server runtime must ensure the use of the third-party engine, and disable the use of the existing WebSphere Application Server JAX-WS web services engine.

WebSphere Application Server does not claim support for any of the third-party JAX-WS runtimes, but has tested the deployment and execution of applications that use such runtimes.

You must complete the following steps before you can use an external JAX-WS runtime in an application.

## Procedure

1. Set the class loader policy to `Classes loaded with local class loader first (parent last)` at the module level.

Changing the class loader policy to parent last ensures that the external third-party JAX-WS runtime and their dependent library JAR files are first in the class loader search path, thereby ensuring that the third-party implementation is used instead of the WebSphere Application Server.

- a. In the administrative console, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Class loading and update detection**.
  - b. Under Class reloading options, select **Override class reloading settings for web and EJB modules**.
  - c. Under Class loader order, select **Class loader order** property to `Classes loaded with local class loader first (parent last)`.
  - a. Click **OK**, and then **Save** to save your changes.
2. Turn off web services annotation scanning.

Annotation scanning can be turned off at the application level or at the server level.

To turn off annotation scanning at the application level, set the `DisableIBMJAXWSEngine` property in the `META-INF/MANIFEST.MF` of a WAR file or EJB module to true. Example:

```
Manifest-Version: 1.0
DisableIBMJAXWSEngine: true
```

To turn off web services annotation scanning at the server level:

- a. In the administrative console, go to the Custom properties page for the Java virtual machine. Click **Servers > Server Types > WebSphere application servers > *server\_name***, and then, in the Server Infrastructure section, click **Java and process management > Process definition > Control > Java virtual machine > Custom properties**.
- b. Set the `com.ibm.websphere.webservices.DisableIBMJAXWSEngine` property to true. If this property does not already exist for your configuration, click **New**, and add `com.ibm.websphere.webservices.DisableIBMJAXWSEngine` in the **Name** field and true in the **Value** field.

## Results

### What to do next

- Deploy and run an application EAR file with a third-party JAX-WS implementation on WebSphere Application Server.

## Deploying web services client applications

After you have created an enterprise archive (EAR) file for the web services client application, you can deploy the web services client application into the Application Server.

### Before you begin

To deploy a Java-based web services client, you need an enterprise application, also known as an enterprise archive (EAR) file that is configured and enabled for web services.

A Java API for XML-Based Web Services (JAX-WS) application is packaged as a web application archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. A JAX-WS application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications. For JAX-RPC web services clients, you must configure the client deployment descriptors.

## About this task

You can use either the administrative console or the wsadmin scripting tool to deploy an EAR file. If you are installing an application containing web services by using the wsadmin command, specify the `-deployws` option for JAX-RPC applications.

Use the `wsdeploy` command only with JAX-RPC applications. The `wsdeploy` command is not applicable for JAX-WS applications.

If you are installing an application containing web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. Read about installing a new application for more information on using the administrative console.

The following actions deploy the EAR file with the wsadmin command:

### Procedure

1. Start `install_root/bin/wsadmin` from a command prompt.
2. Deploy the EAR file.
  - For JAX-WS web service applications, enter the `$AdminApp install EARfile "-usedefaultbindings"` command at the wsadmin prompt.
  - For JAX-RPC web service applications, enter the `$AdminApp install EARfile "-usedefaultbindings -deployws"` command at the wsadmin prompt.

### Results

You have a deployed a web service client in the application server runtime environment.

### What to do next

Test the web services client. You can now test a web services-enabled managed client EAR file or an unmanaged client JAR file.

## Making deployed web services applications available to clients

You can publish WSDL files to the file system. If you are a client developer or a system administrator, you can use WSDL files to enable clients to connect to web services.

### Before you begin

The publish WSDL administrative console panel supports both JAX-RPC and JAX-WS services. The publish WSDL panel generates a compression file that contains WSDL files for all modules in an application that contains JAX-WS or JAX-RPC web services. Read about providing the HTTP endpoint URL information to learn how the URL information affects the content of the published WSDL.

To publish a Web Services Description Language (WSDL) file you need an enterprise application, also known as an enterprise archive (EAR) file, that contains a Web services-enabled module and has been deployed into WebSphere Application Server. To learn how to deploy web services, see the deploying web services applications onto application servers information.

## About this task

The purpose of publishing the WSDL file is to provide clients with a description of the web service, including the URL identifying the location of the service.

After installing a web services application, and optionally modifying the endpoint information, you might need WSDL files containing the updated endpoint informations to make deployed web services application to be available to clients.

Before you publish a WSDL file, you can configure web services to specify endpoint information in the form of URL fragments to enable full URL specification of WSDL ports. Refer to the tasks describing configuring endpoint URL information.

The WSDL files for each web services-enabled module are published to the file system location you specify. You can provide these WSDL files to clients that want to invoke your Web services.

You can specify endpoint information for HTTP ports, for Java Message Service (JMS) ports, or you can directly access enterprise beans that are acting as web services.

## Procedure

1. Configure the web services client bindings.
2. Configure the URL endpoint information for HTTP bindings. Do one of the following depending on what kind of bindings you are using:
  - Configure the URL endpoint information for HTTP bindings.
  - Configure the URL endpoint information for JMS bindings.
  - Configure the URL endpoint information to directly access enterprise beans.
3. Externalize or publish the WSDL file out of the application. You can complete this task in the following ways:
  - Publish a WSDL file with the administrative console
  - Publish a WSDL file using a URL.
  - Publish a WSDL file with the wsadmin tool.

## What to do next

Apply security to your web services. To learn more, see the securing web services applications using message level security information.

## Configuring web services client bindings

When a web services application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the web module or enterprise JavaBeans (EJB) module, including client bindings.

## Before you begin

Deploy a web service into your WebSphere Application Server instance. Read about deploying web services applications onto application servers.

You must know the topology of the URL endpoint address of the web services servers and which web service the client depends upon. You can view the deployment descriptors in the administrative console to find the topology information. To learn more, see the View web services server deployment descriptors information.

## About this task

The client bindings define the Web Services Description Language (WSDL) file name and preferred ports. The relative path of a web service in a module is specified within a compatible WSDL file that contains the actual URL to be used for requests. The address is only needed if the original WSDL file did not contain a URL, or when a different address is needed. For a service endpoint with multiple ports, you need to define an alternative WSDL file name.

The following steps describe how to edit bindings for a web service after these bindings are deployed on a server. When one web service communicates with another web service, you must configure the client bindings to access the downstream web service.

You can also configure client bindings with the wsadmin tool. Read about configuring a web service client deployed WSDL file name with the wsadmin tool.

To configure client bindings through the administrative console:

## Procedure

1. Open the administrative console.
2. Click **Applications > Enterprise Applications > *application\_instance* > Manage Modules > *module\_instance* > Web services client bindings**.
3. Find the web service you want to update.  
The web services are listed in the **Web Service** field.
4. Select the WSDL file name from the drop down box in the WSDL file name field.
5. Click **Edit** in the Preferred port mappings field to configure the default port to use.
  - a. Specify the port type and the preferred ports in the Port type and Preferred ports fields.  
Configuring the preferred port enables you to select an optimal port implementation use non-SOAP protocols. See the RMI-IIOP web services using JAX-RPC information to learn more about using non-SOAP protocols.
  - b. Click **Apply** and **OK**.
6. Click **Edit** in the Port information field to configure the request timeout, the overridden endpoint, and the overridden binding namespace for a port.  
Configuring the request timeout accommodates complex topologies that can have multiple cascaded Web services that involve multiple hops or long-running services.  
You can configure Timeout values based on observed behavior of the overall system as integration proceeds. For example, a web service client might time out because of changing network conditions or the performance of an external web service. When you have applications containing web services clients that timeout, you can change the request time out values for the clients.  
You can specify an endpoint URL to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. You can specify the **Overridden endpoint URL** value for both Java API for XML-Based Web Services (JAX-WS) clients and Java API for XML-based RPC (JAX-RPC) clients.  
**Note:** The **Overridden endpoint URL** field is applicable for both JAX-WS and JAX-RPC clients. The other fields on this administrative console page are only applicable for JAX-RPC clients.
  - a. Click **Apply** and **OK**.

## Results

Your web service client bindings are configured.

## What to do next

Now you can finish any other configurations, start or restart the application, and verify the expected behavior of the web service.

### ***Web services client bindings:***

The client bindings define the Web Services Description Language (WSDL) file name, preferred ports and other port information. Use this page to specify the client bindings and the port mappings for the web services in a module.

A web service can specify the relative path within the module of a compatible WSDL file containing the actual URL to be used for requests. The relative path only needs to be specified if the original WSDL file does not contain a URL or when a different URL is needed. For a service endpoint with multiple ports defined, a preferred mapping specifies the default port to use for a port type.

To view this administrative console page, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications > *application\_name***.
2. Click **Manage modules > *URI\_file\_name* > web services client bindings**.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

*Web service:*

Identifies the name of this web service. A module can contain one or more web services.

*EJB:*

Identifies the name of the EJB for the EJB modules.

*WSDL file name:*

Specifies the WSDL file name, which is relative to the module. Locate the WSDL file name in the drop down menu.

*Preferred port mappings:*

Specifies and manages the preferred port type mapping for a web service when a particular port type is requested.

Click **Edit** to edit the preferred port mapping information on the **Preferred port mappings** panel.

*Port information:*

Specifies additional configuration information for the ports of this web service.

Click **Edit** to edit the port information on the **Port information** panel. You can set a request timeout, override an endpoint and override a binding namespace for each client port.

*Preferred port mappings:*

Use this page to view and manage a preferred portType mapping for a web service.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

When you have multiple ports that reference the same portType (service endpoint interface), a preferred port specifies the port to use when the `Service.getPort(Class SEI)` method is called with only the service endpoint interface.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Manage Modules > *module instance* > Web services client bindings > Edit > *preferred\_port\_instance***.

*portType:*

Specifies the portType.

The preferred port and the portType values are both of the type `java.xml.namespace.QName`.

*Preferred port:*

Specifies the preferred port to be associated with a particular portType. The `Service.getPort(Class)` method returns the preferred port associated with the specified service endpoint interface class (portType).

The preferred ports available are listed, as well as a value of None, which indicates no preferred port is selected.

*Web services client port information:*

Use this page to specify a request timeout, override an endpoint, and override a binding namespace for a web services client port.

A web service can have multiple ports. You can view and configure the port attributes for each defined web service port. The web services are listed on the web services client bindings panel.

To view this page, click **Applications > Application Types > WebSphere enterprise applications *application\_name* > Manage Modules > *module\_instance* > Web services client bindings > Edit** .

This administrative console panel applies to both Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. The **Overridden endpoint URL** field is the only field supported for JAX-WS clients. The other fields are not applicable for JAX-WS clients.

*Port:*

Specifies the name of a port.

*Request timeout:*

Specifies the time, in seconds, that a web service client waits for a request to complete on this port. If a timeout is not specified, the default request timeout for the client to wait is 300 seconds. If the value is set at 0 (zero), the timeout used is the default value for the underlying transport mechanism. This field is supported only for JAX-RPC clients.

A typical use for this setting is to customize the client's behavior when it is configured to use a JMS transport to access a web service to make it wait longer for an expected completion. Depending upon network conditions, or the nature of a web service implementation, it might be necessary to tune the timeout.

*Overridden endpoint URL:*

Specifies the name of an endpoint that is used to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. This field is supported for both JAX-WS and JAX-RPC clients.

If an assembled application contains a web service client that is statically bound, the client is locked into using the implementation (service end point) identified in the WSDL file used during development. Overriding the endpoint is an alternative to configuring the deployed WSDL attribute.

The overridden endpoint URI attribute is specified on a per port basis. It does not require an alternative WSDL file within the module. The overridden endpoint URI takes precedence over the deployed WSDL attribute. The client uses this value for the service end point URI or SOAP address, instead of the value in the static client bindings.

**Note:** You can edit this field if you have managed clients or a mixture of both managed and unmanaged clients. You cannot edit the field if you have unmanaged clients only.

If you do not want a request by an unmanaged JAX-WS client service to be sent to the endpoint URL that is specified in this field, you can specify the `com.ibm.ws.websvcs.unmanaged.client.dontUseOverriddenEndpointUri` Java virtual machine (JVM) system property. For more information about this custom property, read about the Java virtual machine custom properties.

*Overridden binding:*

Specifies the WSDL file binding namespace URI to use with this port, instead of the namespace in the WSDL file. This binding does not need to exist in the WSDL file. A client invoking a request on this port uses this binding instead of the binding specified in the WSDL file. An overridden binding namespace cannot be specified unless an overridden endpoint is specified. This field is supported only for JAX-RPC clients.

## Configuring endpoint URL information for HTTP bindings

Configuring a service endpoint is necessary to connect Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services clients to any web services among the components being assembled or to any external web services.

### Before you begin

You can develop an HTTP accessible Java API for XML-based remote procedure call (JAX-RPC) or Java API for XML Web Services (JAX-WS) web service when you have an existing JavaBeans object to enable as a web service. For additional information, see the using HTTP to transport web services requests information.

You can use either the administrative console or property files to configure and manage HTTP endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information for HTTP bindings.

### About this task

You can specify HTTP URL prefixes for web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. The HTTP URL prefixes provide location specific information and are used to form complete endpoint URLs that are included within published WSDL files.

**Note:** The Provide HTTP panel in the administrative console displays modules that contain Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. You can use the Provide HTTP panel to provide URL information for both types of web services, however, the panel does not indicate which type of service that you are working with.

To configure these prefixes with the administrative console:

### Procedure

1. Open the administrative console.
2. Click **Applications > Enterprise Applications > *application\_instance* > Provide HTTP endpoint URL information**.
3. Specify the URL prefixes for the web service.

In this step you specify the protocol (HTTP or HTTPS), as well as the *host\_name* and *port\_number* used in the endpoint URL. You can select a prefix from a predefined list, by selecting the default HTTP URL prefix, or you can use a custom HTTP URL prefix.

- a. Select **Default HTTP URL prefix** or **Custom HTTP URL Prefix**.

If you select the default HTTP URL prefix, a list provides you with a choice of endpoint URL prefixes. The list is a combination of two sets of ports in the module: the virtual host ports and the application server ports. Use a prefix from this list if the application server of the web service is accessed directly. Select a value and also select the check box of the modules to use the prefix.

If you want to use a custom HTTP URL prefix, type the value in the field. Select the check box to use in the prefix.

If you configure a custom HTTP URL prefix, you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTTPrefix` in the administrative console and set the value to `true`. You must restart the application server after this custom property has been defined so that this property is used by the system. Setting this custom JVM property is required so the custom HTTP endpoint prefix information is correctly displayed in the `?WSDL` query that is returned from the browser and the URL field of the WSDL file that is returned to the client. If this custom property is not defined with the value of `true`, the custom HTTP URL prefix is not reflected in the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional HTTP transport properties using the JVM custom property panel in the administrative console.

**Note:** The `com.ibm.ws.webservices.enableHTTTPrefix` custom property applies to JAX-RPC web services applications only.

- b. Click **Apply**.

The URL prefix, whether default or custom, is copied to the selected module HTTP URL prefix field.

- c. Click **OK**. The URL information is saved to your workspace.

## Results

You have specified the partial URL information that is used to form the target endpoint addresses in the WSDL files that are published using the Publish WSDL files panel.

## What to do next

Configure any other URL endpoint information for Java Message Service (JMS) bindings and direct Enterprise JavaBeans (EJB) access. Then publish the WSDL files to make the deployed web services application available to clients.

### ***Provide HTTP endpoint URL information:***

Use this page to specify endpoint URL prefix information for web services accessed by HTTP. Prefixes are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Provide HTTP endpoint URL information**.

You can specify a portion of the endpoint URL to be used in each web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

In addition to the using the administrative console, you can use property files to configure and manage HTTP endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

*Specify endpoint URL prefixes for web services:*

Specifies the *protocol* (either http or https), *host\_name*, and *port\_number* to be used in the endpoint URL.

You can select a prefix from a predefined list using the **HTTP URL prefix** or **Custom HTTP URL prefix** field.

The URL prefix format is *protocol://host\_name:port\_number*, for example, `http://myHost:9045`. The actual endpoint URL that is contained in a published WSDL file consists of the prefix followed by the module's context-root and the web service url-pattern, for example, `http://myHost:9045/services/myService`.

*Select default HTTP URL prefix:*

Specifies the drop down list associated with a default list of URL prefixes. This list is the intersection of the set of ports for the module's virtual host and the set of ports for the module's application server. Use items from this list if the web services application server is accessed directly.

To set an HTTP endpoint URL prefix, select **Select default HTTP URL prefix** and select a value from the drop down list. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP URL prefix** field of any module whose check box is selected.

*Select custom HTTP URL prefix:*

Specifies the *protocol*, *host*, and *port\_number* of the intermediate service if the web services in a module are accessed through an intermediate node, for example the web services gateway or an IHS server.

To set a custom HTTP endpoint URL prefix, you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTTPrefix` in the administrative console and set the value to true. Setting this custom JVM property is required so the custom HTTP URL is correctly populated in the URL field of the WSDL file that is returned to the client. If this custom JVM property is not configured, the custom HTTP URL prefix is not in the URL field in the copy of the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional HTTP transport properties using the JVM custom property panel in the administrative console. You must restart the application server after this custom property has been defined so that this property is used by the system.

After the `com.ibm.ws.webservices.enableHTTTPrefix` custom JVM property is configured, select **Select custom HTTP URL prefix** and enter a value. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP endpoint URL prefix** field of any module whose check box is selected.

**Note:** The `com.ibm.ws.webservices.enableHTTTPrefix` custom property applies to JAX-RPC web services applications only.

## Configuring endpoint URL information for JMS bindings

WebSphere Application Server supports the use of the Java Message Service (JMS) API to transport web services requests, as an alternative to using HTTP.

## Before you begin

The application server supports use of the Java Message Service (JMS) API to transport web services requests, as an alternative to HTTP transport. Read about using the Java Message Service (JMS) to transport web services requests to learn more about how web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

You can use either the administrative console or property files to configure and manage JMS endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information for JMS bindings.

## About this task

Configuring a service endpoint is necessary to connect web service clients to any web services among the components being assembled or to any external web services. You can configure the endpoint URL information for JMS during application installation.

In this task, enter the JMS endpoint URL prefix to use for each web service-enabled Enterprise JavaBeans (EJB) Java archive (JAR) file that belong to the application. The JMS endpoint URLs are included in the Web Services Description Language (WSDL) files published for clients to use.

You can specify HTTP URL prefixes for web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. These prefixes are used to form complete endpoint addresses that are included in WSDL files when published.

You can specify JMS URL prefixes by using the Provide JMS and EJB endpoint URL information panel in the administrative console during or after application installation.

This task applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

To configure JMS URL prefixes:

## Procedure

1. Open the administrative console.
2. Click **Applications > Enterprise Applications > *application\_instance* > Provide JMS and EJB endpoint URL information**.
3. Locate the list of web services modules that are accessible through JMS transport.
4. Type the JMS URL fragment in the **URL fragment** field. Enter a URL fragment that is a prefix to the initial URL part that is obtained by examining the deployment information of the Web service. See the usage scenario following this task for more information.

The value that you enter is used to define the location attribute of the port soap:address element within the WSDL file that is published using the *application\_name\_ExtendedWSDLFiles.zip* or the *application\_name\_WSDLFiles.zip* file on the Publish WSDL zip files panel.

## Results

You have a web service that is accessible through the JMS transport and configured with JMS bindings.

## Example

Suppose an application called `StockQuoteService` contains an EJB JAR file that is named `StockQuoteEJB`, which contains one or more web services that are accessible through the JMS transport.

See the using SOAP over Java Message Service to transport web services information to review the example that defines a queue with the Java Naming and Directory Interface (JNDI) name of `jms/StockQuote_Q`, and a connection factory with the JNDI name of `jms/StockQuote_CF`, for your application.

In this example, you specify the following string as the JMS URL prefix within the Provide JMS and EJB endpoint URL information panel:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF
```

The WSDL publisher uses this partial URL string to produce the actual JMS URL for each port component that is defined in the module. The `targetService=<port_name>` string is added to the end of the JMS URL, for example:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF&targetService=getQuote
```

The published WSDL file is used by clients to invoke the web service.

## What to do next

Publish the WSDL files to make the deployed web services application available to clients.

### ***Provide JMS and EJB endpoint URL information:***

Use this page to specify Java Message Service (JMS) and Enterprise JavaBeans (EJB) endpoint URL fragments for web services accessed through SOAP and Java Message Service (JMS) or directly as enterprise beans. Fragments are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Provide JMS and EJB endpoint URL information.**

You can specify a fragment of the endpoint URL to be used in each web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

If you are using web services modules that are configured to use JMS or configured to access enterprise beans directly, these modules are listed on this panel.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

In addition to the using the administrative console, you can use property files to configure and manage JMS and EJB endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

### *URL fragment for JMS:*

Specifies a URL fragment for web services accessed through a JMS transport. You can enter a value that is used to define the `soap:address` of a web service. When WSDL files are published, a URL is formed using this fragment and is contained in the WSDL files.

The URL fragment that is entered as a value is a prefix to which the `targetService` property is appended to form a complete JMS URL endpoint. The default value is obtained by examining the installed service's deployment information, for example, `jms:jndi:jms/MyQueue&jndiConnectionFactoryName=jms/MyCF`.

This information is obtained from the configured JMS endpoint for the web service, which is a Message Driven Bean (MDB) defined by the **endpointEnabler** command-line tool. You can modify the URL fragment, for example, by adding properties. The URL fragment is combined with the `targetService` property to form the complete URL, for example, `jms:jndi:jms/MyQueue&jndiConnectionFactoryName=jms/MyCF&priority=5&targetService=GetQuote`.

#### *URL fragment for EJB:*

Specifies a URL fragment for web services accessed through an EJB binding. You can enter a value used to define the location attribute of the port's `generic:address` element of a Web service. This port address is contained in the WSDL compression file when the compression file is published using the `application_name_ExtendedWSDLFiles.zip` field on the **Publish WSDL zip file** panel.

The URL fragment value entered is a suffix, which is appended to the initial part of the URL obtained by examining the web service's deployment information. For example, the following URL fragment can be obtained from the EJB's deployment information: `wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome`.

In this case, you can enter the following information in the URL fragment field, `jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809`, which results in this endpoint URL, `wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome&jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809`.

## **Configuring endpoint URL information to directly access enterprise beans**

WebSphere Application Server supports directly accessing an enterprise bean as a web service, as an alternative to using HTTP or Java Message Service (JMS) to transport requests between the server and the client. The Enterprise JavaBeans (EJB) module that is used as a web service contains a Web Services Description Language (WSDL) file that contains EJB bindings.

### **Before you begin**

To learn more about the process of directly accessing an enterprise bean as a web service, see the using WSDL EJB bindings to invoke an EJB from a JAX-RPC web services client.

You can use either the administrative console or property files to configure and manage EJB endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information to directly access enterprise beans.

### **About this task**

Configuring a service endpoint is necessary to connect web service clients to any web services among the components being assembled or to any external web services.

You can specify web address endpoints of the enterprise bean for web services that are accessed directly by EJB bindings using the Provide JMS and EJB endpoint web address information panel in the administrative console.

If you have modules that are configured for using direct EJB access, the modules are listed on the Provide JMS and EJB endpoint web address information panel in the administrative console. The EJB endpoint is only available in the WSDL that is found in the *application\_name\_ExtendedWSDLfiles.zip* file.

You can specify a fragment of the endpoint web address for the web services in each module.

To configure the web address endpoints of the enterprise bean with the administrative console:

### Procedure

1. Open the administrative console.
2. Click **Applications > Enterprise Applications > *application\_instance* > Provide JMS and EJB endpoint URL information**.
3. Locate the list of EJB modules.
4. Select the application module.
5. Type the web address fragment in the **URL fragment** field.

Enter a web address fragment that is a suffix to the initial web address part that is obtained by examining the web service deployment information. See the example following this task for more information.

The value that you enter is used to define the location attribute of the port generic:address element within the WSDL file that is published using the *application\_name\_ExtendedWSDLfiles.zip* file name link on the Publish WSDL zip files panel. The zip file names are listed as links on the panel.

6. Click **OK**.
7. Click **Save**.

### Results

You have configured endpoints of the enterprise bean for Web services that are accessed directly by EJB bindings.

### Example

The following example illustrates a web address fragment to enter in the URL fragment field.

The following web address information can be obtained from the deployment descriptor of an enterprise bean:

```
wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome
```

Enter the following web address fragment in the URL fragment field:

```
jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2089
```

The results are shown in the following example:

```
wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome&jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2089
```

### What to do next

Provide a description of the web service to the service requestor by publishing WSDL files. To learn more, read about making deployed web services applications available to clients.

### Publishing WSDL files using the administrative console

You can publish a Web Services Description Language (WSDL) file using the WebSphere Application Server administrative console.

## Before you begin

Before completing this task, you need to install or deploy the web service. After deployment, configure the URL endpoint tasks for your transport:

- Configure endpoint URL information for HTTP bindings
- Configure endpoint URL information for JMS bindings
- Configure endpoint URL information to directly access enterprise beans

## About this task

By publishing a WSDL file, you are providing clients with a description of the web service, including the URL identifying the location of the service.

The WSDL files in each web services-enabled module are published to the file system location you specify. You can provide these WSDL files in the development and configuration process of the web service clients so they can invoke your web services.

This task applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

To learn about more ways to publish WSDL files, see the making deployed web services applications available to clients information.

To publish an application's WSDL file with the administrative console:

## Procedure

1. Open the administrative console.
2. Click **Applications > Application Types > WebSphere enterprise applications > *application\_name***.
3. Under Web Services Properties, click **Publish WSDL files**. This takes you to the **Publish WSDL zip files** page.
4. Click the WSDL compression file to download. The compression file contains the application's published WSDL files. The compression file `ExtendedWDLFiles.zip` contains EJB binding information. It can also contain JMS or HTTP binding information. The compression file `WSDLFiles.zip` only contains JMS or HTTP binding information.

The compression file `ExtendedWDLFiles.zip` can contain HTTP binding information. The compression file `WSDLFiles.zip` only contains HTTP binding information.

## What to do next

Apply security to your web services. To learn more, see the securing web services applications using message level security information.

### ***Publish WSDL compressed files settings:***

Use this page to publish Web Services Description Language (WSDL) files.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

The publish WSDL panel generates a compressed file that contains WSDL files for all modules in an application that contains a JAX-WS or JAX-RPC web service. Read about providing the HTTP endpoint URL information to learn how the URL information affects the content of the published WSDL.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Publish WSDL files.**

When you click **OK**, a panel showing one or several compressed file names displays. Each compressed file contains a WSDL file that represents the web services-enabled modules in the application. When you select a compressed file to publish, a dialogue displays from which you can choose where to create the compressed file. Within the published compressed files, the directory structure is *application\_name/module\_name/[META-INF|WEB-INF]/wsdl/wsdl\_file\_name*.

In a published WSDL file, the location attribute of a port's soap:address element contains the endpoint URL through which the web service is accessed. Using the **Provide HTTP endpoint URL information** and the **Provide JMS and EJB endpoint URL information** panels, configure the endpoint URLs to be used for the web services in each module.

*application\_name\_WSDLFiles.zip*:

Specifies the *application\_name\_WSDLFiles.zip* file containing the WSDL that describes web services that are accessible by standard SOAP-based ports.

*application\_name\_ExtendedWSDLFiles.zip*:

Specifies the *application\_name\_ExtendedWSDLFiles.zip* file containing the WSDL file that describes the web services available, including SOAP-based and non-SOAP based (for example, EJB) ports.

If there are no web services configured for direct EJB access, this compressed file name is not displayed. Do not use this compressed file if you want to produce a WSDL file compliant to standards.

## Publishing WSDL files using a URL

You can publish a Web Services Description Language (WSDL) file using a URL.

### Before you begin

Before you can publish a WSDL file using a URL, ensure the web services-enabled application is installed and running.

The files referenced by the <wsdl-file> element in the webservices.xml might import other WSDL or XML Schema Definition (XSD) files. Typically, all WSDL or XSD files are initially placed into the META-INF/wsdl directory when using Enterprise JavaBeans (EJB) or the WEB-INF/wsdl directory when using JavaBeans. If your WSDL or XSD files are not placed in one of these directories, the file referenced by the <wsdl-file> and its imported files are copied to the wsdl directory for publishing purposes.

There are two different forms of URL query strings. The first appends /wsdl to the service and returns only HTTP and JMS bindings. The second appends /extwsdl to the service and returns the extended WSDL file, including HTTP, JMS, and EJB bindings. If a WSDL file contains only EJB bindings and the /wsdl query is used, an error message displays in the browser saying there are no HTTP or JMS bindings in the WSDL file. The error message suggests using the /extwsdl query instead. Publishing a WSDL file using a URL requires that the application have a web module; either provided by the application or in the form of an HTTP router module. If an EJB application contains a WSDL file with only JMS or EJB Web service bindings, the endptEnabler command can be used to add an HTTP router module to the application.

**Note:** Only HTTP URLs are supported for publishing.

### About this task

To publish a WSDL file using a URL:

## Procedure

1. Retrieve the outer-most WSDL file. The outer-most WSDL file is the WSDL file defined by the `<wsdl-file>` element in the `webservices.xml` file.

Each web service has an endpoint address, like `http://example.com/services/stockquote`. You can retrieve the outer-most WSDL file (defined by the `<wsdl-file>` element within the `webservices.xml` file) by appending the string `"/wsdl"` or `"/wsdl/"` to the endpoint address, for example, `http://example.com/services/stockquote/wsdl`.

2. Retrieve the imported WSDL files. When the outer-most WSDL file imports other WSDL or XSD files, these imported files can be retrieved by appending the relative path to the URL, which is used to retrieve the outer-most WSDL file. This is also true for WSDL files that import other files. This process is similar to the use of relative hyperlinks in HTML documents. If an HTML document contains a hyperlink to other documents, the relative path is appended to create the URL to access the hyperlinked documents.

## Example

Suppose you have an application with the following directory structure:

```
<module-root>/
WEB-INF/
 webservices.xml /* the <wsdl-file> element points to "WEB-INF/wsdl/fooImpl.wsdl"*/
 web.xml
 ibm-webservices-bnd.xml

wsdl/
 fooImpl.wsdl /* imports foo.wsdl which is an interface wsdl */
 foo.wsdl /* type definition for the interface */
```

If the SOAP address for the foo service is `http://examples.com:9080/services/foo`, the simple way to retrieve the foo service's outer-most WSDL is with the following form: `http://examples.com:9090/services/foo/wsdl` or `http://examples.com:9090/services/foo/wsdl/`. The URL is redirected to `http://examples.com:9090/services/foo/wsdl/fooImpl.wsdl`, where `fooImpl.wsdl` is the name of the outer-most WSDL file.

Since the `fooImpl.wsdl` file has the import `<import namespace="http://examples.com/foo" location="a/b/foo.wsdl">`, use the URL `http://examples.com:9090/services/foo/wsdl/a/b/foo.wsdl` to obtain the `foo.wsdl` file.

## Running an unmanaged web services JAX-RPC client

WebSphere Application Server Version 8.0 and the Application Client for WebSphere Application Server Version 8.0 provides a thin Java Platform, Standard Edition 6 (Java SE 6) web services client runtime implementation that is based on the Java API for XML-based RPC (JAX-RPC) 1.1 specification. The Thin Client for JAX-RPC with WebSphere Application Server is a stand-alone Java SE 6 client environment that enables running unmanaged JAX-RPC web services client applications in a non-WebSphere environment to invoke web services that are hosted by the application server.

## Before you begin

**Note:** You can use the Thin Client for JAX-RPC with WebSphere Application Server as a stand-alone client run time in a pure Java SE environment, or within an OSGi environment. The Thin Client for JAX-RPC is not supported when running within WebSphere Application Server or WebSphere Application Client environments. In this version of the application server, with the exception of the Administration Thin Client, other Thin Client run times provided with the application server can also reside in the CLASSPATH and coexist with the Thin Client for JAX-RPC.

Before you can set up a JAX-RPC unmanaged client environment you will need to obtain the Thin Client for JAX-RPC Java archive (JAR) file. To obtain the Thin Client for JAX-RPC, you must either install the application server or the application client.

The Thin Client for JAX-RPC JAR file, `com.ibm.ws.webservices.thinclient_8.0.0.jar`, is located in the `app_server_root\runtimes` directory. Refer to the license agreements to ensure correct usage and for limitations on copies of the Thin Client for JAX-RPC outside of the WebSphere environment.

The Thin Client for JAX-RPC is supported in the following environments:

- IBM Software Development Kits (SDKs) Version 6.0
- Sun Java Development Kit (JDK) Version 6.0 that are provided by IBM
- non-IBM SDKs Version 6.0 with this limitation:
  - Xerces limitation on non-IBM SDKs  
If you are using a non-IBM SDK, because of dependencies with the Xerces implementation, you will need to download Xerces-J version 2.6.2 and set it in the classpath before attempting to run the Thin Client for JAX-RPC.
  - Equinox 3.6 OSGi runtime environments

## About this task

**Note:** WS-Addressing is not supported for JAX-RPC web services in an unmanaged client environment. If you need to use WS-Addressing, or a web service standard that relies on WS-Addressing, such as WS-Notification, you must use the Thin Client for Java API for XML-based Web Services (JAX-WS) instead. To learn how to setup and run the Thin Client for JAX-WS, see the Thin Client for JAX-WS documentation.

## Procedure

1. Configure the path. You can add the Java bin directories to your path by typing:

```
set PATH=<your_JDK_bin_directory>;%PATH%
```

2. Configure the classpath.

```
set CLASSPATH=.;<your_web_services_thin_client_install_directory>\com.ibm.ws.webservices.thinclient_8.0.0.jar;
<your_application_jars>;%CLASSPATH%
```

- If you are using a non-IBM SDK, obtain a Xerces `xml-apis.jar` and `xercesImpl.jar` from the Xerces web site and configure the classpath definition.

```
set CLASSPATH=.;<your_Xerces_install_directory>\xml-apis.jar;<your_Xerces_install_directory>
\xercesImpl.jar;%CLASSPATH%
```

3. Configure SSL for the client.

a. Add the following system properties to the Java command:

```
-Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props
```

You can obtain the `ssl.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the `com.ibm.ssl.keyStore` and `com.ibm.ssl.trustStore` key files in the `ssl.client.props` file to the match location of your target environment. For example, use these SSL configuration settings when running the application with a Sun JRE:

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.trustManager=SunX509
com.ibm.ssl.keyManager=SunX509
com.ibm.ssl.contextProvider=SunJSSE
```

```
com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.keyStoreProvider=SUN
com.ibm.ssl.keyStore=/home/user1/etc/key.jks
```

```
com.ibm.ssl.trustStoreType=JKS
com.ibm.ssl.trustStoreProvider=SUN
com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
```

The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

4. Enter the following command to run your client application:

```
%JAVA_HOME%/bin/java -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

## Results

You have set up an unmanaged JAX-RPC client runtime environment that can be used to invoke web services hosted on a WebSphere Application Server.

## Running an unmanaged web services JAX-WS client

WebSphere Application Server provides a thin Java Platform, Standard Edition 6 (Java SE 6) web services client runtime implementation that is based on the Java API for XML-based Web Services (JAX-WS) 2.2 specification. The Thin Client for JAX-WS with WebSphere Application Server is a stand-alone Java SE 6 client environment that enables running unmanaged JAX-WS web services client applications in a non-WebSphere environment to invoke web services that are hosted by the application server.

### Before you begin

**Note:** You can use the Thin Client for JAX-WS with WebSphere Application Server as a stand-alone client run time in a pure Java SE environment, or within an OSGi environment. The Thin Client for JAX-WS is not supported running within WebSphere Application Server or WebSphere Application Client environments. In this version of the application server, with the exception of the Administration Thin Client, other Thin Client run times provided with the application server can also reside in the CLASSPATH and coexist with the Thin Client for JAX-WS.

Before you set up a JAX-WS unmanaged client execution environment, obtain the Thin Client for JAX-WS Java archive (JAR) file. To obtain the Thin Client for JAX-WS, install WebSphere Application Server Version 8.0 or the Application Client for WebSphere Application Server Version 8.0. The Thin Client for JAX-WS JAR file, `com.ibm.jaxws.thinclient_8.0.0.jar`, is located in the `app_server_root\runtimes` directory.

Copy the Thin Client for JAX-WS, `com.ibm.jaxws.thinclient_8.0.0.jar` file and the `endorsed_apis_8.0.0.jar` files, to other machines to create a lightweight client environment that enables communications with the product. Copies of the Thin Client for JAX-WS are subject to the same terms and conditions of the license agreement for the WebSphere product where you obtained the Thin Client for JAX-WS. Refer to the license agreements for correct usage and other limitations.

The Thin Client for JAX-WS is supported in the following environments:

- IBM Software Development Kits (SDKs) Version 6.0
- non-IBM SDKs V6.0 with the following limitation:
  - Xerces limitation on non-IBM SDKs  
You must download Xerces-J Version 2.6.2, and add the file to the classpath when setting up the Thin Client for JAX-WS environment.
  - WS-SecurityKerberos on non-IBM SDKs  
WS-SecurityKerberos is not supported with the Sun JDK or other non-IBM SDKs. Applications running in a Thin Client for JAX-WS environment that make use of WS-Security message level protection and use Kerberos security tokens as described in the Web Services Security Kerberos Token Profile 1.1 specification, do not correctly work on non-IBM JDKs. This limitation exists because of a dependency on the IBM JGSS provider that is only available within IBM SDKs.
- Equinox 3.6 OSGi runtime environments

### About this task

Set up a Thin Client for JAX-WS environment by completing the following steps.

## Procedure

1. Copy the Thin Client for JAX-WS JAR file, `com.ibm.jaxws.thinclient_8.0.0.jar`, to other machines to create a lightweight client environment.
2. Use the Java Endorsed Standards Override Mechanism to override APIs that are available in the JDK on your system.

Because the Thin Client for JAX-WS with WebSphere Application Server Version 8.0 requires APIs that are more current than what is available in JDKs to support JAX-WS 2.2 and JAXB 2.2 implementations, you must override the default JDK APIs in use by your system by using the Java Endorsed Standards Override Mechanism.

Copy the `app_server_root\runtimes\endorsed\endorsed_apis_8.0.0.jar` file into the default directory, `JAVA_JRE\lib\endorsed`. Alternatively, you can use the `java.endorsed.dirs` property to specify a directory of your choice. If you choose to use an alternative directory, it is a best practice to only include the `endorsed_apis` JAR file.

3. Configure the path. Enter the following command to add the Java bin directories to your path:

```
set PATH=<your_JDK_bin_directory>;%PATH%
```

4. Configure the classpath.

- Add the Thin Client for JAX-WS JAR file to the classpath definition.

**Important:** If the Thin Client is to use the Java Message Service (JMS), then **all** the JAR files that are required must be in the classpath for JMS and for the client so that entries exist for all the required files. Otherwise, required files will not be identified as installed and ready for use.

```
set CLASSPATH=.;<your_jax-ws_thin_client_install_directory>\com.ibm.jaxws.thinclient_8.0.0.jar;
<your_application_jars>;%CLASSPATH%
```

- If you are using a non-IBM SDK, obtain a Xerces `xml-apis.jar` file and `xercesImpl.jar` file from the Xerces website, and configure the classpath definition.

```
set CLASSPATH=.;<your_Xerces_install_directory>\xml-apis.jar;<your_Xerces_install_directory>
\xercesImpl.jar;%CLASSPATH%
```

5. Configure SSL for the client.

- a. Add the following system properties to the Java command:

```
-Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props
```

You can obtain the `ssl.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the `com.ibm.ssl.keyStore` and `com.ibm.ssl.trustStore` key files in the `ssl.client.props` file to the match location of your target environment. For example, use these SSL configuration settings when running the application with a Sun JRE:

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.trustManager=SunX509
com.ibm.ssl.keyManager=SunX509
com.ibm.ssl.contextProvider=SunJSSE
```

```
com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.keyStoreProvider=SUN
com.ibm.ssl.keyStore=/home/user1/etc/key.jks
```

```
com.ibm.ssl.trustStoreType=JKS
com.ibm.ssl.trustStoreProvider=SUN
com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
```

The key store file and trust store file must be created using the Java `keytool` utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

6. Run your client application:

- Enter the following command if you have copied the `endorsed_apis_8.0.0.jar` file into the `JAVA_JRE\lib\endorsed` default directory; for example:

```
%JAVA_HOME%\bin\java -Dcom.ibm.SSL.ConfigURL=file:\\home\sample\ssl.client.props <your_client_application>
```

- Enter the following command if you have copied the `endorsed_apis_8.0.0.jar` file into a directory other than the default `JAVA_JRE\lib\endorsed` directory; for example:

```
%JAVA_HOME%\bin\java
-Djava.endorsed.dirs=<directory_that_includes_endorsed_apis_8.0.0.jar>
-Dcom.ibm.SSL.ConfigURL=file:\\home\sampl\ssl.client.props <your_client_application>
```

## Results

You have set up an unmanaged JAX-WS client runtime environment to invoke web services hosted on a WebSphere Application Server.

## Testing web services-enabled clients

Once you have developed, assembled, deployed and configured your web service, you can test to confirm your web service runs in the application server environment.

### Before you begin

Before testing your web services Java client to confirm your web service runs in the WebSphere Application Server environment, verify that the server endpoint specified in the client Web Services Description Language (WSDL) file is running and available.

### About this task

Tests are run differently depending on whether the client module is in a Java EE container or if the client is running in the Thin Client for Java API for XML-based RPC (JAX-RPC) with WebSphere Application Server application environment or the Thin Client for Java API for XML-Based Web Services (JAX-WS) with WebSphere Application Server application environment.

### Procedure

1. Test an unmanaged client JAR file by running your application with the **java** command.

For JAX-WS applications:

```
"$JAVA_HOME/bin/java"
-Djava.endorsed.dirs=<your_jax-ws_thin_client_install_directory>/endorsed_apis_8.0.0.jar
-classpath
"<your_JAX-WS_thin_client_install_directory>/runtimes/com.ibm.jaxws.thinclient_8.0.0.jar:
<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

For JAX-RPC applications:

```
"$JAVA_HOME/bin/java"
-classpath
"<your_JAX-RPC_thin_client_install_directory>/runtimes/com.ibm.ws.webservices.thinclient_8.0.0.jar:
<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

The unmanaged client application runs.

2. Test a managed JAX-RPC client EAR file or an unmanaged JAX-WS client EAR file.
  - a. Run your client application with the **launchClient** command. The following example illustrates the use of this command:

```
!launchClient clientEar
```

## Results

You have a web services-enabled client that is tested. Now you can add security measures to the web service. Security measures are optional.

---

## Administering deployed web services applications

You can administer deployed web services applications using the administrative console.

## Before you begin

Before you can administer a web service application, you need to deploy your web service application.

## About this task

You can use the administrative console to administer Java API for XML-Based Web Services (JAX-WS) service provider or service client applications or Java API for XML-based RPC (JAX-RPC) web services.

## Procedure

- Administer service providers. You can administer your service providers using the following ways:
  - View service providers at the cell level using the administrative console. You can view the details of your service provider, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment at the cell level.
  - View service providers at the application level using the administrative console. You can view the details of your service provider, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment at the application level.
  - Manage policy sets and bindings for service providers. You can view the details of your service provider, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment.
  - Manage policy sets and bindings for service providers at the application level using the administrative console. You can manage policy sets for the provider, its endpoints, and operations, and assign bindings for the policy set attachment at the application level.
  - View WSDL document using the administrative console . You can view the WSDL document for your JAX-WS application.
- Administer service clients. You can administer your service clients using the following ways:
  - View service clients at the cell level . Your application server instance can have one or more applications deployed on it that contain service clients. You can view a list of your service clients at the cell level using the administrative console.
  - View service clients at the application level . Your application server instance can have one or more applications deployed on it that contains service clients. You can view the service client names that are referenced in an application.
  - Manage policy sets and bindings for service clients. You can view details of your service client reference, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment.
  - Manage policy sets and bindings for service clients at the application level. You can manage policy sets for your service client applications or its service references, endpoints, or operations and assign bindings for the policy set attachment at the application level.
- View the deployment descriptors.. View the web services server and client deployment descriptors for a deployed web services application. You can view the bindings in the deployment descriptors. The deployment descriptors are required for JAX-RPC web services. You can optionally use the `webservices.xml` deployment descriptor to augment or override application metadata specified in annotations within your JAX-WS web services.
- Configure the scope of a web service port..**(JAX-RPC applications only)** When a web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the web module or enterprise bean module, including implementation scope and client bindings information. There are three levels of scope that you can set: application, session and request.
- Suppress the compensation service Not all web servers are configured to handle SOAP messages containing `CoordinationContext` elements. WebSphere Application Server allows you to configure a custom property for the compensation service which processes a predefined list of Enterprise Java Beans for which no `CoordinationContext` should be sent on web service requests.

## Overview of service and endpoint listeners

Using the administrative function of this product, you can control throughput by starting and stopping individual service listeners and endpoint listeners. When you stop a service listener, this causes any associated endpoint listeners to stop listening to any new inbound requests and the application server rejects any new incoming requests for that service. Additionally, resources become free that can be used to service requests that are already being processed for the service or to service new incoming requests for other services.

### Service listener

The service listener can be started or stopped. When a service listener is stopped, all the endpoints for the service are stopped and new inbound requests are no longer processed. The endpoints for the service send out 404 error message response code to indicate that the service listener is currently stopped and cannot service new inbound requests. When the service listener is started, all the endpoints for the service resume processing of new inbound requests.

### Endpoint listener

The endpoint listener can be started or stopped. When a service endpoint listener is stopped, the specific endpoint stops listening to any new inbound request. The requests that are already being processed are not affected. The endpoint sends out a 404 error message response code to indicate that the endpoint is currently stopped and cannot service a new, inbound request. When the endpoint listener is started, the specific endpoint resumes listening on new inbound requests. The state of a particular service endpoint does not impact the listening function of other endpoints for the same service.

## Administration of service and endpoint listeners

The administration function of the product is enhanced to support service and endpoint listeners. You can use MBeans such as `EndpointManager` and the `EndpointCentralManager` to invoke service and endpoint listeners.

After an application containing a web service is installed, you want to verify that the service is installed correctly. You also want to monitor its service listener state, and update the listener state as needed to control the throughput. One option is to use the collection view of service providers in the administrative console of the product to locate the service provider of interest and observe its listener state.

If you do not want the listener state, then select the service and choose to start or stop the service listener. As the system starts or stops the service listener, the status indicator for the service is updated to show that it is started or stopped. This scenario helps you to throttle back traffic to a specific service as needed but leaves the containing application and other services in the application running. See service providers at the cell level using the administrative console. You can also reference service providers at the application level using the administrative console.

**Important:** You can only start or stop the service listener using the administrative console.

Another option is to use MBeans. With MBeans, you can invoke the `startListener` or `stopListener` operations in the `EndpointCentralManager` MBean or `EndpointManager` MBean to start or stop the listener service. The administrative console option does not expose the function of starting or stopping the listening state of a specific endpoint in a service. However, the MBeans option provides this capability. You can use scripting to invoke the MBean operations to start or stop the endpoint listener.

### EndpointCentralManager MBean

There is an `EndpointCentralManager` MBean instance in the deployment manager, `AdminAgent`, and stand-alone server. The `EndpointCentralManager` MBean provides the administrative convenience to start and stop the service or endpoint listeners across all the deployment targets such as the cluster members in a cluster. You do not have to know the target servers for the service application.

## EndpointManager MBean

There is an EndpointManager MBean instance for each web services application module in a server. This MBean instance is created when the application module is started. The MBean instance is deleted when the module is stopped. The MBean provides the start and stop operations to change the service and endpoint listener state. The MBean can also send a Java Management Extension (JMX) notification whenever the listener state has changed.

## Viewing service providers at the cell level using the administrative console

You can use this administrative console page to view and manage your service providers at the cell level.

### Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS).

### About this task

You can view a list of your installed service providers, such as JAX-WS web services providers in a cell. You can start or stop the service listener.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

### Procedure

1. Open the administrative console.
2. In the navigation pane, expand **Services > Service providers**.
3. Locate the web service of interest by name and the associated deployed asset in Deployed Asset column.
4. [Optional] Click the service of interest in the Name column to view the detail of the service and manage the policy sets and bindings for that service.
5. Click **Start Listener** or **Stop Listener** to start or stop the service listener. Starting the service listener makes all the endpoints for the service provider available and ready to receive messages. Stopping the listener makes all the endpoints for the service provider unavailable.

### Results

When you finish this task, you have viewed the service providers at the cell level. You have also started or stopped the service listener.

### What to do next

Proceed to view service providers at the application level using the administrative console.

### Service providers collection at the cell level

Use this page to view and manage service providers at the cell level. Java Application Programming Interface (API) for XML-Based Web Services (JAX-WS) service providers are displayed in this view. Java API for XML Remote Procedure Call (JAX-RPC) service providers are not displayed in this view.

To view a service provider using this administrative console page, perform the following steps:

1. Expand **Services > Service Providers**.
2. Locate the service of interest by name in the Name column.

3. Click the service of interest in the Name column.
4. View the detail of the service.

To change the listening state of a service, perform the following steps:

1. Select the service of interest, and click **Start Listener** to start the listener service or click **Stop Listener** to stop the listener service. Starting the service listener makes all the endpoints for the service provider to be available and to receive messages. Stopping the listener makes all the endpoints for the service provider unavailable.
2. [Optional] Select the deployed asset link in the Deployed Asset column to access the deployed asset settings page.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

**Name:**

Specifies the name of the service provider. The service, *QName* (Java class `javax.xml.namespace.QName`), is displayed when you hover your mouse pointer over the Name field.

**Type:**

Specifies the type of service, such as a JAX-WS web service and Web Services Notification (WSN) client service. You can filter by the type of service. If your service was migrated from the Feature Pack for Web Services, you can only filter by the name of the service.

**Deployed Asset:**

Represents a Java Platform, Enterprise Edition (Java EE) application or a WS-Notification service point.

Table 254. Type of deployed asset. Indicates the type of deployed asset.

	Java EE application
	WS-Notification Service point application

**Status:**

Indicates the status for the service listener.

Table 255. Status for the service listener. This table describes the status indicators for the deployed asset, service endpoints and service listener.

	Service endpoints are listening.
	Service endpoints are running, but the listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.
	Either the deployed asset is partially started or the service endpoints are listening on some, but not all the target servers.
	The deployed asset is partially started and the listener control is not supported.
	Service endpoints are not listening, but the deployed asset is running.
	Service endpoints are not listening because the deployed asset is not running.
	Service endpoints are not listening because the deployed asset is not running. Listener control is not supported.
	Deployed asset is partially stopped. Service endpoints are not listening.
	Deployed asset is partially stopped. Service endpoints are not listening. Listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.

Table 255. Status for the service listener (continued). This table describes the status indicators for the deployed asset, service endpoints and service listener.

	Status cannot be determined.
-----------------------------------------------------------------------------------	------------------------------

## Viewing service providers at the application level using the administrative console

You can use this administrative console page to view and manage your service providers at the application level.

### Before you begin

Before completing this task, you need to install a Java API for XML-Based Web Services (JAX-WS) web service.

### About this task

You can view a list of your service providers, such as JAX-WS web services providers at the application level. You can start the service listener to make all the endpoints for the service to be available and to receive messages. You can also stop the service listener.

### Procedure

1. Open the administrative console.
2. To view the service providers, click **Applications > Application Types > WebSphere enterprise applications > Service\_provider\_application\_instance > Service providers**.
3. [Optional] Click a module that contains a service to view the module information.
4. Depending on the current application status, click **Start Listener** or **Stop Listener** to start or stop the service listener. Starting the service listener makes all the endpoints for the service available and ready to receive messages. Stopping the listener makes all the endpoints for the service unavailable. See Endpoint and service listeners overview.

### Results

When you complete this task, you have viewed and managed the service providers at the application level.

### What to do next

You can proceed to managing policy sets using the administrative console. You can click on a service provider to manage the policy sets and bindings for that service.

### Service providers collection at the application level

Use this page to view and manage service providers at the application level.

To view a service provider using this administrative console page, perform the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications > Service\_provider\_application\_instance > Service providers**.
2. Locate the service of interest by name in the Name column.
3. Click the service of interest in the Name column.
4. View the detail of the service.

To change the listening state of a service, perform the following steps:

1. Select the service of interest, and click **Start Listener**, to start the service listener or **Stop Listener**, to stop the service listener. Starting the service listener makes all the endpoints for the service provider to be available and to receive messages. Stopping the listener makes all the endpoints for the service provider to be unavailable.
2. [Optional] Click a module name in the Module column to access the module detail page.

**Name:**

Specifies the name of the service provider. The service *QName* (Java class `javax.xml.namespace.QName`) is displayed when you hover your mouse pointer over the Name field.

**Type:**

Specifies the type of service.

**Module:**

Specifies the name of the module that contains the service.

**Status:**

Indicates the status for the service listener.

*Table 256. Status for the service listener. This table describes the status indicators for the deployed asset, service endpoints and service listener.*

	Service endpoints are listening.
	Service endpoints are running, but the listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.
	Either the deployed asset is partially started or the service endpoints are listening on some, but not all the target servers.
	The deployed asset is partially started and the listener control is not supported.
	Service endpoints are not listening, but the deployed asset is running.
	Service endpoints are not listening because the deployed asset is not running.
	Service endpoints are not listening because the deployed asset is not running. Listener control is not supported.
	Deployed asset is partially stopped. Service endpoints are not listening.
	Deployed asset is partially stopped. Service endpoints are not listening. Listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.
	Status cannot be determined.

## Viewing the detail of a service provider and managing policy sets using the administrative console

Use this administrative console task to view the detail of your service provider and to manage the policy sets for the service, its endpoints and operations. You can also use this page to manage policy sets and bindings or to access additional information for a Service Component Architecture (SCA) composition unit for service providers.

### Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS) or SCA artifacts.

## About this task

You have developed a web service that contains all the necessary artifacts and deployed your web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, WS-I RSP is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: WS-I RSP (inherited). If there is no policy set attached directly or at a higher level, then None is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.
- *Binding\_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, MyBindings1. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding\_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0 and later, there are two types of bindings, application specific bindings and general bindings.

### Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

### General bindings

General bindings were introduced in Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

## Procedure

1. Open the administrative console.
2. In the navigation pane, expand **Services > Service providers > Service\_provider\_application\_instance Service providers**.
3. [Optional] Use the **WSDL document** link under the **Additional Properties** section to view the Web Services Description Language (WSDL) for the service. The Application and Module links provide access to the application and module settings page.

For SCA service providers, the **Additional Properties** section does not show the WSDL document link, instead, there is a composition unit link. Click **Composition unit** to see the composition unit detail page.

4. Select one or more service, endpoints and operations of interest and view the associated service, endpoints and operations.
5. Do one or more of the following actions:
  - Click **Attach**, to attach a policy to a selected service, endpoint or operation.
  - Click **Detach**, to detach a policy set from a list of attached policy sets for a service, endpoint or operation.
6. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:

Table 257. Binding descriptions. Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
<b>Default</b>	<p>Specifies the default binding for the selected service, endpoint or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the Default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.</p> <p>For any policy set attachment, the runtime checks to see if the attachment includes a binding. If so, it uses that binding. If not, the runtime checks in the following order and uses the first available default binding:</p> <ol style="list-style-type: none"> <li>1. Default general bindings for the server</li> <li>2. Default general bindings for the domain in which the server resides</li> <li>3. Default general bindings for the global security domain</li> </ol>
<b>New Application Specific Binding</b>	Select this option to create a new application specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.
<b>Provider sample</b>	Select this option to use the Provider sample binding.
<b>Provider sample V2</b>	Select this option to use the Provider sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.
<b>Saml Bearer Provider sample</b>	Select this option to use the Saml Bearer Provider sample. The Saml Bearer Provider sample extends the Provider sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.

Table 257. Binding descriptions (continued). Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
<b>Saml HoK Symmetric Provider sample</b>	Select this option to use the Saml HoK Symmetric Provider sample. The Saml HoK Symmetric Provider sample extends the Provider sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

7. To close the drop down list for the assign binding action, click **Assign Binding**.

## Results

When you finish this task, a policy set is attached, detached or a binding is assigned to the service artifact.

## Example

You have configured a service provider, `EchoService12` in the application instance, `WSSampleServicesSei`. Now you want to attach the WS-Security policy to the `EchoService12Port` endpoint of the `EchoService12` service provider. First locate **EchoService12** in the **Services > Service providers** collection. Click the **EchoService12** service provider. Select the check box for the `columoService12Port` resource. Click **Attach** and select **WSSecurity** default policy from the list. Click **Save**, to save your changes to the master configuration.

## What to do next

You can now proceed to manage policy sets and bindings for service providers at the application level using the administrative console.

## Service provider settings

Use the Service provider settings page to manage the settings for your service providers. You can attach and detach policy sets to an application, its service, endpoints or operations. You can create new bindings, or use bindings that you have already created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

Use the **WSDL document** link to view the Web Services Description Language (WSDL) for the service. The **Application** and **Module** links provide access to the application and module settings page.

To view this administrative console page, click **Services > Service providers > *service\_provider\_instance***.

You can also view this page by clicking **Applications > Application Types > WebSphere enterprise applications > *service\_provider\_application\_instance* > Service providers > *service\_provider\_instance***.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Table 258. Button descriptions. Use the buttons to manage policy sets and policy set bindings for a service provider, its endpoints, or operations.

Bindings	Description
<b>Attach Policy Set</b>	Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click <b>Attach Policy Set</b> .

Table 258. Button descriptions (continued). Use the buttons to manage policy sets and policy set bindings for a service provider, its endpoints, or operations.

Bindings	Description
<p><b>Detach Policy Set</b></p>	<p>Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the <b>Attached Policy Set</b> column displays <b>None</b> and the <b>Binding</b> column displays <b>Not Applicable</b>.</p> <p>If there is a policy set attached to an upper level service resource, the <b>Attached Policy Set</b> column displays <i>policy_set_name (inherited)</i> and the binding used for the upper level attachment is applied. The binding name is displayed followed by <b>(inherited)</b>.</p>
<p><b>Assign Binding</b></p>	<p>Click this button to select from a list of available bindings for the selected policy set attachment. The options include the following:</p> <p><b>Default</b> Specifies the default binding for the selected service reference, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.</p> <p>For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding:</p> <ol style="list-style-type: none"> <li>1. Default general bindings for the server</li> <li>2. Default general bindings for the domain in which the server resides</li> <li>3. Default general bindings for the global security domain</li> </ol> <p><b>New Application Specific Binding</b> Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.</p> <p><b>Provider sample</b> Select this option to use the Provider sample binding.</p> <p><b>Provider sample V2</b> Select this option to use the Provider sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.</p> <p><b>Saml Bearer Provider sample</b> Select this option to use the Saml Bearer Provider sample. The Saml Bearer Provider sample extends the Provider sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.</p> <p><b>Saml HoK Symmetric Provider sample</b> Select this option to use the Saml HoK Symmetric Provider sample. The Saml HoK Symmetric Provider sample extends the Provider sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.</p> <p>To close the menu list, click <b>Assign Binding</b>.</p>

**Service provider:**

Specifies the name of the service provider that is displayed.

**Policy Set Attachments:**

**Service/Endpoint/Operation:**

Specifies the name of the service provider, endpoint, or operation that is contained in a service.

### **Attached Policy Set:**

Specifies the policy set that is attached to a service provider, endpoint, or operation.

The Attached Policy Set column can contain the following values:

- **None.** No policy set is attached, either directly or to a higher-level service resource.
- **Policy\_set\_name.** The name of the policy set that is attached directly to the service resource, for example, WS-I RSP.
- **Policy\_set\_name (inherited).** The name of the policy set that is not attached directly to a service resource, but that is attached to a higher-level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

### **Binding:**

Specifies the binding configuration that is available for a service provider, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable.** No policy set is attached, either directly or to a higher-level service resource.
- **Binding\_name** or **Default.** The binding name is displayed if a policy set is attached directly and an application specific binding or a general binding is assigned, for example, MyBindings1. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- **Binding\_name (inherited)** or **Default (inherited).** A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

### **About policy set bindings**

In this release, there are two types of bindings: application-specific bindings and general bindings.

#### **Application-specific bindings**

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

#### **General bindings**

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel, or by clicking **Services > Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

### ***Policy Sharing:***

Specifies whether the service provider can share its current policy configuration.

The Policy sharing column can contain the following values:

- **Not applicable.** The resource does not have a policy set attached, so there is no policy configuration to share.
- **Disabled.** The policy set of the resource cannot be shared. This is the default setting if a policy set is attached to a service.
- **Enabled.** The policy set of the resource can be shared.

When the value in the column is a link, click the link to view or change settings about how the policy configuration can be shared.

For a service, if the policy set is inherited from the parent application, the policy sharing value is also inherited, and you cannot change it. The value is not a link and it is followed by the term *inherited* in parentheses.

For an endpoint or operation, the value is not a link and it is followed by the term *inherited* in parentheses. The setting is inherited from the parent application or service and you cannot change it.

## **Managing policy sets and bindings for service providers at the application level using the administrative console**

Use this administrative console task to manage policy sets for an application or its services, endpoints, and operations.

### **Before you begin**

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS) and attach a policy set to each web service.

### **About this task**

You have developed a web service that contains all the necessary artifacts and deployed your web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, WS-I RSP is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: WS-I RSP (*inherited*). If there is no policy set attached directly or at a higher level, then None is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.
- *Binding\_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, MyBindings1. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding\_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0 and later, there are two types of bindings, application specific bindings and general bindings.

### Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

### General bindings

General bindings were introduced in Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

## Procedure

1. Open the administrative console.
2. **Applications > Application Types > WebSphere enterprise applications**  
 >*Service\_provider\_application\_instance* > **Service provider policy sets and bindings**.  
 [Optional] When you are accessing a business-level application, click **Business-level applications (BLA) > My\_BLA > BLA\_instance > Service provider policy sets and bindings**. Alternatively, click **Services > Service providers > My\_BLA > BLA\_instance > Service provider policy sets and bindings**.
3. Select the check box next to a service resource of interest.
4. Click **Attach** to attach a policy set to an application, service, endpoint or operation.
5. [Optional] Click **Detach** to detach a policy set from a list of attached policy sets for an application, service provider, endpoint or operation.
6. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:

Table 259. Binding descriptions. Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
<b>Default</b>	<p>Specifies the default binding for the selected service, endpoint or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the Default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.</p> <p>For any policy set attachment, the runtime checks to see if the attachment includes a binding. If so, it uses that binding. If not, the runtime checks in the following order and uses the first available default binding:</p> <ol style="list-style-type: none"> <li>1. Default general bindings for the server</li> <li>2. Default general bindings for the domain in which the server resides</li> <li>3. Default general bindings for the global security domain</li> </ol>
<b>New Application Specific Binding</b>	Select this option to create a new application specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.
<b>Provider sample</b>	Select this option to use the Provider sample binding.
<b>Provider sample V2</b>	Select this option to use the Provider sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.
<b>Saml Bearer Provider sample</b>	Select this option to use the Saml Bearer Provider sample. The Saml Bearer Provider sample extends the Provider sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.
<b>Saml HoK Symmetric Provider sample</b>	Select this option to use the Saml HoK Symmetric Provider sample. The Saml HoK Symmetric Provider sample extends the Provider sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

7. To close the drop down list for the assign binding action, click **Assign Binding**.

## Results

When you finish this task, a policy set is attached or detached, and a binding is assigned to the service artifact.

## Example

If you have configured a service provider application instance, app1 and you want, for example, to attach theUsername WSSecurity default policy set to your application, first locate app1 application in the **Applications > Application Types > WebSphere enterprise applications**. Click app1 > **Service**

**provider policy sets and bindings** under the Web Services Properties section. Select the check box next to the app1 service application. Click **Attach** and select Username WSSecurity default policy set. Click **Save**, to save your changes to the master configuration. You are returned to the **Applications > Application Types > WebSphere enterprise applications** page.

To assign a binding to the attached policy set, click app1 > **Service provider policy sets and bindings**. Select the check box next to the app1 service application and click **Assign Binding**. Select **Provider sample** binding from the list. Click **Save**, to save your changes to the master configuration.

## What to do next

You can proceed to view service providers at the cell level using the administrative console.

## Service provider policy sets and bindings collection

Use this page to attach and detach policy sets to an application, a service provider, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use bindings that you created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

This page provides detail information for an application and its associated web service providers, endpoints, and operations. You can view and manage policy set attachments and bindings information using this page.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > Service\_provider\_application\_instance > Service provider policy sets and bindings**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

*Table 260. Binding descriptions. Use the descriptions of the default bindings for the selected policy set attachment.*

Bindings	Description
<b>Attach Policy Set</b>	Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click <b>Attach Policy Set</b> .
<b>Detach Policy Set</b>	Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the <b>Attached Policy Set</b> column displays <b>None</b> and the <b>Binding</b> column displays <b>Not Applicable</b> .  If there is a policy set attached to an upper level service resource, the <b>Attached Policy Set</b> column displays <i>policy_set_name (inherited)</i> and the binding used for the upper level attachment is applied. The binding name is displayed followed by <b>(inherited)</b> .

Table 260. Binding descriptions (continued). Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
<b>Assign Binding</b>	<p>Click this button to select from a list of available bindings for the selected policy set attachment. The options include the following:</p> <p><b>Default</b> Specifies the default binding for the selected service reference, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.</p> <p>For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding:</p> <ol style="list-style-type: none"> <li>1. Default general bindings for the server</li> <li>2. Default general bindings for the domain in which the server resides</li> <li>3. Default general bindings for the global security domain</li> </ol> <p><b>New Application Specific Binding</b> Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.</p> <p><b>Provider sample</b> Select this option to use the Provider sample binding.</p> <p><b>Provider sample V2</b> Select this option to use the Provider sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.</p> <p><b>Saml Bearer Provider sample</b> Select this option to use the Saml Bearer Provider sample. The Saml Bearer Provider sample extends the Provider sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.</p> <p><b>Saml HoK Symmetric Provider sample</b> Select this option to use the Saml HoK Symmetric Provider sample. The Saml HoK Symmetric Provider sample extends the Provider sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.</p> <p>To close the menu list, click <b>Assign Binding</b>.</p>

**Application/Service/Endpoint/Operation:**

Specifies the name of the application and the associated service providers, endpoints or operations.

The Application/Service/Endpoint/Operation column lists the service application and the service providers, endpoints, or operations that the application contains.

**Attached Policy Set:**

Specifies the policy set that is attached to a service provider, endpoint, or operation.

The Attached Policy Set column can contain the following values:

- **None.** No policy set is attached, either directly or to a higher-level service resource.
- **Policy\_set\_name.** The name of the policy set that is attached directly to the service resource, for example, WS-I RSP.

- **Policy\_set\_name (inherited).** The name of the policy set that is not attached directly to a service resource, but that is attached to a higher-level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

### **Binding:**

Specifies the binding configuration that is available for a service provider, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable.** No policy set is attached, either directly or to a higher-level service resource.
- **Binding\_name** or **Default.** The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, MyBindings1. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- **Binding\_name (inherited)** or **Default (inherited).** A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

### **About policy set bindings**

In this release, there are two types of bindings: application-specific bindings and general bindings.

#### **Application-specific bindings**

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

#### **General bindings**

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel, or by clicking **Services >**

**Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

### ***Policy Sharing:***

Specifies whether the service provider can share its current policy configuration.

The Policy sharing column can contain the following values:

- **Not applicable.** The resource does not have a policy set attached, so there is no policy configuration to share.
- **Disabled.** The policy set of the resource cannot be shared. This is the default setting if a policy set is attached to a service.
- **Enabled.** The policy set of the resource can be shared.

When the value in the column is a link, click the link to view or change settings about how the policy configuration can be shared.

For a service, if the policy set is inherited from the parent application, the policy sharing value is also inherited, and you cannot change it. The value is not a link and it is followed by the term *inherited* in parentheses.

For an endpoint or operation, the value is not a link and it is followed by the term *inherited* in parentheses. The setting is inherited from the parent application or service and you cannot change it.

## **Viewing WSDL documents for service providers using the administrative console**

You can locate and view a Web Services Description Language (WSDL) document from the administrative console.

### **Before you begin**

Before completing this task, you need to install or deploy a Java API for XML Web Services (JAX-WS) application. Read about the JAX-WS application deployment model.

### **About this task**

JAX-WS integration with the WebSphere Application Server provides the option to view a Web Services Description Language (WSDL) document that is associated with your web service using the administrative console.

A web service application that contains all the necessary artifacts has been developed and deployed to the Application Server. Now you can view the WSDL document for each service using the administrative console.

### **Procedure**

1. Open the administrative console.
2. In the navigation pane, expand **Services > Service providers**.
3. Select a web service of interest in the **Service providers** collection view.
4. Click the **WSDL document** link to view the WSDL document.

## Results

When you finish this task, you have viewed the WSDL document for a service artifact.

## What to do next

You can attach and detach policy sets and configure bindings information for your application. See managing policy sets and bindings for service providers at the application level using the administrative console.

## Viewing service clients at the cell level using the administrative console

You can view all your service clients at the cell level using the administrative console.

## Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS).

## About this task

You can view a list of your service clients, such as JAX-WS Web services clients using the administrative console. The Name column displays the service client references. The Deployed Asset column displays the name of the deployed asset that contains the service client.

## Procedure

1. Open the administrative console.
2. In the navigation pane, expand **Services > Service clients**.
3. View the web service client of interest in the Name column and the associated application in the Deployed Asset column. For JAX-WS (WSN) references, the name of the containing WS-Notification service that is a part of the System Integration (SI) is displayed. Hovering over this name displays the Bus:<busName>.

## Results

When you complete this task, you have viewed the service clients at the cell level.

## What to do next

Proceed to view service clients at the application level using the administrative console. Click each service to see and manage the policy sets and bindings associated with a particular service.

## Service client collection at the cell level

Use this page to view and manage service clients at the cell level. Server-based Java API for XML-Based Web Services (JAX-WS) service clients are the only clients that are displayed in this view. Java API for XML-based RPC (JAX-RPC) service clients are not displayed in this view.

To view this administrative console page, click **Services > Service clients**. Select the service name link in the Name column to access the service client settings page. Select the deployed asset link in the Deployed Asset column to access the deployed asset settings page.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

**Name:**

Specifies the name of the service client, which is the name of the service provider that is referenced by the client. The full QName, Java class `javax.xml.namespace.QName`, is displayed when you hover the mouse pointer over the **Name** field.

If a web services reference has been defined for a service client, the **Name** field contains the name of the service reference under the corresponding service client. The full name of the service reference in name-value pair format is displayed when you hover the mouse pointer over the **Name** field.

**Type:**

Specifies the type of service such as a JAX-WS client service and Web Services Notification (WSN) client service. You can filter by the type of service.

**Deployed Asset:**

Represents a Java Platform, Enterprise Edition (Java EE) application or a WS-Notification service. For JAX-WS or WSN clients, the name of the containing WS-Notification service that is a part of the System Integration (SI) is displayed. Hovering over this name displays the Bus:<busName>.

*Table 261. Type of deployed asset and service broker. This table describes the representations for the types of deployed assets.*

	Java EE application
	WS-Notification service

## Viewing service clients at the application level using the administrative console

You can view your installed service clients for an application using this task.

### Before you begin

Before completing this task, you need to install a Java API for XML-based Web Services (JAX-WS) web service.

### About this task

You can view a list of your service client references.

Your application server instance can have one or more applications deployed on it that contain service clients. This task enables you to view the service names that are referenced in an application.

### Procedure

1. Open the administrative console.
2. View the service clients in an application by expanding **Applications > Application Types > WebSphere enterprise applications > Service\_client\_application\_instance > Service clients**.  
[Optional] When you are accessing a business-level application, click **Services > Service clients > BLA\_client\_instance**.
3. Select a client from the Name column to view the client and to manage the policy sets and bindings associated with it.
4. [Optional] Select a module name from the Module column to access the module detail page.

5. [Optional] In the **Additional Properties** section, click **Composition unit**, to see the composition unit detail page.

## Results

When you finish this task, you have viewed service clients at the application level.

## What to do next

You can now proceed to managing policy sets using the administrative console.

### Service clients collection at the application level

Use this page to view and manage service clients at the application level.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *Service\_client\_application\_instance* > Service client**.

#### **Name:**

Specifies the name of the service client. The service *QName*, Java class `javax.xml.namespace.QName`, is displayed when you hover your mouse pointer over the **Name** field. If a web services reference has been defined for a service client, the **Name** field contains the name of the service reference under the corresponding service client. The full name of the service reference in name-value pair format is displayed when you hover the mouse pointer over the **Name** field.

#### **Type:**

Specifies the type of service such as a Java API for XML-Based Web Services (JAX-WS) web service. You can filter by the type of service.

#### **Module:**

Specifies the name of the module that contains the service. Selecting a module name accesses the module detail page.

## Viewing detail of a service client and managing policy sets using the administrative console

Use this administrative console task to view the detail of your service client reference and to manage the policy sets for the service, its endpoints and operations.

### Before you begin

Before completing this task, you need to install one or more Java API for XML-based Web Services (JAX-WS) web services, and attach a policy set to each web service.

### About this task

You have developed a web service that contains all the necessary artifacts and deployed your web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, WS-I RSP is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is

appended to the policy set name, as the following example demonstrates: WS-I RSP (inherited). If there is no policy set attached directly or at a higher level, then None is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.
- *Binding\_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, MyBindings1. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding\_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0 and later, there are two types of bindings, application specific bindings and general bindings.

### Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service clients policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

### General bindings

General bindings were introduced in Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general client policy set bindings by accessing **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

## Procedure

1. Open the administrative console.
2. In the navigation pane, click **Applications > Application Types > WebSphere enterprise applications > Service\_client\_application\_instance > Service clients**.
3. Select one or more service, endpoints and operations of interest and view the associated service, endpoints and operations.
4. You can perform any of the following actions:
  - Click **Attach**, to attach a policy set to a selected service, endpoint or operation.
  - Click, **Detach**, to detach a policy set from a list of attached policy sets for a service, endpoint or operation. The service name is the service client reference in the application.
5. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:

Table 262. Binding descriptions. Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
<b>Default</b>	<p>Specifies the default binding for the selected service client, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.</p> <p>For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding:</p> <ol style="list-style-type: none"> <li>1. Default general bindings for the server</li> <li>2. Default general bindings for the domain in which the server resides</li> <li>3. Default general bindings for the global security domain</li> </ol>
<b>New Application Specific Binding</b>	Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.
<b>Client sample</b>	Select this option to use the Client sample binding.
<b>Client sample V2</b>	Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.
<b>Saml Bearer Client sample</b>	Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.
<b>Saml HoK Symmetric Client sample</b>	Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

6. To close the drop down list for the assign binding action, click **Assign Binding**.

## Results

When you finish this task, a policy set is attached, detached or a binding is assigned to the service artifact.

## Example

You have configured a service client reference, EchoService12 in the application instance, WSSampleClientSei. Now you want to attach the WSSecurity default policy to the EchoService12Port endpoint of the EchoService12 service client reference. First locate EchoService12 in the Services > Service clients collection. Click the **EchoService12** service client reference. Select the check box for the EchoService12Port resource and click **Attach**. Select the **WSSecurity** default policy from the list. Click **Save**, to save your changes to the master configuration.

## What to do next

You can now proceed to manage policy sets and bindings for service clients at the application level using the administrative console.

### Service client settings

Use this administrative console page to manage the settings for your service clients. You can attach and detach policy sets to a service, its endpoints, or operations. You can select default bindings, create new application-specific bindings, or use existing bindings for an attached policy set. You can view or change whether the client uses the policy of the service provider.

This service client page displays configuration information for a service client and the associated endpoints and operations. You can view and manage policy set attachments, bindings information, and whether the client uses the policy of the service provider.

The Application and Module links provide access to the application and module settings page.

To view this administrative console page, click **Services > Service clients > *service\_client\_instance***.

You can also view this page by clicking **Applications > Application Types > WebSphere enterprise applications > *service\_client\_application\_instance* > Service clients > *service\_client\_instance***.

To attach or detach a policy set or binding, do the following:

1. Select a service client, endpoint, or operation from **Service/Endpoint/Operation**. The **Service/Endpoint/Operation** list is nested, indicating parent-child relationships. When you select a parent, the children automatically inherit the settings of the parent.
2. Click the desired button.

*Table 263. Button descriptions. Use the buttons to manage policy sets and policy set bindings for service clients.*

Button	Resulting action
<b>Attach Client Policy Set</b>	Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click <b>Attach Client Policy Set</b> .
<b>Detach Client Policy Set</b>	Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the Attached Client Policy Set column displays <b>None</b> and the Binding column displays <b>Not Applicable</b> .  If there is a policy set attached to an upper level service resource, the Attached Client Policy Set column displays <b><i>policy_set_name</i> (inherited)</b> and the binding used for the upper level attachment is applied. The binding name is displayed followed by <b>(inherited)</b> .

Table 263. Button descriptions (continued). Use the buttons to manage policy sets and policy set bindings for service clients.

Button	Resulting action
<b>Assign Binding</b>	<p>Click this button to select from a list of available bindings for the selected policy set attachment. The options include the following:</p> <p><b>Default</b> Specifies the default binding for the selected service, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.</p> <p>For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding:</p> <ol style="list-style-type: none"> <li>1. Default general bindings for the server</li> <li>2. Default general bindings for the domain in which the server resides</li> <li>3. Default general bindings for the global security domain</li> </ol> <p><b>New Application Specific Binding</b> Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.</p> <p><b>Client sample</b> Select this option to use the Client sample binding.</p> <p><b>Client sample V2</b> Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.</p> <p><b>Saml Bearer Client sample</b> Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.</p> <p><b>Saml HoK Symmetric Client sample</b> Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.</p> <p>To close the menu list, click <b>Assign Binding</b>.</p>

**Service client:**

Specifies the name of the service client that is displayed.

**Policy Set Attachments:**

**Service/Endpoint/Operation:**

Specifies the name of the service client, endpoints or operations. The full QName (Java class javax.xml.namespace.QName) is displayed when you hover the mouse pointer over a service client name.

**Attached Client Policy Set:**

Specifies the policy set that is attached to the service client, endpoints or operations.

The Attached Client Policy Setcolumn can contain the following values:

- **None.** No policy set is attached, either directly or to a higher level service resource.
- **policy\_set\_name.** The name of the policy set that is attached directly to the service resource, for example, WS-I RSP.

- ***policy\_set\_name (inherited)***. The name of the policy set that is not attached directly to a service resource, but that is attached to a higher level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

### ***Policies Applied:***

Specifies the policies that are applied to the resource.

The Policies Applied column can contain the following values:

- **None**. No policies are applied to the service. This is the default setting if there is no policy set attached to the client.
- **Client only**. The client policy set is applied to the service. This is the default setting if a policy set is attached to the client.
- **Provider only**. The policy configuration of the service provider is applied to the service, as long as the client can support those policies.
- **Client and provider**. A policy that is based on both the client policy set and the policy of the service provider is applied to the service.

When the value in the column is a link, click the link to view or change settings about how the policies are applied.

For a service, if the value in the column is a link followed by the word *inherited* in parentheses, this shows a setting that is inherited from the parent application. You can click the link to change the setting for the service.

For an endpoint or operation, the value is not a link and it is followed by the word *inherited* in parentheses. The setting is inherited from the parent application or service and you cannot change it. If there is no applied policy, the entry in the column is *None*.

### ***Binding:***

Specifies the binding information available for a service client, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable**. There is no policy set attached, either directly or to a higher level service resource.
- ***Binding\_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, *MyBindings1*. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding\_name (inherited)*** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

### **About policy set bindings**

In this release, there are two types of bindings: application-specific bindings and general bindings.

#### **Application-specific bindings**

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can

provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

### General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel, or by clicking **Services > Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. Read about defining and managing service client or provider bindings for more information. General provider policy set bindings might also be used for trust service attachments.

## Managing policy sets and bindings for services references using the administrative console

Use this administrative console task to manage policy sets and bindings for the service reference, its endpoints, and operations.

### Before you begin

Before completing this task, you must install one or more Java API for API for XML-based Web Services (JAX-WS) web services, that contain at least one client service reference.

### About this task

You have developed a web service that contains all the necessary artifacts and deployed your web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

**Note:** When you configure the policy set attachments for a service reference, you can override the policy set attachments that are inherited from the service client using the administrative console. You can attach a policy set and binding for a service reference that is different from the policy set attachment for the service client. You can also specify to not attach a policy set to a service reference, even if a policy set is attached to the service client.

The default behavior is that a service reference, and its endpoints and operations, inherits the policy set attachment of the corresponding resources of the service. Service references are only valid for service clients.

Using the administrative console, you can configure the service reference to either inherit policy set and bindings configuration from the service client or to specify individual settings for the service reference by attaching policy sets and bindings that are different from the policy sets and bindings attached to the service client.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name is displayed; for example, WS-I RSP. If there is no policy set attached, and a policy set is attached at a higher level or to the service client, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: WS-I RSP (inherited). If there is no policy set attached directly or at a higher level, then None is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly, to a service client resource, or to a higher level service reference resource.
- *Binding\_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, MyBindings1. Default is displayed if a policy set is attached directly but the service reference resource uses the default bindings.
- *Binding\_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a service client resource or a higher level service reference resource.

There are two types of bindings, application specific bindings and general bindings.

### Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high-level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service clients policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

### General bindings

General bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings

- General client policy set bindings

You can create general client policy set bindings by accessing **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

**Note:** In a mixed cell environment, the following limitations apply to service reference attachments or resource attachments that are specified in name-value pair format:

- You must not create these types of attachments for applications that are deployed on an application server that is prior to WebSphere Application Server Version 8. Service reference attachments are only supported on WebSphere Application Server V8 and later.
- An application that contains these types of attachments must not be deployed on an application server that is prior to WebSphere Application Server Version 8.
- If an application that is deployed in a cluster environment contains these types of attachments, you must not add a member application server that is prior to WebSphere Application Server Version 8 to the cluster.

## Procedure

1. Open the administrative console.
2. In the navigation pane, click **Applications > Application Types > WebSphere enterprise applications > *Service\_client\_application\_instance* > Service clients**.
3. Select a service references and view the associated service reference, endpoints, and operations.
4. You can perform any of the following actions:
  - Click **Inherit**, to clear existing policy set and binding settings for the service reference and to use policy set attachments that are defined by the service client. By default, a service reference, and its endpoints and operations, inherits the policy set attachment of the corresponding resources of the service.
  - Click **Override**, to override existing policy set and binding settings for the service client and to either define separate policy sets and bindings for the service reference or to specify that a policy set is not attached to the service reference.
  - Click **Attach Client Policy Set**, to attach a policy set to a selected service reference, endpoint, or operation. This button is active only after you have clicked the **Override** button.
  - Click, **Detach Client Policy Set**, to detach a policy set from a list of attached policy sets for a service reference, endpoint, or operation. The service name is the service client reference in the application. This button is active only after you have clicked the **Override** button.
5. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. This button is active only after you have clicked the **Override** button. All the bindings are listed along with the following options:

Table 264. Binding descriptions. Use the descriptions of the default bindings to determine which binding to apply to service references.

Bindings	Description
Default	<p>Specifies the default binding for the selected service reference, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.</p> <p>For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding:</p> <ol style="list-style-type: none"> <li>1. Default general bindings for the server</li> <li>2. Default general bindings for the domain in which the server resides</li> <li>3. Default general bindings for the global security domain</li> </ol>
New Application Specific Binding	Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.
Client sample	Select this option to use the Client sample binding.
Client sample V2	Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.
Saml Bearer Client sample	Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.
Saml HoK Symmetric Client sample	Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

6. To close the drop-down list for the assign binding action, click **Assign Binding**.
7. (optional) Display inherit policy set attachments confirmation. Selecting this check box enables the inherit policy set attachments confirmation panel. You must expand the Preferences section to select this check box.

## Results

When you finish this task, you have specified policy sets and bindings for a service reference.

## Example

Suppose that you have configured a service client reference, EchoService12 in the application instance, WSSampleClientSei. You want to attach the WSSecurity default policy to the EchoService12Port endpoint of the EchoService12 service client reference. You must override the current service client policy set and bindings. Complete the following steps:

1. Locate EchoService12 in the **Applications > Application Types > WebSphere enterprise applications > WSSampleClientSei > Service clients** collection. Alternatively, you can locate EchoService12 in the **Services > Service clients** collection.
2. Click **Override**, to override the service client attachments.
3. Select the check box for the EchoService12Port resource, and click **Attach Client Policy Set**.
4. Select the **WSSecurity default** policy from the list.
5. Click **Save** to save your changes to the master configuration.

Suppose later, you want your service reference, EchoService12 to not use the WSSecurity default policy. Instead, you want to use the policy sets and attachments from the service client, WSSampleClientSei. Complete the following steps:

1. Locate EchoService12 in the **Applications > Application Types > WebSphere enterprise applications > WSSampleClientSei > Service clients** collection. Alternatively, you can locate EchoService12 in the **Services > Service clients** collection.
2. Click **Inherit**, to clear the existing policy set and binding settings for the service reference and to use policy set attachments that are defined by the service client.
3. Click **OK** on the Inherit policy sets page to confirm that you want to inherit the policy set attachments that are defined by the service client. You can optionally select the check box to not show the inherit confirmation page in the future.
4. Click **Save** to save your changes to the master configuration.

## What to do next

You can now proceed to manage other service references for the service client or to manage policy sets and bindings for service clients at the application level using the administrative console.

### Service reference settings

Use this administrative console page to manage the settings for your service references. Service references can inherit the policy sets and bindings of the service client or you can specify policy sets and bindings that are different from those of the service client.

This service references page displays configuration information for a service reference and the associated endpoints and operations. You can view and configure the service reference to either inherit policy set and binding configurations from the service client or to specify individual settings for the service reference by attaching policy sets and bindings that are different from the policy sets and bindings that are attached to the service client.

The Application, Module, and Service client links provide access to the application, module, and service client settings page.

To view this administrative console page, click **Services > Service clients > *service\_reference\_instance***.

You can also view this page by clicking **Applications > Application Types > WebSphere enterprise applications > *service\_client\_application\_instance* > Service clients > *service\_reference\_instance***.

You can specify a policy set and binding for a service reference that is different from the policy set attachment for the service. In addition, you can indicate to not attach a policy set to a service reference, even if a policy set is attached to the service. The default behavior is that a service reference, and its endpoints and operations, inherits the policy set attachment of the corresponding resources of the service. Service references are only valid for the client attachment type.

To attach or detach a policy set or binding, complete the following actions:

1. Select a service reference, endpoint, or operation from **Service Reference/Endpoint/Operation**. The **Service Reference/Endpoint/Operation** list is nested, indicating parent-child relationships. When you select a parent, the children automatically inherit the settings of the parent.
2. Click the button for the action that you want to complete.

Table 265. Button descriptions. Use the buttons to manage policy sets and policy set bindings for service references.

Button	Resulting action
<b>Inherit</b>	Click this button to clear the existing policy set and binding settings for the service reference and to use policy set attachments that are defined by the service client. By default, a service reference, as well as its endpoints and operations, inherits the policy set attachment of the corresponding resources of the service.
<b>Override</b>	Click this button to override the existing policy set and binding settings for the service client and to either define separate policy sets and bindings for the service reference or to specify that a policy set is not attached to the service reference.
<b>Attach Client Policy Set</b>	Click this button to view a list of policy sets available for attachment to the selected service reference, endpoint, or operation. Select a policy set from the list to attach; that policy set is attached to the selected service, endpoint, or operation. To close the menu list, click <b>Attach Client Policy Set</b> . This button is active only after you have clicked the <b>Override</b> button.
<b>Detach Client Policy Set</b>	<p>Click this button to detach a policy set from a selected service reference, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper-level service resource, the Attached Client Policy Set column displays <b>None</b> and the Binding column displays <b>Not Applicable</b>.</p> <p>If there is a policy set attached to an upper-level service reference resource or service client, the Attached Client Policy Set column displays <b>policy_set_name (inherited)</b> and the binding used for the upper-level attachment is applied. The binding name is displayed followed by <b>(inherited)</b>.</p> <p>This button is active only after you have clicked the <b>Override</b> button.</p>
<b>Assign Binding</b>	<p>Click this button to select from a list of available bindings for the selected policy set attachment. The options include the following:</p> <p><b>Default</b> Specifies the default binding for the selected service reference, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level for a particular server or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this <b>Assign Binding</b> action, the default specified at the nearest scope is used.</p> <p>For any policy set attachment, the runtime environment verifies whether the attachment includes a binding. If so, it uses that binding. If not, the runtime environment checks in the following order and uses the first available default binding:</p> <ol style="list-style-type: none"> <li>1. Default general bindings for the server</li> <li>2. Default general bindings for the domain in which the server resides</li> <li>3. Default general bindings for the global security domain</li> </ol> <p><b>New Application Specific Binding</b> Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.</p> <p><b>Client sample</b> Select this option to use the Client sample binding.</p> <p><b>Client sample V2</b> Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.</p> <p><b>Saml Bearer Client sample</b> Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.</p> <p><b>Saml HoK Symmetric Client sample</b> Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.</p> <p>To close the menu list, click <b>Assign Binding</b>.</p> <p>This button is active only after you have clicked the <b>Override</b> button.</p>

**Display inherit policy set attachments confirmation:** Selecting this check box specifies that you want to enable the inherit policy set attachments confirmation. You must expand the Preferences section to select this check box.

**Service Reference/Endpoint/Operation:**

Specifies the name of the service reference, endpoints, or operations. The full resource name is displayed when you hover the mouse pointer over a service reference, endpoint or operation.

**Client Policy Set:**

Specifies the policy set that is attached to the service reference, endpoints, or operations.

The Attached Client Policy Set column can contain the following values:

- **None.** No policy set is attached, either directly to the service client, or to a higher-level service reference resource.
- **policy\_set\_name.** The name of the policy set that is attached directly to the service reference resource, for example, WS-I RSP.
- **policy\_set\_name (inherited).** The name of the policy set that is not attached directly to a service reference resource; the policy set is attached to a higher-level service reference resource or to a service client resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

**Policies Applied:**

Specifies the policies that are applied to the service reference.

The Policies Applied service reference link is only enabled after you have clicked the Override button.

The Policies Applied column can contain the following values:

- **None.** No policies are applied to the service. This is the default setting if there is no policy set attached to the client.
- **Client only.** The client policy set is applied to the service. This is the default setting if a policy set is attached to the client.
- **Provider only.** The policy configuration of the service provider is applied to the service, as long as the client can support those policies.
- **Client and provider.** A policy that is based on both the client policy set and the policy of the service provider is applied to the service.

When the value in the column is a link, click the link to view or change settings about how the policies are applied.

For an endpoint or operation, the value is not a link and it is followed by the word *inherited* in parentheses. The setting is inherited from the parent application or service and you cannot change it. If there is no applied policy, the entries in the column are **None** or **None (inherited)**.

**Binding:**

Specifies the binding information available for a service reference, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable.** There is no policy set attached, either directly to the service client, or to a higher-level service reference resource.
- **Binding\_name** or **Default.** The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, MyBindings1. Default is displayed if a policy set is attached directly but the service reference resource uses the default bindings.
- **Binding\_name (inherited)** or **Default (inherited).** A service resource inherits the bindings from an attachment to a higher-level service reference resource or to a service client resource.

## About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings.

### Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high-level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

### General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel, or by clicking **Services > Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. Read about defining and managing service client or provider bindings for more information. General provider policy set bindings might also be used for trust service attachments.

## Managing policy sets and bindings for service clients at the application level using the administrative console

Use this administrative console task to manage policy sets for service clients applications or its services, endpoints, or operations.

## Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS) applications.

## About this task

You have developed a web service that contains all the necessary artifacts and deployed your web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, WS-I RSP is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: WS-I RSP (inherited). If there is no policy set attached directly or at a higher level, then None is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.
- *Binding\_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, MyBindings1. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding\_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0 and later of this product, there are two types of bindings, application specific bindings and general bindings.

### Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service clients policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

### General bindings

General bindings were introduced in Version 7.0 of this product. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service

attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general client policy set bindings by accessing **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

## Procedure

1. Open the administrative console.
2. In the navigation pane, click **Applications > Application Types > WebSphere enterprise applications > Service\_client\_application\_instance > Service client policy sets and bindings**.
3. Select the check box next to the **Application/Service/Endpoint/Operation** column. The service name is the service client reference in the application.
4. Click **Attach** to attach a policy set to an application, service, endpoint or operation.
5. [Optional] Click **Detach** to detach a policy set from a list of attached policy sets for an application, service client, endpoint or operation.
6. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:

Table 266. Binding descriptions. Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
<b>Default</b>	<p>Specifies the default binding for the selected service client, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.</p> <p>For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding:</p> <ol style="list-style-type: none"> <li>1. Default general bindings for the server</li> <li>2. Default general bindings for the domain in which the server resides</li> <li>3. Default general bindings for the global security domain</li> </ol>
<b>New Application Specific Binding</b>	Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.
<b>Client sample</b>	Select this option to use the Client sample binding.
<b>Client sample V2</b>	Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.
<b>Saml Bearer Client sample</b>	Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.
<b>Saml HoK Symmetric Client sample</b>	Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

## Results

When you finish this task, a policy set is attached or detached, and a binding is assigned to the service artifact.

## Example

If you have configured a service client application instance, *app1* and you want, for example, to attach the Username WSSecurity default policy set to your application, first locate *app1* application in the **Applications > Application Types > WebSphere enterprise applications**. Click *app1* > **Service client policy sets and bindings** under the Web Services Properties section. Select the check box next to the *app1* service application. Click **Attach** and select **Username WSSecurity default** policy set. Click **Save**, to save your changes to the master configuration.

To assign a binding to the attached policy set, click *app1* > **Service client policy sets and bindings**. Select the check box next to the *app1* service application and click **Assign Binding**. Select **client sample** binding from the list. Click **Save**, to save your changes to the master configuration.

## What to do next

You can proceed to view service clients at the cell level using the administrative console.

### Service client policy set and bindings collection

Use this page to attach and detach policy sets to an application, a service client, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use existing bindings for an attached policy set. You can view or change whether the client uses the policy of the service provider.

This page displays detail information for an application and its associated web service clients, endpoints, and operations. You can view and manage policy set attachments and bindings information using this page.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *service\_client\_application\_instance* > Service client policy sets and bindings**.

This console page can also be viewed for WS-Notification service clients by clicking one of the following paths:

- **Service integration > WS-Notification > Services > *service\_name* > [Additional properties] Outbound request policy sets and bindings**
- **Service integration > Buses > *bus\_name* > [Services] WS-Notification services > *service\_name* > [Additional properties] Outbound request policy sets and bindings**

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Table 267. Button descriptions. Use the buttons to manage policy sets and policy set bindings for a service client, its endpoints, or operations.

Button	Resulting action
<b>Attach Client Policy Set</b>	<p>Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click <b>Attach Client Policy Set</b>.</p> <p><b>Note:</b> Attach policy sets at the highest level, the EAR server level for example, and let the lower levels inherit those bindings. This can significantly improve the processing time needed to attach sets to multiple operations.</p> <p>After you attach sets at the highest level, you can then customize the lower levels by detaching sets or removing bindings from those specific operations.</p>
<b>Detach Client Policy Set</b>	<p>Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the Attached Client Policy Set column displays <b>None</b> and the Binding column displays <b>Not Applicable</b>.</p> <p>If there is a policy set attached to an upper level service resource, the Attached Client Policy Set column displays <b>policy_set_name (inherited)</b> and the binding used for the upper level attachment is applied. The binding name is displayed followed by <b>(inherited)</b>.</p>
<b>Assign Binding</b>	<p>Click this button to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:</p> <p><b>Default</b> Specifies the default binding for the selected service, endpoint or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used.</p> <p>For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding:</p> <ol style="list-style-type: none"> <li>1. Default general bindings for the server</li> <li>2. Default general bindings for the domain that the server resides</li> <li>3. Default general bindings for the global security domain</li> </ol> <p><b>New Application Specific Binding</b> Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.</p> <p><b>Client sample</b> Select this option to use the Client sample binding.</p> <p><b>Client sample V2</b> Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.</p> <p><b>Saml Bearer Client sample</b> Select this option to use the SAML Bearer Client sample. The SAML Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.</p> <p><b>Saml HoK Symmetric Client sample</b> Select this option to use the SAML HoK Symmetric Client sample. The SAML HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.</p> <p>To close the menu list, click <b>Assign Binding</b>.</p> <p><b>Note:</b> Assign bindings at the highest level, the EAR server level for example, and let the lower levels inherit those bindings. This can significantly improve the processing time needed to attach sets and bindings to multiple operations.</p> <p>After you assign bindings at the highest level, you can then customize the lower levels by detaching sets or removing bindings from those specific operations.</p>

**Application/Service/Endpoint/Operation:**

Specifies the name of the application and the associated service client, endpoints, or operations. For WS-Notification service clients, the first entry is associated with the WS-Notification service, not an application.

#### ***Attached Client Policy Set:***

Specifies the policy set that is attached to the application, service clients, endpoints, or operations.

The Attached Client Policy Set column can contain the following values:

- **None.** No policy set is attached directly, or is attached at an upper level.
- ***policy\_set\_name.*** The name of the policy set that is directly attached, for example, WS-I RSP.
- ***policy\_set\_name* (inherited).** A policy set is not directly attached to the resource, but a policy set is attached to a higher-level resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

#### ***Policies Applied:***

Specifies the policies that are applied to the resource. This column is not applicable and is not shown for WS-Notification service clients.

The Policies Applied column can contain the following values:

- **None.** No policies are applied to the application or service. This is the default setting if there is no policy set attached to the client.
- **Client only.** The client policy set is applied to the application or service. This is the default setting if a policy set is attached to the client.
- **Provider only.** The policy configuration of the service provider is applied to the application or service, as long as the client can support those policies.
- **Client and provider.** A policy that is based on both the client policy set and the policy of the service provider is applied to the application or service.

When the value in the column is a link, click the link to view or change settings about how the policies are applied.

For a service, if the value in the column is a link followed by the word *inherited* in parentheses, this shows a setting that is inherited from the parent application. You can click the link to change the setting for the service.

For an endpoint or operation, the value is not a link and it is followed by the word *inherited* in parentheses. The setting is inherited from the parent application or service and you cannot change it.

#### ***Binding:***

Specifies the name of the binding associated with a policy set.

The Binding column can contain the following values:

- **Not applicable.** There is no policy set attached, either directly or to a higher-level service resource.
- ***Binding\_name* or **Default.**** The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, MyBindings1. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding\_name (inherited)* or **Default (inherited).**** A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

## About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings.

### Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

### General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel, or by clicking **Services > Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

## Viewing web services deployment descriptors in the administrative console

You can view the web services client and server deployment descriptors for a deployed web services application. You can view the bindings in the deployment descriptors.

### Before you begin

Before you can view the deployment descriptors, you need to complete all tasks required to implement a JAX-RPC web service, create the deployment descriptor templates that were generated by the WSDL2Java command-line tool, configure the deployment descriptors and bindings, and deploy the Web service application into WebSphere Application Server. Review the implementing web services application documentation for more information on developing and implementing web services.

## About this task

Deployment descriptors contain the information that is needed by a web services client to communicate with the server for which the Web services is installed. This information is added to the deployment descriptor templates after a web service is developed or an existing web service is located. The data that you can view in the deployment descriptor includes the following:

- The web service description including the name, WSDL file, WSDL file location and the mapping file.
- The port description, including the port component name, the WSDL port, the service endpoint interface that indicate the service's bindings, and the EJB that is used to implement the web service.

After you have developed a web service that contains all the necessary artifacts, created the deployment descriptors from the deployment descriptor templates, configured the deployment descriptors, and deployed the web services application into WebSphere Application Server; now you can view the deployment descriptors and bindings in the administrative console.

Similar to Java API for XML-based RPC (JAX-RPC) web services, you can use deployment descriptors to describe JAX-WS web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

## Procedure

1. Open the administrative console.
2. Click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Manage Modules**.
  - Click **View web services client deployment descriptor extension**.
  - Click **View web services server deployment descriptor**.
  - Click **View web services server deployment descriptor extension**.
3. Click **Expand All** to view the deployment descriptor contents.
4. Verify deployment descriptor and bindings configurations.

## What to do next

You have viewed and verified the deployment descriptors and bindings for the web services application.

## Configuring the scope of a JAX-RPC web services port

When a Java API for XML-based RPC (JAX-RPC) web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the web module or enterprise bean module, including implementation scope, client bindings and deployment descriptor information. There are three levels of scope that can be set: application, session and request.

## Before you begin

Deploy a web service into the WebSphere Application Server. To learn more, read about deploying web services applications onto application servers.

## About this task

The Web Services for Java Platform, Enterprise Edition (Java EE) specification states that web services implementations must be stateless. Therefore, to maintain specification compliance, the scope can remain at the application level because the state relevant to the individual sessions level or the requests level is

not supposed to be maintained in the implementation. If you want to deviate from the specification and want to access a different JavaBeans instance, because you are looking for information that is located in another JavaBeans implementation, the scope settings need to change.

The setting that you configure for the scope determines how frequently a new instance of a service implementation class is created for the web services ports in a module. Use this task to configure the scope of a web services port.

You can also configure the scope of a web services port with the wsadmin tool. To learn more, see the information on configuring the scope of a web services port with the wsadmin tool.

This task applies only to Java API for XML-based RPC (JAX-RPC) web services.

To change the scope setting in the administrative console:

### Procedure

1. Open the administrative console.
2. Click **Applications > Application Types > WebSphere enterprise applications *application\_name* > Manage Modules > *module\_instance* > Web services implementation scope**
3. Set the scope to application, session or request. The application scope causes the same instance of the implementation to be used for all requests on the application. The session scope causes the same instance to be used for all requests in each session. The request scope causes a new instance to be used for every request. For example, with the scope set to application, every message that comes to the server accesses the same JavaBeans instance because that is the way the scope settings are configured.
4. Click **Apply**.
5. Click **OK**.

### Results

The scope for a web services port is configured.

### What to do next

Now you can finish any other configurations, start or stop the application, and verify the expected behavior of your web service.

### Web services implementation scope

Use this page to view and manage the scope of the ports of a Web service application.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Manage Modules > *module\_instance* > Web services implementation scope**.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

#### **Port:**

Specifies a port name for a web service. A module can contain one or more web services, each of which can contain one or more ports.

#### **Web service:**

Specifies the name of the web service. A module can contain one or more web services.

### **URI:**

Specifies the Uniform Resource Identifier (URI) of the binding file that defines the scope. The URI is relative to the web module.

### **Scope:**

Specifies the scope of a port. The valid values for scope are request, session and application.

The scope value determines when a new instance of a service implementation is created for the web service ports in a module. When the scope value is set to application, the same instance of the implementation is used for all requests on the application. When the scope value is set to session, the same instance is used for all requests on each session. When the scope value is set to request, a new instance is created for every request.

## **Suppressing the compensation service**

Not all web servers are configured to handle SOAP messages containing CoordinationContext elements. You can use WebSphere Application Server to configure a custom property for the compensation service which processes a predefined list of Enterprise Java Beans for which no CoordinationContext should be sent on web service requests.

### **About this task**

When the compensation service is used, CoordinationContext elements are included in the outgoing SOAP header. For example:

```
<wscoor:CoordinationContext soapenv:mustUnderstand="1"
...
</wscoor:CoordinationContext>
```

If such a SOAP message is received by a web server which is not configured to process CoordinationContext elements, an exception message is produced. See the following example:

```
Header block local name 'CoordinationContext' is not defined.
```

You can construct a file containing a list of all Enterprise Java Beans which should not send the CoordinationContext element in web service requests. This file must be in plain text format and must contain one entry per line, in the following format:

```
application_name#module#bean
application_name#module#bean
application_name#module#bean
```

Here application\_name is the name of the application as known on the server; module is the name of the Enterprise Java Bean jar; and bean is the name of the Enterprise Java Bean.

**Note:** This file must only contain entries for beans not configured to use the compensation service. This custom property will not be effective for any beans listed in the file which have compensation service metadata associated with them.

### **Procedure**

1. Start the administrative console.
2. In the navigation pane, click **Servers > Server Types > WebSphere application servers > server\_name > [Container Settings] Container Services > Compensation Service > [Additional Properties] Custom Properties**
3. Click **New**.
4. Enter SUPPRESS\_CSCOPE\_ON\_WS\_CALLS in the Name field.
5. In the Value field, enter a fully qualified file name.
6. Click **Apply** or **OK**.

7. Click **Save** to save your changes to the master configuration.
8. Restart the server.

## Results

Web service requests sent from Enterprise Java Beans listed in the custom property file will not contain CoordinationContext metadata in the outgoing SOAP message header.

---

## Managing policy sets using the administrative console

You can use policy sets, or assertions that define services, to simplify your web services configuration because policy sets group security and other web services settings into reusable units. You can use the administrative console to create, modify, and delete custom policy sets.

### Before you begin

Before creating policy sets, first identify the security and other requirements of the web service.

**Note:** You can only use policy sets with JAX-WS applications that run on the Axis2 web service engine. You cannot use policy sets for JAX-RPC applications.

### About this task

You can use the administrative console to view and manage policy sets. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**. The Application policy sets collection displays a listing of the custom (if you have created custom policy sets) and default policy sets. Use the Application or System policy sets collection page to create, copy, delete, export, and import policy sets.

The following policy sets are ready for you to use as is.

- LTPA WSSecurity Default
- Kerberos V5 HTTPS default
- SSL WSTransaction
- Username SecureConversation
- Username WSSecurity default
- WS-Addressing default
- WSHTTPS default
- WS-I RSP ND
- WS-ReliableMessaging persistent

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

### Procedure

- “Viewing policy sets using the administrative console” on page 2843.  
This topic describes the process of viewing and evaluating policy sets.
- “Creating policy sets using the administrative console” on page 2844.  
This topic describes two ways to create policy sets: creating new policy sets or copying and renaming policy set templates.
- “Modifying policy sets using the administrative console” on page 2854.  
This topic describes how to edit custom policy sets you have created.

- “Importing policy sets using the administrative console” on page 2851.  
This topic describes how to import policy sets from the default repository or from a selected location.
- “Exporting policy sets using the administrative console” on page 2936.  
This topic describes how to export policy sets.
- “Deleting policy sets using the administrative console” on page 2855.  
This topic describes how to delete custom policy sets. You can delete policy set templates and re-import them if needed.
- “Managing policies in a policy set using the administrative console” on page 2887  
This topic describes how you can define policies with policy sets to secure messages.
- “Defining and managing policy set bindings” on page 2856  
This topic describes configuring custom binding configurations.

## Results

Using these tasks, you can determine how to create a new policy set and verify whether you can reuse an existing policy set. You can configure a policy set, and define policies for that policy set.

## What to do next

Depending on how you are using policy sets, you might want to revisit some of the tasks listed in this topic to tweak the configuration for your policy set. You can also proceed to configure bindings for your policy set. See Defining binding information for policy sets.

## Viewing policy sets using the administrative console

You can use the administrative console to view lists of policy sets. Policy sets can either be default policy sets that you cannot edit or custom policy sets that you have created and can edit. You can use policy sets, or assertions that define services, to simplify your web services configuration because policy sets group security and other web services settings into reusable units.

## Before you begin

If you are creating a custom policy set by copying an existing default policy set, you might want to view the existing policy sets to choose a policy set with properties similar to the one you are planning to create.

## About this task

You can view a list of policy sets to decide which policy sets can be reused or copied, modified and reused.

## Procedure

1. To view policy sets from the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. Set the number of policy set rows that you want to view at a time using the Preferences settings. The default value is 20. The Editable column on the table in this view shows which policy sets you can edit. You can only edit the custom policy sets that you create. You cannot edit the provided default policy sets.
3. To view the details for any of the policy sets, click the name of the policy set in the Name column of the table. The Policy set settings page displays details about the selected policy set. If the policy set is a custom policy set you can edit the fields on the page. If the policy set is a provided default, then you can copy and reuse the policy set. You cannot edit the fields otherwise.

## Results

After you have viewed the available policy sets and their settings, you can then decide if you want to create a new policy set, copy an existing policy set that you can rename, or use one of the existing policy sets that meets your needs.

## Creating policy sets using the administrative console

You can use the administrative console to either create a policy set by specifying all the necessary information or by copying an existing policy set that you rename. You can use policy sets, or assertions that define services, to simplify your web services configuration because policy sets group security and other web services settings into reusable units.

### Before you begin

To create a new policy set, you can either specify the information to create a new policy set or you can copy and rename an existing policy set. Using either method, you need basic information about the policy set that you want to create, such as the name, description, policies to include, policy details, attachments, and binding configurations. If you are creating a policy set by copying an existing policy set, then you should also view the existing policy sets to choose one with properties that are most similar to the one you plan to create.

### About this task

Whether you choose to create a new policy set or copy and rename an existing one, start from the Applications policy sets collection in the administrative console.

### Procedure

1. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. If the policy set you are creating is:
  - a new policy set, then click **New**.
  - an existing policy set to be copied and renamed, click the **Select** box beside the name of the policy set to be copied in the **Name** column and click **Copy**.

Using either method, this action opens the Policy set settings view to specify the required information about the policy set being created or copied.

3. Enter the name of the policy set that you want to create or copy in the **Name** field.
4. Enter a brief description of the policy set in the **Description** field. This is the description that displays in the Application policy sets or the System policy set collection, so it must be meaningful to you and other potential users of this policy set.

**Note:** If you created a new policy set, it does not contain policies to edit until you add them to the policy set. The policy set is initially empty.

## Results

You have provided the basic information to create a policy set.

### Example

After you have looked at your web services, you might decide that the WS-I RSP default policy set most closely meets your needs. You would go to the administrative console and click **Services > Policy sets > Application policy sets** to access the Application policy sets collection. Locate the WS-I RSP default in the **Name** column of the table and click the box beside it (in the **Select** column). Click **Copy**. This opens

the Policy set settings window. You might want to name your policy set by your company or division so you could provide a name like ABC WS-I RSP in the Name field. Because you know others in your organization might access and use it, you've chosen a name that is meaningful to those people too. You want to be sure everyone knows exactly what this copy of the WS-I RSP policy is used for, so you add a description in the **Description** field describing it. Now you want to customize the policy set so you edit the policy information by clicking the name of a policy to edit it.

When you identify the requirements of your web service, you might decide that none of the default policy sets meet your needs closely enough to use them as a template so you might decide to create your own policy set. You would first create the policy set with the name you choose to give it. As if you were reusing an existing template, you would go to the administrative console and click **Services > Policy sets > Application policy sets** and click **New**. The Policy set settings window opens but note that the Policy set name field is blank and there are not yet any associated policies in the table. Enter the name and add any policies necessary.

When you add policies to a policy set, the policies are set to their default values. You can then edit the policies to modify any attribute values that need to be changed and save the settings.

## What to do next

If you are creating a new policy set without copying an existing policy set, you need to specify the policy information. If you are copying an existing policy set, you can either accept the default policies associated with the policy set or you can change the policies.

## WS-I RSP default policy sets

The Reliable Asynchronous Message Profile (WS-I RSP) default policy sets are based on the Reliable Asynchronous Message Profile specification. The WS-I RSP default policy sets include the WS-I RSP default policy set, the Lightweight Third-Party Authentication (LTPA) WS-I RSP default policy set and the Username WS-I RSP default policy set. You can use these policy sets to simplify your web services configuration.

The WS-I RSP default policy sets are composed of a set of policies to provide reliable and secure web services. The WS-I RSP default policy sets use the WS-Addressing, WS-ReliableMessaging, and WS-Security specifications. Use the WS-I RSP default policy set, the LTPA WS-I RSP default policy set, or the Username WS-Security WS-I RSP default policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-I RSP default policy sets include the following policies:

### WS-Addressing policy

You can use the WS-Addressing policy to enable the addressing capability of the WS-Addressing specification.

### WS-ReliableMessaging policy

You can use the WS-ReliableMessaging policy to specify the quality of service for reliable delivery.

### WS-Security policy

The WS-Security policy in the WS-I RSP default policy set provides the following security:

- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.
- Traditional RSA cryptography is used to secure a request to a Trust Server to obtain a Secure Context Token (SCT). Thereafter, the conversation is secured using symmetric keys derived from the SCT.

The application server provides additional policy sets that you can use or customize. To use the following default policy sets, you must import the policy sets from the default repository. Read about importing policy sets using the administrative console for more information.

The following WS-I RSP default policy sets exist:

#### **WS-I RSP default**

This policy set provides:

- Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging.
- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.

#### **LTPA WS-I RSP default**

This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

#### **Username WS-I RSP default**

This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

### **SecureConversation default policy sets**

The SecureConversation default policy sets are based on the Web Services Secure Conversation Language (SecureConversation) standard that establishes a secure context, based on shared keys for the client and server to use for a series of messages. This standard provides a framework to define how to secure the message exchange across organizations. The SecureConversation default policy sets include the SecureConversation policy set, the Lightweight Third-Party Authentication (LTPA) SecureConversation policy set, and the Username SecureConversation policy set.

The SecureConversation default policy sets are based on the WS-SecureConversation, the WS-Security, and the WS-Addressing specifications. Use the SecureConversation policy set, the LTPA SecureConversation policy set, or the Username SecureConversation policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-SecureConversation specification alone does not provide a complete security solution. The WS-SecureConversation is built on the WS-Security and WS-Trust specifications to provide secure communication across one or more messages. Specifically, this specification defines mechanisms for establishing and sharing security contexts, and deriving keys from established security contexts or any shared secret.

WS-Security focuses on the message authentication model but not in a security context. The WS-SecureConversation specification defines mechanisms for establishing and sharing security contexts, and deriving keys from security contexts, to enable a secure conversation. By using the SOAP extensibility model, modular SOAP-based specifications are designed to be composed with each other to provide a rich messaging environment.

The following SecureConversation default policy sets exist:

#### **SecureConversation**

This policy set provides:

- Message integrity by digital signature that includes signing the body, timestamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications.
- Message confidentiality by encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications.

#### **LTPA SecureConversation**

This policy set provides the SecureConversation policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

#### **Username SecureConversation**

This policy set provides the SecureConversation policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

### **WS-ReliableMessaging default policy sets**

The WS-ReliableMessaging default policy sets are pre-configured to provide reliable message exchange between web services. Two of these policy sets (WS-I RSP and WS-I RSP ND) are immediately available, and the rest are readily available for import from a default repository.

With WS-ReliableMessaging, you can make your SOAP over HTTP-based web services reliable without writing custom code. You can use the provided non-editable default policy sets without change, or you can create customized copies of them.

All the default policy sets that include the WS-ReliableMessaging policy also include the WS-Addressing policy. The WS-ReliableMessaging policy provides the ability to deliver a message reliably to its intended receiver. The WS-Addressing policy provides a transport-neutral way to uniformly address web services and messages, and WS-ReliableMessaging uses WS-Addressing to provide asynchronous request and reply capabilities.

**Note:** WS-ReliableMessaging Version 1.1 messaging requires WS-Addressing to be mandatory. If you use a policy set that includes WS-ReliableMessaging and WS-Addressing policies, and the WS-Addressing policy is configured as optional, then WebSphere Application Server overrides the WS-Addressing setting and automatically enables WS-Addressing.

The following default policy sets that include the WS-ReliableMessaging policy are immediately available, as described in “Viewing policy sets using the administrative console” on page 2843:

#### **WS-I RSP**

This policy set enables WS-ReliableMessaging Version 1.1 and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. This quality of service is for single server only and does not work in a cluster. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent. Message integrity is provided by digitally signing the body, the time stamp, and the WS-Addressing headers. Message confidentiality is provided by encrypting the body and the signature. This policy set follows the WS-SecureConversation and WS-Security specifications.

#### **WS-I RSP ND**

This is the network deployment version of the WS-I RSP policy set. This policy set provides the WS-I RSP default policy set and adds a *managed non-persistent* quality of service. This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages. This option supports clusters as well as single servers.

The following additional default policy sets that include the WS-ReliableMessaging policy are readily available for import, as described in “Importing policy sets using the administrative console” on page 2851:

#### **LTPA WS-I RSP**

This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

#### **Username WS-I RSP**

This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

#### **WSReliableMessaging 1\_0**

This policy set enables both WS-ReliableMessaging Version 1.0 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. This quality of service is for single server only and does not work in a cluster. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

You can use this policy set with .NET-based web services.

#### **WSReliableMessaging default**

This policy set enables both WS-ReliableMessaging Version 1.1 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. This quality of service is for single server only and does not work in a cluster. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

#### **WSReliableMessaging persistent**

This policy set enables both WS-ReliableMessaging and WS-Addressing and uses the maximum quality of service, *managed persistent*. This quality of service supports asynchronous web service invocations and uses a service integration messaging engine and message store to manage the sequence state. Messages are processed within transactions, are persisted at the web service requester server and at the web service provider server, and are recoverable in the event of server failure. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

Because this policy set specifies managed persistent quality of service, you have to define bindings to the service integration bus and messaging engine that you want to use to manage the WS-ReliableMessaging state. You can attach and bind a WS-ReliableMessaging policy set to a web service application by using the administrative console or the wsadmin tool.

#### **WSAddressing default policy set**

The WSAddressing default policy set provides a transport-neutral way to uniformly address web services and messages.

The WSAddressing default policy set is based on the WS-Addressing specification. The WS-Addressing standard uses endpoint references and message addressing properties to facilitate the addressing of web services in a standard and interoperable way.

Use the WSAddressing default policy set as provided with the application server. To customize the policy set, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

To learn more about the WS-Addressing standard, read about Web Services Addressing support.

## Web Services Security default policy sets

The Web Services Security default policy sets are based on the WS-Security 1.0 and Web Services Addressing (WS-Addressing) specifications. The Web Services Security default policy sets include the WSSecurity default policy set, the Lightweight Third-Party Authentication (LTPA) WSSecurity policy set, the Username WSSecurity policy set, and the Kerberos V5 HTTPS default policy set. These default policy sets are used to build secure web services.

The Web Services Security default policy sets use the WS-Security 1.0 specification enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. Providing quality of protection means to prevent the following potential threats to SOAP messages:

- The message being modified or read by antagonists.
- An antagonist sending messages to a service that are formed correctly, but lack the appropriate security claims to be processed.

The WS-Addressing specification defines XML 1.0 and XML Namespaces elements to identify web services endpoints and to secure end-to-end endpoint identification in messages.

You can use the WSSecurity default policy set, the LTPA WSSecurity policy set, the Username WSSecurity policy set, or the Kerberos V5 HTTPS default policy set as provided with the application server. To customize the other Web Services Security policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

Features and details of the default Web Services Security policy sets are as follows:

### Kerberos V5 HTTPS default

This policy set provides message authentication with a Kerberos Version 5 token. Message integrity and confidentiality are provided by Secure Sockets Layer (SSL) transport security. This policy set follows the OASIS Kerberos Token Profile V1.1 and WS-Security specifications.

When you use this policy set, configure the basic authentication data and custom properties such as the `com.ibm.wsspi.wssecurity.krbtoken.targetServiceName` and `com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost` custom properties in the client bindings. For more information, see the Authentication generator or consumer token settings and Protection token settings (generator or consumer) topics.

### LTPA WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

### Username SecureConversation

This policy set provides:

- Message integrity through digital signature that includes signing the body, time stamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications
- Message confidentiality through encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

### Username WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

### **WSSecurity default**

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.

### **WSTransaction default policy sets**

The WSTransaction default policy sets are based on the WS-Transaction specification and provide transactional integrity for web services. The WSTransaction default policy sets include the WSTransaction policy set and the SSL WSTransaction policy set.

You can use the WSTransaction default policy sets to make your SOAP over HTTP-based web services interoperable and coordinate atomic transactions or business activities without writing custom code. Use the WSTransaction policy set or the SSL WSTransaction policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WSTransaction default policy sets are:

#### **WSTransaction**

Use this policy set to coordinate distributed transactional work atomically and interoperably, by using the WS-AtomicTransaction specification. Also, use this policy set to coordinate loosely coupled business processes that are distributed across the heterogeneous web service environment, with the ability to compensate actions if a failure occurs in the business activity, by using the WS-BusinessActivity specification.

#### **SSL WSTransaction**

Use this policy set to coordinate distributed transactional work atomically, interoperably and securely, by using the WS-AtomicTransaction specification and SSL Transport security. Also, use this policy set to coordinate loosely coupled business processes, with the ability to compensate actions if a failure occurs in the business activity, securely, by using the WS-BusinessActivity specification and SSL Transport security.

### **WSHTTPS default policy set**

The WSHTTPS default policy set provides SSL transport security for the HTTP protocol with web services applications.

The WSHTTPS default policy set is provided with the application server and it contains the HTTP transport policy, the SSL transport policy and the WS-Addressing policy.

You can use the WSHTTPS default policy set as provided with the application server. You cannot edit the WSHTTPS default policy set. You can create a copy of the default policy set and then configure custom policy settings and bindings to meet your needs. Alternatively, you can create a new policy set and specify the policies for it.

### **Copy of default policy set and bindings settings**

Use this page to copy a policy set that you select from a list of available policy sets.

To view this administrative console page:

1. Click **Services > Policy sets > Application policy sets**.
2. Select the policy set that you want to copy, and click **Copy**.
3. Enter a name for the copy of the policy set in the **Name** field.
4. [Optional] Enter a description for the copy of the policy set in the **Description** field.

**Name:**

Specifies the name of the policy set. Use this field to enter a name for the copy of the policy set.

**Description:**

Specifies a description of the policy set that you want to copy.

**Transfer attachments:**

If the policy set that you want to copy is attached to one or more applications, services, or endpoints, then the check box option for **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations**, is available. The default setting for this check box is cleared. You can perform the following actions:

1. Select the **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations** check box to move the attachments to a new policy set. Selecting the check box detaches the original policy set and attaches the replacement policy set in its place.
2. Select **Copy bindings** if you want to copy the bindings of the policy set that is currently attached.
3. [Optional] Select **Restore default bindings** if you want to restore the default bindings.

## Importing policy sets using the administrative console

You can import predefined policy sets or import policy sets from a selected location using the administrative console.

### Before you begin

Before you begin this task, review Application policy sets collection.

### About this task

The policy sets panel has an Import button to allow the import of policy sets. You can import a policy set from the default repository or from a selected location.

### Procedure

1. From the administrative console navigation, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**. The policy sets collection page displays a listing of the custom and default policy sets. Custom policy sets are displayed only if you have created them. If you have not created a custom policy set, then only the default policy sets are displayed.
2. From the Application policy sets panel, click **Import**.
3. Choose the option for importing the policy set. You can choose to import a policy set from the default repository or from a selected location. Selecting **Import from Default Repository** accesses the next panel that displays a set of predefined default policy sets that are available for you to import. Some of the predefined policy sets have already been imported for you from the default repository. You can import additional predefined policy sets that are available in the predefined policy set repository. Select **Import from Selected Location** to provide a path or browse your file system for a policy set file to import.
  - To import a policy set from the default repository, select **Import from Default Repository** and perform task step 4.

- To import a policy set from a selected location, select **Import from Selected Location** and perform task step 7.
4. Select **Import from Default Repository** and select either the **Import** or the **Import a Copy** radio button.  
The behavior of **Import** policy set:
    - Available for selection of one or more policy sets.
    - Imports the default, not editable, policy set. You are returned to the Application policy sets panel after the import of the policy set.
    - The imported policy set can be deleted, but it cannot be modified.The behavior of **Import a Copy** for a policy set:
    - Not available for multiple selection. If multiple policy sets are selected and the **Import a Copy** radio button is selected, an error message is displayed, indicating that only one policy set can be copied at a time.
    - Prompts you for a name and description for the copy. You are returned to the Application policy sets panel after you import the policy set.
    - The imported policy set can be modified or deleted.
  5. If you selected **Import** from the previous step, select one or more policy sets to import in the **Name** column.
    - a. Click **OK**. You are returned to the Application policy set panel.
    - b. Click **Save**, to save your changes to the configuration.
  6. If you selected **Import a Copy** from step 4, select the policy set to import a copy in the **Name** column. You can only select one policy set in the Name column to import its copy.
    - a. Provide a different name for the copy.
    - b. Click **OK**. You are returned to the Application policy set panel.
    - c. Click **Save**, to save your changes to the configuration.
  7. Select **Import from Selected Location**.
    - a. Specify the full path or browse for the policy set file in your file system.
    - b. Select either **Use current policy set name** or **Specify a different name to use for this policy set**.
    - c. Click **OK**. You are returned to the Application policy set panel.
    - d. Click **Save** to save your changes to the configuration.

## Results

When you finish this task, you have been able to import a policy set using either the default repository or from a selected location.

## Example

If you have a policy set, XYZ\_ps and you want to import it from a selected location, perform the following steps:

1. From the Application policy set panel, click **Import**.
2. Select **Import from Selected Location**.
3. Specify the full path or browse to where the XYZ\_ps policy set file is located in your file system.
4. Select either **Use the current policy set name**, XYZ\_ps, or **Specify a different name for the policy set**.
5. Click **OK**.
6. Click **Save**, to save your changes to the configuration.

## What to do next

You can modify or use the policy set that you just imported.

### Import policy sets from default repository settings

Use this page to specify a policy set to import from a default repository. You can import predefined policy sets from the default repository.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets**.
2. Click **Import**.
3. Select **From Default Repository**.
4. You have the **Import** and **Import a copy** options. Select **Import a copy**.
5. In the **Name of copy** field, enter a name for the copy of the policy set that you select to import from the list of policy sets.

The behavior of **Import**:

- Available for selection of one or more policy sets.
- Imports the default, not editable, policy set. You are returned to the Application policy sets panel after the import of the policy set.
- The imported policy set can be deleted, but it cannot be modified.

The behavior of **Import a copy** policy set:

- Not available for multiple selection. If multiple policy sets are selected and the **Import a copy** radio button is selected, an error message is displayed, indicating that only one policy set can be copied at a time.
- Prompts you for a name for the copy. The description of the imported policy set is kept, but you can edit the description after you have imported the policy set. You are returned to the Application policy sets panel after the import of the policy set.
- The imported policy set can be modified or deleted.

#### **Name of copy:**

Use this field to enter a name for the copy of the policy set that you select to import from the list.

Before you can edit this field, you must select **Import a copy** option.

#### **Buttons:**

Click the appropriate button:

Button	Resulting Action
<b>OK</b>	Imports the specified policy set. You are returned to the Application policy set panel after the import.
<b>Cancel</b>	Returns you to the Application policy set panel without importing a policy set.

### Import policy sets from a selected location settings

Use this page to specify a policy set to import from a selected location.

To view this administrative console page, click **Services > Policy sets > Application policy sets > Import policy set from selected location**.

On this page, specify a policy set to import from a selected location.

### **Path and file name for the policy set file:**

Specify a fully qualified path and file name to the policy set file or use the **Browse** to locate the file in your file system.

Select **Use current policy set name** if you are not changing the policy set name and click **OK**.

Select **Specify a different name for this policy set** if you are changing the policy set name. Provide a new name and click **OK**.

Button	Resulting action
OK	Imports the specified policy set file if valid or returns an error if an invalid file is provided. You are returned to the Application policy set panel after the import.
Cancel	Returns you to the Application policy set panel without importing a policy set.

## **Modifying policy sets using the administrative console**

You can use the administrative console to modify existing custom policy sets that you have created. If you have copied an existing default policy set or created a policy set yourself, you can always go back and make changes to them to make them better suit the changing needs of your business.

### **Before you begin**

You can create a copy of a policy set and modify the copy. You must first copy a default policy set before you can modify it. See copy of default policy set and bindings settings.

### **About this task**

To modify a custom policy set, you can use the Policy set settings view to access configuration information for the policy set.

### **Procedure**

1. Create a policy set using the steps in “Creating policy sets using the administrative console” on page 2844
2. From the administrative console, click **Services > Policy sets > Application policy sets** >*policy\_set\_name* or **Services > Policy sets > System policy sets** >*policy\_set\_name* where *policy\_set\_name* is the custom policy set of interest that is displayed in the table. This opens the Policy set settings view. You must specify the required information about the policy set that you want to modify.
3. Change the description of the policy set. Edit the brief description of the policy set in the Description field. This is the description that displays in the Application policy sets collection so it must be meaningful to you and other potential users of this policy set.
4. Edit the policy information. You can include, exclude, add or delete policies from this policy set using the settings in the Policies table. To work more extensively with policies, see “Managing policies in a policy set using the administrative console” on page 2887.
5. This step does not apply to system policy sets. Detach the policy set from an application or replace the policy set attached to the application with another policy set. Click the **Attached applications** link to access applications that are attached to this policy set and applications that contain attached service resources. To detach a policy set from an application, use the following steps:
  - a. In the Filter list, click **Name**.
  - b. Find the application. In the Search term(s) field, enter all or part of the name of the application you want to detach and click **Go**.
  - c. Detach the application. Find and select the application in the listing and click **Detach Policy Set**.

To change the policy set that is attached to an application, use the following steps:

- a. In the Filter list, click **Name**.
- b. Find the application. In the Search term(s) field, enter all or part of the name of the application and click **Go**.
- c. Replace the policy set for this application. Find and select the application in the listing and click **Replace Policy Set**. You then have one of the following options:
  - If there are fewer than 25 policy sets to choose from, the Replace Policy Set button is a drop down list and you can click a policy set to attach to the application.
  - If there are more than 25 policy sets to choose from, the Replace Policy Set button opens a collection of policy sets and you can select the policy set to replace from the listing.

## Results

Performing these tasks modifies the application to which the custom policy set is attached.

## Example

If you had a custom policy set ABC WS-I RSP, for example, that had a misleading description and you want to change the description so that other users know what the policy set really includes, you would access the Policy Set settings view for that policy set. To do this, from the administrative console, you would click **Services > Policy sets > Application policy sets > ABC WS-I RSP**. Then you would click the description field and edit the text so that it better represents the scope of the policy set.

## What to do next

If the policy set you have modified is an attached policy set, restart all affected applications to pick up the changes you made. If the policy set is unattached, then no further action is required.

## Deleting policy sets using the administrative console

You can use the administrative console to delete the default policy sets or the application specific policy sets that you have created.

## Before you begin

If you are deleting an attached policy set, stop all applications and the associated endpoints or operations, then detach and delete the policy set. If the policy set is unattached, then you do not need to detach the policy set before deleting it.

## About this task

If a application specific policy set is no longer needed, you might choose to delete it. To delete a application specific policy set, use the Application policy set collection panel.

## Procedure

1. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. Click the box in the **Select** column next to the policy set that you want to delete.
3. Click **Delete**.
4. Verify that you want to delete this policy set.

## Results

The selected application specific policy set is deleted from the list of policy sets and is no longer available.

## Example

You might decide that the *ABC WS-I RSP* policy set that you created did not meet your needs as you had expected and you have already created the *DEF WS-I RSP* policy set to better meet your needs. You have detached all the applications and endpoints from the *ABC WS-I RSP* policy set and you want to delete the policy set. Click **Services > Policy sets > Application policy sets** and find the *ABC WS-I RSP* policy set in the listing. Select the *ABC WS-I RSP* policy set and click **Delete**. Confirm that you want to delete the policy set and it is removed from the listing of policy sets. Restart the applications that you detached the *ABC WS-I RSP* policy from, and you have successfully deleted the policy set.

Alternatively, and depending on your use case, you might want to reassign the attachment to another resource before deleting the policy set. Make a copy of the policy set that you are about to delete, then attach it later to your application or service artifact. See attaching a policy set to a service artifact. You can now delete the policy set.

## What to do next

If you have detached and then deleted a policy set from an application, restart all affected applications to pick up this change.

## Defining and managing policy set bindings

Policy set bindings contain platform specific information, like keystore, authentication information or persistent information, required by a policy set attachment. Use this task to create and manage bindings.

### About this task

In Version 7.0 and later, there are two types of bindings, application specific bindings and general bindings.

#### Application specific bindings

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

#### General bindings

General bindings were introduced in Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though

general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

**Important:** The general bindings that are shipped with the product are provider and client sample bindings. These bindings are initially set as the cell default bindings. Do not use these bindings in their current state in a production environment. To use the sample bindings, modify them to meet your security needs in a production environment. Alternatively, create a copy of the bindings and then modify the copy. For example, change the key and keystore settings to ensure security, and modify other settings to match your environment. You must also configure the username and password for Username or LTPA token authentication. See the topic *Configuring the username and password for WS-Security Username or LTPA token authentication* for more information.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

To view or work with your current policy sets bindings, perform the following:

## Procedure

1. To view your current policy set and application specific bindings from the administrative console, click **Services > Policy sets > Application policy sets > *policy\_set\_name* > Attached applications** and then click an application.

Depending on the application that you select, you can manage the bindings attached to the following policy sets:

- Service provider policy sets and bindings
- Service client policy sets and bindings

To learn more about managing the bindings attached to policy sets, see the service provider or service client policy sets and bindings information.

Sort on the **Attached policy set** column on either of the policy sets and bindings pages to select the service resources with the same policy set attached. Likewise, sort on the **Binding** column to select the service resources that share the same custom binding to attach to a different policy set. If you sort on the **Policy Set** or the **Binding** column, the hierarchical relationship of the service resources in the first column is not accurate. You can sort again on the **Application/Service/Endpoint/Operation** column to restore the hierarchical relationship. The entries in the **Application/Service/Endpoint/Operation** column display in ascending order.

2. To work with an existing bindings from the administrative console, click **Services > Policy sets > Application policy sets > *policy\_set\_name* > Attached applications**. Click an application name, and then click either the **Service provider policy sets and bindings** or the **Service client policy sets and bindings**. Then click a binding name in the Bindings column of the table.

**Note:** If no applications appear when you click **Attached applications**, you do not have any applications attached to the selected policy set. To attach a policy set and binding to an application using the administrative console, click **Applications > Enterprise Applications >**

*application name*. Then, click either **Service provider policy sets and bindings** or **Server client policy sets and bindings** to attach resources to your policy set and to assign bindings.

3. [Optional] To work with general bindings, click **Services > Policy sets > General client policy set bindings** or **Services > Policy sets > General provider policy set bindings**.

You can complete the following actions for general bindings:

- “Importing policy set bindings using the administrative console”
- “Export policy sets bindings settings” on page 2865
- “Defining and managing service client or provider bindings” on page 2861
- “Creating new or configuring existing general binding settings” on page 2864
- “Copy policy set binding settings” on page 2865
- “Deleting policy set bindings” on page 2866

## Results

When you finish this task, you would have performed one or more of the following:

- Created an application specific or general policy set binding
- Imported a policy set binding
- Exported a policy set binding
- Deleted a policy set binding
- Modified an application attachment to apply an application specific binding for single security domain
- Modified an application attachment to apply an application specific binding for multiple security domain

## Importing policy set bindings using the administrative console

You can import predefined client or provider policy set bindings using the administrative console.

### Before you begin

This task only applies to general client or provider bindings. Before you begin this task, review the defining and managing service client or provider bindings.

### About this task

The general bindings panel has an Import button to allow the import of client or provider policy set bindings. You can import a policy set binding by specifying the full path and filename of the binding to import.

### Procedure

1. Navigate to the General client policy set bindings or the General provider policy set bindings panel using one of the following ways:
  - **Services > Policy sets > General client policy set bindings**
  - **Services > Policy sets > General provider policy set bindings**
2. Click **Import**.
3. Specify the full path and file name of the policy set binding to import.
4. Select either **Use current binding name** or **Specify a different name to use for this binding**. If you are importing a binding and that binding name already exists in the repository, you must specify a different name to use for the binding import.
5. Click **OK**.

## Results

When you finish this task, you have been able to import a policy set binding using the administrative console.

## Example

If you have a policy set binding, XYZ\_psbind and you want to import it, perform the following steps:

1. From the General client or provider policy set bindings panel, click **Import**.
2. Specify the full path and file name of the policy set binding to import or use **Browse** to locate the binding in your file system.
3. Select either **Use current binding name** or **Specify a different name to use for this binding**.
4. Click **OK**.
5. Click **Save**, to save your changes to the configuration.

## What to do next

You can export a policy set binding to reuse it.

### ***Import policy set bindings settings:***

Use this page to specify a service client or provider policy set binding to import for your service.

Navigate to the General client policy set bindings or the General provider policy set bindings panel using one of the following ways:

- **Services > Policy sets > General client policy set bindings**
- **Services > Policy sets > General provider policy set bindings**

Click **Import**. Specify a fully qualified path and binding name that you want to use to import the policy set binding. The policy set binding file must be a compressed file.

*Full Path with file name:*

Specify a fully qualified path and file name to the policy set file or use the browse button to locate the file in your file system.

Select **Use current binding name** if you are not changing the binding name and click **OK**.

Select **Specify a different name for this binding** if you are changing the binding name. Provide a new name and click **OK**.

Button	Resulting action
OK	Imports the specified binding file if valid or returns an error if an incorrect file is provided. You are returned to the General client or provider policy set binding panel after the import.
Cancel	Returns you to the General client or provider policy set binding panel without importing a binding.

## Web services policy set bindings

A set of bindings is a named object that is associated with a specific policy set and service resource that is attached to the policy set.

Bindings contain environment and platform specific information, like the following types of information:

- Keys used for signature and encryption
- Keystore information
- Authentication information
- Persistent information

Typically, bindings are specific to the application or the platform, and they are not shared.

There are two types of bindings, application specific bindings and general bindings.

### Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and defined by the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

### General bindings

General bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they do not provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings > New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

### Important:

The sample general bindings that are shipped with the product are provider and client sample. Do not use these sample bindings in their current state in a production environment. However, if they were modified to contain non-sample data, you can use these sample bindings in a production environment.

You cannot assign a binding to a service provider resource that does not have a policy set or has an inherited attachment. To assign a binding to such a service provider resource, you

must first attach a policy set to the resource. Also, you cannot assign a binding to a service client resource that does not have an effective policy configuration or has an inherited policy attachment. To assign a binding to such a service client resource, you must first attach a policy set or specify the use of the provider policy.

## Defining and managing service client or provider bindings

Service client or provider bindings are general bindings. You can create, copy, and manage general bindings such as the client or provider policy set bindings. These bindings provide system-specific configuration and can be reused across policy set attachments.

### Before you begin

You cannot assign a binding to a service provider resource that does not have a policy set or has an inherited attachment. To assign a binding to such a service provider resource, you must first attach a policy set to the resource. Also, you cannot assign a binding to a service client resource that does not have an effective policy configuration or has an inherited policy attachment. To assign a binding to such a service client resource, you must first attach a policy set or specify the use of the provider policy. For more information, read about attaching a policy set to a service artifact.

### About this task

There are two types of bindings, application specific bindings and general bindings.

#### Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and defined by the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in an unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set.

#### General bindings

General bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they do not provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

**Important:** The general bindings that are included with the product are provider and client sample bindings. Do not use these bindings in their current state in a production environment. However, if they were modified to contain non-sample data, they could be used in a production environment.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

You can complete the following tasks to define and manage general client or provider policy set bindings.

## Procedure

1. To create a new general client or provider policy set binding or to manage the binding configuration from the administrative console, click **Services > Policy sets > General client policy set bindings > New**. You can also access this panel by clicking **Services > Policy sets > General provider policy set bindings > New**. Use the resulting detail panel to create a new client or provider policy set binding. For more information, read about creating new or configuring existing general binding settings.
2. To copy a specific policy set binding, select the binding name from the table and click **Copy**. For more information, read about copying a policy set binding settings.
3. To import a client or provider policy set binding, click **Import**. Read about importing policy set bindings using the administrative console to complete the import task.
4. To export a client or provider policy set binding, select the binding name from the table, and click **Export**. For more information, read about export policy set binding settings.
5. To delete a policy set binding, select the binding name from the table, and click **Delete**. For more information, read about deleting policy set bindings.

## Results

When you finish this task, you have created, copied, exported, imported or deleted a client or provider policy set binding.

### ***Service client or provider policy set bindings collection:***

Use this page to create, copy, and manage general policy set bindings, such as the service client or provider bindings. These bindings provide system-specific configuration, and can be reused across policy set attachments. You can select the general default bindings, create new general bindings, or use existing bindings for an attached policy set.

To view this administrative console page, click **Services > Policy Sets > General client policy set bindings**. You can also view this page by clicking **Services > Policy Sets > General provider policy set bindings**.

## About policy set bindings

There are two types of bindings, application specific bindings and general bindings.

### Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and defined by the characteristics of the defined policy. Application specific bindings can provide configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in an unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

## General bindings

General bindings were introduced in WebSphere Application Server Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings > New** in the general provider policy sets panel. Or, you can create general client policy set bindings by accessing **Services > Policy sets > General client policy set bindings > New** in the general client policy sets panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

### Important:

The sample general bindings that are shipped with the product are provider and client sample. Do not use these sample bindings in their current state in a production environment. However, if they were modified to contain non-sample data, you can use these sample bindings in a production environment.

You cannot assign a binding to a service provider resource that does not have a policy set or has an inherited attachment. To assign a binding to such a service provider resource, you must first attach a policy set to the resource. Also, you cannot assign a binding to a service client resource that does not have an effective policy configuration or has an inherited policy attachment. To assign a binding to such a service client resource, you must first attach a policy set or specify the use of the provider policy.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

*Name:*

Specifies the name of the service client or provider policy set binding.

The following list of buttons are available to create and manage service client or provider policy set bindings:

Button	Resulting Action
<b>New</b>	Creates a new client or provider policy set binding. This option accesses the New binding panel. The binding is empty initially; you must enter a name and an optional description for a new client or provider policy set binding.

Button	Resulting Action
<b>Delete</b>	Removes the selected client or provider general policy set binding. The default general bindings are being used as the default for a server or a security domain, including the global security domain. You cannot delete default bindings for global security or other security domains. An attempt to delete such default general binding generates an error message that the selected binding cannot be deleted because it is currently the default binding for a security domain.
<b>Copy</b>	Creates a modifiable copy of the selected client or provider policy set binding using a new name that you provide.
<b>Import</b>	Imports a client or provider policy set binding. This is a menu item with the option of importing a binding with the same name or providing a different name for the import.
<b>Export</b>	Exports the selected client or provider policy set binding to an archive file.

*Security Domain:*

Indicates which security domain uses the general policy set binding. The default domain is global security. This column in the collection table appears only when there are multiple security domains to which the binding can be scoped.

*Description:*

Specifies the user-defined description for the client or provider policy set bindings.

**Creating new or configuring existing general binding settings:**

Use this page to create a new client or provider policy set binding. You can also use this page to configure an existing general binding. Empty bindings will be deleted. Scoping a binding to a security domain constrains the configuration options to those applicable to that domain and limits use of the binding to the specified domain.

To view this administrative console page, click **Services > Policy sets > General client policy set bindings > New**. You can also view this page by clicking **Services > Policy sets > General provider policy set bindings > New**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

*Bindings configuration name:*

Specifies the name of the new binding configuration.

You must enter a binding configuration name to proceed. The name of the binding is automatically applied when you add a policy type and provide additional configuration information. At that time, the initial **Cancel** button is replaced with an **OK** button. Each binding that you add is initially empty, and you are directed to the binding configuration panel to provide additional information for the binding.

Button	Resulting Action
Add	Adds a policy type, such as WS-Security, to a new binding that you create or to an existing binding. You can access the configuration of each policy type binding through the policy type name link. If you click <b>Cancel</b> without providing any configuration information for the policy type, that policy type is not saved or included in the list of policy types. You might receive an attention message that the policy type was not saved as part of the binding configuration.

Button	Resulting Action
Delete	Deletes a policy type from the list.
OK	Associates the name of the binding to the policy type information after you add a policy type and provide additional configuration information.
Cancel	Returns you to the General client or provider policy set bindings panel without creating a new binding configuration.

*Security domain:*

This field is only available in a multiple security domain environment and specifies a valid security domain. You can scope the binding to that particular security domain, which is scoped to the global security domain by default.

*Description:*

Specifies a brief description of the new client or provider policy set binding.

### Export policy sets bindings settings

This task only applies to general client or provider bindings. Use this page to export either a client or provider policy set binding for reuse.

Navigate to the General client policy set bindings or the General provider policy set bindings panel using one of the following paths:

- **Services > Policy sets > General client policy set bindings**
  - **Services > Policy sets > General provider policy set bindings**
1. Select a binding from the list and click **Export**.
  2. Click the binding to download the archive file.
  3. Use the file dialog box to select a location for the exported binding. The policy set binding file is exported as a compressed file.
  4. Click **Done**.

### Copy policy set binding settings

Use this page to view and copy general policy set bindings for either a single security or a multiple security domain environment.

To access this administrative console page, perform the following steps:

1. Click **Services > Policy sets > General client policy set bindings**. You can also access this page by clicking **Services > Policy sets > General provider policy set bindings**.
2. Select an existing binding from the list, and click **Copy**.
3. Provide a name and description for the copy.
4. Click **OK**.
5. Click **Save**, to save your changes.

**Name:**

Specifies the name of copy. You must provide a different name for the copy of the binding configuration.

**Security domain:**

Specifies a valid security domain. This field is only available in a multiple security domain environment. You can scope the binding to a particular security domain; it is scoped to the global security domain by default.

### **Description:**

Specifies a brief description of the copy of the policy set binding.

### **Deleting policy set bindings**

Use this task to delete general policy set bindings using the administrative console.

### **About this task**

You cannot delete general bindings specified as the default for any server or domain. You also cannot delete general bindings that are assigned to a policy set attachment. To delete other bindings, perform the following steps:

### **Procedure**

1. Click **Services > Policy sets > General client policy set bindings**. You can also access this page by clicking **Services > Policy sets > General provider policy set bindings**.
2. Select an existing binding from the list, and click **Delete**.
3. Click **Save**, to save your changes.

### **Results**

When you finish this task, you have deleted a general policy set binding.

### **Creating application specific bindings for policy set attachment**

After you attach a policy set to a service artifact such as an application, service, or endpoint, you can define application specific bindings for the attached policy set.

### **Before you begin**

Before you can start this task, you must deploy an application containing web services, and attach a policy set. See attaching a policy set to a service artifact.

### **About this task**

The application specific binding panels display options based on the definitions in the attached policy set. For example, if the policy set does not have WS-ReliableMessaging configured, then the application specific binding panels do not display an option to configure WS-ReliableMessaging bindings. To create application specific bindings for an attached policy set, perform the following steps:

### **Procedure**

1. Open the administrative console.
2. To create application specific bindings for a service provider policy attachment, click **Applications > Application Types > WebSphere enterprise applications > *Service\_provider\_application\_instance* > Service provider policy sets and bindings**.  
To create application specific bindings for a service client policy attachment, click **Applications > Enterprise applications > *application\_name* > Service client policy sets and bindings**.
3. Select the check box for the service artifact with an attached policy set.
4. Click **Assign Binding** to see a list of available bindings to assign.
5. [Optional] Select a previously defined application specific attachment binding from the list.  
If you decide to create a new application specific binding, complete steps 6 through 9.
6. Click **New**.
7. Specify a name for the binding and select which policies that you want to include in this application specific binding. Click **Add**, and select the policies to add.

8. Complete the information for the specified policies to define associated configuration data.
9. Click **Save**, to save your changes to the master configuration.

## Results

When you finish this task, a application specific binding is created for the service artifact with the attached policy set.

## Example

You have the application, app1 with the attached policy set Username WSSecurity default, and you want to define application specific bindings. First locate the application in the **Applications > Application Types > WebSphere enterprise applications** collection. Click the **app1** application. You can then click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link. Select the check box for the app1 application where the policy set is attached. Click **Assign Binding** and click **New**. Specify a name for the binding, such as myBinding. Click **Add** and select **WS-Security** from the list. Next, click the link for **WS-Security** policy and complete the panels with the appropriate information. Click **Save**, to save your changes to the master configuration.

## What to do next

Restart the application that contains the service artifact with the application specific bindings you created.

## Setting server default bindings for policy sets

You can set server default bindings if you want the policy set attachments for service providers and clients that are deployed to the server to use bindings that are different than those that are specified for the cell. If you use multiple security domains, your default server bindings will also override the security domain default bindings.

## Before you begin

Before you can set server default bindings for your Java API for XML-Based Web Services (JAX-WS) application, you must first configure at least one general provider policy set binding or general client policy set binding. To define and manage these general bindings, use the administrative console and select **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings** .

## About this task

**Note:** In WebSphere Application Server Version 7.0 and later, the security model was enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0 and later, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings, and then select one of each binding type to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding

configuration by assigning the binding to each application deployed to the server or by setting default bindings for a security domain and assigning the security domain to one or more servers.

You can specify default bindings for your service provider or client that are used at the global security (cell) level, for a security domain, for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The following list is the order of precedence from lowest to highest that the application server uses to determine which default bindings to use:

1. Server level default
2. Security domain level default
3. Global security (cell) default

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify your global security (cell) default bindings, use the administrative console, and click **Services > Policy sets > Default policy set bindings**. For environments with multiple security domains, you can optionally choose the general provider and general client bindings that you want to use as the default bindings for a domain.

In addition to choosing default bindings for the global security (cell), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. This is only necessary if you want to use different default bindings for a particular server than those used by the other servers in the security domain or cell.

To choose the default bindings for a server from the administrative console, click **Servers > Server Types > WebSphere application servers > server\_name** and then under Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the global security (cell) are used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the global security (cell) default bindings. You cannot delete a binding that is used as part of any policy set attachment or specified as the default binding for server, a domain, or the cell. To learn more about defining default bindings for a server, see the server default bindings documentation.

**Note:**

If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server Version 6.1 level, this application is a V6.1 application. If you have applications that are deployed to V6.1 servers within the Version 7.0 or later application server environment, or you have V6.1 applications that are deployed to V7.0 or later versions of the application server, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to the bindings that are used by WebSphere Application Server V7.0 and later versions. Use the `upgradeBindings` command using the `wsadmin` tool to upgrade the bindings level, if the V6.1 application is not installed on WebSphere Application Server V6.1.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation

to learn more about the valid roles for the application server.

## Procedure

1. Open the administrative console.
2. To set default policy set bindings for your server, select **Servers > Server Types > WebSphere application servers > *server\_name* > Default policy set bindings**.
3. Select the server default provider binding.

If you specify a server default provider binding, the selected binding overrides the default provider bindings that are specified for the cell or the security domain to which the server is deployed. The default setting is **None**.

If multiple security domains are in use, the name of the security domain to which each binding is scoped displays beside the name of each available provider binding. Only the bindings that are scoped to the global security level or to the security domain to which the server is deployed are displayed.
4. Select the server default client binding.

If you specify a server default client binding, the selected binding overrides the default client bindings that are specified for the cell or the security domain to which the server is deployed. The default setting is **None**.

If multiple security domains are in use, the name of the security domain to which each binding is scoped displays beside the name of each available provider binding. Only the bindings that are scoped to the global security level or to the security domain to which the server is deployed are displayed.
5. Click **Apply** or **OK** to submit your changes.
6. Click **Save** to save your changes to the master configuration.
7. (optional) If you are using a Version 6.1 application, you can specify server V6.1 default policy set bindings. To set these bindings, select **Servers > Server Types > WebSphere application servers > *server\_name* > Default policy set bindings > Version 6.1 default policy set bindings**.

**Note:** Select the V6.1 default bindings for this server. If your application contains one or more application specific bindings that are configured at the WebSphere Application Server V6.1 level, this application is a V6.1 application. These default bindings are used for client and provider policy set attachments for applications that are deployed to V6.1 servers, and for V6.1 applications that are deployed to V7.0 and later servers. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding.

## Results

When you complete these steps, the server default bindings are defined and all policy set attachments that specify use of the default binding for your web service applications that are deployed to the server will use server level default bindings.

## Example

Suppose you have configured an application server, *server1*, and you have deployed several web service applications to the *server1* application server. Because these applications have similar security and quality of service requirements and you plan for them to share security configuration, you want to define the default bindings for policy set attachments to service providers and clients using the *server1*.

Suppose also that you want to modify the provided general provider binding, **Provider sample**. You can copy and modify this provided sample to take advantage of existing bindings.

1. Copy and modify the provided **Provider sample** and **Client sample** to meet your security and quality of service requirements. Include binding configuration for all policy types.

- Click **Services > Policy sets > General provider policy set bindings**. Select **Provider sample > copy**. Name the new general provider binding, MyServiceProviderbinding , and provide a description for the new binding.
  - Click **Services > Policy sets > General client policy set bindings**. Select **Client sample > copy**. Name the new general client binding, MyServiceClientbinding, and provide a description for the new binding.
2. Locate *server1* in the Application servers collection and click the instance. From the administrative console, select **Servers > Server Types > WebSphere application servers** , and click the *server1* instance.
  3. Click **Default policy set bindings**.
  4. Select the bindings that you want to use for your provider and client policy set attachments. In this example, select your customized general bindings, MyServiceProviderbinding and MyServiceClientbinding.
  5. Click **Apply** or **OK** to submit your changes.
  6. Click **Save** to save your changes to the master configuration.

Each time you attach a policy set to a service or client deployed to the *server1* application server, it is initially set to use the specified bindings.

## What to do next

After setting server default bindings, you can start deploying services to the server and start attaching policy sets. Alternatively, you might already have services deployed to the server, and the server is using the global default bindings because there is no server default binding. Now that you have set server default bindings, ensure that the server default bindings are used for the service messages as specified.

### **Server default binding settings:**

Use this page to specify the server default bindings if you want to override the default bindings that are specified for the cell (global security) or the security domain to which the server is deployed.

To view this administrative console page, complete the following actions:

1. Click **Servers > Server Types > WebSphere application servers > server\_name**.
2. From Security, click **Default policy set bindings**.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

### **Policy set bindings for servers**

To understand default policy set bindings, it is important to first understand policy set bindings.

Policy set bindings contain platform-specific information, such as keystore, authentication information or persistent information that is required by a policy set attachment. A policy set attachment is a policy set that is attached to an application resource. In WebSphere Application Server Version 7.0 and later, there are two types of bindings, general bindings and application specific bindings.

There are two types of general bindings, general service provider bindings and general service client bindings. You can configure one or more general service provider bindings and one or more general service client bindings across a range of policy sets. Additionally, you can re-use these general bindings across applications and for trust service attachments. To define and manage general bindings, in the administrative console click **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**. The general service provider and client bindings

have independent settings that you can customize to meet the needs of your environment. To learn more about general bindings, read about defining and managing policy set bindings.

You can create application specific bindings when you attach a policy set to an application resource. These bindings are specific to and defined to the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets. To assign application specific bindings to an application for service providers, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications > *application\_name* > Service provider policy sets and bindings > Assign Binding > New Application Specific Binding**. To assign application specific bindings to an application for service clients, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications > *application\_name* > Service client policy sets and bindings > Assign Binding > New Application Specific Binding**.

### Default policy set bindings for servers

**Note:** In WebSphere Application Server Version 7.0 and later, the security model was enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0 and later, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by assigning a security domain with a default binding to your server.

You can specify default bindings for your service provider or client that are used at the cell (global security) level, for a security domain, or for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The application server uses the following order of precedence, from lowest to highest, when determining which default bindings to use:

1. Server level default
2. Security domain level default
3. Cell (global security) default

The general bindings that are provided with the product are initially set as the cell (global security) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify a cell (global security) default bindings, in the administrative console click **Services > Policy sets > Default policy set bindings**. For environments with multiple security domains, you can optionally choose the

general provider and general client bindings that you want to use as the default bindings for a domain. To learn more about default policy set bindings for the cell (global security), see the default policy set bindings documentation.

In addition to choosing default bindings for the cell (global security), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. Use this page to choose the default bindings for a server from the administrative console. Click **Servers > Server Types > WebSphere application servers > server\_name** and then from Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the cell (global security) is used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the cell (global security) default bindings. You cannot delete a binding that has been selected as the default binding for server, a domain, or the cell. Before you delete the binding, you must select a different binding as the default or choose to use the defaults for the cell (global security).

**Note:**

If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server Version 6.1 level, this application is a V6.1 application. If you have applications that are deployed to V6.1 servers within the Version 7.0 or later application server environment, or you have V6.1 applications that are deployed to V7.0 or later versions of the application server, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to the bindings that are used by WebSphere Application Server V7.0 and later versions. Use the `upgradeBindings` command using the `wsadmin` tool to upgrade the bindings level, if the V6.1 application is not installed on WebSphere Application Server V6.1.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

*Server default provider binding:*

Specifies the default server binding. Select the name of the binding you want to use as the default for service providers deployed to this server.

If you are using multiple security domains, the name of the security domain to which the binding is scoped is specified with the name of the server default provider binding. Only bindings that are scoped to global security or to the security domain to which the server is assigned are available in the list.

**Note:** It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service provider binding has the necessary configuration for all policy types that you want to use.

*Server default client binding:*

Specifies the default client binding. Select the name of the binding you want to use as the default for service clients deployed to this server.

If you are using multiple security domains, the name of the security domain to which the binding is scoped is specified with the name of the server default client binding. Only bindings that are scoped to global security or to the security domain to which the server is assigned are available in the list.

**Note:** It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service client binding has the necessary configuration for all policy types that you want to use.

#### *Version 6.1 default bindings:*

If you have a Version 6.1 application that you want to use in the Version 7.0 and later application server environment and you want to specify Version 6.1 default bindings for this server, you can click this link to specify Version 6.1 default bindings.

#### **Server Version 6.1 default policy set bindings:**

Use this page to specify the server Version 6.1 default policy set bindings for this server. These default bindings are used for client and provider policy set attachments for applications that are deployed to Version 6.1 servers, and for Version 6.1 applications that are deployed to Version 7.0 servers. The default bindings are used for Version 6.1 attachments unless overridden at the attachment point.

To view this administrative console page, complete the following actions:

1. Click **Servers > Server Types > WebSphere application servers > *server\_name***
2. Under Security, click **Default policy set bindings**
3. Click **Version 6.1 default policy set bindings**

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

#### **Version 6.1 default policy set bindings**

You can install a WebSphere Application Server Version 6.1 Feature Pack for Web Services application within the WebSphere Application Server Version 7.0 and later environment. If your application contains Version 6.1 custom bindings, the application is defined as a Version 6.1 application to the application server. Additionally, if your application is installed on a WebSphere Application Server Version 6.1 Feature Pack for Web Services server within the WebSphere Application Server Version 7.0 and later environment, the custom binding is created as a Version 6.1 custom binding.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

#### *Bindings configuration name:*

Specifies the name of the policy set bindings configuration. This field is read-only for default policy set bindings.

<b>Button</b>	<b>Resulting action</b>
<b>Add</b>	Adds a policy to the collection.
<b>Delete</b>	Removes a policy from the collection.

#### **Setting default policy set bindings**

You can set provider and client default policy set bindings that are used as the global security default policy set bindings. The specified global security default bindings apply to all web services unless the bindings are overridden at the attachment point, at the server, or at a security domain.

#### **Before you begin**

You must first install and configure an application server. After the application server is installed, you must install a Java API for XML-Based Web Services (JAX-WS) application onto your server. Now, you are

ready to attach a policy set to the web service application. You can define and manage general service provider and client policy set bindings for your web service resource by using the administrative console.

## About this task

### Policy set bindings for servers

After you understand policy set bindings, then it is easier to understand how the default bindings are used.

Policy set bindings contain platform-specific information, such as keystore, authentication information or persistent information that is required by a policy set attachment. A policy set attachment is a policy set that is attached to an application resource. Starting with WebSphere Application Server Version 7.0 and later, there are two types of bindings, general bindings and application specific bindings.

There are two types of general bindings, *general service provider bindings* and *general service client bindings*. You can configure one or more general service provider bindings and one or more general service client bindings and then use them across a range of policy sets. Additionally, you can re-use these general bindings across applications and for trust service attachments. To define and manage general bindings, in the administrative console click **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**. The general service provider and client bindings have independent settings that you can customize to meet the needs of your environment.

You can create *application specific bindings* when you attach a policy set to a web service application resource. These bindings are specific to and defined by to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets. To assign application specific bindings to an application for service providers, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications > application\_name > Service provider policy sets and bindings**. Select a web service resource with an attached policy and click **Assign Binding > New Application Specific Binding**. To assign application specific bindings to an application for service clients, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications > application\_name > Service client policy sets and bindings**. Select a web services resource with an attached policy and click **Assign Binding > New Application Specific Binding**. You can additionally assign application specific bindings for service providers or service clients using the administrative console and click **Services > Service providers > application\_name** or **Services > Service clients > application\_name** and then select a web services resource with an attached policy and assign your bindings.

To learn more about general bindings or application specific bindings, read about defining and managing policy set bindings.

### Default policy set bindings

**Note:** In WebSphere Application Server Version 7.0 and later, the security model was enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0 and later, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding type to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also share binding configuration by either assigning the binding to each application that is deployed to the server or by setting default bindings for a security domain and assigning the security domain to one or more servers.

You can specify default bindings for your service provider or client that are used at the global security (cell) level, for a security domain, for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The following list is the order of precedence from lowest to highest that the application server uses to determine which default bindings to use:

1. Server level default
2. Security domain level default
3. Global security (cell) default

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify your global security (cell) default bindings, in the administrative console click **Services > Policy sets > Default policy set bindings**. For environments with multiple security domains, you can optionally choose the general provider and general client bindings that you want to use as the default bindings for a domain.

In addition to choosing default bindings for the global security (cell), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. This is only necessary if you want to use different default bindings for a particular server than those used by the other servers in the security domain or cell. To choose the default bindings for a server from the administrative console, click **Servers > Server Types > WebSphere application servers > server\_name** and then from Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the global security (cell) are used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the global security (cell) default bindings. You cannot delete a binding that is used as part of any policy set attachment or specified as the default binding for the server, a domain, or the cell. To learn more about defining default bindings for a server, see the server default bindings documentation.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

## Procedure

1. Open the administrative console.
2. To set global security default policy set bindings, select **Services > Policy sets > Default policy set bindings**.
3. Select the default service provider binding. The default service provider binding is used as the default for policy set attachments unless the provider or client binding is overridden at the attachment point, at the server, or at a security domain. The default setting is **Provider sample**.

4. Select the default service client binding. If you specify a default service client binding, the selected binding overrides the default bindings that are specified for the cell or the security domain to which the server is deployed. The default setting is **Client sample**.
5. If multiple security domains are enabled, you can view the default provider bindings and the default client bindings for each security domain that is defined in the security domain default bindings collection. You can select the security domain name link if you want to access the domain and select different default bindings. Additionally, you can select the default provider binding links or the default client binding links to access the default bindings and select different default binding settings.
6. Click **Apply** to apply selected bindings as the global default bindings.
7. Click **Save** to save your changes to the master configuration.
8. (optional) If you are using a Version 6.1 application, you can specify server V6.1 default policy set bindings. To set these bindings, select **Services > Policy sets > Default policy set bindings > Version 6.1 default policy set bindings**.

**Note:**

If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server Version 6.1 level, this application is a V6.1 application. If you have applications that are deployed to V6.1 servers within the Version 7.0 or later application server environment, or you have V6.1 applications that are deployed to V7.0 or later versions of the application server, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to the bindings that are used by WebSphere Application Server V7.0 and later versions. Use the upgradeBindings command using the wsadmin tool to upgrade the bindings level, if the V6.1 application is not installed on WebSphere Application Server V6.1.

## Results

When you complete these steps, you have defined your global security (cell) default policy set bindings and domain default policy set bindings, if applicable.

## Example

Suppose that you do not want to use the provided general provider binding, **Provider sample**, as your default service provider binding. To take advantage of existing bindings, you can copy and modify the **Provider sample** to meet your business needs. This example assumes that your server environment has SecurityDomain1 and SecurityDomain2 defined.

1. Copy and modify the provided **Provider sample** general service provider binding. Click **Services > Policy sets > General provider policy set bindings**. Select **Provider sample > copy**. Name the new general provider binding, MyServiceProviderbinding, and provide a description for the new binding.
2. Copy and modify the provided **Client sample** general service client binding. Click **Services > Policy sets > General client policy set bindings**. Select **Client sample > copy**. Name the new general client binding, MyServiceClientbinding, and provide a description for the new binding.
3. To specify the default policy set bindings for your global security (cell) and for your domains, click **Services > Policy sets > Default policy set bindings**. From this page, select MyServiceProviderbinding as the default service provider binding, and select MyClientProviderbinding as the default service client binding.
4. Click **Apply** and **Save** to save your changes to the master configuration.

Assigning a domain default binding is optional. Generally, you assign domain default policy set bindings only when you want the servers in the domain to use different default bindings than the rest of the cell. In this example, suppose you have defined another general provider binding, MyServiceProviderbinding2, and you want to specify this binding as the domain default binding for your SecurityDomain1 domain.

1. From the security domain default bindings collection click **SecurityDomain1 > Default policy set bindings**. From this page, you can select MyServiceProviderbinding2 as the service provider domain default binding.
2. Click **Apply** and **Save** to save your changes to the master configuration.

### ***Default policy set bindings collection:***

Use this page to specify the service provider and client default bindings. The specified service provider and client bindings are used at the cell (global security) level unless these specified bindings are overridden at the attachment point, at the server, or at a security domain.

To view this administrative console page, click **Services > Policy sets > Default policy set bindings**.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

### **Policy set bindings for servers**

To understand default policy set bindings, it is important to first understand policy set bindings.

Policy set bindings contain platform-specific information, such as keystore, authentication information or persistent information that is required by a policy set attachment. A policy set attachment is a policy set that is attached to an application resource. There are two types of bindings, general bindings and application specific bindings.

There are two types of general bindings, general service provider bindings and general service client bindings. You can configure one or more general service provider bindings and one or more general service client bindings across a range of policy sets. Additionally, you can re-use these general bindings across applications and for trust service attachments. To define and manage general bindings, in the administrative console click **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**. The general service provider and client bindings have independent settings that you can customize to meet the needs of your environment. To learn more about general bindings, read about defining and managing policy set bindings.

You can create application specific bindings when you attach a policy set to an application resource. These bindings are specific to and defined to the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets. To assign application specific bindings to an application for service providers, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications > *application\_name* > Service provider policy sets and bindings > Assign Binding > New Application Specific Binding**. To assign application specific bindings to an application for service clients, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications > *application\_name* > Service client policy sets and bindings > Assign Binding > New Application Specific Binding**.

### **Default policy set bindings for servers**

**Note:** In WebSphere Application Server Version 7.0 and later, the security model was enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default

bindings for each server. In Version 7.0 and later, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by assigning a security domain with a default binding to your server.

You can specify default bindings for your service provider or client that are used at the cell (global security) level, for a security domain, or for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The application server uses the following order of precedence, from lowest to highest, when determining which default bindings to use:

1. Server level default
2. Security domain level default
3. Cell (global security) default

The general bindings that are provided with the product are initially set as the cell (global security) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify a cell (global security) default bindings, in the administrative console click **Services > Policy sets > Default policy set bindings**. For environments with multiple security domains, you can optionally choose the general provider and general client bindings that you want to use as the default bindings for a domain. To learn more about default policy set bindings for the cell (global security), see the default policy set bindings documentation.

In addition to choosing default bindings for the cell (global security), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. Use this page to choose the default bindings for a server from the administrative console. Click **Servers > Server Types > WebSphere application servers > server\_name** and then from Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the cell (global security) is used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the cell (global security) default bindings. You cannot delete a binding that has been selected as the default binding for server, a domain, or the cell. Before you delete the binding, you must select a different binding as the default or choose to use the defaults for the cell (global security).

**Note:**

If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server Version 6.1 level, this application is a V6.1 application. If you have applications that are deployed to V6.1 servers within the Version 7.0 or later application server environment, or you have V6.1 applications that are deployed to V7.0 or later versions of the application server, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1

applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to the bindings that are used by WebSphere Application Server V7.0 and later versions. Use the `upgradeBindings` command using the `wsadmin` tool to upgrade the bindings level, if the V6.1 application is not installed on WebSphere Application Server V6.1.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

*Default service provider binding:*

Specifies the default service provider binding that is used as the default for policy set attachments. You can override this default at the attachment point or by a lower level default.

**Note:** It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service provider binding has the necessary configuration for all policy types that you want to use..

*Default service client binding:*

Specifies the default service client binding that is used as the default for policy set attachments. You can override this default at the attachment point or by a lower level default.

**Note:** It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service client binding has the necessary configuration for all policy types that you want to use.

*Security domain default bindings:*

Specifies a collection of security domain default bindings. This collection only displays if you are using multiple security domains.

If you are using multiple security domains, this collection displays the default client and provider bindings for each security domain. You can select the security domain name link if you want to access the domain and select different default bindings.

*Security domain:*

Specifies the name of a security domain.

*Default provider binding:*

Specifies the default service provider binding for the security domain. You can view the default provider binding settings by clicking on the name of default provider binding.

*Default client Binding:*

Specifies the default client binding for the security domain. You can view the default client binding settings by clicking on the name of default client binding.

*Version 6.1 default bindings:*

If you have a Version 6.1 application that you want to use in the Version 7.0 application server environment and you want to specify Version 6.1 default bindings for this server, you can click this link to specify Version 6.1 default bindings.

### **Version 6.1 default policy set bindings:**

Use this page to specify Version 6.1 default policy set bindings for the cell (global security). These bindings are used for both client and provider policy set attachments within Version 6.1 applications and attachments to service applications that are deployed to a Version 6.1 server. These default bindings are used for Version 6.1 attachments unless they are overridden at the attachment point or by a Version 6.1 server default binding.

To view this administrative console page when you are specifying Version 6.1 cell level default policy set bindings, complete the following actions:

1. Click **Services > Policy sets > Default policy set bindings**
2. Click **Version 6.1 default policy set bindings**

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

### **Version 6.1 default policy set bindings**

You can install a WebSphere Application Server Version 6.1 Feature Pack for Web Services application within the WebSphere Application Server Version 7.0 and later environments. If your application contains Version 6.1 custom bindings, the application is defined as a V6.1 application to the application server. Additionally, if your application is installed on a WebSphere Application Server Version 6.1 Feature Pack for Web Services server within the WebSphere Application Server Version 7.0 and later environments, the custom binding is created as a V6.1 custom binding.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

#### *Bindings configuration name:*

Specifies the name of the policy set bindings configuration. This field is read-only for default policy set bindings.

#### *Policies – HTTP transport:*

Links to the HTTP transport policy settings page where you define the HTTP transport settings. The HTTP features and HTTP connection policies are applied to outbound messages. The response listener policy is enforced on inbound messages.

#### *Policies – SSL transport:*

Links to the SSL transport policy configuration settings page where you define the SSL transport settings.

#### *Policies – WS-Addressing:*

Links to the configuration settings page for the WS-Addressing policy. In a network deployment environment, use this page to enable or disable workload management. Otherwise, you can attach the WS-Addressing policy set to service resources. No additional configuration is required.

#### *Policies – WS-ReliableMessaging:*

Links to the page where you configure the WS-ReliableMessaging bindings.

### *Policies – WS-Security:*

Links to the WS-Security policy set bindings settings page where the WS-Security binding are configured.

#### **Domain default bindings settings:**

Use this page to specify the default policy set bindings for this security domain.

To view this administrative console page, complete the following actions:

1. Click **Security domains** > *domain\_name*
2. From Web Services Bindings, click **Default policy set bindings**

Alternatively, you can view this administrative console page when multiple security domains are defined:

1. Click **Services** > **Policy sets** > **Default policy set bindings**>*domain\_name*
2. In the Security Domain Default Bindings collection, click *domain\_name*
3. From Web Services Bindings, click **Default policy set bindings**

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

#### *Domain default provider binding:*

Specifies the default provider binding for a specific security domain. You can specify None if you want to use the server or global default bindings for services deployed to this server. If you specify a server default binding, this binding takes precedence over the default bindings that are specified for the security domain to which the server is deployed. The name of the security domain to which each binding is scoped is displayed to the right of the name of the binding.

**Note:** It is a best practice to specify a binding that includes all of the policy types. This practice ensures that your default service provider binding has the necessary configuration for all policy types that you want to use.

#### *Domain default client binding:*

Specifies the default client binding for a specific security domain. You can specify None if you want to use the server or global default bindings for services deployed to this server. If you specify a server default binding, this binding will take precedence over the default bindings specified for the security domain to which the server is deployed. The name of the security domain to which each binding is scoped is displayed to the right of the name of the binding.

**Note:** It is a best practice to specify a binding that includes all of the policy types. This practice will ensure that your default client binding has the necessary configuration for all policy types that you want to use.

### **Modifying default bindings at the server or cell level for policy sets**

You can define default bindings for HTTP transport, JMS transport, Secure Sockets Layer (SSL) transport, WS-Addressing, WS-ReliableMessaging, and WS-Security policies.

#### **Before you begin**

To create or modify server default bindings, you must first install and configure an application server.

## About this task

You can modify default cell bindings that are delivered with the product. Default bindings are not linked to a particular policy set and they provide default settings that might be used for sharing configuration information across multiple applications.

You can create default bindings for individual application servers and customize those bindings to meet your requirements. The policy set bindings are optional. If a policy set binding is not defined at the server level, then the default cell level bindings are used. To modify these default bindings, complete the following steps:

### Procedure

1. Open the administrative console.
2. To see which bindings are defined as the defaults for the cell or server, click **Services > Policy sets > Default policy sets bindings**.  
After seeing which bindings are defaults, you can select and edit them from the General provider or General client policy set bindings pages.
3. To edit the default bindings, see “Setting default policy set bindings” on page 2873.

### Results

When you finish these steps, the default policy set bindings are modified. If you created default bindings at the server level, those default bindings are used instead of the default bindings at the cell level.

### What to do next

You can create application specific bindings for your policy sets. Read about creating application specific bindings for policy set attachments.

## Reassigning bindings to policy sets attachments

After you create a custom attachment binding, you can reassign that binding to another service artifact if necessary. You can reset a service artifact, such as an application, service, or endpoint to use the inherited bindings or default bindings.

### Before you begin

To reassign an application specific binding or a default binding, there must be an assigned binding for the service artifact.

## About this task

You can assign bindings to policy sets and other service artifacts. If you created a policy set and attached it to a service artifact, you can reassign the binding that was initially assigned to that policy set.

### Procedure

1. Open the administrative console.
2. To reassign a binding for your service provider, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Service provider policy sets and bindings**.  
To reassign a binding for your service client, click **Applications > Application Types > WebSphere enterprise applications > *application\_name* > Service client policy sets and bindings**.
3. Select the check box for the service artifact with an attachment binding.
4. Select **Assign Binding**.
5. Select the binding that you want to assign.

6. Click **Save**, to save your changes to the master configuration.

## Results

The service artifact now inherits the policy set bindings that are indicated in either the **Service provider policy sets and bindings** or **Service client policy sets and bindings** panel.

**Restriction:** Reassigning the binding for a service artifact only reassigns it for that service artifact and any inherited artifacts. It does not reassign the binding for other non-related and non-inherited attachments to the same policy set or to a different policy set.

## Example

If you have the application, app1 with an attached policy set Username WSSecurity default, and you want to define custom bindings, then perform the following steps:

1. Locate the application in the **Applications > Application Types > WebSphere enterprise applications > application\_name** collection.
2. Click the **app1** application.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link.
4. Select the check box for the **app1** application where the custom attachment binding is defined.
5. Click **Assign Binding** and select **New**.
6. Provide a name for the application specific bindings.
7. Add required policies to the new application specific bindings.
8. Configure the bindings.
9. Click **Save**, to save your changes to the master configuration.

## What to do next

Restart the application that contains the policy set where you reassigned the bindings.

## Policy set bindings settings

Use this page to view or define general, application specific, or trust service specific bindings configuration information for policies that you can associate with the selected policy set. This bindings configuration information is specific to a system. Use the links on this page to work with bindings for each specific policy.

To view this administrative console page when you are creating or editing a trust service specific binding, click **Services > Trust service > Trust service attachments**. Select a binding by clicking the binding name in the table if the binding has been assigned to an attachment. To create a new trust service specific binding, click **Assign binding > New Trust Service Specific Binding**.

To view this administrative console page when you are editing a general binding, click **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**.

To view this administrative console page when you are creating or editing an application specific binding, complete the following actions:

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains web services. The application must contain a service provider or a service client.
3. Click **Service provider policy sets and bindings** or **Service client policy sets and bindings** in the Web Services Properties section.

4. Select a binding by clicking the binding name in the table if the binding has been assigned to an attachment. You must have previously attached a policy set and assigned an application specific binding.
5. [Optional] To edit a default cell binding or default server binding, click either **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

### About Policy set bindings

Policy set bindings contain platform-specific information, like keystore, authentication information or persistent information, required by a policy set attachment. Each policy set attachment to a service provider or service client must have exactly one binding. When you create a policy set attachment, the general default bindings are used initially. When general bindings are used in association with a policy set attachment, the cell-level general bindings are applied at run time. If application server level bindings exist, the server-level general bindings override the cell-level definition. General bindings specify configuration for both service client and service provider attachments and the general bindings are not tailored to a specific policy set or application. When you define server-level general bindings, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP Transport, that you want to override the general binding and you must fully configure the bindings for each policy that you have added.

An application specific binding is a named binding that you create. Application specific bindings enable you to provide platform-specific configuration information for specific policy set attachments. When you create an application specific binding, the available binding configuration options are tailored to the definitions in the attached policy set. You can reuse application specific bindings for multiple service resources within an application. For example, if you create a trust service specific binding, that binding can be reused only for trust service attachments. When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP Transport, that you want to override the general binding and you must fully configure the bindings for each policy that you have added.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

#### ***Bindings configuration name:***

Specifies the name of the policy set bindings configuration. The binding name is not editable when you are editing a binding. When you are creating a new binding, you must specify the binding name.

**Note:** If you are running a Version 6.1 application, the Binding configuration name is displayed as Version 6.1 default policy set bindings.

Use the following actions to create, edit, or delete policy set bindings.

Button	Resulting action
Add	Adds the selected policy set binding to the application.
Delete	Removes the selected policy set binding from the application.

#### ***Policies – HTTP transport:***

Links to the HTTP transport policy configuration settings page where you define the HTTP transport settings. The HTTP features and HTTP connection polices are applied to outbound messages. The response listener policy is enforced on inbound messages.

***Policies – SSL transport:***

Links to the SSL transport policy configuration settings page where you define the SSL transport settings.

***Policies – JMS transport:***

Links to the JMS transport policy configuration settings page where you define the JMS transport settings.

***Policies – WS-Addressing:***

Links to the configuration settings page for the WS-Addressing policy. In a WebSphere Application Server, Network Deployment environment, use this page enable or disable workload management. Otherwise, you can attach the WS-Addressing policy set to service resources. No additional configuration is required.

***Policies – WS-ReliableMessaging:***

Links to the panel where the WS-ReliableMessaging bindings are configured.

***Policies – WS-Security:***

Links to the WS-Security policy set bindings settings page where the WS-Security bindings are configured.

***Policies – Custom properties:***

Links to the Custom properties policy set bindings settings page where the Custom properties bindings are configured. The CustomProperties binding is only supported for service clients.

**Web Services Addressing policy set binding**

Use this page to modify the endpoint reference binding for Web Services Addressing (WS-Addressing). The product enforces this binding on JAX-WS web service applications that use WS-Addressing. This panel applies only to the WebSphere Application Server, Network Deployment version of the product.

To view this administrative console page, click **Services > Policy Sets > Default policy set bindings > WS-Addressing**.

***Prevent workload management of referenced endpoints in clusters:***

By default, when an application uses the WS-Addressing API createEndpointReference(service, port) method to create an endpoint reference in a cluster environment, that endpoint reference is workload managed. Select this option to prevent the workload management of such endpoint references.

If you select this option, messages that are targeted at such an endpoint reference are always sent to the node on which the endpoint reference was created. This behavior is useful when the endpoint contains in-memory state that is held on a single node, for example, in Web Services Resource Framework (WS-RF) applications.

**Note:** Although the endpoint reference always represents the same endpoint, the state that is held at that endpoint is not reliable. If the node that is hosting the endpoint fails, the state might be lost. Note also that if the node fails, the endpoint reference is no longer valid.

<b>Data type</b>	Check box
<b>Default</b>	Cleared

## Range

### Cleared

Endpoint references that are created by the application in a cluster environment are workload managed.

### Selected

Endpoint references that are created by the application in a cluster environment are not workload managed.

## Attaching a policy set to a service artifact

Attach a policy set to a service artifact, such as an application, service, endpoint or operation, to define the quality of services that are supported. Policy sets can define the policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport.

### Before you begin

Before you can start this task, you must deploy an application containing web services. Also, if none of the default policy sets contain the necessary policy definitions, then you must create a custom policy set with the necessary definitions.

### About this task

Develop a web service that contains each of the necessary artifacts, and deploy your web services application into your application server instance. Now you can attach policy sets to your service artifacts, such as an application, service, or endpoint.

To attach a policy set to a service artifact, perform the following steps:

### Procedure

1. Open the administrative console.
2. To attach a policy set to a service provider, click **Applications > Enterprise applications > *application\_name* > Service provider policy sets and bindings**.  
To attach a policy set to a service client, click **Applications > Enterprise applications > *application\_name* > Service client policy sets and bindings**.
3. Select the check box for the service artifact.
4. Select **Attach** to display a list of available policy sets to attach. Select a policy set from the list.
5. Click **Save**, to save your changes to the master configuration.
6. [Optional] To see what attachments are defined for a given policy set, select **Services > Policy sets > Application policy sets > *policy\_set\_name* > Attached applications**.

### Results

When you finish these steps, a policy set is attached to the service artifact.

### Example

If you have the application, app1 and you want to attach the policy set, WSSecurity default, then perform the following steps:

1. Locate the app1 application in the **Applications > Enterprise applications** collection.
2. Click the **app1** application.

3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link.
4. Select the check box for the service artifact where the policy set is to be attached.
5. Click **Attach**. Select **WSecurity default** policy set.
6. Click **Save**, to save your changes to the master configuration.

## What to do next

You can create custom bindings for policy set attachments. Read about creating custom bindings for policy set attachments.

You can configure the service client or service provider to share their policies. Read about using WS-Policy to exchange policies in a standard format.

## Attached deployed assets collection

Use this page to view assets that are attached to a policy set, detach or replace a policy set.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name***.
2. Click **Attached deployed assets** link in the Additional Properties section.

### Name

Specifies a list of deployed assets. The deployed asset names that are displayed in the Name column are either attached explicitly to the specified policy set or have service resources attached to this policy set.

To alter the policy set that is attached to a deployed asset, select a deployed asset, and click a button to enable the following actions:

*Table 268. Button descriptions. Use the buttons to detach or replace policy sets.*

Button	Resulting action
<b>Detach Policy Set</b>	Detaches the current policy set from the selected deployed asset or deployed assets. This action also detaches any attached deployed asset service resources. This action does not detach other policy sets from the deployed asset or deployed asset service resources. To perform this action, select a resource in the <b>Name</b> column, and click <b>Detach Policy Set</b> . This action detaches the policy set from the selected asset.
<b>Replace Policy Set</b>	Displays a list of policy sets that can be attached to the selected deployed asset or deployed assets and any contained attached service resources. The policy set is replaced with the one selected. This action does not replace other policy sets that are attached to resources in the deployed asset that you select. To perform this action, select a resource in the <b>Name</b> column, and click <b>Replace Policy Set</b> . This action enables you to select a different policy set to attach to the selected deployed asset in place of the current policy set.

### Type

Specifies the type of deployed asset, such as a composition unit (CU) or a Java Platform, Enterprise Edition (Java EE) application.

## Managing policies in a policy set using the administrative console

When working with policy sets in the administrative console, you can customize the included policies to ensure message security. You can enable, disable, customize, add, or delete policies from a policy set. With your policy sets, you can define policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport. The policies for all but WS-Security are relatively straightforward to define.

## Before you begin

You can customize the policies for custom policy sets. The provided default policy sets cannot be edited. Make sure that you have created a copy of the default policy set or created a completely new policy set to specify the policies for this policy set.

## About this task

Customize policies associated with a policy set using the administrative console.

## Procedure

1. Click one of the following:
  - **Services > Policy sets > Application policy sets > *policy\_set\_name***
  - **Services > Policy sets > System policy sets > *policy\_set\_name***You can also click **Services > Policy sets > Application policy sets > New** or **Services > Policy sets > System policy sets > New**. Follow this path when you want to create a new policy set and the associated policy or policies.
2. Add a policy to a custom policy set. To do this, see “Adding policies to policy sets using the administrative console.”
3. Enable a policy for a custom policy set. To do this, see “Enabling policies for policy sets using the administrative console” on page 2933.
4. Optional: You can also disable a policy from a custom policy set. To do this, see “Disabling policies from policy sets using the administrative console” on page 2934.
5. Optional: You can also delete a policy from a custom policy set. To do this, see “Deleting policies from policy sets using the administrative console” on page 2889.

## Results

After you have customized your policies, the associated policy set can protect messages according to the policy or policies defined.

## What to do next

If the policy set you have modified is an attached policy set, restart all affected applications to pick up the changes you made. If the policy set is unattached, then no further action is required.

## Adding policies to policy sets using the administrative console

You can use the administrative console to add policies to policy sets. Adding and configuring policies to a policy set further defines the rules governing the policy set.

## Before you begin

Before adding a policy to a policy set, check that it is not listed as disabled in the **Policies** table. A disabled policy can be listed for the policy set and only need to be enabled to be included in the policy set. If this is the case, the policy does not need to be added and it is not available to be added.

## About this task

All policies are initially set to their default values. These values can be edited and the attributes changed using the administrative console.

## Procedure

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name*** or **Services > Policy sets > System policy sets > *policy\_set\_name***. This displays a listing of available policies in the

**Policies** table for the policy set selected. If you created a new policy set and did not copy and rename an existing policy set, this table might contain no policies and you must add them.

2. Add a policy. To add a policy not listed in the **Policies** table of the Policy set settings page, click the **Add** drop down button. This button displays a list of available policies that are not already listed in the **Policies** table and therefore not included in the policy set.
3. Click the policy to be added. The selected policy is added to the **Policies** table. Each policy you add has default settings that can be modified.

## Results

After you have added a policy, it is then included in the policy set.

## Example

If you were working on policy set ABC\_ps (that you created and it therefore has no policies associated with it) you would click the ABC\_ps name in the **Policy Sets** collection and then click the **Add** button in the **Policies** table on the **Policy set** settings window. The drop down list displays all available policies for you to choose from. You might decide you want to include the WS-Addressing and WS-Security policies for this policy set. You would select each of those from the list. Then, click the policy name in the table to edit the properties of these policies.

## What to do next

If the modified policy set is an attached policy set, restart all affected applications to apply the changes. If the policy set is unattached, then no further action is required.

## Deleting policies from policy sets using the administrative console

You can use the administrative console to delete policies from policy sets. Deleting the policy removes the policy that further defined the rules governing the policy set.

## Before you begin

Before deleting a policy from a policy set, be sure that you no longer want the policy to be available to the policy set. Otherwise, consider disabling it so that it is still available to the policy set but not currently associated with the policy set. You can disable the policy and leave it available for the policy set by clicking the **Select** button by the policy to be disabled and then clicking the **Disable** button. That policy (and any configuration changes you have made to it) is still available to the policy set but is not currently included in the policy set.

## About this task

To delete a policy from a policy set, use the administrative console.

## Procedure

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name*** or **Services > Policy sets > System policy sets > *policy\_set\_name***. The Policy set settings page displays a listing of available policies in the **Policies** table of the Policy set settings page for the policy set selected. If you created a new policy set and did not copy and rename an existing policy set, this table might contain no policies to delete.
2. Delete the policy from the policy set.
  - a. Click the **Select** box beside the policy that you want to delete in the **Policies** table of the Policy set settings page.
  - b. Click the **Delete** button.
3. Verify that you want to delete the selected policy from the policy set.

## Results

You have deleted the policy from the policy set.

## Example

If you have a policy set containing a policy that you no longer want included in that policy set, you have two options: disable it or delete it. In some cases, you might want to disable the policy if you have configured attributes for it that you might want to enable at a later time. You can disable the policy and leave it available for the policy set by clicking the **Select** button by the policy to be disabled and then clicking the **Disable** button. But for this example, you have decided that the policy WS-Addressing is no longer valid for your custom policy set ABC\_ps and you want to delete it. To delete it, click the **Select** button beside the WS-Addressing policy and then click **Delete**. Confirm that you want to delete the policy.

## What to do next

You can now add other policies to the policy set or enable or disable existing policies.

## Modifying policies using the administrative console

With your policy sets, you can define policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport. The policies for all but WS-Security are relatively straightforward to define.

## Before you begin

The provided default policy sets cannot be edited. You can create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

## About this task

Policies are associated with policy sets, so you can change an instance of a policy for a particular policy set.

## Procedure

1. Select the policy set containing the policy you want to modify. To customize the policies associated with a policy set, from the administrative console, click:
  - **Services > Policy sets > Application policy sets** > *policy\_set\_name*. Click a policy name in the Policies table.
  - Or **Services > Policy sets > System policy sets** > *policy\_set\_name*. Click a policy name in the Policies table.
2. Modify the settings. Depending on which Policy you choose, different settings can be modified.
3. [Optional] If the policy to be modified is not already in the Policies table, click **Add** and select a policy from the list to modify.
4. Save the changes you have made. Once you change the settings on a policy, you need to save the changes to return to the policy set.

## Results

The policy set configuration is saved with the selected modifications.

## Example

You have created a copy of the WSReliableMessaging persistent policy set and named it WSRM\_p1. You want to change the settings on the WSReliableMessaging policy that is included, by default, in the copy of

this policy set. So you click your WSRM\_p1 policy set from the Application policy sets window and then click the WSReliableMessaging policy from the Policies table. You can then alter the following settings:

#### **Standard**

The default setting is WSReliableMessaging 1.1.

#### **Deliver messages in the order that they were sent**

The default setting is false. Valid values are true or false.

#### **Quality of service**

The default is Unmanaged non-persistent

Save your changes and return to the Application policy sets window for the WSRM\_p1 policy set.

#### **What to do next**

You can use the policy set as you have configured or you can change the bindings, attach or detach the policy set from applications.

**Note:** Because this policy set specifies managed persistent quality of service, you have to define bindings to the service integration bus and messaging engine that you want to use to manage the WS-ReliableMessaging state. You can attach and bind a WS-ReliableMessaging policy set to a web service application by using the administrative console or the wsadmin tool.

#### ***Configuring the WS-ReliableMessaging policy:***

When working with policy sets in the administrative console, you can customize some policies.

#### **Before you begin**

This task assumes that you are working with a policy set to which the WS-ReliableMessaging policy has been added.

Do not edit the policies associated with the provided default policy sets. If you have to modify the reliable messaging policy settings, use a copy of a default policy set or create a new policy set.

At any stage - that is, before or after you have built your reliable web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

#### **About this task**

To configure the WS-ReliableMessaging policy for a given policy set, use the administrative console to complete the following steps:

#### **Procedure**

1. In the navigation pane, click **Services > Policy sets > Application policy sets > *policy\_set\_name* > WS-ReliableMessaging**. The “WS-ReliableMessaging settings” on page 2893 form is displayed.
2. Modify one or more of the following properties:

#### **Standard**

Select the WS-ReliableMessaging specification to use for reliable transmission of your messages. WS-ReliableMessaging Version 1.1 is the default value. Select the WS-ReliableMessaging specification to use for reliable transmission of your messages. WS-ReliableMessaging Version 1.1 is the default value. Details of the supported WS-ReliableMessaging specifications are available at the following web addresses:

- The WS-ReliableMessaging specification Version 1.0, February 2005.

- The OASIS WS-ReliableMessaging specification Version 1.1, February 2007.

**Note:** If you plan to invoke a .NET-based web service, you must select WS-ReliableMessaging Version 1.0.

### **Deliver messages in the order that they were sent**

Select this option if the sender of a request has to receive a response before it sends the next request, or if you want to enable transaction support for inbound (provider) message exchanges as described in “Providing transactional recoverable messaging through WS-ReliableMessaging” on page 3358, or if you want to marginally increase reliability as described in A message is not recovered after a server becomes unavailable, even with the managed persistent quality of service.

**Tip:** When you enable this option, WS-ReliableMessaging ensures that the messages are made available to the requester application in the order that they were sent. That is, if WS-ReliableMessaging cannot make a given message available, it will not make any subsequent messages available. However, the requester application must also poll for the messages in the order in which it is to receive them. For example:

- a. WS-ReliableMessaging makes message 1 available, then message 2, then message 3.
- b. The requester application uses asynchronous polling to deliberately poll for message 2, then message 3, then message 1. All three messages are available, so this polling out of order is successful.

Even though WS-ReliableMessaging is delivering the messages in the order that they were sent, the requester application is choosing to receive them out of order.

### **Quality of service**

Select the radio button for your required quality of service. The three choices are:

#### **Unmanaged non-persistent**

You can configure web service applications to use WS-ReliableMessaging with a default in-memory store. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. This quality of service is for single server only and does not work in a cluster. This quality of service is not supported on the z/OS platform.

#### **Managed non-persistent**

This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages. This option supports clusters as well as single servers.

#### **Managed persistent**

This quality of service for asynchronous web service invocations is recoverable. This option also uses a messaging engine and message store to manage the sequence state. Messages are persisted at the web service requester server and at the web service provider server, and are recoverable if the server becomes unavailable. Messages that have not been successfully transmitted when a server becomes unavailable can continue to be transmitted after the server restarts.

The default is unmanaged non-persistent.

**Note:** All three qualities of service are supported when applications are deployed to the application server. Thin client and client container applications use the first option only.

**Note:** In WebSphere Application Server Version 6.1, you could also configure whether to use the WS-MakeConnection protocol. This configuration option has now been removed from the administrative console panel, because the product now automatically determines whether WS-MakeConnection is used, based on the following criteria:

- Whether you are using WS-ReliableMessaging Version 1.0 or Version 1.1.
- Whether the requester supports WS-MakeConnection.
- Whether the message exchange protocol is synchronous or asynchronous.

3. Click **OK**.

4. Save your changes to the master configuration.

## Results

After you have customized the reliable messaging policy, the associated policy set uses this policy to help ensure reliable delivery of messages.

*WS-ReliableMessaging settings:*

For the WS-ReliableMessaging policy you can configure the version of the WS-ReliableMessaging standard that you want to use, the order in which messages are delivered, and the required quality of service (the reliability level) for message delivery. The product can enforce these policies on inbound messages and applies them to outbound messages.

To view this page in the console, click the following path: **Services > Policy sets > Application policy sets > *policy\_set\_name* > WS-ReliableMessaging**.

With WebSphere Application Server, you can use WS-ReliableMessaging with Java API for XML-Based Web Services (JAX-WS) web services applications that use a SOAP over HTTP binding. Select the WS-ReliableMessaging specification to use for reliable transmission of your messages. WS-ReliableMessaging Version 1.1 is the default value. Select the WS-ReliableMessaging specification to use for reliable transmission of your messages. WS-ReliableMessaging Version 1.1 is the default value. Details of the supported WS-ReliableMessaging specifications are available at the following web addresses:

- The WS-ReliableMessaging specification Version 1.0, February 2005.
- The OASIS WS-ReliableMessaging specification Version 1.1, February 2007.

**Note:** If you plan to invoke a .NET-based web service, you must select WS-ReliableMessaging Version 1.0.

Do not edit the policies associated with the provided default policy sets. If you have to modify the reliable messaging policy settings, use a copy of a default policy set or create a new policy set.

At any stage - that is, before or after you have built your reliable web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

*Standard:*

*Deliver messages in the order that they were sent:*

Select this option if the sender of a request has to receive a response before it sends the next request.

If you enable in-order delivery, you must also ensure that the requester application polls for the messages in the order in which it is to receive them. For more information, see “Configuring the WS-ReliableMessaging policy” on page 2891.

Specifying in-order delivery also marginally increases reliability if you are using the managed persistent quality of service.

*Quality of Service:* Select one of the following qualities of service:

#### **Unmanaged non-persistent - Tolerates network and remote system failures**

You can configure web service applications to use WS-ReliableMessaging with a default in-memory store. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. This quality of service is for single server only and does not work in a cluster. This quality of service is not supported on the z/OS platform. The default is Unmanaged Non-Persistent.

#### **Managed non-persistent - Tolerates system, network, and remote system failures, but state is discarded after messaging engine restart**

This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages. This option supports clusters as well as single servers.

#### **Managed persistent - Tolerates system, network, and remote system failures**

This quality of service for asynchronous web service invocations is recoverable. This option also uses a messaging engine and message store to manage the sequence state. Messages are persisted at the web service requester server and at the web service provider server, and are recoverable if the server becomes unavailable. Messages that have not been successfully transmitted when a server becomes unavailable can continue to be transmitted after the server restarts.

#### **Note:**

- All three qualities of service are supported when applications are deployed to the application server. Thin client and client container applications use the first option only.
- For the unmanaged non-persistent quality of service, the messages are stored only in memory. For both of the managed qualities of service, the messages are managed by a messaging engine and stored in a message store. You specify a binding to a bus and messaging engine on the “WS-ReliableMessaging policy binding” form. If your chosen quality of service is Unmanaged Non-Persistent, which does not use a binding to a messaging engine, then any binding that you specify is ignored.

*WS-ReliableMessaging policy binding:*

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. The managed qualities of service, managed persistent and managed non-persistent, are supported by the service integration bus. Use this page to select the bus and messaging engine to use for the reliable messaging protocol state.

To view this page in the console, click one of the following paths:

- **Services > Policy sets > Default policy set bindings > Version 6.1 default policy set bindings > WS-ReliableMessaging** (This is the default binding for client and provider policy set attachments within WebSphere Application Server Version 6.1 applications, and attachments to service applications that are deployed to a Version 6.1 server.)
- **Services > Policy sets > General provider policy set bindings > *provider\_policy\_set\_binding\_name* > WS-ReliableMessaging** (This binding is used for the specified provider policy set.)

- **Services > Policy sets > General client policy set bindings > *client\_policy\_set\_binding\_name* > WS-ReliableMessaging** (This binding is used for the specified client policy set.)

**Note:**

- You only have to specify a binding to a bus and messaging engine if you are using a managed quality of service. If your chosen quality of service is Unmanaged Non-Persistent, any binding that you specify is ignored. The quality of service is defined on the “WS-ReliableMessaging settings” on page 2893 form for your chosen policy set. For more information, see “Configuring the WS-ReliableMessaging policy” on page 2891.
- When many applications use the same messaging engine, it can impact performance. Factors to consider include the number of applications that are already binding to the messaging engine, the CPU utilization, and the message throughput. To improve performance for a single server configuration, create a new messaging engine to bind to your application.

*Bus name:*

Specifies a list of available service integration buses in the cell. Use the list to select a bus, or click **Manage buses, bus members, and messaging engines** to add a new bus. The bus that you add is selected for this binding configuration when you return to this panel.

*Messaging engine:*

Specifies a list of each bus member for the selected bus. Use the list to select a bus member, or click **Manage buses, bus members, and messaging engines** to add a new bus member. The bus member that you add is selected for this binding configuration when you return to this panel.

**Configuring the WS-Addressing policy:**

When working with policy sets in the administrative console, you can add and configure policies to enable standard addressing of web services.

**Before you begin**

You can specify policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

**About this task**

Adding a WS-Addressing policy enables the support for WS-Addressing. This support provides a standard way to address Web services and include addressing information in messages. Adding a WS-Addressing policy is equivalent to configuring the WSDL file for the web service to specify that WS-Addressing should be used.

To specify or configure the policies associated with a policy set, use the administrative console.

**Procedure**

1. In the navigation pane of the administrative console, click **Services > Policy sets > Application policy sets > *policy\_set\_name* > [Policies] WS-Addressing**. The WS-Addressing settings pane is displayed.
2. Select **WS-Addressing is mandatory** to specify that WS-Addressing information must be included in SOAP message headers. For servers, this setting means that the server returns a fault if it receives a message that does not contain a WS-Addressing header. For clients, this setting means that WS-Addressing headers are always added to SOAP messages. If you have enabled WS-Policy, this requirement is communicated between servers and clients that support WS-Policy.

3. In the **Messaging style** box, select the message exchange pattern to use:
  - **Synchronous and asynchronous**. The targeting of response messages is not restricted.
  - **Synchronous only**. Response messages must be targeted at the WS-Addressing anonymous URI.
  - **Asynchronous only**. Response messages must not be targeted at the WS-Addressing anonymous URI.
4. Click **OK**.
5. Save your changes to the master configuration.

## Results

After you have included the WS-Addressing policy in a policy set, the associated policy set uses this policy to address web services.

*WS-Addressing policy settings:*

Use this page to define the appropriate WS-Addressing policy assertions for this policy set.

To view this administrative console page, click **Services > Policy sets > Application policy sets > *policy\_set\_name* > [Policy] WS-Addressing**, when the policy set includes the WS-Addressing policy type.

You can configure the WS-Addressing policy type for both client-side and provider-side policy sets. If you enable WS-Policy, this configuration is communicated between servers and clients that support WS-Policy.

*WS-Addressing is mandatory:*

Specifies whether a WS-Addressing SOAP header is included on messages.

<b>Data type</b>	Check box
<b>Default</b>	Cleared
<b>Range</b>	<p><b>Cleared</b></p> <p>WS-Addressing is not mandatory. Servers will not generate a fault if they receive a message that does not contain a WS-Addressing header. Clients might not include WS-Addressing headers in SOAP messages, for example, if WS-Policy is enabled and the server does not specify that WS-Addressing is mandatory.</p> <p><b>Selected</b></p> <p>WS-Addressing is mandatory. Servers return a fault if they receive a message that does not contain a WS-Addressing header. Clients always include WS-Addressing headers in SOAP messages.</p>

*Messaging style:*

Specifies the messaging style supported by this policy set.

Use the radio buttons to configure the messaging style.

- Select **Synchronous and asynchronous** to specify that there is no restriction on the targeting of response messages.
- Select **Synchronous only** to specify that response messages must be targeted at the WS-Addressing anonymous URI. You might want to use this messaging style in the following situations:

- The SOAP headers are not signed, and WS-Security is not enabled. Specifying the synchronous message exchange pattern prevents the server sending messages to a third party, thereby preventing the server from potentially taking part in a Denial of Service attack.
- Clients with a NAT device between themselves and the endpoint. In this configuration, non-anonymous URIs cannot be routed. Use this setting to prevent the client from sending a message containing a ReplyTo endpoint reference with a non-anonymous URI.
- Select **Asynchronous only** to specify that response messages must not be targeted at the WS-Addressing anonymous URI. This setting does not mean that all non-anonymous URIs are supported, therefore a server can return a fault if it receives a response endpoint reference that it cannot process. You might want to use this messaging style if the endpoint has a very long-running invocation time, and you do not want to hold the connection open while waiting for a response.

The following table shows how the messaging style options correspond to WS-Policy assertions.

*Table 269. WS-Addressing messaging style and WS-Policy. This table provides a mapping between messaging style options and WS-Policy assertions.*

Messaging style	WS-Policy mapping
Synchronous and asynchronous	wsam:AnonymousResponses or wsam:NonAnonymousResponses
Synchronous only	wsam:AnonymousResponses
Asynchronous only	wsam:NonAnonymousResponses

**Required** No  
**Data type** Radio button

### **Configuring the HTTP transport policy:**

When working with policy sets in the administrative console, you can customize policies to ensure message security. You can customize the Hypertext Transfer Protocol (HTTP) transport policy configuration or use the policy as it is provided with the default settings.

### **Before you begin**

You can configure some settings for default policies for custom policy sets. The provided default policy sets cannot be edited. To customize a policy set, you must create a copy of the default policy set or create a new policy set and specify the policies for the custom policy set.

### **About this task**

You can configure HTTP transport with the HTTP transport policy. HTTP is an application-level protocol for distributed, collaborative, hypermedia information systems. It is a generic, stateless, protocol that can be used for many tasks beyond its use for hypertext, such as name servers and distributed object management systems, through extension of request methods, error codes and headers. A feature of HTTP is the typing and negotiation of data representation, allowing systems to be built independently of the data being transferred. HTTP features and HTTP connections properties are applied to outbound messages for both the service client and service provider.

You can only configure a policy through a policy set. Therefore, before you can configure the HTTP transport policy, a policy set must exist that contains the HTTP transport policy. The provided default WSHTTPS policy set is read only and it cannot be edited. To customize a policy set that contains the HTTP transport policy, you must first create a copy of the WSHTTPS default policy set or create a new policy set and add the HTTP transport policy to the new policy set.

**Note:** The WSHTTPS default policy set contains the HTTP transport policy, the SSL transport policy and WS-Addressing policy. If you do not require the SSL transport policy or the WS-Addressing policy, you can customize your copy of the WSHTTPS default policy set to delete the policies that you do not require.

After you have created a copy of the WSHTTPS default policy set or created a new policy set with the HTTP transport policy added, you can customize the HTTP transport policy. Use the HTTP transport policy settings panel to customize the values of the HTTP transport policy properties such as read or write timeout values. Your customized values for the HTTP transport policy now apply for your policy set that contains that custom HTTP transport policy. You can attach this policy set containing your customized HTTP transport policy to your Java API for XML-Based Web Services (JAX-WS) application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

For example, if you have multiple policy sets, *mypolicyset1* and *mypolicyset2*, containing the HTTP transport policy, you can customize the HTTP transport policy for each policy set to reflect different properties, such as timeout values. Now, you can attach these customized policy sets to one or more applications and these applications will use the HTTP property values associated with the HTTP transport policy that is contained within the attached policy set.

## Procedure

1. Create a policy set that contains the HTTP transport policy.
  - a. Create a custom policy set.

From the administrative console, click **Services > Policy Sets > Application policy sets** . From this panel you can create a new policy set, copy an existing default policy set such as WSHTTPS, import a copy of a policy set from the default repository or you can import an existing policy set from your specified location.
  - b. Add the HTTP transport policy to the policy set. From the administrative console, click **Services > Policy Sets > Application policy sets > policy\_set\_name**. In the policy collection, click **HTTP transport**. The HTTP transport window displays options for configuring the HTTP settings for the transport policy.
  - c. In the **Protocol Version** drop down list, click the HTTP version to use. HTTP 1.1 is the default setting but HTTP 1.0 is also available. Selecting HTTP 1.1 enables more of the function on the rest of the HTTP transport window as some of the options are not available for HTTP version 1.0.
  - d. Complete the HTTP Features section. The following check boxes determine which HTTP features are enabled for this transport:

### Session Enabled

Whether the HTTP session is enabled when a message is sent.

### Enable chunked transfer encoding

Whether chunked transfer encoding is enabled when a message is sent. This option is only available if HTTP 1.1 is selected in the **Protocol version** field (it is greyed out and disabled if HTTP 1.0 is selected).

### Send expect "100-request" header

Displays whether the expect "100-request" header is enabled when a message is sent. This option is only available if HTTP 1.1 is selected in the **Protocol version** field (it is greyed out and disabled if HTTP 1.0 is selected).

### Accept URL redirection automatically

Displays whether the URL is automatically redirected when a message is sent.

### Compress request content

Displays whether the request content is compressed when a message is sent.

**Compress response content**

Displays whether the response content is compressed when a message is sent.

- e. Complete the HTTP Connections section. The following fields determine how HTTP connections are configured for this transport:

**Read timeout**

Displays the length of time, in seconds, for the read to time out when a message is sent.

**Write timeout**

Displays the length of time, in seconds, for the write to time out when a message is sent.

**Connection timeout**

Displays the length of time, in seconds, for the connection to time out when a message is sent.

**Use persistent connection**

Displays whether a persistent connection is to be used when a message is sent. This option is only available if HTTP 1.1 is selected in the **Protocol version** field.

**Resend enabled**

Displays whether or not a message can be resent. Click this check box to enable a message to be sent again.

2. Customize the HTTP transport provider bindings.

- a. Navigate to the HTTP transport provider bindings. From the administrative console, click **Services > Policy Sets > General provider policy set bindings > *provider\_policy\_set\_binding\_name* > HTTP transport**.

The HTTP transport (bindings) window displays options for configuring the HTTP transport bindings.

- b. Specify the properties for the Proxy for outbound asynchronous service responses.

The following fields determine proxy specifications for outbound asynchronous service responses:

**Host** Displays the host name for the outbound asynchronous service responses proxy.

**Port** Displays the port number for the outbound asynchronous service responses proxy. You can enter or edit the port number.

**User name**

Displays the user name for the outbound asynchronous service responses proxy.

**Password**

Displays a placeholder for the password for the outbound asynchronous service responses proxy. You can enter or edit the password. The actual password is masked.

**Confirm password**

Displays a placeholder for the password for the outbound asynchronous service responses proxy that must match the one in the **Password** field. The actual password is masked.

- c. Specify the properties for the Basic authentication for outbound asynchronous responses.

The following fields determine authentication specifications for outbound asynchronous responses:

**User name**

Displays the user name for basic authentication of outbound asynchronous responses.

**Password**

Displays a placeholder for the password for basic authentication of outbound asynchronous responses. The actual password is masked.

**Confirm password**

Displays a placeholder for the password for basic authentication of outbound asynchronous responses that must match the one in the **Password** field. The actual password is masked.

3. Customize the HTTP transport client bindings.

- a. Navigate to the HTTP transport client bindings. From the administrative console, click **Services > Policy Sets > General client policy set bindings > *provider\_policy\_set\_binding\_name* > HTTP transport**.

The HTTP transport (bindings) window displays options for configuring the HTTP transport bindings.

- b. Specify the properties for the Proxy for outbound service requests. The following fields determine proxy specifications for outbound service requests:

**Host** Displays the host name for the outbound service request proxy.

**Port** Displays the port number for the outbound service request proxy.

**User name**

Displays the user name for the outbound service request proxy.

**Password**

Displays a placeholder for the password for the outbound service request proxy. The actual password is masked.

**Confirm password**

Displays a placeholder for the password for the outbound service request proxy that must match the one in the **Password** field. The actual password is masked.

- c. Specify the properties for Basic authentication for outbound service requests. The following fields determine authentication specifications for outbound service requests:

**User name**

Displays the user name for basic authentication of outbound service requests.

**Password**

Displays a placeholder for the password for basic authentication of outbound service requests. The actual password is masked.

**Confirm password**

Displays a placeholder for the password for basic authentication of outbound service requests that must match the one in the **Password** field. The actual password is masked.

## Results

After you have customized the HTTP transport policy, the associated policy set uses this policy to protect message transmission.

## Example

You can attach policy sets to an application, its services, endpoints, or operations. In this example scenario, suppose you have two different JAX-WS service clients for your application, but you want to use different HTTP transport property values for each service client. Specifically, you want to configure a different read or write timeout value for each service client. To modify the HTTP timeout values, you can edit the values of the HTTP transport policy that is contained within the policy set that is attached to your application or in this case, your service client. This change affects all applications to which the policy set containing the custom HTTP transport policy is attached.

This example describes the steps for configuring different read, write, and connection timeout values for service clients deployed in the same application server. This example makes the following assumptions:

- There are two JAX-WS service clients, `ServiceClient1` and `ServiceClient2`, that are deployed in the application server.
  - The HTTP transport policy has not been previously attached to these applications.
1. Create two new policy sets and add the HTTP transport policy to them. For example: *HTTPServiceClient1Policy* and *HTTPServiceClient2Policy*

- a. Click **Services > Policy sets > Application policy sets > New** .
  - b. Enter the name of the new application policy set, *HTTPServiceClient1Policy*.
  - c. From the Policies collection, click **Add > HTTP transport**.
  - d. Click **Apply** and **Save** to save your changes to the master configuration.
  - e. Repeat these steps to create the *HTTPServiceClient2Policy*.
2. Customize the HTTP transport policy settings for the newly created *HTTPServiceClient1Policy* and *HTTPServiceClient2Policy* policy sets. For example, customize the read and write timeout values for the HTTP transport policy contained in the *HTTPServiceClient1Policy* policy set and the connection timeout value for the HTTP transport policy contained in the *HTTPServiceClient2Policy* policy set.
    - a. Click **Services > Policy sets > Application policy sets > HTTPServiceClient1Policy** .
    - b. From the Policies collection, click **HTTP transport**.
    - c. From the HTTP transport policy configuration panel, change the HTTP connection read and write timeout values to 500 seconds.
    - d. Click **Apply** and **Save** to save your changes to the master configuration.
    - e. Click **Services > Policy sets > Application policy sets > HTTPServiceClient2Policy** .
    - f. From the Policies collection, click **HTTP transport**.
    - g. From the HTTP transport policy configuration panel, change the HTTP connection timeout value to 360 seconds.
    - h. Click **Apply** and **Save** to save your changes to the master configuration.
  3. Attach the custom HTTP transport policy, *HTTPServiceClient1Policy*, to your application, *ServiceClient1*. Similarly, attach the custom HTTP transport policy, *HTTPServiceClient2Policy*, to *ServiceClient2*.
    - a. Click **Services > Service clients > ServiceClient1**.
    - b. From the Policy set attachments collection, select the service, *ServiceClient1*.
    - c. Click **Attach Client Policy Set** and click on *HTTPServiceClient1Policy*.
    - d. Click **Save** to save your changes to the master configuration.
    - e. Click **Services > Service clients > ServiceClient2**.
    - f. From the Policy set attachments collection, select the service, *ServiceClient2*.
    - g. Click **Attach Client Policy Set** and click on *HTTPServiceClient2Policy*.
    - h. Click **Save** to save your changes to the master configuration.

As a result, the *ServiceClient1* application now has the *HTTPServiceClient1Policy* attached and the HTTP sessions will use a read and write timeout value of 500 seconds. The *ServiceClient2* application has the *HTTPServiceClient2Policy* attached and the HTTP sessions will use a connection timeout value of 360 seconds.

## What to do next

You can customize policies to ensure message security by configuring the SSL transport policy.

*HTTP transport policy settings:*

Use this page to define HTTP transport policy configuration. HTTP features and HTTP connection policies are applied to outbound messages. Any changes to the HTTP transport policy from this console page affects all Java API for XML-Based Web Services (JAX-WS) applications to which this custom HTTP transport policy is attached.

To view this administrative console page, click **Services > Policy sets > Application policy sets > *policy\_set\_name* > HTTP transport**, where *policy\_set\_name*, applies to any policy set that contains HTTP transport policy.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

You can only configure a policy through a policy set. Therefore, before you can configure the HTTP transport policy, a policy set must exist that contains the HTTP transport policy.

The WSHTTPS default policy set is provided with the application server and it contains the HTTP transport policy, the SSL transport policy and the WS-Addressing policy. The provided default WSHTTPS policy set is read only and it cannot be edited. To customize a policy set that contains the HTTP transport policy, you must first create a copy of the WSHTTPS default policy set or create a new policy set and add the HTTP transport policy to the new policy set.

After you customize values for the HTTP transport policy, these values now apply for your policy set that contains that custom HTTP transport policy. You can attach this policy set that contains your customized HTTP transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

*Protocol version:*

Specifies the version of HTTP protocol to use. Use this list to specify the version of HTTP protocol. The default value is HTTP 1.1. The HTTP 1.0 value is also a valid option.

Some of the remaining options on the HTTP Transport panel only work with HTTP Version 1.1. The following brief descriptions compare these options:

**HTTP 1.0**

Allows messages to be in MIME-like format, containing meta information about the data transferred and modifiers on the request, response, or both. However, HTTP 1.0 does not sufficiently address the effects of hierarchical proxies, caching, the need for persistent connections, or virtual hosts.

**HTTP 1.1**

Enables each of two communicating applications to determine the true capabilities of the other. This protocol includes more stringent requirements than HTTP 1.0 to ensure reliable implementation of features.

*Session enabled:*

Specifies whether the HTTP session is enabled when a message is sent. Select this check box to enable an HTTP session.

If this property is used within a policy set that is attached to a service client, then it indicates whether HTTP session information is propagated to subsequent requests invoked by the same client application. If the property is enabled, the HTTP session information is returned to the service client in a response message is sent in subsequent requests invoked using the same RequestContext object.

If this property is used within a policy set that is attached to a service provider, then it indicates whether or not a new HTTP session is created when a request is being processed. If the property is enabled, then as a request is being processed, a new HTTP session is created if one does not already exist. This HTTP session information is then returned to the service client in the response message.

*Enable chunked transfer encoding:*

Specifies whether chunked transfer encoding is enabled when a message is sent. Select this check box to enable a chunked transfer encoding. This option is only available if you select HTTP 1.1 in the **Protocol version** field. This option is disabled if you selected the HTTP 1.0 protocol.

The default for this property is true.

*Send expect "100-request" header:*

Specifies whether the expect "100-request" header is enabled when a message is sent. Select this check box to enable the expect "100-request" header. This option is only available if you selected HTTP 1.1 in the **Protocol version** field. This option is disabled if you selected the HTTP 1.0 protocol.

The purpose of the 100 status is to allow a client that is sending a request message with a request body to determine if the origin server accepts the request, based on the request headers, before the client sends the request body. In some cases, you might not want the client to send the body if the server rejects the message without looking at the body.

The Expect request-header field is used to indicate that particular server behaviors are required by the client. A server that cannot comply with any of the expectation values in the Expect field if a request responds with an appropriate error status.

*Accept URL redirection automatically:*

Specifies whether the automatic URL redirection is accepted when a message is sent. Select this check box to enable a URL that has been automatically redirected to be accepted.

*Compress request content:*

Specifies whether the request content is compressed when a message is sent. Content coding is used to allow a document to be compressed without losing the identity of its underlying media type and without loss of information. Select this check box to enable request content that you want to compress. Clicking the Compress request content button enables the **Compression format** option to select the compression method. The default value for the compression format is gzip.

*Compress response content:*

Specifies whether the response content is compressed when a message is sent. Content coding is used to allow a document to be compressed without losing the identity of its underlying media type and without loss of information. Select this check box to enable response content that you want to compress. Clicking the Compress response content button enables the **Compression format** option as the compression method. The default value for the compression format is gzip.

*Read timeout:*

Specifies the length of time, in seconds, for the Web services client to completely read the SOAP response. If the read process does not complete within the specified time, a SOAP fault error is generated on the client machine.

*Write timeout:*

Specifies the length of time, in seconds, for the write action to time out when a message is sent. Specify the time, in seconds, to enable the write to time out length of time.

*Connection timeout:*

Specifies the length of time, in seconds, for the connection to time out when a message is sent. Specify the time, in seconds, to enable the connection to time out length of time.

*Use persistent connection:*

Specifies whether a persistent connection is used when a message is sent. Select this check box to enable use of a persistent connection. This option is only available if you selected HTTP 1.1 in the **Protocol version** field. This option is disabled if you selected the HTTP 1.0 protocol.

*Resend enabled:*

Specifies whether a message can be resent. Select this check box to resend a message.

*HTTP transport bindings settings:*

Use this page to define the HTTP transport bindings for the HTTP transport policy.

To configure the HTTP transport bindings for the HTTP transport policy, perform the following:

1. Navigate to the general bindings collection panel using either the **Services > Policy sets > General client policy set bindings** or **Services > Policy sets > General provider policy set bindings** path.
2. Click a general binding in the Name column.
3. Click the **HTTP transport** policy in the Policies table.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

**Important:** You can also configure HTTP transport properties such as read or write timeout values for JAX-WS applications that are deployed in the same application server. If you want to customize these HTTP properties, you must edit the HTTP transport policy. To customize the HTTP transport policy settings, click **Services > Policy sets > Application policy sets > *policy\_set\_name* > HTTP transport policy** where *policy\_set\_name* applies to any policy set that contains the HTTP transport policy. Your customized values for the HTTP transport policy now apply for your policy set that contains that custom HTTP transport policy. You can attach this policy set that contains your customized HTTP transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

*Proxy for outbound service requests – Host:*

Specifies the host name for the outbound service request proxy. In this field, you can change the name of the host if you are editing an existing set of application specific bindings or you can enter the host name for the outbound service request proxy.

*Proxy for outbound service requests – Port:*

Specifies the port number for the outbound service request proxy. You can edit an existing port number, or enter a new port number for the outbound service request proxy in this field.

*Proxy for outbound service requests – User name:*

Specifies the user name for the outbound service request proxy. Enter a user name in this field.

*Proxy for outbound service requests – Password:*

Specifies a placeholder for the outbound service request proxy password. The actual password is masked.

*Proxy for outbound service requests – Confirm password:*

Specifies a placeholder for the outbound service request proxy password. Re-enter the password you entered in the **Password** field. The actual password is masked.

*Basic authentication for outbound service requests – User name:*

Specifies the user name for basic authentication of outbound service requests. Enter or edit the user name.

*Basic authentication for outbound service requests – Password:*

Specifies a placeholder for basic authentication of outbound service requests password. The actual password is masked.

*Basic authentication for outbound service requests – Confirm password:*

Specifies a placeholder for basic authentication of outbound service requests password. Re-enter the same password as in the **Password** field. The actual password is masked.

*Proxy for outbound asynchronous service responses – Host:*

Specifies the host name for the outbound asynchronous service responses proxy. You can enter or edit the host name.

*Proxy for outbound asynchronous service responses – Port:*

Specifies the port number for the outbound asynchronous service responses proxy. You can enter or edit the port number.

*Proxy for outbound asynchronous service responses – User name:*

Specifies the user name for the outbound asynchronous service responses proxy. You can enter or edit the user name.

*Proxy for outbound asynchronous service responses – Password:*

Specifies a placeholder for the outbound asynchronous service responses proxy password. You can enter or edit the password. The actual password is masked.

*Proxy for outbound asynchronous service responses – Confirm password:*

Specifies a placeholder for the outbound asynchronous service responses proxy password. You can re-enter or edit the password. The actual password is masked.

*Basic authentication for outbound asynchronous service responses – User name:*

Specifies the user name for basic authentication of outbound asynchronous responses. You can enter or edit the user name.

*Basic authentication for outbound asynchronous service responses – Password:*

Specifies a placeholder for basic authentication of outbound asynchronous responses password. You can enter or edit the password in this field. The actual password is masked.

*Basic authentication for outbound asynchronous service responses – Confirm password:*

Specifies a placeholder for basic authentication of outbound asynchronous responses password. Re-enter the password in this field. The actual password is masked.

*Custom Properties – Name:*

Specifies the name of custom property. Custom properties are not initially displayed in this column until you define them.

#### *Custom Properties – Value:*

Specifies the value of the custom property. With the **Value** entry field, you can enter, edit, or delete the value for a custom property.

Click one of the following buttons to enable the action described:

<b>Button</b>	<b>Resulting Action</b>
<b>New</b>	Creates a new custom property entry. To add a custom property, enter the name and value.
<b>Delete</b>	Removes the selected custom property.
<b>Edit</b>	You can edit a selected custom property. It is only displayed when one or more properties exist.

### ***Configuring the Java Message Service (JMS) transport policy:***

You can define a Java Message Service (JMS) transport policy configuration if you are using SOAP over JMS with your Java API for XML-Based Web Services (JAX-WS) applications.

#### **Before you begin**

You can configure some settings for policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a new policy set in order to specify the policies for it.

#### **About this task**

When using the SOAP over JMS transport with JAX-WS applications, you can customize the transport by configuring the JMS transport policy. The SOAP over JMS transport provides an alternative to HTTPS for transporting SOAP requests and response messages between clients and servers. See the documentation on using SOAP over JMS to transport web services to learn more about this transport protocol.

You can only configure a policy through a policy set. Therefore, before you can configure the JMS transport policy, a policy set must exist that contains the JMS transport policy. To customize a policy set that contains the JMS transport policy, you must first create a policy set and add the JMS transport policy to the new policy set.

Use the JMS transport policy settings panel to customize the values of the JMS transport policy properties, such as the request timeout value. Your customized values for the JMS transport policy now apply for your policy set that contains that custom JMS transport policy. You can attach this policy set containing your customized JMS transport policy to your JAX-WS application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

#### **Procedure**

1. Create a policy set that contains the JMS transport policy.
  - a. Create a custom policy set. From the administrative console, click **Services > Policy Sets > Application policy sets**. From this panel you can create a new policy set, import a copy of a policy set from the default repository, or you can import an existing policy set from your specified location.

- b. Add the JMS transport policy to the policy set. From the administrative console, click **Services > Policy Sets > Application policy sets > *policy\_set\_name***. In the policy collection, click **JMS transport**. The JMS transport window displays options for configuring the JMS settings for the transport policy.
- c. Specify the JMS connection properties for the JMS transport requests. The following fields configure the JMS features for this transport:

**Request timeout**

Specifies whether to enable a request timeout value. The request timeout value is the amount of time that the client waits for a response after sending the request to the server. The range is from 0 to 2147483647.

**Allow transactional messaging for one-way and asynchronous operations**

Specifies to enable a client to use transactions in one-way or asynchronous two-way requests. Select this check box to enable transactional messaging.

When this option is selected, the client runtime environment exchanges SOAP request and response messages with the server over the JMS transport in a transactional manner if the client is operating under a transaction. This process indicates that the clients transaction is used to send the SOAP request message to the destination queue or topic, and the server receives the request message only after the client commits the transaction. Similarly, the server receives the request message under the control of a container-managed transaction and sends the reply message, if applicable, back to the client using that same transaction. The client then receives the reply message only after the server transaction has been committed.

If this option is not selected, then the client and server runtime environments perform messaging operations in a non-transactional manner as transactions are temporarily suspended for the JMS request. The transactions are enabled again after the request has completed.

**Note:** Transactional messaging operations are not supported for two-way synchronous operations as this leads to a deadlock condition.

2. Customize the JMS transport provider bindings.
  - a. Navigate to the JMS transport provider bindings. From the administrative console, click **Services > Policy Sets > General provider policy set bindings > *provider\_policy\_set\_binding\_name* > JMS transport**.

The JMS transport provider bindings window displays options for defining basic authentication for asynchronous service responses and custom properties for the JMS service provider binding configuration.

- b. Specify the properties for basic authentication for asynchronous service responses.

You can use the JMS transport provider policy bindings to configure a service that uses the JMS transport to send asynchronous response messages back to the client. The application server runtime environment uses the user name and password that you configure when connecting to the JMS messaging provider and this configuration enables the service to send an asynchronous response message to the client in a secure manner.

The following fields determine the authentication requirements for responses from the server:

**User name**

Specifies the user name for the asynchronous service responses for the service provider.

**Password**

Specifies a placeholder for the password for the asynchronous service responses from the service provider. You can enter or edit the password in this field. The actual password is masked.

### **Confirm password**

Specifies a placeholder for the password for the asynchronous service responses from the service provider that must match the one in the **Password** field. The actual password is masked.

### 3. Customize the JMS transport client bindings.

- a. Navigate to the JMS transport client bindings. From the administrative console, click **Services > Policy Sets > General client policy set bindings > *client\_policy\_set\_binding\_name* > JMS transport**.

The JMS transport provider bindings window displays options for defining basic authentication for outbound service requests and custom properties for the JMS client binding configuration.

- b. Specify the Basic Authentication for Outbound Service Requests properties.

You can use the JMS transport client policy bindings to configure a client that uses the JMS transport to send a request message to the server. The client runtime environment uses the user name and password that you configure when connecting to the JMS messaging provide. This configuration enables the client to send the request message to the server in a secure manner.

The following fields determine the authentication requirements for requests sent to the server:

#### **User name**

Specifies the user name that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. Enter a user name in this field.

#### **Password**

Specifies a placeholder for the password that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. You can enter or edit the password in this field. The actual password is masked.

#### **Confirm password**

Specifies a placeholder for the password that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. Re-enter the password in this field. This password must match the one in the **Password** field. The actual password is masked.

## **Results**

After you have customized the JMS transport policy, the associated policy set uses this policy to configure the runtime behavior of the SOAP over JMS transport.

## **Example**

You can attach policy sets to an application, its services, endpoints, or operations. In this example scenario, suppose you have two different JAX-WS service clients for your application, but you want to use different JMS transport request timeout values for each service client. To modify the JMS request timeout values, you can edit the values of the JMS transport policy that is contained within the policy set that is attached to your application or in this case, your service client. This change affects all applications to which the policy set containing the custom JMS transport policy is attached.

This example describes the steps for configuring different request timeout values for service clients deployed in the same application server. This example includes the following assumptions:

- Two JAX-WS service clients exist, *ServiceClient1* and *ServiceClient2*, that are deployed in the application server.
- The JMS transport policy has not been previously attached to these applications.

1. Create two new policy sets and add the JMS transport policy to them. For example:

*JMSServiceClient1Policy* and *JMSServiceClient2Policy*

- a. Click **Services > Policy sets > Application policy sets > New** .
  - b. Enter the name of the new application policy set, `JMSServiceClient1Policy`.
  - c. From the Policies collection, click **Add > JMS transport**.
  - d. Click **Apply** and **Save** to save your changes to the master configuration.
  - e. Repeat these steps to create the `JMSServiceClient2Policy`.
2. Customize the JMS transport policy settings for the newly created `JMSServiceClient1Policy` and `JMSServiceClient2Policy` policy sets. For example, set the request timeout value to 180 seconds for the JMS transport policy contained in the `JMSServiceClient1Policy`. The JMS transport policy contained in the `JMSServiceClient2Policy` specifies 300 seconds as the request timeout value.
    - a. Click **Services > Policy sets > Application policy sets > JMSServiceClient1Policy** .
    - b. From the Policies collection, click **JMS transport**.
    - c. From the JMS transport policy configuration panel, specify 180 seconds for the request timeout value.
    - d. Click **Apply** and **Save** to save your changes to the master configuration.
    - e. Click **Services > Policy sets > Application policy sets > JMSServiceClient2Policy** .
    - f. From the Policies collection, click **JMS transport**.
    - g. From the JMS transport policy configuration panel, specify 300 seconds for the request timeout value.
    - h. Click **Apply** and **Save** to save your changes to the master configuration.
  3. Attach the custom JMS transport policy, `JMSServiceClient1Policy`, to your application, `ServiceClient1`. Similarly, attach the custom JMS transport policy, `JMSServiceClient2Policy`, to `ServiceClient2`.
    - a. Click **Services > Service clients > ServiceClient1**.
    - b. From the Policy set attachments collection, select the service, `ServiceClient1`.
    - c. Click **Attach Client Policy Set**, and click `JMSServiceClient1Policy`.
    - d. Click **Save** to save your changes to the master configuration.
    - e. Click **Services > Service clients > ServiceClient2**.
    - f. From the Policy set attachments collection, select the service, `ServiceClient1`.
    - g. Click **Attach Client Policy Set**, and click `JMSServiceClient2Policy`.
    - h. Click **Save** to save your changes to the master configuration.

As a result, the `ServiceClient1` application now has the `JMSServiceClient1Policy` attached, and the JMS sessions use a request timeout of 180 seconds. The `ServiceClient2` application has the policy, `JMSServiceClient2Policy`, attached and the JMS sessions use a request timeout of 300 seconds.

## What to do next

You can customize other policies that you might need for your application.

### *JMS transport policy settings:*

Use this page to configure settings for the Java Message Service (JMS) transport policy. You can configure a client that is using the JMS transport policy to exchange request and response messages with the server.

To view this administrative console page:

1. Click **Services**, expand **Policy sets**, and click **Application policy sets**.
2. Click **New** to create a new application policy set and provide a name for it in the **Name** field.
3. Under the **Policy** heading, click **Add** and select **JMS transport**.
4. Click **OK** or **Apply**.

5. Click **JMS transport** to view the JMS transport policy settings panel.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

You can only configure a policy through a policy set. Therefore, before you can configure the JMS transport policy, a policy set must exist that contains the JMS transport policy.

To customize a policy set that contains the JMS transport policy, you must create a new policy set, import a copy of a policy set from the default repository, or you can import an existing policy set from your specified location. After you have an editable policy set, you can add the JMS transport policy to your policy set.

After you customize values for the JMS transport policy, these values now apply for your policy set that contains that customized JMS transport policy. You can attach this policy set that contains your customized JMS transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, read about managing policy sets for service providers and service clients at the application level.

*Client JMS connection properties - Request timeout:*

Specifies the request timeout value. The request timeout value is the amount of time that the client waits for a response after sending the request to the server. The default value is 300 seconds.

*Client JMS connection properties - Allow transactional messaging for one-way and asynchronous operations:*

Specifies to enable a client to use transactions in one-way or asynchronous two-way requests. Select this check box to enable transactional messaging.

If this option is selected, the client runtime exchanges SOAP request and response messages with the server over the JMS transport in a transactional manner if the client is operating under a transaction. Therefore, the client transaction is used to send the SOAP request message to the destination queue or topic, and the server receives the request message only after the client commits the transaction. Similarly, the server receives the request message under the control of a container-managed transaction and sends the reply message, if applicable, back to the client using that same transaction. The client then receives the reply message only after the server transaction is committed.

If this option is not selected, the client and server runtimes perform messaging operations in a non-transactional manner.

**Note:** Transactional messaging operations are not supported for two-way synchronous operations as this leads to a deadlock condition.

*JMS transport bindings:*

Use this page to define the Java Message Service (JMS) transport provider or client bindings configuration.

If you are using JMS transport provider bindings, to view this administrative console page, complete the following actions:

1. Click **Services > Policy Sets > General provider policy set bindings**.
2. Click *provider\_policy\_set\_binding\_name*.
3. In the policy collection, click **JMS transport**.

If the JMS transport policy has not been added to the selected general provider policy set, then use the create general provider bindings panel to add the JMS transport policy to the selected general provider policy set.

You can use the JMS transport provider policy bindings to configure a service that uses the JMS transport to send asynchronous response messages back to the client. The application server run time uses the user name and password that you configure when connecting to the JMS messaging provider and this configuration enables the service to send an asynchronous response message to the client in a secure manner.

If you are using JMS transport client bindings, to view this administrative console page, complete the following actions:

1. Click **Services > Policy Sets > General client policy set bindings**.
2. Click *client\_policy\_set\_binding\_name*.
3. In the policy collection, click **JMS transport**.

If the JMS transport policy has not been added to the selected general client policy set, then use the create general client bindings panel to add the JMS transport policy to the selected general client policy set.

You can use the JMS transport client policy bindings to configure a client that uses the JMS transport to send a request message to the server. The client run time uses the user name and password that you specify when connecting to the JMS messaging provider, and this configuration enables the client to send the request message to the server in a secure manner.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

**Important:** You can also configure JMS transport properties, such as request timeout values or whether to enable transactional messaging for one-way asynchronous operations for JAX-WS applications that are deployed in the same application server. If you want to customize these JMS properties, you must edit the JMS transport policy. To customize the JMS transport policy settings, click **Services > Policy sets > Application policy sets > *policy\_set\_name* > JMS transport policy**, where *policy\_set\_name* applies to any policy set that contains the JMS transport policy. Your customized values for the JMS transport policy now apply for your policy set that contains that custom JMS transport policy. You can attach this policy set that contains your customized JMS transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

#### *Basic Authentication – User name:*

For the service provider, this field specifies the user name for the asynchronous service responses. For the client, this field specifies the user name that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. Enter a user name in this field.

#### *Basic Authentication – Password:*

For the service provider, this field specifies a placeholder for the password of the asynchronous service responses. For the client, this field specifies the password that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. You can enter or edit the password in this field. The actual password is masked.

#### *Basic Authentication – Confirm password:*

For the service provider, this field specifies a placeholder for the password for the asynchronous service responses. For the client, this field specifies the password that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. Re-enter the password in this field. The actual password is masked.

#### *Custom Properties – Name:*

Specifies the name of custom property. Custom properties are not initially displayed in this column until you define them.

Click one of the following buttons to enable the described action:

<b>Button</b>	<b>Resulting Action</b>
<b>New</b>	Creates a new custom property entry. To add a custom property, enter the name and value.
<b>Delete</b>	Removes the selected custom property.
<b>Edit</b>	Edit a selected custom property. This button is only displayed when one or more properties exist.

#### *Custom Properties – Value:*

Specifies the value of the custom property. With the **Value** entry field, you can enter, edit, or delete the value for a custom property.

#### **Configuring the WS-Transaction policy:**

When you work with policy sets in the administrative console, you can configure the WS-Transaction policy type for the WS-AtomicTransaction (WS-AT) and the WS-BusinessActivity (WS-BA) protocols. You can configure whether a client propagates, and a server receives, a WS-AT context, and whether a client propagates, and a server receives, a WS-BA context.

#### **Before you begin**

You must be working with a policy set that includes the WS-Transaction policy type.

Do not edit the policies associated with the provided default policy sets. To modify the WS-Transaction policy settings, use a copy of a default policy set or create a new policy set.

#### **About this task**

You can configure the policies for the WS-AtomicTransaction and WS-BusinessActivity protocols. The WS-AT protocol supports coordination of activities so that either all the activities occur, or none of them occur. The WS-BA protocol supports coordination of activities that are more loosely coupled than atomic transactions and that therefore require a compensation process if a failure occurs in the business activity.

When you add a WS-Transaction policy, it is equivalent to setting the following deployment descriptors that are associated with an EJB or web module:

- Use Web Services Atomic Transaction
- Send Web Services Atomic Transaction on requests
- Execute using Web Services Atomic Transaction on incoming requests

A WS-BA context is sent if the client is running in a BusinessActivity scope (BAScope). A provider runs in a BAScope if it receives a message that contains a WS-BA context, as long as the provider is set to run Enterprise JavaBeans (EJB) methods in a Business Activity scope.

## Procedure

1. In the navigation pane of the administrative console, click **Services > Policy sets > Application policy sets > *policy\_set\_name* > [Policies] WS-Transaction**. The WS-Transactions settings pane is displayed.
2. In the WS-AtomicTransaction section, select the option you require:
  - **Mandatory**. For a client, the client always propagates a WS-AT context on an outbound request. For a server, any request that is received must include a WS-AT context, otherwise the request is rejected.
  - **Supports**. For a client, the client can propagate a WS-AT context on an outbound request when that context is available. For a server, if a request includes a WS-AT context, the context is imported and established on the thread before the request is processed.
  - **Never**. For a client, the client never propagates a WS-AT context on an outbound request. For a server, any request that is received must not include a WS-AT context, otherwise the request is rejected.
3. In the WS-BusinessActivity section, select the option you require:
  - **Mandatory**. For a client, the client always propagates a WS-BA context on an outbound request. For a server, any request that is received must include a WS-BA context, otherwise the request is rejected.
  - **Supports**. For a client, the client can propagate a WS-BA context on an outbound request when that context is available. For a server, if a request includes a WS-BA context, the context is imported and established on the thread before the request is processed.
  - **Never**. For a client, the client never propagates a WS-BA context on an outbound request. For a server, any request that is received must not include a WS-BA context, otherwise the request is rejected.
4. Click **OK**.
5. Save your changes to the master configuration.

## Results

After you configure the WS-Transaction policy, the associated policy set uses this policy to support WS-AtomicTransaction and WS-BusinessActivity.

*WS-Transaction policy settings:*

Use this page to specify the policies for the WS-AtomicTransaction (WS-AT) and WS-BusinessActivity (WS-BA) protocols. WS-AT supports coordination of activities so that either all the activities occur, or none of them occur. WS-BA supports coordination of activities that are more loosely coupled than atomic transactions, and that therefore, require a compensation process if an error occurs.

To view this page in the console, click the following path: **Services > Policy sets > Application policy sets > *policy\_set\_name* > [Policy] WS-Transaction**, when the policy set includes the WS-Transaction policy type.

You can configure the WS-Transaction policy type for both client and provider policy sets.

*WS-AtomicTransaction:* Specifies behavior with the WS-AT policy. The options are:

### Mandatory

For a client, the client always propagates a WS-AT context on an outbound request. If there is no transaction on the thread when the request is made, the attempt to make the request fails.

For a server, any request that is received must include a WS-AT context, otherwise the request is rejected. If any Web Services Description Language (WSDL) is generated for the web service with

which the policy type is associated, a policy assertion is included that indicates that an operation must be invoked with an atomic transaction context.

### **Supports**

For a client, the client can propagate a WS-AT context on an outbound request when it is available. For example, a transaction is associated with the thread that makes the request, and the policy of the provider requires WS-AT context.

For a server, if a request includes a WS-AT context, the context is imported and established on the thread before the request is processed. If a request does not include a WS-AT context, the request is processed as usual. If any WSDL is generated for the web service with which the policy type is associated, a policy assertion is included that indicates that an operation supports invocation with an atomic transaction context when that context is available.

**Never** For a client, the client never propagates a WS-AT context on an outbound request.

For a server, any request that is received must not include a WS-AT context, otherwise the request is rejected with a MustUnderstand error. If any WSDL is generated for the web service with which the policy type is associated, that WSDL does not include a policy assertion for an atomic transaction context.

*WS-BusinessActivity:* Specifies behavior with the WS-BA policy. The options are:

### **Mandatory**

For a client, the client always propagates a WS-BA context on an outbound request. If there is no business activity scope on the thread when the request is made, the attempt to make the request fails.

For a server, any request that is received must include a WS-BA context, otherwise the request is rejected. If any WSDL is generated for the web service with which the policy type is associated, a policy assertion is included that indicates that an operation must be invoked with a business activity context.

### **Supports**

For a client, the client can propagate a WS-BA context on an outbound request when it is available. For example, a business activity scope is associated with the thread that makes the request, and the policy of the provider requires a WS-BA context.

For a server, if a request includes a WS-BA context, the context is imported and established on the thread before the request is processed. If a request does not include a WS-BA context, the request is processed as usual. If any WSDL is generated for the web service with which the policy type is associated, a policy assertion is included that indicates that an operation supports invocation with a business activity context when that context is available.

**Never** For a client, the client never propagates a WS-BA context on an outbound request.

For a server, any request that is received must not include a WS-BA context, otherwise the request is rejected with a MustUnderstand error. If any WSDL is generated for the web service with which the policy type is associated, that WSDL does not include a policy assertion for a business activity context.

### ***Configuring the WS-Security policy:***

When working with policy sets in the administrative console, you can customize policies to ensure message security. The WS-Security policy can be configured to apply a message security (WS-Security) profile to requests. Message security policies are applied to requests and enforced on responses to support interoperability.

## Before you begin

You can configure some settings for default policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

## About this task

Message security policies are applied to requests and enforced on responses to support interoperability.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

## Procedure

1. Use the WS-Security policy panel to begin configuring the WS-Security policy. To access the WS-Security policy panel, from the administrative console, click **Services > Policy sets > Application policy sets > *policy\_set\_name* > WS-Security policy**.
2. Choose which type of message security to configure.
  - Click the Main policy link to specify how message security policies are applied to requests and enforced on responses to support interoperability.
  - Click the Bootstrap policy link to configure how secure conversations are established. A bootstrap policy might already be configured. If no bootstrap policy is currently configured, first ensure that you have enabled message security with symmetric signature and encryption policies and secure conversation tokens for both integrity and confidentiality protection.
3. Use the Main policy settings panel or the Bootstrap policy settings panel to specify how message security policies are applied to requests and enforced on responses. Assertions for WS-Security versions are already generated based on assertions in the policy set. If the policy set includes a WS-S 1.1 assertion, then WS-S 1.1 itself is asserted. Configure the settings on this panel to configure main or bootstrap policy settings:
  - a. Select whether Message level protection is required. Select this check box if any of the message parts should be digitally signed or encrypted or if a timestamp should be inserted in the message. If this box is unchecked, the Signature confirmation, Key symmetry, and Timestamp and Security header layout options are disabled.
  - b. Specify whether signature confirmation is required. Click this check box to require signature confirmation.
  - c. Configure the settings in the Key Symmetry section. The following fields can be configured in the Key symmetry section:

### Use symmetric tokens

Click this radio button to use symmetric tokens. You can then configure symmetric tokens with the **Symmetric signature and encryption policies** link. Click this link to access the Symmetric Signature and Encryption Policies panel where you can create the trust context in which to use symmetric tokens. Using the same token for signing and validating messages and encrypting and decrypting messages provides better performance than can be achieved with asymmetric tokens. Symmetric tokens should be used within a trust context.

### Use asymmetric tokens

Click this link to access the Asymmetric Signature and Encryption Policies panel where you can create the trust context (message integrity and confidentiality) in which to use asymmetric tokens. You can do this by specifying which token type to use for the initiator and recipient signature as well as the initiator and recipient encryption.

### Include timestamp in header

Click this check box to include a timestamp in the header. You can then specify if the timestamp is positioned first or last in the header by using the Security header layout radio button options:

- **Strict: Declarations must precede use**
  - **Layout (Lax): Order of contents can vary**
  - **Lax but timestamp required first in header**
  - **Lax but timestamp required last in header**
- d. Optional: Click the **Algorithms** link under the **Policy Details** section if you want to access the Algorithms panel to view and select from available algorithms. The available algorithms include cryptographic algorithms and their key lengths, as well as canonicalization algorithms for reconciling XML differences. Click this link to view the cryptographic and canonicalization algorithms that are supported.
- e. Optional: Configure the request settings. Click either of the following links to configure request settings:

#### Request message part protection

Links to configuration for request message part protection. Click this link to define which message parts are to be protected and how that protection is provided.

#### Request token policies

Links to configuration for request token policies. Click this link to define policies that specify which types of security tokens are supported and the properties of those token types.

- f. Optional: Configure the response settings. Click either of the following links to configure response settings:

#### Response message part protection

Links to configuration for response message part protection. Click this link to define which message parts are to be protected and how that protection is provided.

#### Response token policies

Links to configuration for response token policies. Click this link to define policies that specify which types of security tokens are supported and the properties of those token types.

## Results

Once you have customized the WS-Security policy, the associated policy set uses this policy to protect messages.

*WS-Security policy settings:*

Use this page to configure the WS-Security policy and apply a message security WS-Security profile to requests. WS-Security policies are applied to requests and enforced on responses to support inter-operability.

To view this administrative console page, click **Services > Policy sets > Application policy sets > *policy\_set\_name* > WS-Security policy**.

*Main policy:*

Links to configuration settings for a main policy. Use the Main policy link if you want to configure how WS-Security policies are applied to requests and enforced on responses to support interoperability.

*Secure conversation bootstrap policy:*

Links to configuration settings for a secure conversation bootstrap policy. Use the bootstrap policy link if you want to configure how secure conversations are established. To configure a secure conversation bootstrap policy, first ensure that you have enabled message security in the main policy with symmetric signature and encryption policies and secure conversation tokens for both integrity and confidentiality protection.

Click **Remove bootstrap policy** to discontinue using secure conversation policy settings.

*Configuring the request or response token policies:*

You can configure the request and response token policies that are part of the WS-Security policy using the administrative console. Message requests token policies are applied to requests and enforced on responses to support both quality and interoperability.

### **Before you begin**

You can configure some settings for the policies within your policy sets. The default policy sets provided in the product cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

### **About this task**

Use this administrative console task to define policies that specifically support security tokens and properties.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

### **Procedure**

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name* > WS-Security policy**.
2. Click one of the following links:
  - **Main policy** or
  - **Bootstrap policy**
  - Click the Main policy link to specify how message security policies are applied to requests and enforced on responses to support interoperability.
  - Click the Bootstrap policy link to configure how secure conversations are established. A bootstrap policy might already be configured. If no bootstrap policy is currently configured, first ensure that you have enabled message security with symmetric signature and encryption policies and secure conversation tokens for both integrity and confidentiality protection. See *Configuring the WS-Security policy*.
3. Click **Request token policies** under Request Policies or **Response token policies** under Response Policies. Use this panel to define policies that specify which types of security tokens are supported for the properties of each token type.

### **Results**

Once you have customized the WS-Security policy with the associated properties, including the request and response token policies, you can then send and receive protect messages.

*Request or Response token policies collection:*

Use this page to define policies that specify supporting security tokens and properties.

To view this administrative console page, complete the following:

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name***.
2. Click the **WS-Security** policy in the policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click **Request token policies** or **Response token policies** from the Policy Details section.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

#### *Add:*

Add a token from a list of supported token types. You can only add a token to a custom policy set.

This option provides the following supported token types:

- Username
- X.509
- LTPA
- Custom

To change the settings for a token after adding it, click on the token identifier name in the table.

#### *Delete:*

Removes the selected token name. This action is only available for a custom policy set.

#### *Token Identifier:*

Specifies the name of the token.

#### *Type:*

Specifies the token type in the Supported token types table. This list displays a token type for each token name in the list.

#### *Version:*

Specifies the version of the token in the Supported token types table. This list displays the version of each token in the list.

#### *Token type settings:*

Use the administrative console to define the details about the token types. This panel is displayed differently for each different token type. Policies can be defined that specify which types of security tokens are supported as well as properties for the token type.

To view token types for a policy set, complete the following steps:

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click one of the following:
  - **Request token policies** from the Policy detail section.
  - **Response token policies** from the Policy detail section.

- **Symmetric signature and encryption policies** from the Key symmetry section.
  - **Asymmetric signature and encryption policies** from the Key symmetry section.
5. For a Request token policy or a Response token policy, click a token from the Supported Token Types table or click the **Add Token Type** button to select the type of token to add.
  6. For a symmetric signature and encryption policy or an asymmetric signature and encryption policy, click **Edit Selected Type Policy**.

This panel is displayed for each token type you are configuring or adding. It displays fields for some token types and not for others. This help topic contains all of the fields for each of the token types and describes which token is being configured for each field.

*Custom token name:*

For a custom token, specify the name of the token being configured. Enter or edit the name for the custom token in this entry field.

*Local name:*

For a custom token, specify the local name.

If the custom token type is used to generate a Kerberos token as defined in the OASIS Web Services Security Specification for Kerberos Token Profile v1.1, use one of the values in the following table for the local name. The value you choose depends on the specification level of the Kerberos token generated by the Key Distribution Center (KDC). The table lists the values and the specification level associated with each value. For purposes of interoperability, the Basic Security Profile V1.1 standard requires the use of the local name, [http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS\\_Kerberosv5\\_AP\\_REQ](http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ).

Local Name Value for Kerberos Token	Associated Specification Level
<a href="http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ">http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ</a>	Kerberos V5 AP-REQ as defined in the Kerberos specification. This value is used when the Kerberos ticket is an AP Request.
<a href="http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ">http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ</a>	GSS-API Kerberos V5 mechanism token containing a KRB_AP_REQ message as defined in RFC-1964 [1964], Sec. 1.1 and its successor RFC-4121, Sec. 4.1. This value is used when the Kerberos ticket is an AP Request (ST + Authenticator).
<a href="http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510">http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510</a>	Kerberos V5 AP-REQ as defined in RFC1510. This value is used when the Kerberos ticket is an AP Request per RFC1510.
<a href="http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510">http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510</a>	GSS-API Kerberos V5 mechanism token containing a KRB_AP_REQ message as defined in RFC-1964, Sec. 1.1 and its successor RFC-4121, Sec. 4.1. This value is used when the Kerberos ticket is an AP Request (ST + Authenticator) per RFC1510.
<a href="http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120">http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120</a>	Kerberos V5 AP-REQ as defined in RFC4120. This value is used when the Kerberos ticket is an AP Request per RFC4120.
<a href="http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120">http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120</a>	GSS-API Kerberos V5 mechanism token containing a KRB_AP_REQ message as defined in RFC-1964, Sec. 1.1 and its successor RFC-4121, Sec. 4.1. This value is used when the Kerberos ticket is an AP Request (ST + Authenticator) per RFC4120.

*URI:*

For a custom token, specify the uniform resource identifier (URI).

Leave this field empty, if the custom token type is used to generate a Kerberos token as defined in the OASIS Web Services Security Specification for Kerberos Token Profile v1.1.

*LTPA token name:*

For an LTPA token, specify the name of the token being configured. Enter or edit the name for the LTPA token in this entry field.

*Propagate the JAAS subject:*

For an LTPA token, specify whether the associated Java Authentication and Authorization Service (JAAS) subject is propagated. Select this check box to propagate the JAAS subject. The default value is not selected. Therefore, the JAAS subject is not propagated by default.

*Username token name:* Specify the name of the token being configured. Enter or edit the name for the username token in this entry field.

*WS-Security version:*

For a Username token, specify the version of Web Services Security, the WS-Security specification, that is used to secure the message transmission.

The following versions are available:

- WS-Security V1.0
- WS-Security V1.1

*X.509 token name:*

For a X.509 token, specify the name of the token being configured. Enter or edit the name for the X.509 token in this entry field.

*WS-Security version:*

For a X.509 token, specify the version of Web Services Security that is used to secure the message transmission.

The following versions are available:

- WS-Security V1.0
- WS-Security V1.1

*X.509 type:*

For a X.509 token, specify the type of X.509 token being configured.

The following types are available for the X.509 token:

- X.509 Version 1. This option is available with WS-Security Version 1.1 only.
- X.509, Version 3
- X.509 PKCX7
- PKI Path Version 1

*Secure conversation token:* The secure conversation token is available only when using symmetric signature and encryption policies.

*Require reference to secure context token issuer:*

For a secure conversation token, select this option to specify a reference to the issuer of the security context token.

After selecting the **Require reference to secure context token issuer** option, specify the URI of the security context token issuer.

*Transform algorithms settings:*

Use this administrative console page to select the uniform resource locator (URL) for the transform algorithms that are needed to protect the message part.

To view this administrative console page, complete the following:

1. Click **Services > Policy sets > General provider policy set bindings** or **General client policy set bindings**.
2. Click the name of the binding you want to edit.
3. Click **WS-Security** policy in the Policies table
4. Click the **Authentication and Protection** link in the Main message security policy bindings section.
5. Select a signature protection in the Request message and encryption protection section or the Response message signature and encryption protection section.
6. Click the **Additional bindings > Signed part reference default** at the end of the panel.
7. Click a URL in the Transform algorithms table.

You can also get to this administrative console page by completing the following actions:

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains web services.
3. Select **Service provider policy sets and bindings** or **Service client policy sets and bindings**.
4. Select a binding.

**Important:** You must have previously attached a policy set and assigned an application specific binding before you can do this step.

5. Select **WS-Security**.

**Important:** You must have previously added WS-Security to the bindings.

6. Click the **Authentication and Protection** link in the Main message security policy bindings section.
7. Select a signature protection in the Request message and encryption protection section or the Response message signature and encryption protection section.
8. Click the **Additional bindings > Signed part reference default** at the bottom of the panel.
9. Click **New** to add a transform.
10. [Optional] Click a URL in the Transform algorithms table. This step assumes that a transform algorithm has previously been configured.

*URL:*

Specifies the URL for the transform algorithms that are used to protect the message part.

The URLs of the supported transform algorithms are listed in the table. The recommended transform is <http://www.w3.org/2001/10/xml-exc-c14n#> and it is the Exclusive XML Canonicalization, as well as the default value provided in the URL field when a transform is added.

List of URLs for the transform algorithms
<a href="http://www.w3.org/2001/10/xml-exc-c14n#">http://www.w3.org/2001/10/xml-exc-c14n#</a>
<a href="http://www.w3.org/TR/1999/REC-xpath-19991116">http://www.w3.org/TR/1999/REC-xpath-19991116</a>
<a href="http://www.w3.org/2002/06/xmldsig-filter2">http://www.w3.org/2002/06/xmldsig-filter2</a>
<a href="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform">http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform</a>
<a href="http://www.w3.org/2002/07/decrypt#XML">http://www.w3.org/2002/07/decrypt#XML</a>
<a href="http://www.w3.org/2000/09/xmldsig#enveloped-signature">http://www.w3.org/2000/09/xmldsig#enveloped-signature</a>

*Custom properties:*

Specifies the custom properties name and value pair for the transform algorithms. Click **New** to add a new custom property. Click **Delete** to delete a custom property.

**Name** Specifies the name of a custom property that you choose to set to protect the message part.

**Value** Specifies the value of a custom property that you choose to set to protect the message part.

*Signed part reference default bindings settings:*

Use this administrative console page to configure the signed part reference general bindings and the uniform resource locator (URL) for the transform algorithms that are needed to protect the message part.

You can view and configure bindings for WS-Security using this administrative console page:

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains web services
3. Select **Service provider policy sets and bindings** or **Service client policy sets and bindings**
4. Select a binding.

**Note:** You must have previously attached a policy set and assigned an application specific binding before you can do this step.

5. Select **WS-Security**.

**Note:** You must have previously added WS-Security to the bindings.

6. Click the **Authentication and Protection** link in the Main message security policy bindings section.
7. Select a signature protection in the Request message and encryption protection section or the Response message signature and encryption protection section.
8. Click the **Additional bindings - Signed part reference default** at the bottom of the panel. For the custom, select an assigned message part and click **Edit**. In the custom version, there is also a reference field, **Specifies the name of the signature protection in the policy set**. Use this field to specify the name of the signature protection in the policy set.
9. Check the **Include timestamp** check box to include the timestamp when the message part is signed.
10. Check the **Include nonce** check box to include the nonce when the message part is signed.

*Part reference properties:*

Specifies the name of the part reference properties that include the transform algorithms used to protect the message part.

1. Check the **Include timestamp** check box to include the timestamp for the message part.

2. Check the **Include nonce** check box to include the nonce when the message part is signed.

*Transform algorithms:*

Specifies the uniform resource locator (URL) description for the transform algorithms. Click the URL to view the transform algorithms.

*Main policy and bootstrap policy settings:*

Use this page to specify how message security policies are applied to requests and enforced on responses, as defined by the main policy settings and the bootstrap policy settings. Assertions for Web Services Security (WS-Security) versions are already generated based on assertions in the policy set. If the policy set includes a Web Services Security Version 1.1 assertion, then Web Services Security Version 1.1, itself, is asserted.

To view this administrative console page, use one of the following steps:

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.

*Message level protection:*

Specifies whether message level protection, using digital signatures and encryption, is required.

**Require signature confirmation**

Specifies whether the signature confirmation is required. Select this check box to require a signature confirmation.

*Message part protection:*

Specifies whether message part protection, using digital signatures and encryption, is required.

**Request message part protection**

Click this link to define which request message parts you want protected and how that protection is provided.

**Response message part protection**

Click this link to define policies that specify which response message parts you want protected and how that protection is provided.

When the Message level protection check box is cleared, the link to Request message part protection is disabled, because the configuration information associated with message level security is removed when message level protection is cleared.

*Key symmetry – Use symmetric tokens:*

Specifies whether to use symmetric tokens. Select this radio button to use symmetric tokens. You can then configure symmetric tokens using the **Symmetric signature and encryption policies** link. Click this link to access the Symmetric signature and encryption policies panel where you can create the trust context in which to use symmetric tokens. Using the same token for signing and validating messages and encrypting and decrypting messages provides higher performance than can be achieved with asymmetric tokens. Use symmetric tokens within a trust context. If a custom Kerberos token type is used, you must select the Use symmetric tokens option.

*Key symmetry – Use asymmetric tokens:*

Specifies whether to use asymmetric tokens. Select this button to use asymmetric tokens. You can then configure asymmetric tokens using the **Asymmetric signature and encryption policies** link. Click this link to access the Asymmetric signature and encryption policies panel where you can create the trust context (message integrity and confidentiality) in which to use asymmetric tokens. Specify which token type to use for the initiator and recipient signature as well as the initiator and recipient encryption.

*Include time stamp in security header:*

Specifies whether to use a time stamp in the header. Select this check box to include a time stamp in the header. You can then specify where in the header to place the time stamp by using the **Security header layout** radio buttons.

*Security header layout:*

Specifies the layout rules for the security header.

You can use the following radio buttons for the security header layout:

**Strict: declarations must precede use**

The declarations in the header must precede the use.

**Layout (Lax): order of contents can vary**

The order of contents in the header can vary.

**Lax but timestamp required first in header**

The timestamp must be first in the header, but the order of the remaining elements can vary.

**Lax but timestamp required last in header**

The timestamp must be last in the header, but the order of the remaining elements can vary.

*Policy details:*

Specifies links for accessing the request token policies, response token policies, and algorithms for asymmetric tokens. Click these links to view token policies and canonicalization algorithms that are supported. Algorithms are used to reconcile XML differences.

*Request token policies:*

Click this link to define policies that specify which types of supporting authentication tokens are used in the request and the properties of those token types.

*Response token policies:*

Click this link to define policies that specify which types of supporting authentication tokens are used in the response and the properties of those token types.

*Algorithms for symmetric or asymmetric tokens:*

Links to a view of available algorithms. Click this link to view the cryptographic and canonicalization algorithms that are supported. Algorithms are used to reconcile XML differences.

*Asymmetric signature and encryption policies settings:*

Use this page to create the trust context, message integrity and confidentiality, to use asymmetric tokens. You can create the trust context by specifying which token type to use for the initiator and recipient signature as well as the initiator and recipient encryption.

To view this administrative console page complete the following actions:

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name* > WS-Security policy type**.
2. Click **Main policy** or **Bootstrap policy**.
3. Click the **Asymmetric signature and encryption policies** link.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

*Message integrity policies – Initiator signature token:*

Specifies the token type of the initiator signature token. To add a token type or change the current token type that is displayed in the **Initiator signature token** field, or to edit the displayed token type, click **Action**.

*Message integrity policies – Recipient signature token:*

Specifies the token type of the recipient signature token. To add a token type or change the current token type that is displayed in the **Recipient signature token** field, or to edit the displayed token type, click **Action**.

*Message confidentiality policies – Use the same token types that are used for integrity protection:*

Specifies whether the token type set for initiator signature token and recipient signature token are used for the initiator encryption token and the recipient encryption token. When the box is checked the fields are empty and are cleared of data when **Ok** or **Apply** is selected.

*Message confidentiality policies – Initiator encryption token:*

Specifies the initiator encryption token type. To add a token type or change the current token type that is displayed in the **Initiator encryption token** field, or to edit the displayed token type, click **Action**.

*Message confidentiality policies – Recipient encryption token:*

Specifies recipient encryption token type. To add a token type or change the current token type that is displayed in the **Recipient encryption token** field, or to edit the displayed token type, click **Action**.

*Action:*

Specifies an option for each of the signature and encryption token fields. Use the **Action** button to change, delete, add, or edit the listed token type.

The Action button lists supported token types and provides the following options:

**Edit selected type policy**

Opens a page to edit the token type shown in the signature or encryption token fields.

**Delete selected type policy**

Removes the token type from the signature or encryption token fields.

**Change to custom type**

Opens the Custom type page to specify the uniform resource identifier (URI) for a custom token type.

**Add custom type**

Adds the custom type entry in the signature or encryption token fields.

**Change to X.509**

Changes the listed token type to X.509.

## Add X.509

Adds the X.509 token type.

When you change the token type, any values you specified for the former token type are lost and the default values for the newly assigned token type are used.

### *Symmetric signature and encryption policies settings:*

Use this page to create the trust context to use symmetric tokens. Using the same token for signing and validating messages and encrypting and decrypting messages increases performance. Use symmetric tokens within a trust context.

To view this administrative console page, complete the following options:

1. Click **Services > Policy sets > Application policy sets**.
2. Select a **policy\_set\_name** in the policy sets table that contains WS-Security content.
3. Click **WS-Security** in the policies table.
4. Click the **Main policy** link or the **Bootstrap policy** link.
5. Click the **Symmetric signature and encryption policies** link.

### *Message Integrity – Token type for signing and validating messages:*

Specifies the current token type used for signing and validating messages.

To change the current token type that is displayed in the **Token type for signing and validating messages** field or to edit the displayed token type, click **Action**.

### *Message Confidentiality – Use same token type for confidentiality that is used for integrity:*

Specifies whether the token type set for signing and validating messages is also used for encrypting and decrypting messages. For a Kerberos token, message confidentiality uses the same token that is used for the message integrity.

If you select this check box, then the **Token type for encrypting and decrypting messages** field is blank. If you clear this check box, then a different token can be used for message confidentiality.

### *Message Confidentiality – Token type for encrypting and decrypting messages:*

Specifies the current token type that is used for encrypting and decrypting messages.

To change the current token type that is displayed in the **Token type for encrypting and decrypting messages** field or to edit the displayed token type, verify that the **Use the same token type for confidentiality that is used for integrity protection** check box is cleared, and click **Action**.

### *Action:*

Enables the token type selected to be changed or edited.

The **Action** button lists supported token types and provides the following options:

#### **Edit selected type policy**

Opens a page to edit the token type for signing or encrypting fields.

#### **Change to Secure Conversation**

Changes the token type to Secure Conversation.

## Change to custom type

Opens the custom type page to specify the Uniform Resource Identifier (URI) for a custom token type.

When you change the token type, any values that you specified for the former token type are lost, and the default values for the newly assigned token type are used.

### Algorithms settings:

Use this page to view the supported cryptographic and canonicalization algorithms. Algorithms are used to reconcile XML differences.

To view this administrative console page:

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Algorithms for symmetric tokens** link or the **Algorithms for asymmetric tokens** link.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

### Algorithm suite:

Specifies the supported algorithms that are required for performing cryptographic operations with symmetric or asymmetric key-based security tokens.

All of the algorithm values in this field specify an algorithm suite. Algorithm suites and the values they each represent are detailed in the *Web Services Security Policy Language (WS-SecurityPolicy) July 2005 Version 1.1* specification. Select a supported algorithm from the following list:

- Basic256
- Basic192
- Basic128
- TripleDes
- Basic256Rsa15
- Basic192Rsa15
- Basic128Rsa15
- TripleDesRsa15
- Basic256Sha256
- Basic192Sha256
- Basic128Sha256
- TripleDesSha256
- Basic256Sha256Rsa15
- Basic192Sha256Rsa15
- Basic128Sha256Rsa15
- TripleDesSha256Rsa15

This table defines values for the components for each algorithm suite.

Table 270. Algorithm suite components. The algorithms are used to perform cryptographic operations on tokens.

Algorithm Suite	Digest	Encryption	Symmetric Key Wrap	Asymmetric Key Wrap	Encryption key Derivation	Signature key Derivation	Minimum Symmetric Key Length
Basic256	Sha1	Aes256	KwAes256	KwRsaOaep	PSha1L256	PSha1L192	256

Table 270. Algorithm suite components (continued). The algorithms are used to perform cryptographic operations on tokens.

Algorithm Suite	Digest	Encryption	Symmetric Key Wrap	Asymmetric Key Wrap	Encryption key Derivation	Signature key Derivation	Minimum Symmetric Key Length
Basic192	Sha1	Aes192	KwAes192	KwRsaOaep	PSha1L192	PSha1L192	192
Basic128	Sha1	Aes128	KwAes128	KwRsaOaep	PSha1L128	PSha1L128	128
TripleDes	Sha1	TripleDes	KwTripleDes	KwRsaOaep	PSha1L192	PSha1L192	192
Basic256Rsa15	Sha1	Aes256	KwAes256	KwRsa15	PSha1L256	PSha1L192	256
Basic192Rsa15	Sha1	Aes192	KwAes192	KwRsa15	PSha1L192	PSha1L192	192
Basic128Rsa15	Sha1	Aes128	KwAes128	KwRsa15	PSha1L128	PSha1L128	128
TripleDesRsa15	Sha1	TripleDes	KwTripleDes	KwRsa15	PSha1L192	PSha1L192	192
Basic256Sha256	Sha256	Aes256	KwAes256	KwRsaOaep	PSha1L256	PSha1L192	256
Basic192Sha256	Sha256	Aes192	KwAes192	KwRsaOaep	PSha1L192	PSha1L192	192
Basic128Sha256	Sha256	Aes128	KwAes128	KwRsaOaep	PSha1L128	PSha1L128	128
TripleDesSha256	Sha256	TripleDes	KwTripleDes	KwRsaOaep	PSha1L192	PSha1L192	192
Basic256Sha256Rsa15	Sha256	Aes256	KwAes256	KwRsa15	PSha1L256	PSha1L192	256
Basic192Sha256Rsa15	Sha256	Aes192	KwAes192	KwRsa15	PSha1L192	PSha1L192	192
Basic128Sha256Rsa15	Sha256	Aes128	KwAes128	KwRsa15	PSha1L128	PSha1L128	128
TripleDesSha256Rsa15	Sha256	TripleDes	KwTripleDes	KwRsa15	PSha1L192	PSha1L192	192

When using a Kerberos custom token based on the OASIS Web Services Security Specification for Kerberos Token Profile V1.1, only Aes128, Aes256, and TripleDes encryption-based algorithm suites are supported.

*Canonicalization algorithm:*

Specifies whether to use inclusive or exclusive canonicalization.

The following supported canonicalization algorithms are available in this list:

- Exclusive canonicalization
- Inclusive canonicalization

The default value is Exclusive canonicalization.

*XPath version:*

Specifies the version of the XPath filter to use.

The following supported XPath versions are available:

- XPath 1.0
- XPathfilter 2.0

The XPathfilter 2.0 version is the default value.

*Use security token reference transformation:*

Specifies whether the security token reference is transformed. Indicate whether the security token reference transform is either True or False.

*Message part protection settings:*

Use this page to define the message parts that you want protected and how that protection is provided.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets** > *policy\_set\_name*.

2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Request message part protection** link or the **Response message part protection** link from the Message Part Protection section.

*Integrity protection – Signed parts:*

Specifies the signed parts that you have added for message integrity protection. You can select parts to edit or delete, or add new signed parts.

<b>Button</b>	<b>Resulting Action</b>
<b>Add</b>	Specifies each element of a new signed part and to add those elements to the Signed parts listing.
<b>Edit</b>	Loads the specific part you selected for editing.
<b>Delete</b>	Removes the selected signed part from the list.

*Confidentiality protection – Encrypted parts:*

Specifies the encrypted parts that have been added for message confidentiality protection. You can select parts to edit or delete, or add new encrypted parts.

<b>Button</b>	<b>Resulting Action</b>
<b>Add</b>	Enables you to specify each of the elements of a new encrypted part and to add those elements to the Encrypted parts listing.
<b>Edit</b>	Loads the specific part you selected for editing.
<b>Delete</b>	Removes the selected encrypted part from the list.

*Signed part settings:*

Use this page to define the elements of a signed part. Signed parts are used to protect message integrity and, in this case, the signed parts are being defined as part of the policy set process.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click either the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Request message part protection** link or the **Response message part protection** link in the Message Part Protection section.
5. In the Integrity protection section, complete one of the following actions:
  - Click **Add** to add a new signed part.
  - Select an existing signed part and click **Edit**.

*Name of part to be signed:*

Specifies the name of this set of one or more message parts that you have selected to sign. The name you choose is a label and must be unique within the Response message part protection or Request message part protection collections for this WS-Security policy.

*Elements in part:*

Specifies a list of the message elements included in the signed part. The **Elements in part** field contains a listing of message elements that are included in this signed part to provide message integrity.

Click **Add** to add an element to the signed part of the message. To remove a message element from a signed part of a message, first click the selection box next to the element to be removed, then click **Remove**. Use the **OK**, **Apply**, **Reset** or **Cancel** buttons for the text entry fields. The QName or the Xpath expression value is required and can be edited at any time, such as when adding a new element, or after the element is added.

*Protect message body:*

Specifies if the message body is protected in this part. To protect the message body in this part, click **Protect message body**.

*XPath expression:*

Specifies if the displayed XPath expression is used as the method for specifying that a specific element is included in this part.

Select **XPath** from the **Add** menu list and provide an expression in the new XPath entry that is displayed in the table. Any Xpath expression row on the table that has no corresponding value is removed when you click **OK** or **Apply**.

*QName for SOAP header elements only:*

Specifies the QName type for a namespace value for the SOAP header element that you want to encrypt. To encrypt a SOAP header element, select **Qname** and provide the **namespace** and optionally the **localname** of the SOAP header element in the **Value** field. When specifying the QName, if using the optional localname, a comma must be inserted between the namespace and the localname, for example **<namespace>,<localname>**. If the **localname** is omitted, all SOAP header elements with the specified **namespace** are encrypted. To use the **Qname** selection method, the SOAP header elements must be the immediate children of the SOAP header. Any QName row in the table that has no corresponding value is removed when you click **OK** or **Apply**.

**Restriction:**

You cannot select header elements that are sub-elements of other elements in the SOAP header using **Qname**. In this case, you must use an **Xpath expression** to select these header elements.

*Encrypted message part settings:*

Use this page to define the elements of an encrypted part of a message. Encrypted parts are used to protect message confidentiality, and in this case, the encrypted parts are being defined as part of the policy set process. A message part is a named set of one or more message elements.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets > policy\_set\_name**.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Request message part protection** link or the **Response message part protection** link in the Message Part Protection section.
5. In the Confidentiality protection section, you can perform any of the following:
  - Click **Add** to add a new encrypted part.
  - Select an existing encrypted part, and click **Edit**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

### *Name of part to encrypt:*

Specifies the name of the set of one or more message parts that you have selected to encrypt. The name you choose is a label and must be unique within the Response message part protection or Request message part protection collections for this WS-Security policy.

### *Elements in part:*

Specifies a list of the message elements that are included in the encrypted part. The **Elements in part** field contains a listing of message elements that are included in this encrypted part to provide message confidentiality.

Click **Add** to add an element to the encrypted part of the message. To remove a message element from an encrypted part of a message, first click the selection box next to the element to be removed, then click **Remove**. The value of the QName namespace, or the Xpath expression, is required and can be edited at any time, while adding a new element or after the element is added.

**Body** Specifies the body of the message part.

### **Qname for SOAP header elements only**

Specifies the QName type for a namespace value for the SOAP header element that you want to encrypt. To encrypt a SOAP header element, select **Qname** and provide the **namespace** and optionally the **localname** of the SOAP header element in the **Value** field. When specifying the QName, if using the optional localname, a comma must be inserted between the namespace and the localname, for example `<namespace>,<localname>`. If the **localname** is omitted, all SOAP header elements with the specified **namespace** are encrypted. To use the **Qname** selection method, the SOAP header elements must be the immediate children of the SOAP header. Any QName row in the table that has no corresponding value is removed when you click **OK** or **Apply**.

**Restriction:** You cannot select header elements that are sub-elements of other elements in the SOAP header using QName. In this case, you must use an Xpath expression to select these header elements.

### **Xpath expression**

Specifies if the displayed Xpath expression is used as the method for specifying that a specific element is included in this part. Select **XPath** from the **Add** menu list, and provide an expression in the new XPath entry that is displayed in the table. Any Xpath expression row on the table that has no corresponding value is removed when you click **OK** or **Apply**.

### ***Configuring the Custom properties policy:***

When working with policy sets in the administrative console, you can customize policies to set generic properties that are not supported in other policy types. You must customize the Custom properties policy configuration because all properties within the policy are user-defined.

### **About this task**

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

You can configure generic properties that are not supported in other policy types with the Custom properties policy. These additional properties are set in the binding. The Custom properties policy provides an alternative way to set a binding property instead of using the JAX-WS programming model to set the property on the BindingProvider object. The CustomProperties binding is only supported for service clients.

After you have created a new policy set with the Custom properties policy added, you must create a Custom properties binding and add at least one custom property to configure the binding. A Custom

properties binding type can be added to a general client binding or an application specific client binding. You cannot create an empty Custom properties binding. You must define at least one name and value pair within the binding.

**Note:** In a mixed cell environment, the following limitations apply to attachments to policy sets containing CustomProperties policy:

- You must not create attachments to policy sets containing CustomProperties policy for applications that are deployed on an application server that is prior to WebSphere Application Server Version 8. The CustomProperties policy is only supported on WebSphere Application Server V8 and later.
- An application that contains an attachment to a policy set containing CustomProperties policy must not be deployed on an application server that is prior to WebSphere Application Server Version 8.
- If an application that is deployed in a cluster environment contains an attachment to a policy set containing CustomProperties policy, you must not add a member application server that is prior to WebSphere Application Server Version 8 to the cluster.

## Procedure

1. Create the Custom properties policy.
  - a. Navigate to the Application policy sets or the System policy sets. From the administrative console, click **Services > Policy Sets > Application policy sets** or **Services > Policy Sets > System policy sets**.
  - b. Click the **New...** button.
  - c. Enter a unique policy set name.
  - d. Click the **Add** button and choose the **Custom properties** policy in the Policies table.
  - e. Click the **Apply** button.
  - f. Click the **Save** link.

You cannot configure the Custom properties policy from this panel. You must configure your Custom properties with a Custom properties binding.

2. Customize the Custom properties bindings.
    - a. Navigate to the Custom properties bindings. From the administrative console, click **Services > Policy Sets > General client policy set bindings > client\_policy\_set\_binding\_name**.
    - b. Click **Add > Custom properties**.
- The Custom properties (bindings) window displays options for adding Custom properties bindings.
- c. Specify the properties for each custom property you want to add. The following fields are required:

**Name** Displays the name of the custom property.

**Value** Displays the value of the custom property.

The application specific bindings can be customized similarly, from the application policy set and bindings attachments panel.

## Results

After you have customized the Custom properties policy, the associated policy set uses this policy to set generic properties that are not supported in other policy types.

*Policy set bindings settings for Custom properties:*

Use this page to view, define, or configure general bindings or application specific bindings, for the Custom properties policy.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

To view this administrative console panel, click **Services > Policy sets > General client policy set bindings**.

To edit or configure the general bindings, complete the following steps:

1. Click **New**.
2. For **Bindings configuration name**, specify a unique binding name.
3. Optionally, specify a description.
4. Click **Add** and select the **Custom properties** policy in the Policies table.
5. Specify a unique name and value pair.
6. Optionally, to add additional properties, click **New**.
7. Optionally, to edit a property, select a property and click **Edit**.
8. Optionally, to delete a property, select a property and click **Delete**.
9. Click **Apply**.
10. Click **Save**.

**Note:** This product supports using the Custom properties policy and binding to set generic properties that are not supported in other policy types. The additional properties are set in the binding. The Custom properties policy provides an alternative way to set a binding property instead of using the JAX-WS programming model to set the property on the BindingProvider object. You cannot create an empty Custom properties binding. You must define at least one name and value pair within the binding. Additionally, there are no predefined properties in the binding because all properties are user-defined. The CustomProperties binding is only supported for service clients.

**Note:** In a mixed cell environment, the following limitations apply to attachments to policy sets containing CustomProperties policy:

- You must not create attachments to policy sets containing CustomProperties policy for applications that are deployed on an application server that is prior to WebSphere Application Server Version 8. The CustomProperties policy is only supported on WebSphere Application Server V8 and later.
- An application that contains an attachment to a policy set containing CustomProperties policy must not be deployed on an application server that is prior to WebSphere Application Server Version 8.
- If an application that is deployed in a cluster environment contains an attachment to a policy set containing CustomProperties policy, you must not add a member application server that is prior to WebSphere Application Server Version 8 to the cluster.

*Name:*

Specifies the name associated with this property.

**Data type** String

*Value:*

Specifies the value associated with this property.

**Data type** String

## Enabling policies for policy sets using the administrative console

Policies can be listed in a policy set in the disabled state so that they are not currently included in the policy set. You can enable a policy to be included in a policy set using the administrative console.

## Before you begin

To enable a policy for a policy set, be sure the policy is listed in the policy set and shown in the **Disabled** state in the **State** column of the **Policies** table on the Policy set settings page.

## About this task

To enable a policy in a policy set, use the administrative console.

## Procedure

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name*** or **Services > Policy sets > System policy sets > *policy\_set\_name***. The Policy Set Settings page displays a listing of available policies in the **Policies** table for the policy set selected. If this table contains no policies to enable, no policies exist for the policy set of interest. In this case, you must add the policies to the policy set.
2. Click the **Select** box beside the disabled policy that you want to enable. You can select multiple policies if you want to enable more than one.
3. Click the **Enable** button. The **State** column of the **Policies** table is updated to display the selected policy as enabled.

## Results

You have enabled a policy for the selected policy set.

## What to do next

If the policy is not listed in the Policies table, it cannot be enabled and must be added. You can modify the policy after it is enabled.

## Disabling policies from policy sets using the administrative console

You can have policies listed in a policy set that are in the enabled state so that they are currently included in the policy set. You can disable a policy from being included in a policy set without deleting it from the policy set. You might want to do this if you want the policy included in the policy set in the future. You can use the administrative console to change this setting.

## Before you begin

To disable a policy for a policy set, be sure the policy is listed in the policy set and shown in the **Enabled** state in the **State** column of the **Policies** table on the Policy set settings page. If the policy is not listed, it might have been deleted and you must add it again and then disable it.

## About this task

You can disable a policy in a policy set, from the menu of the administrative console.

## Procedure

1. Click **Services > Policy sets > Application policy sets > *policy\_set\_name*** or **Services > Policy sets > System policy sets > *policy\_set\_name***. Clicking a policy set name from the listing in the policy sets collection opens the Policy set settings panel for that policy set. This panel displays a listing of available and enabled policies in the **Policies** table for the policy set you selected. If this table contains no policies, there are no existing policies to disable.
2. Click the **Select** box beside the enabled policy to be disabled. You can select multiple policies if you want to disable more than one.
3. Click **Disable**. The **State** column of the **Policies** table is updated to display the selected policy as disabled. The policy was not deleted from the policy set and is still available to be enabled.

## Results

You have disabled a policy for the selected policy set.

## What to do next

You could now enable other policies or add or modify existing policies for this policy set.

## Web services policies

Policies define the type of web service policy based on the quality of service type. Policies are initially set with default settings but the attributes can be edited and changed.

Provided policies include:

### WS-Addressing

Based on the World Wide Web Consortium (W3C) WS-Addressing specifications for web services. This family of specifications provide transport-neutral mechanisms to address web services and to facilitate end-to-end addressing. This specification provides asynchronous support.

### WS-Security

Based on the WS-Secure Conversation (WS-SC) and WS-Security specifications along with the associated token profiles. The WS-Security specification and its associated token profiles define a way to send security tokens and provide message integrity and confidentiality. The WS-Secure Conversation specification establishes a secure context, based on shared keys, for the client and server to use for a series of messages. This standard provides a framework across organizations that defines how to secure the entire conversation. Use the WS-Security policy to define how the SOAP messages are secured. It has options such as:

- which message parts are signed and encrypted
- the tokens types to be included
- whether to use symmetric or asymmetric cryptography

You can also use WS-Security policies to define the bootstrap policy that is used to acquire security context tokens. Security context tokens are used by secure conversation.

### WS-Reliable Messaging (WS-RM)

This specification enables the sender and receiver to assure the quality of services in a set of messages. It helps the application developer deal with latency issues, maintenance interruption, and other problems that prevent messages from being completed. This quality assurance is critical for stateful applications.

### WS-Transaction

This specification provides support for coordination of atomic transactions or business activities for web services applications. You can enable WS-Transaction on both the client (outbound) and server (inbound) side by attaching a policy set that enables the WS-Transaction policy as part of the policy set. This policy is based on the WS-AtomicTransaction specification and the WS-BusinessActivity specification, together with the WS-Coordination specification.

### HTTP Transport

The HTTP transport policy applies the HTTP features and HTTP connections polices to outbound messages. The response listener policy is enforced on inbound messages.

### SSL Transport

Provides SSL transport security for the HTTP protocol with web services applications.

### JMS Transport

When using the SOAP over JMS transport with JAX-WS applications, you can customize the transport by configuring the JMS transport policy. The SOAP over JMS transport provides an alternative to HTTPS for transporting SOAP requests and response messages between clients and

servers. Use the JMS transport policy to configure a service that uses the JMS transport to send asynchronous response messages back to the client.

### **Custom Properties**

Provides the ability to specify generic binding properties for web service applications. The CustomProperties binding is only supported for service clients.

## **Exporting policy sets using the administrative console**

You can export policy sets between a client and a provider or between servers using the administrative console.

### **Before you begin**

Before you begin this task, select the policy set to be exported. Read about the application policy sets collection and exporting policy sets to client or server environments using the wsadmin tool.

### **About this task**

Static export is used in development environment to exchange a policy sets between a client and a provider. You can also export between servers. The exported format is a .zip file.

### **Procedure**

1. From the administrative console navigation, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**. The Application policy sets collection page displays a listing of the custom and default policy sets. Custom policy sets are displayed only if you have created them. If you have not created a custom policy set, then only the default policy sets are displayed.
2. From the Application policy sets panel, select a policy set and click **Export**.
3. Locate the export archive file. From the Export policy set archive file settings panel, click the archive file to export.
4. Choose a location to export the file. Do not export the file to a browser.

### **Results**

When you finish this task, the policy set archive file has been exported to the location you specified.

### **Example**

If you have a policy set, ABC\_ps and you want to move it from ServerA to ClientA, you can use the export function. The export policy set can be used by importing it into another application server. Read about the command task for importing an exported policy set compression file.

### **What to do next**

You can import the policy set to reuse it.

## **Application policy sets collection**

Use this page to manage policy sets. You can create, copy, export, and import policy sets. You can also view or delete existing policy sets. You can use policy sets, or assertions that define services, to simplify your web services configuration because policy sets group security and other web services settings into reusable units.

To view this administrative console page, click **Services > Policy sets > Application policy sets**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

## Name

Specifies a list of available policy sets. Click a policy set name to access the details panel for that policy set. Use the buttons on the page to create a new policy set or manage the existing policy sets. You can also import a policy set to display in the list of available policy sets.

The following list of buttons are available to you for creating and managing policy sets:

Button	Resulting action
<b>New</b>	Creates a new policy set. This option opens an empty policy set and allows you to provide additional details, such as the name, description, and policy configuration options.
<b>Delete</b>	Removes the selected policy set.
<b>Copy</b>	Creates a copy of the policy set that is selected from a list. After you create a copy, you can provide a name and a description for the copy. You must also specify whether to transfer attachments and binding information, where these options are available, from the original to the copy.
<b>Import</b>	Imports a policy set. This is a menu item with the option of importing a policy set from a default repository or a selected location. You can select and import the default policy sets from the default repository. The default repository for the import function in the administrative console is the directory that contains the default policy sets. Initially, a subset of pre-configured policy sets are exposed. However, there are other default policy sets that are available to import when you select <b>Import &gt; From Default Repository</b> . The administrative console also displays the default policy sets in a list that includes descriptions, that you can use to select the policy set that you want to import.
<b>Export</b>	Exports the selected policy set to an archive file.

## Editable

This column shows whether the policy set is a user-defined, custom policy set that can be edited or whether the policy set is a default policy set that is not editable.

Values displayed in this field are Editable or Not editable. Even though a policy set is identified as not editable, it is deletable. For example, you cannot edit information for the default system policy set, but you can delete the policy set. You can change the properties for a default, not editable policy set by copying it, and then modifying the properties of the copy. For more information on modifying a default policy set, see copy of default policy set and bindings settings document.

**Data type:** String  
**Default:** Not editable

## Description

Provides a brief description of the application policy sets that currently exist. You cannot edit information for the default application policy sets; however, you can delete the policy sets. The list of contained policies for each policy set that it relates to are displayed in the Name column. The contained policies that are displayed are only those that are enabled. From this panel, the field is not editable.

For custom policy sets that you create or modify, you can edit this description when you create or customize policy sets on the details panel. The description is the same one that you entered in the **Description** field when you created that policy set. The included and enabled policies appear at the top followed by a bulleted list of the key attributes of the policy set.

## Application policy set settings

Use this page to view, create, enable or disable your policy sets. You can use policies, or assertions that define services, to simplify your web services configuration.

To view this administrative console page, click one of the following paths:

- **Services > Policy sets > Application policy sets > *policy\_set\_name*.**
- **Services > Policy sets > Application policy sets > New.**

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

**Important:** You can only edit the fields on this page if you open this page for a custom policy set. You cannot edit default policies.

### Policy set name

Specifies the name of a selected policy set. This field is empty if you are creating a new policy set and you can enter a policy set name. If you select an existing policy set from the Policy set page, then this field displays the name of that policy set. This field is also not editable for existing custom policy sets and default policy sets.

### Description

Specifies a brief description of the policy set being viewed, modified or created. This field displays a brief description of the policy set displayed in the Policy set name field or is empty if a new policy set is being created. You can edit this field for custom policy sets only.

### Policies

The Policies table displays a list of policies that are contained in the policy set. This table initially contains no policies when you are creating a new custom policy set. If this is a default policy set, then you cannot add, delete, enable or disable the policy. The configuration of a policy in a default policy set cannot be altered but you can view a policy by clicking on the policy name link. If the policy is a custom policy, you can modify the configuration of the policy by clicking the policy name link. You can alter the policies contained in a custom policy set using the following buttons:

Button	Resulting Action
Add	Provides a list of valid policies, instances of which are not already included in the collection, that can be added to the policy set collection. The following policies are available: <ul style="list-style-type: none"><li>• Custom properties</li><li>• HTTP transport</li><li>• JMS transport</li><li>• SSL transport</li><li>• WS-Addressing</li><li>• WS-ReliableMessaging</li><li>• WS-Security</li><li>• WS-Transaction</li></ul>
Delete	Removes the selected policy from the policy set and from the listing in the Description column of the table.
Enable	The policy is enabled for the policy set and displayed as enabled in the State column.
Disable	The policy is disabled for the policy set. The policy remains in the list but the State field shows the policy as Disabled.

## Policies - Policy

Specifies the name of a policy. This field is empty if you are creating a new policy set. If you select an existing policy, then this field displays the name of that policy. If the policy settings are viewable, then you can click on the policy name to view the settings. For custom policy sets, you can click on the policy name to configure the policy settings.

## Policies - State

Specifies an Enabled or Disabled status for each policy in the policy set. You cannot change the state for default policy sets. To change the state of the policy, select the policy and click **Enable** or **Disable**. The state is refreshed in this column to reflect your change.

If you disable a policy, you are temporarily removing the policy from the policy set without losing the configuration details for that policy. When a policy is disabled, you can easily enable the policy again by selecting **Enable**. If the policy is deleted, the configuration for that policy no longer exists. After you delete a policy, to enable that policy in a policy set, you must add the policy to the policy set and enter the configuration details for that policy.

## Policies - Description

Specifies a brief description of each policy in the policies table. The product does not support custom policies; therefore, this field is not editable. You cannot create a new policy.

## Additional properties – Attached deployed assets

Click this link to search for applications to which this policy set is attached. You can also find applications that contain service resources to which the policy set is attached.

## Search attached applications collection

Use this page to search for applications and other resources that are attached to a specific policy set or to search for applications and other resources that have attached service resources.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets** > *policy\_set\_name*.
2. Click **Attached applications** link in the Additional Properties section.

## Name

Specifies a list of applications that match the search text. The application names that are displayed in the Name column are either attached explicitly to the specified policy set or have service resources attached to this policy set.

To alter the policy set that is attached to an application, select an application, and click a button to enable the following options:

### Button

**Detach Policy Set**

### Resulting Action

Detaches the current policy set from the selected application or applications. This action also detaches any attached application service resources. This action does not detach other policy sets from the application or application service resources.

**Replace Policy Set**

Displays a list of policy sets that can be attached to the selected application or applications and any contained attached service resources. The policy set is replaced with the one selected. This action does not replace other policy sets that are attached to resources in the application that you select.

Click the application name to complete actions such as attaching policy sets to the application, its services, or its endpoints.

## Mapping abstract intents and managing policy sets

Use this task topic to specify abstract intents in the Service Component Architecture (SCA) composite file or with annotations to achieve a quality of service (QoS) for a service or reference when you are working with web services policy sets and bindings. The intents in the composite file must be mapped to policy sets that can satisfy those intents during deployment to achieve the QoS that is required.

### Before you begin

Before you begin this task, install an Service Component Architecture (SCA) application.

### About this task

Use the composite file to specify intents and policy sets for web services bindings to achieve quality of services (QoS).

**Note:** In a mixed cell environment, the following limitations apply to attachments to policy sets containing the CustomProperties policy:

- You must not create attachments to policy sets containing the CustomProperties policy for applications that are deployed on an application server that is prior to WebSphere Application Server Version 8. The CustomProperties policy is only supported on WebSphere Application Server V8 and later.
- An application that contains an attachment to a policy set containing the CustomProperties policy must not be deployed on an application server that is prior to WebSphere Application Server Version 8.
- If an application that is deployed in a cluster environment contains an attachment to a policy set containing the CustomProperties policy, you must not add a member application server that is prior to WebSphere Application Server Version 8 to the cluster.

### Procedure

1. Specify abstract intents at the <binding.ws> element of the service or reference level of the component.

You can specify intents at any level in the composite file using a required attribute. The intent inheritance rules specified in the SCA Policy specification is enforced in the product. The following code example illustrates how to specify intents in a composite file.

#### Specifying intents in a composite file

```
<service name="AccountService" requires="authentication">
 <binding.ws
 requires="confidentiality.transport"
 ... />
</service>
```

Valid intents that can be mapped to a policy set are:

```
confidentiality
confidentiality.message
confidentiality.transport
integrity
integrity.message
integrity.transport
authentication
authentication.message
authentication.transport
propagatesTransaction
```

The table provides a list of intents and the supported bindings to achieve QoS.

Table 271. Intents supported by different types of bindings. Intents and the supported bindings to achieve QoS

Intent	binding.ws	binding.ejb and binding.sca
authentication.message	Intent requires the attachment of a web service policy set and policy binding that contains the WS–Security policy type	Not supported; CSiv2 can be configured to use basic auth or security token (LTPA, Kerberos)
confidentiality.message and integrity.message	Both intents require the attachment of a Web service policy set and policy binding that contains the WS–Security policy type	Not supported
authentication.transport	Basic auth only. Reference requires the attachment of a web service policy set that contains the HTTPTransport policy type. Service does not require any attachments.	Intent is not supported. CSiv2 can be configured to use client certificates for authentication.
confidentiality.transport and integrity.transport	Requires the attachment of a web service policy set that contains the SSLTransport policy type	Intent is not supported. CSiv2 can be configured to require SSL.
propagatesTransaction	Requires the attachment of a web service policy set that contains the WS–Transaction policy type	Supported; no configuration required
