It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Required

It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

Target inbound transport chain:

The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging

This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging

This is the InboundBasicMessaging protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required	No
Data type	String

Provider endpoints:

A comma-separated list of endpoint triplets, with the syntax `hostName:portNumber:chainName`, used to connect to a bootstrap server. For example `Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging`. If `hostName` is not specified, the default is `localhost`. If `portNumber` is not specified, the default is `7276`. If `chainName` is not specified, the default is `BootstrapBasicMessaging`. Refer to the information center for more information.

You only have to modify this property if you have client applications running outside of an application server, or applications on a server in another cell, that want to use this connection factory to connect to the target service integration bus specified on the connection factory.

To use JMS destinations of the default messaging provider, an application connects to a messaging engine on the target service integration bus to which the destinations are assigned. For example, a JMS queue is assigned to a queue destination on a service integration bus.

Client applications running outside of an application server - for example, running in a client container or outside the WebSphere Application Server environment - cannot locate directly a suitable messaging engine to connect to in the target bus. Similarly, an application running on a server in one cell to connect to a target bus in another cell cannot locate directly a suitable messaging engine to connect to in the target bus.

In these scenarios, the clients (or servers in another bus) must complete a bootstrap process through a *bootstrap server* that is a member of the target bus. A bootstrap server is an application server running the SIB Service, but does not have to be running any messaging engines. The bootstrap server selects a messaging engine that is running in an application server that supports the required *target transport chain*. For the bootstrap process to be possible, you must configure one or more *provider end points* in the connection factory used by the client.

A bootstrap server uses a specific port and bootstrap transport chain. The port is the **SIB_ENDPOINT_ADDRESS** (or **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled), of the messaging engine that hosts the remote end of the link. Together with host name, these form the *endpoint address* of the bootstrap server.

The properties of a JMS connection factory used by an application control the selection of a suitable messaging engine and how the application connects to the selected messaging engine.

- If no security credentials are provided, then by default
 - If no host is specified then localhost is used
 - If no port is specified then port 7276 is used
 - If no bootstrap channel chain is specified then bootstrap transport chain called `BootstrapBasicMessaging` is used
- If security credentials are provided, then by default
 - If no host is specified then localhost is used
 - If no port is specified then port 7286 is used
 - If no bootstrap channel chain is specified then bootstrap transport chain called `BootstrapBasicMessaging` is used

If you want an application to use a bootstrap server with a different endpoint address, you must specify the required endpoint address on the **Provider endpoints** property of the JMS connection factories that the client application uses. You can specify one or more endpoint addresses of bootstrap servers.

The endpoint addresses for bootstrap servers must be specified in every JMS connection factory that is used by applications outside of an application server. To avoid having to specify a long list of bootstrap servers, you can provide a few highly-available servers as dedicated bootstrap servers. Then you only have to specify a short list of bootstrap servers on each connection factory.

Note: When configuring a connection to a non-default bootstrap server, specify the required values for the endpoint address and use colons as separators.

For example: for a server assigned non-secure port 7278, on host `boothost1`, that uses the default transport chain `BootstrapBasicMessaging`:

```
boothost1:7278:BootstrapBasicMessaging  
or  
boothost1:7278
```

and for a server assigned secure port 7289, on host `boothost2`, that uses the predefined transport chain `BootstrapTunneledSecureMessaging`:

```
boothost2:7289:BootstrapTunneledSecureMessaging
```

The syntax for an endpoint address is as follows:

```
[ [host_name] [ ":" [port_number] [ ":" chain_name] ] ]
```

where:

host_name

is the name of the host on which the server runs. It can be an IP address. For an IPv6 address, put square braces ([]) around *host_name* as shown in the example below:

```
[2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
```

. If a value is not specified, the default is localhost.

port_number

where specified, is one of the following addresses of the messaging engine that hosts the remote end of the link:

- **SIB_ENDPOINT_ADDRESS** if security is not enabled
- For secure connections, **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled.

If *port_number* is not specified, the default is 7276.

To find either of these values by using the administrative console, click **Servers -> Server Types -> WebSphere application servers -> server_name -> [Communications] Ports**.

chain_name

is the name of a predefined bootstrap transport chain used to connect to the bootstrap server. If not specified, the default is BootstrapBasicMessaging.

The following predefined bootstrap transport chains are provided:

BootstrapBasicMessaging

This corresponds to the server transport chain InboundBasicMessaging (JFAP-TCP/IP)

BootstrapSecureMessaging

This corresponds to the server transport chain InboundSecureMessaging (JFAP-SSL-TCP/IP)

BootstrapTunneledMessaging

Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers -> Server Types -> WebSphere application servers -> server_name -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

BootstrapTunneledSecureMessaging

Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers -> Server Types -> WebSphere application servers -> server_name -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

Specifying *host_name : chain_name* instead of *host_name : : chain_name* (with two colons) is incorrect. It is valid to enter nothing, or to enter any of the following: "a", "a:", ":7276", "::chain", and so on. The default value applies if you do not specify a value, but you must separate the fields with ":"s.

If you want to provide more than one bootstrap server, identify all the required endpoint addresses. Separate each endpoint address by a comma character. For example, to use the servers from the earlier example:

```
boothost1:7278:BootstrapBasicMessaging,
boothost2:7289:BootstrapTunneledSecureMessaging,
[2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
```

Required	No
Data type	Text area

Connection proximity:

The proximity of messaging engines that can accept connection requests, in relation to the bootstrap messaging engine.

When a client issues a client connect request, the processing attaches to the required bus according to the following logic:

- If a target group is specified, connect to the first messaging engine that satisfies the following conditions for the target type:
 - **Server** Look for a messaging engine in the same server.
 - **Cluster** Look for a messaging engine in the same server, then on other servers in the same cluster.

- **Host** Look for a messaging engine in the same server, then on other servers in the same cluster, then on other servers in the same host.
- **Bus** Look for a messaging engine in the same server, then on other servers in the same cluster, then on other servers in same host, then any other messaging engine on the same bus.
- If a target group is not specified, or a target group is specified but no suitable messaging engine is found and target significance is Preferred, connect to the first messaging engine that satisfies the following conditions for the target type:
 - **Server** Look for a messaging engine in the same server.
 - **Cluster** Connection fails.
 - **Host** Look for a messaging engine in the same server, then on other servers in the same host.
 - **Bus** Look for a messaging engine in the target group in same server, then on other servers in same host, then any other messaging engine on the same bus.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required	No
Data type	drop-down list
Range	<p>Bus Connections can be made to messaging engines in the same bus.</p> <p>Cluster Connections can be made to messaging engines in the same server cluster.</p> <p>Host Connections can be made to messaging engines in the same host.</p> <p>Server Connections can be made to messaging engines in the same application server.</p>

Nonpersistent message reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

You can change the delivery reliability option for the destination of a message that is sent by a JMS application as Nonpersistent. The default is Express nonpersistent but you have a range of other options, including those with persistent characteristics, with Assured persistent being the most reliable. For more information see the topic Message reliability levels - JMS delivery mode and service integration quality of service.

Required	No
Data type	drop-down list

Range

Best effort nonpersistent

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent

Messages are discarded when a messaging engine stops or fails.

Reliable persistent

Messages might be discarded when a messaging engine fails.

Assured persistent

Messages are not discarded.

As bus destination

Use the delivery option configured for the bus destination.

Persistent message reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

You can change the delivery reliability option for the destination of a message that is sent by a JMS application as Persistent. The default is Reliable persistent but you have a range of other options including those with nonpersistent characteristics, with Best effort nonpersistent being the least reliable. For more information see the topic Message reliability levels - JMS delivery mode and service integration quality of service.

Important: If you change the delivery reliability options of a message sent by a JMS application from one of the **Persistent message reliability** options (Assured persistent and Reliable persistent) to one of the **Nonpersistent message reliability** options (Best effort nonpersistent, Express nonpersistent, and Reliable nonpersistent), you risk losing messages in certain circumstances. For example, at server restart, or when there is heavy workload.

Required
Data type

No
drop-down list

Range

Best effort nonpersistent

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent

Messages are discarded when a messaging engine stops or fails.

Reliable persistent

Messages might be discarded when a messaging engine fails.

Assured persistent

Messages are not discarded.

As bus destination

Use the delivery option configured for the bus destination.

Read ahead:

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

You can override this property for individual JMS destinations by setting the **Read ahead** property on the JMS destination.

Required

No

Data type

drop-down list

Range

Default The message provider preemptively assigns messages to consumers on nondurable subscriptions and unshared durable subscriptions. That is, read ahead optimization is turned on only when there can only be a single consumer.

Enabled

The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Disabled

The messaging provider does not preemptively assign messages to consumers.

Temporary queue name prefix:

The prefix used at the start of temporary queues created by applications using this connection factory.

Required	No
Data type	String

Pass message payload by reference: When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION:

The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic Why and when to pass the JMS message payload by reference, or you risk losing data integrity.

Applications that use this connection factory to send messages must obey the following rules::

- The application does not modify the data object contained in a JMS object message.
- The application populates a JMS bytes message by using a single call to `writeBytes(byte[])` and does not modify the byte array after it is set in the message.

When enabled, Object/Bytes Messages sent by a message producing application that has connected to the bus using this connection factory will not have their data copied when set and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message.

Required	No
Data type	Boolean

Applications that use this connection factory to receive messages must obey the following rule::

- The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When enabled, Object Messages received by a message consuming application that has connected to this connection factory will only have their message data serialized by the system when absolutely necessary. The data obtained from these messages must be treated as readOnly by applications.

Required	No
Data type	Boolean

Log missing transaction contexts:

Whether or not the container logs that there is a missing transaction context when a connection is obtained.

The Java EE programming model indicates that connections should always have a transaction context. However, some applications do not correctly have a transaction context associated with them.

Select this property to log connections being created without a transaction context.

Required	No
Data type	Boolean

Manage cached handles:

Whether cached handles (handles held in instance variables in a bean) should be tracked by the container.

Select this option to track handle management, which can be useful for debugging purposes. However, tracking handles can significantly reduce performance if used at run time.

Required	No
Data type	Boolean

Share data source with CMP:

Allow sharing of connections between JMS and container-managed persistence (CMP) entity EJB beans.

This option is used as part of the task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. This has been estimated as a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

For more information about using this option, see the topic Enabling CMP entity beans and messaging engine data stores to share database connections.

Required	No
Data type	Boolean

XA recovery authentication alias:

The authentication alias used during XA recovery processing.

Select the alias to be used during transaction recovery processing.

This property provides a list of the JCA authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate during XA recovery processing.

If you have enabled security for the associated service integration bus, select the alias that specifies the user ID and password used for XA recovery that is valid in the user registry for WebSphere Application Server. This property must be set if bus security is enabled and XA transactions are to be used.

Required	No
Data type	drop-down list

Mapping-configuration alias:

Specifies the mapping configuration alias for the Java Authentication and Authorization Service (JAAS) mapping configuration that is used by this connection factory.

This field will be used only in the absence of a loginConfiguration on the component resource reference. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the DefaultPrincipalMapping login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. See related item JAAS - J2C authentication data entry to define a new alias.

Required	No
Data type	drop-down list

Container-managed authentication alias:

This alias specifies a user ID and password to be used to authenticate connections to the JMS provider for container-managed authentication. This setting is only used when the res-auth value is container, and the authentication alias was not set when the application was deployed.

Required	No
Data type	drop-down list

Additional Properties

Connection pool properties

An optional set of connection pool settings.

Related Items

JAAS - J2C authentication data

Specifies a list of user identities and passwords for Java 2 connector security to use.

Buses

A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

Default messaging provider queue [Settings]

A JMS queue is used as a destination for point-to-point messaging. Use JMS queue destination administrative objects to manage JMS queues for the default messaging provider.

To view this page in the console, click one of the following paths:

- **Resources -> JMS -> Queues -> *queue_name***
- **Resources -> JMS -> JMS providers -> *a_messaging_provider* -> [Additional Properties] Queues -> *queue_name***

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Scope:

Specifies the highest topological level at which application servers can use this resource object.

Required	No
Data type	String

Provider:

Specifies a JMS provider, which enables asynchronous messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for specific JMS queue or topic destinations. JMS provider administrative objects are used to manage JMS resources for the associated JMS provider.

Required	No
Data type	String

Name:

The required display name for the resource.

Required	Yes
Data type	String

JNDI name:

The JNDI name for the resource.

As a convention, use a JNDI name of the form `jms/Name`, where *Name* is the logical name of the resource. For more information about the use of JNDI and its syntax, see the topic JNDI support in WebSphere Application Server.

Required	Yes
Data type	String

Description:

An optional description for the resource.

Required No
Data type Text area

Bus name:

Enter the name of the bus on which the associated queue exists, or leave blank to use the bus to which the application connects.

Required No
Data type Custom

Queue name:

The name of the associated queue on the service integration bus.

Type the name of a queue that has been created on the service integration bus.

Required Yes
Data type Custom

Delivery mode:

The delivery mode for messages sent to this destination. This controls the persistence of messages on this destination.

Required No
Data type drop-down list
Range

Application
The persistence of messages on this topic is defined by the producing application.

Nonpersistent
All messages sent to this topic are treated as nonpersistent.

Persistent
All messages sent to this topic are treated as persistent.

Time to live:

The default length of time in milliseconds from its dispatch time that a message sent to this destination should be kept by the system.

Required No
Data type Integer
Range 0 through 574476389546486783

A value of 0 (zero) means that messages are kept indefinitely. The default for this property is null, which allows the application to determine the time to keep messages.

Priority:

The relative priority for messages sent to this destination, in the range 0 to 9, with 0 as the lowest priority and 9 as the highest priority.

If a value is not specified for this property, the message priority set by the producing application is used.

Required	No
Data type	Integer
Range	0 through 9

The message priority range is from 0 (lowest) through 9 (highest).

Read ahead:

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

This property overrides the value set by the **Read ahead** property on the JMS connection factory.

Required	No
Data type	drop-down list
Range	Enabled The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests for this destination. Disabled The messaging provider does not preemptively assign messages to consumers for this destination. Inherit from connection factory Read ahead optimization is defined on the connection.

Restrict messages to the local queue point if a queue point is configured on the connected messaging engine:

Indicates whether the underlying service integration bus queue destination is scoped to a local queue point when addressed by using this JMS queue. A local queue point is a queue point of the service integration bus queue that is configured on the messaging engine to which the JMS application is connected.

This option applies when using this JMS queue to send and receive messages, and when setting a reply queue in a request message. When a reply queue is set in a request message, the local queue point is on the messaging engine to which the application setting the reply queue is connected, not the messaging

engine to which the application that uses the reply queue sends the reply message. If the connected messaging engine does not have a queue point for the destination this option is ignored. The default value is FALSE.

This option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Required	Yes
Data type	Boolean
Default	FALSE

Local queue point preference:

Prefer to send messages to a local queue point

If a queue point for this queue exists on the messaging engine that the application is connected to, prefer to send all messages to it to improve performance. If this local queue point is not accepting new messages, the messages are sent to other queue points, if possible.

Required	No
Data type	Radio button

Do not prefer a local queue point over other queue points

All available queue points are treated equally, with no preference given to a local queue point. Messages are workload balanced across all queue points. This option is supported only when used by a JMS application that is running with a WebSphere Application ServerVersion 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application ServerVersion 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Required	No
Data type	Radio button

Message affinity across queue points:

Send all messages to the same queue point

A message producer created to use this queue sends all messages to the same queue point. This option does not influence the initial choice of queue point. This option applies to a message producer only if the queue is identified at the time the message producer is created, not at the time of sending messages. This option is supported only when used by a JMS application that is running with a WebSphere Application ServerVersion 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application ServerVersion 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Required	No
Data type	Radio button

Messages may be sent to different queue points

A message producer can send messages to different queue points, based on the availability of the queue points and workload balancing of the system.

Required	No
Data type	Radio button

Message visibility:

Only messages on a single queue point are visible

A consumer or browser has access to messages on only one queue point, not the entire queue. The single queue point is chosen by the messaging system. A queue point that is defined on the same messaging engine that the application is connected to is preferred to other queue points.

Required No
Data type Radio button

Messages on all queue points are visible

A consumer or browser has access to messages on all queue points of the queue. If you enable this option, all queue points are actively checked for messages. This means that no messages are left on an unattended queue point. However, there is a performance cost in scanning all queue points for messages, and you can no longer control the order in which messages are taken off the queue. This option is supported only when used by a JMS application that is running with a WebSphere Application ServerVersion 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application ServerVersion 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Required No
Data type Radio button

Related Items

Buses

A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

Default messaging provider topic connection factory [Settings]

A JMS topic connection factory is used to create connections to the associated JMS provider of JMS topics, for publish/subscribe messaging. Use topic connection factory administrative objects to manage JMS topic connection factories for the default messaging provider.

To view this page in the console, click one of the following paths:

- **Resources -> JMS -> Topic connection factories -> *factory_name***
- **Resources -> JMS -> JMS providers -> *a_messaging_provider* -> [Additional Properties] Topic connection factories -> *factory_name***

Use this panel to browse or change the configuration properties of the selected JMS topic connection factory for use with the default messaging JMS provider. These configuration properties control how connections are created to associated JMS topics.

By default, connections created by using this JMS connection factory in the server containers (for example, from an enterprise bean) are pooled by using Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection pooling. You can modify the connection pool settings for this connection factory by selecting **Connection pool properties** in the Additional properties section of the administrative console panel.

The configuration of a container-managed authentication alias and mapping module on a connection factory are deprecated. You now set these properties in the bindings for the resource reference of the application. If you do not want to modify the bindings for an existing application, locate this connection factory in the J2C panels where you can still find these properties.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Scope:

Specifies the highest topological level at which application servers can use this resource object.

Required	No
Data type	String

Provider:

Specifies a JMS provider, which enables asynchronous messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for specific JMS queue or topic destinations. JMS provider administrative objects are used to manage JMS resources for the associated JMS provider.

Required	No
Data type	String

Name:

The required display name for the resource.

Required	Yes
Data type	String

JNDI name:

The JNDI name for the resource.

As a convention, use a JNDI name of the form `jms/Name`, where *Name* is the logical name of the resource. For more information about the use of JNDI and its syntax, see the topic JNDI support in WebSphere Application Server.

Required	Yes
Data type	String

Description:

An optional description for the resource.

Required	No
Data type	Text area

Category:

An optional category string to use when classifying or grouping the resource.

Required	No
Data type	String

Bus name:

The name of the bus to connect to.

This is the name of the service integration bus that this connection factory is used to create connections to.

Enter the name of the local bus in situations where an application makes connection to foreign buses.

Required	Yes
Data type	Custom

Target:

The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property.

This indicates the name of a target that is to be used to determine one or messaging engines to handle work. The type of target is indicated by the Target type property

Connections are load balanced across the available messaging engines that satisfy the selection criteria.

If want applications to be able to connect to any messaging engine in the bus, do not set this property.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required	No
Data type	String

Target type:

The type of target named in the Target property.

Required	No
Data type	drop-down list

Range**Bus member name**

The name of a bus member. This option retrieves the active messaging engines that are hosted by the named bus member (an application server or server cluster).

To specify a non-clustered bus member the Target property must be set to <Node01>.<server1>, for example Node01.server1. For a cluster bus member the Target property must be set to the cluster name.

Custom messaging engine group name

The name of a custom group of messaging engines (that form a self-declaring cluster). This option retrieves the active messaging engines that have registered with the named custom group.

Messaging engine name

The name of a messaging engine. This option retrieves the available endpoints that can be used to reach the named messaging engine.

Target significance:

This property specifies the significance of the target group.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required
Data type
Range

No
drop-down list

Preferred

It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Required

It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

Target inbound transport chain:

The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging

This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging

This is the InboundBasicMessaging protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required	No
Data type	String

Provider endpoints:

A comma-separated list of endpoint triplets, with the syntax `hostName:portNumber:chainName`, used to connect to a bootstrap server. For example `Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging`. If `hostName` is not specified, the default is `localhost`. If `portNumber` is not specified, the default is `7276`. If `chainName` is not specified, the default is `BootstrapBasicMessaging`. Refer to the information center for more information.

You only have to modify this property if you have client applications running outside of an application server, or applications on a server in another cell, that want to use this connection factory to connect to the target service integration bus specified on the connection factory.

To use JMS destinations of the default messaging provider, an application connects to a messaging engine on the target service integration bus to which the destinations are assigned. For example, a JMS queue is assigned to a queue destination on a service integration bus.

Client applications running outside of an application server - for example, running in a client container or outside the WebSphere Application Server environment - cannot locate directly a suitable messaging engine to connect to in the target bus. Similarly, an application running on a server in one cell to connect to a target bus in another cell cannot locate directly a suitable messaging engine to connect to in the target bus.

In these scenarios, the clients (or servers in another bus) must complete a bootstrap process through a *bootstrap server* that is a member of the target bus. A bootstrap server is an application server running the SIB Service, but does not have to be running any messaging engines. The bootstrap server selects a messaging engine that is running in an application server that supports the required *target transport chain*. For the bootstrap process to be possible, you must configure one or more *provider end points* in the connection factory used by the client.

A bootstrap server uses a specific port and bootstrap transport chain. The port is the **SIB_ENDPOINT_ADDRESS** (or **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled), of the messaging engine that hosts the remote end of the link. Together with host name, these form the *endpoint address* of the bootstrap server.

The properties of a JMS connection factory used by an application control the selection of a suitable messaging engine and how the application connects to the selected messaging engine.

- If no security credentials are provided, then by default
 - If no host is specified then localhost is used
 - If no port is specified then port 7276 is used
 - If no bootstrap channel chain is specified then bootstrap transport chain called `BootstrapBasicMessaging` is used
- If security credentials are provided, then by default
 - If no host is specified then localhost is used
 - If no port is specified then port 7286 is used
 - If no bootstrap channel chain is specified then bootstrap transport chain called `BootstrapBasicMessaging` is used

If you want an application to use a bootstrap server with a different endpoint address, you must specify the required endpoint address on the **Provider endpoints** property of the JMS connection factories that the client application uses. You can specify one or more endpoint addresses of bootstrap servers.

The endpoint addresses for bootstrap servers must be specified in every JMS connection factory that is used by applications outside of an application server. To avoid having to specify a long list of bootstrap servers, you can provide a few highly-available servers as dedicated bootstrap servers. Then you only have to specify a short list of bootstrap servers on each connection factory.

Note: When configuring a connection to a non-default bootstrap server, specify the required values for the endpoint address and use colons as separators.

For example: for a server assigned non-secure port 7278, on host `boothost1`, that uses the default transport chain `BootstrapBasicMessaging`:

```
boothost1:7278:BootstrapBasicMessaging  
or  
boothost1:7278
```

and for a server assigned secure port 7289, on host `boothost2`, that uses the predefined transport chain `BootstrapTunneledSecureMessaging`:

```
boothost2:7289:BootstrapTunneledSecureMessaging
```

The syntax for an endpoint address is as follows:

```
[ [host_name] [ ":" [port_number] [ ":" chain_name] ] ]
```

where:

host_name

is the name of the host on which the server runs. It can be an IP address. For an IPv6 address, put square braces ([]) around *host_name* as shown in the example below:

```
[2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
```

. If a value is not specified, the default is localhost.

port_number

where specified, is one of the following addresses of the messaging engine that hosts the remote end of the link:

- **SIB_ENDPOINT_ADDRESS** if security is not enabled
- For secure connections, **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled.

If *port_number* is not specified, the default is 7276.

To find either of these values by using the administrative console, click **Servers -> Server Types -> WebSphere application servers -> server_name -> [Communications] Ports**.

chain_name

is the name of a predefined bootstrap transport chain used to connect to the bootstrap server. If not specified, the default is BootstrapBasicMessaging.

The following predefined bootstrap transport chains are provided:

BootstrapBasicMessaging

This corresponds to the server transport chain InboundBasicMessaging (JFAP-TCP/IP)

BootstrapSecureMessaging

This corresponds to the server transport chain InboundSecureMessaging (JFAP-SSL-TCP/IP)

BootstrapTunneledMessaging

Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers -> Server Types -> WebSphere application servers -> server_name -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

BootstrapTunneledSecureMessaging

Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers -> Server Types -> WebSphere application servers -> server_name -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

Specifying *host_name : chain_name* instead of *host_name : : chain_name* (with two colons) is incorrect. It is valid to enter nothing, or to enter any of the following: "a", "a:", ":7276", "::chain", and so on. The default value applies if you do not specify a value, but you must separate the fields with ":"s.

If you want to provide more than one bootstrap server, identify all the required endpoint addresses. Separate each endpoint address by a comma character. For example, to use the servers from the earlier example:

```
boothost1:7278:BootstrapBasicMessaging,
boothost2:7289:BootstrapTunneledSecureMessaging,
[2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
```

Required	No
Data type	Text area

Connection proximity:

The proximity of messaging engines that can accept connection requests, in relation to the bootstrap messaging engine.

When a client issues a client connect request, the processing attaches to the required bus according to the following logic:

- If a target group is specified, connect to the first messaging engine that satisfies the following conditions for the target type:
 - **Server** Look for a messaging engine in the same server.
 - **Cluster** Look for a messaging engine in the same server, then on other servers in the same cluster.

- **Host** Look for a messaging engine in the same server, then on other servers in the same cluster, then on other servers in the same host.
- **Bus** Look for a messaging engine in the same server, then on other servers in the same cluster, then on other servers in same host, then any other messaging engine on the same bus.
- If a target group is not specified, or a target group is specified but no suitable messaging engine is found and target significance is Preferred, connect to the first messaging engine that satisfies the following conditions for the target type:
 - **Server** Look for a messaging engine in the same server.
 - **Cluster** Connection fails.
 - **Host** Look for a messaging engine in the same server, then on other servers in the same host.
 - **Bus** Look for a messaging engine in the target group in same server, then on other servers in same host, then any other messaging engine on the same bus.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required	No
Data type	drop-down list
Range	<p>Bus Connections can be made to messaging engines in the same bus.</p> <p>Cluster Connections can be made to messaging engines in the same server cluster.</p> <p>Host Connections can be made to messaging engines in the same host.</p> <p>Server Connections can be made to messaging engines in the same application server.</p>

Client identifier:

The JMS client identifier needed for durable topic subscriptions on all connections created using this connection factory.

Required	No
Data type	String

Durable subscription home:

The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS connection factory.

To enable applications to use durable subscriptions, you must set this property.

Required	No
Data type	Custom

Nonpersistent message reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

You can change the delivery reliability option for the destination of a message that is sent by a JMS application as Nonpersistent. The default is Express nonpersistent but you have a range of other options, including those with persistent characteristics, with Assured persistent being the most reliable. For more information see the topic Message reliability levels - JMS delivery mode and service integration quality of service.

Required
Data type
Range

No
drop-down list

Best effort nonpersistent

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent

Messages are discarded when a messaging engine stops or fails.

Reliable persistent

Messages might be discarded when a messaging engine fails.

Assured persistent

Messages are not discarded.

As bus destination

Use the delivery option configured for the bus destination.

Persistent message reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

You can change the delivery reliability option for the destination of a message that is sent by a JMS application as Persistent. The default is Reliable persistent but you have a range of other options including those with nonpersistent characteristics, with Best effort nonpersistent being the least reliable. For more information see the topic Message reliability levels - JMS delivery mode and service integration quality of service.

Important: If you change the delivery reliability options of a message sent by a JMS application from one of the **Persistent message reliability** options (Assured persistent and Reliable persistent) to one of the **Nonpersistent message reliability** options (Best effort nonpersistent, Express nonpersistent, and Reliable nonpersistent), you risk losing messages in certain circumstances. For example, at server restart, or when there is heavy workload.

Required
Data type

No
drop-down list

Range

Best effort nonpersistent

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent

Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent

Messages are discarded when a messaging engine stops or fails.

Reliable persistent

Messages might be discarded when a messaging engine fails.

Assured persistent

Messages are not discarded.

As bus destination

Use the delivery option configured for the bus destination.

Read ahead:

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

You can override this property for individual JMS destinations by setting the **Read ahead** property on the JMS destination.

Required

No

Data type

drop-down list

Range

Default The message provider preemptively assigns messages to consumers on nondurable subscriptions and unshared durable subscriptions. That is, read ahead optimization is turned on only when there can only be a single consumer.

Enabled

The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Disabled

The messaging provider does not preemptively assign messages to consumers.

Temporary topic name prefix:

The prefix used at the start of temporary topics created by applications using this connection factory.

Required
Data type

No
String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Usually, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Required
Data type
Range

No
drop-down list

In cluster

Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared

Durable subscriptions can be shared across connections.

Never shared

Durable subscriptions are never shared across connections.

Pass message payload by reference: When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION:

The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic *Why and when to pass the JMS message payload by reference*, or you risk losing data integrity.

Applications that use this connection factory to send messages must obey the following rules::

- The application does not modify the data object contained in a JMS object message.
- The application populates a JMS bytes message by using a single call to `writeBytes(byte[])` and does not modify the byte array after it is set in the message.

When enabled, Object/Bytes Messages sent by a message producing application that has connected to the bus using this connection factory will not have their data copied when set and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message.

Required	No
Data type	Boolean

Applications that use this connection factory to receive messages must obey the following rule::

- The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When enabled, Object Messages received by a message consuming application that has connected to this connection factory will only have their message data serialized by the system when absolutely necessary. The data obtained from these messages must be treated as `readOnly` by applications.

Required	No
Data type	Boolean

Log missing transaction contexts:

Whether or not the container logs that there is a missing transaction context when a connection is obtained.

The Java EE programming model indicates that connections should always have a transaction context. However, some applications do not correctly have a transaction context associated with them.

Select this property to log connections being created without a transaction context.

Required	No
Data type	Boolean

Manage cached handles:

Whether cached handles (handles held in instance variables in a bean) should be tracked by the container.

Select this option to track handle management, which can be useful for debugging purposes. However, tracking handles can significantly reduce performance if used at run time.

Required	No
Data type	Boolean

Share data source with CMP:

Allow sharing of connections between JMS and container-managed persistence (CMP) entity EJB beans.

This option is used as part of the task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. This has been estimated as a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

For more information about using this option, see the topic Enabling CMP entity beans and messaging engine data stores to share database connections.

Required	No
Data type	Boolean

XA recovery authentication alias:

The authentication alias used during XA recovery processing.

Select the alias to be used during transaction recovery processing.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate during XA recovery processing.

If you have enabled security for the associated service integration bus, select the alias that specifies the user ID and password used for XA recovery that is valid in the user registry for WebSphere Application Server. This property must be set if bus security is enabled and XA transactions are to be used.

Required	No
Data type	drop-down list

Mapping-configuration alias:

Specifies the mapping configuration alias for the Java Authentication and Authorization Service (JAAS) mapping configuration that is used by this connection factory.

This field will be used only in the absence of a loginConfiguration on the component resource reference. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the DefaultPrincipalMapping login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. See related item JAAS - J2C authentication data entry to define a new alias.

Required	No
Data type	drop-down list

Container-managed authentication alias:

This alias specifies a user ID and password to be used to authenticate connections to the JMS provider for container-managed authentication. This setting is only used when the res-auth value is container, and the authentication alias was not set when the application was deployed.

Required	No
-----------------	----

Data type

drop-down list

Additional Properties

Connection pool properties

An optional set of connection pool settings.

Related Items

JAAS - J2C authentication data

Specifies a list of user identities and passwords for Java 2 connector security to use.

Buses

A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

Default messaging provider topic [Settings]

A JMS topic is used as a destination for publish/subscribe messaging. Use topic destination administrative objects to manage JMS topics for the default messaging provider.

To view this page in the console, click one of the following paths:

- **Resources -> JMS -> Topics -> *topic_name***
- **Resources -> JMS -> JMS providers -> *a_messaging_provider* -> [Additional Properties] Topics > *topic_name***

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Scope:

Specifies the highest topological level at which application servers can use this resource object.

Required	No
Data type	String

Provider:

Specifies a JMS provider, which enables asynchronous messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for specific JMS queue or topic destinations. JMS provider administrative objects are used to manage JMS resources for the associated JMS provider.

Required	No
Data type	String

Name:

The required display name for the resource.

Required	Yes
Data type	String

JNDI name:

The JNDI name for the resource.

As a convention, use a JNDI name of the form `jms/Name`, where *Name* is the logical name of the resource. For more information about the use of JNDI and its syntax, see the topic JNDI support in WebSphere Application Server.

Required	Yes
Data type	String

Description:

An optional description for the resource.

Required	No
Data type	Text area

Topic name:

The name of the topic that this JMS topic is assigned to, in the topic space defined by the Topic space property.

To specify a multi-level topic name, separate each level by a forward slash character (/); for example:
`schools/eton/subjects/maths`

Required	No
Data type	String

Bus name:

Name of bus hosting topic.

Required	No
Data type	Custom

Topic space:

The name of the topic space that contains the topic, on the service integration bus defined by the Bus name property

Type the name of a topic space that has been created on the service integration bus.

Required	Yes
Data type	Custom

JMS delivery mode:

The delivery mode for messages sent to this destination. This controls the persistence of messages on this destination.

Required
Data type
Range

No
drop-down list

Application

The persistence of messages on this topic is defined by the producing application.

Nonpersistent

All messages sent to this topic are treated as nonpersistent.

Persistent

All messages sent to this topic are treated as persistent.

Time to live:

The default length of time in milliseconds from its dispatch time that a message sent to this destination should be kept by the system.

Messages are deleted after the specified time. If a value is not specified for this property, the time limit set by the producing application is used.

Required
Data type
Range

No
Long
0 through 574476389546486783

A value of 0 (zero) means that messages are kept indefinitely. The default for this property is null, which allows the application to determine the time to keep messages.

Message priority:

The relative priority for messages sent to this destination, in the range 0 to 9, with 0 as the lowest priority and 9 as the highest priority.

If a value is not specified for this property, the message priority set by the producing application is used.

Required
Data type
Range

No
Integer
0 through 9

The message priority range is from 0 (lowest) through 9 (highest).

Read ahead:

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

This property overrides the value set by the **Read ahead** property on the JMS connection factory.

Required	No
Data type	drop-down list
Range	
	Enabled The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests for this destination.
	Disabled The messaging provider does not preemptively assign messages to consumers for this destination.
	Inherit from connection factory Read ahead optimization is defined on the connection.

Related Items

Buses

A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

SIBJMSAdminCommands command group for the AdminTask object

You can use these administrative commands to manage JMS resources for the default messaging provider.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

createSIBJMSActivationSpec command

Use the createSIBJMSActivationSpec command to create a new JMS activation specification for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The createSIBJMSActivationSpec command creates a new JMS activation specification at a specific scope.

Target object

The scope of the default messaging provider at which the JMS activation specification is to be created.

Required parameters

-name

The administrative name assigned to this activation specification.

-jndiName

The JNDI name that is specified in the bindings for message-driven beans associated with this activation specification.

-destinationJndiName

The JNDI name of the destination JMS queue or topic used by the message-driven bean.

Optional parameters

-description

An optional description for the activation specification.

-destinationType

An option to determine whether the message_driven bean uses a JMS queue or a JMS topic. Select one of the following values:

Queue

The message-driven bean uses a JMS queue. The JNDI name of the JMS queue is specified on the **Destination JNDI name** property.

Topic The message-driven bean uses a JMS topic. The JNDI name of the JMS topic is specified on the **Destination JNDI name** property.

-messageSelector

The JMS message selector used to determine which messages the message-driven bean receives.

The value is a string that is used to select a subset of the available messages. The syntax is based on a subset of the SQL 92 conditional expression syntax, as described in the JMS specification. Refer to the information center for more information.

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

A null value (an empty string) indicates that there is no message selector for the message consumer.

-busName

The name of the service integration bus to which connections are made. This must be the name of the bus on which the destination identified by the **-destinationJndiName** property is defined.

-acknowledgeMode

The acknowledge mode indicates how a message received by a message-driven bean should be acknowledged. Select one of the following values:

Auto-acknowledge

The session automatically acknowledges the delivery of a message.

Duplicates-ok auto-acknowledge

The session lazily acknowledges the delivery of messages, which can improve performance, but can lead to a message-driven bean receiving a message more than once.

-target

The name of a target that identifies a group of messaging engines. Specify the type of target by using the **Target type** property.

-targetType

The type of target named in the **-target** property. Select one of the following values:

Bus member name

The name of a bus member. This option retrieves the active messaging engines that are hosted by the named bus member (an application server or server cluster).

Custom messaging engine group name

The name of a custom group of messaging engines (that form a self-declaring cluster). This option retrieves the active messaging engines that have registered with the named custom group.

Messaging engine name

The name of a messaging engine. This option retrieves the available endpoints that can be used to reach the named messaging engine.

-targetSignificance

This property specifies the significance of the target group. Select one of the following values:

Preferred

It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Required

It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

-targetTransportChain

The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging

This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging

This is the InboundBasicMessaging protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

-providerEndpoints

A comma-separated list of endpoint triplets, with the syntax *host_name:port_number:chain_name*, that is used to connect to a bootstrap server. For example

```
Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging.
```

Provider endpoints are used if the specified bus cannot be found in the local cell. Message-driven bean applications first attempt to connect the specified bus in the local cell. If this attempt fails, provider endpoints are used to allow the applications to consume messages from a remote cell.

If the host name is not specified, localhost is used as a default value.

If the port number is not specified, 7276 is used as the default value.

If the protocol is not specified, a predefined chain such as BootstrapBasicMessaging is used as the default value.

-authenticationAlias

The name of a J2C authentication alias used for component-managed authentication of connections to the service integration bus.

A Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JMS provider.

-maxBatchSize

The maximum number of messages in a single batch delivered serially to a single message-driven bean instance. Batching of messages can improve performance particularly when used with Acknowledge mode set to Duplicates-ok auto-acknowledge. If message ordering must be retained across failed deliveries, set the batch size to 1.

-maxConcurrency

The maximum number of endpoints to which messages are delivered concurrently.

Increasing this number can improve performance but can increase the number of threads that are in use at any one time. If message ordering must be retained across failed deliveries, set the maximum concurrent endpoints to 1. Message ordering applies only if the destination that the message-driven bean is consuming from is not a partitioned destination. Partitioned destinations are used in a workload sharing scenario in a cluster.

-subscriptionDurability

This option specifies whether a JMS topic subscription is durable or nondurable.

Usually, only one application at a time can have a consumer for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers. Select one of the following values:

Durable

The messaging provider stores messages while the message-driven bean is not available, and delivers the messages when the message-driven bean becomes available again.

Nondurable

The messaging provider does not store and redeliver messages if a message-driven bean is not available.

-subscriptionName

The subscription name needed for durable topic subscriptions. Required field when using a durable topic subscription.

Each JMS durable subscription is identified by a subscription name (specified on this property). A JMS connection also has an associated client identifier (specified on the Client identifier property), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client.

This subscription name must be unique within a given client identifier.

-clientId

The JMS client identifier needed for durable topic subscriptions on all connections created using this activation specification.

The value specified is a unique identifier for a client (message-driven bean). The client identifier is used to associate a client connection with the list of messages (on a durable subscription) that the messaging provider keeps for the client. When a client becomes available, after it has been unavailable, the messaging provider uses the client identifier to re-deliver stored messages to the correct client.

-durableSubscriptionHome

The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS activation specification. This is a required field when using a durable topic subscription.

Administrators can manage the runtime state of durable subscriptions through publication points for this messaging engine.

-shareDurableSubscriptions

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Usually, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers, one on each application server in the server cluster.

Select one of the following values:

In cluster

Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared

Durable subscriptions can be shared across connections.

Never shared

Durable subscriptions are never shared across connections.

-shareDataSourceWithCmp

Allow sharing of connections between JMS and container-managed persistence (CMP) entity beans.

True | False

This option is used as part of the task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. This has been estimated as a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

For more information about using this option, see “Enabling CMP entity beans and messaging engine data stores to share database connections” on page 610.

-readAhead

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

You can override this property for individual JMS destinations by setting the **Read ahead** property on the JMS destination.

Select one of the following values:

Enabled

The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Disabled

The messaging provider does not preemptively assign messages to consumers.

Default

The message provider preemptively assigns messages to consumers on nondurable subscriptions and unshared durable subscriptions. That is, read ahead optimization is turned on only when there can only be a single consumer.

The “pass message payload by reference” properties:

-forwarderDoesNotModifyPayloadAfterSet

true | false (default false)

Applications resending messages that were originally received using this activation specification must obey the following rules:

- The application can replace the data object in a JMS object message, provided that the data object has not yet been set in the message. The application does not modify or replace the data object after it is set in the message.
- The application can replace the byte array in a JMS bytes message, but only by using a single call to `writeBytes(byte[])`, and provided that the byte array has not yet been set in the message. The application does not modify or replace the byte array after it is set in the message.

-consumerDoesNotModifyPayloadAfterGet

true | false (default false)

Applications that use this activation specification to receive messages must obey the following rule: The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass**

message payload by reference properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION: The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic *Why and when to pass the JMS message payload by reference*, or you risk losing data integrity.

-alwaysActivateAllMDBs

True | False

This property is only used when the MDB application is running on a server that is a member of the bus that the application is targeting. It has no effect when the MDB is running on a server that is not a member of the target bus.

If the MDB application is running on a server that is a member of the target bus, enabling this option allows the MDB application to process messages whether or not the server also hosts a running messaging engine. If this option is not enabled, then MDB applications on servers that do not have a local ME running do not process messages.

For MDB applications connecting to a cluster bus member, you can also use this option to enable either of the following additional configurations:

- All servers in the cluster can receive messages from the MDB application, to make full use of the processing power in the cluster.
- Just one server at a time can receive messages from the MDB application, to ensure sequential processing of the messages.

To enable all servers in the cluster to receive messages from the MDB application, select this option. To enable just one server at a time to receive messages from the MDB application, check that this option is not selected and select the **receive exclusive** option on the destination.

For more information, see *../ae/cjn_mdb_endpt_overview.dita*.

-retryInterval

The delay (in seconds) between attempts to connect to a messaging engine, both for the initial connection, and any subsequent attempts to establish a better connection.

-userName

The user identity for Java 2 connector security to use.

-password

The password for Java 2 connector security to use.

-WAS_EndpointInitialState

ACTIVE | INACTIVE

This property determines whether the endpoint is activated when the endpoint is registered. If the property is set to active, message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

Example

- The following example shows an activation specification being created using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01" )
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.createSIBJMSActivationSpec("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml)", ["-name", "myjmsas", "-jndiName", "jms/myjmsas",
"-destinationJndiName", "jms/mqueue", "-busName", "abus"])
'myjmsas(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098726667851)'
```

```
wsadmin>AdminTask.listSIBJMSActivationSpecs("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml)")
'myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)'
```

- The following example shows an activation specification being created using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
```

```
wsadmin>$AdminTask createSIBJMSActivationSpec
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
{-name myjmsas -jndiName jms/myjmsas -destinationJndiName jms/mqueue -busName
abus} myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)
```

```
wsadmin>$AdminTask listSIBJMSActivationSpecs 9994GKCNode01
(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)
```

- The following example creates an activation specification with the `WAS_EndpointInitialState` optional parameter activated, using Jython:

```
wsadmin>attrs = '[[name "WAS_EndpointInitialState" [required "false" [type "java.lang.String" [value "ACTIVE"]]]'
wsadmin>AdminConfig.getid("/Node:myNode01")
myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)'
wsadmin>theActSpec = AdminTask.createSIBJMSActivationSpec("myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)", '
wsadmin>AdminConfig.create('J2EEResourceProperty',theActSpec, attrs)
'WAS_EndpointInitialState(cells/myCell01/nodes/myNode01|resources.xml#J2EEResourceProperty_1298546239332)'
```

deleteSIBJMSActivationSpec command

Use the `deleteSIBJMSActivationSpec` command to delete a JMS activation specification for the default messaging provider at a specific scope.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes the specified JMS activation specification.

Target object

A JMS activation specification.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminTask.listSIBJMSActivationSpecs("9994GKCN01(cells/
9994GKCN01Cell/nodes/9994GKCN01|node.xml)")
'myjmsas(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098726667851)
anojmsas(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098729538669)
test(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098729811201)'
```

```
wsadmin>AdminTask.deleteSIBJMSActivationSpec("anojmsas(cells/
9994GKCN01Cell/nodes/
9994GKCN01|resources.xml#J2CActivationSpec_1098729538669)")
'myjmsas(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098729538669)'
```

```
wsadmin>AdminTask.listSIBJMSActivationSpecs("9994GKCN01(cells/
9994GKCN01Cell/nodes/9994GKCN01|node.xml)")
'myjmsas(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098726667851)
test(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098729811201)'
```

- Using Jacl:

```
wsadmin>$AdminTask listSIBJMSActivationSpecs
9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)
myjmsas(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098726667851)
anojmsas(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098729538669)
test(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098729811201)
```

```
wsadmin>$AdminTask deleteSIBJMSActivationSpec
anojmsas(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098729538669)
myjmsas(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098729538669)
```

```
wsadmin>$AdminTask listSIBJMSActivationSpecs
9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)
myjmsas(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098726667851)
test(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098729811201)
```

listSIBJMSActivationSpecs command

Use the listSIBJMSActivationSpecs command to list all JMS activation specifications for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command lists all JMS activation specifications for the default messaging provider at a specific scope.

Target object

Scope of the default messaging provider at which the JMS activation specifications were created.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCN01" )
'9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.listSIBJMSActivationSpecs("9994GKCN01(cells/
9994GKCN01Cell/nodes/9994GKCN01|node.xml)")
'myjmsas(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098726667851)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCN01
9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listSIBJMSActivationSpecs
9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)
myjmsas(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098726667851)
```

modifySIBJMSActivationSpec command

Use the modifySIBJMSActivationSpec command to change properties of a JMS activation specification for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command changes the properties of a JMS activation specification.

Target object

The scope of the default messaging provider at which the JMS activation specification is to be modified.

Required parameters

None.

Optional parameters

-name

The administrative name assigned to this activation specification.

-jndiName

The JNDI name that is specified in the bindings for message-driven beans associated with this activation specification.

-description

An optional description for the activation specification.

-destinationType

Use this parameter to determine whether the message-driven bean uses a JMS queue or a JMS topic. Select one of the following values:

Queue

The message-driven bean uses a JMS queue. The JNDI name of the JMS queue is specified on the **Destination JNDI name** property.

Topic The message-driven bean uses a JMS topic. The JNDI name of the JMS topic is specified on the **Destination JNDI name** property.

-destinationJndiName

The JNDI name of the destination JMS queue or topic used by the message-driven bean.

-messageSelector

string

-busName

Enter the name of the service integration bus to which connections are made. This must be the name of the bus on which the destination identified by the **-destinationJndiName** property is defined.

-acknowledgeMode

The acknowledge mode indicates how a message received by a message-driven bean should be acknowledged. Select one of the following values:

Auto-acknowledge

The session automatically acknowledges the delivery of a message.

Duplicates-ok auto-acknowledge

The session lazily acknowledges the delivery of messages, which can improve performance, but can lead to a message-driven bean receiving a message more than once.

-target

The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property.

-targetType

The type of target named in the **-target** property. Select one of the following values:

Bus member name

The name of a bus member. This option retrieves the active messaging engines that are hosted by the named bus member (an application server or server cluster).

Custom messaging engine group name

The name of a custom group of messaging engines (that form a self-declaring cluster). This option retrieves the active messaging engines that have registered with the named custom group.

Messaging engine name

The name of a messaging engine. This option retrieves the available endpoints that can be used to reach the named messaging engine.

-targetSignificance

This property specifies the significance of the target group. Select one of the following values:

Preferred

It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Required

It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

-targetTransportChain

The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging

This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging

This is the InboundBasicMessaging protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

-providerEndpoints

A comma-separated list of endpoint triplets, with the syntax *host_name:port_number:chain_name*, used to connect to a bootstrap server. For example
Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging.

Provider endpoints are not used unless the specified bus cannot be found in the local cell. MDB applications first attempt to connect the specified bus in the local cell. If this attempt fails, provider endpoints are used to allow the applications to consume messages from a remote cell.

If the host name is not specified, localhost is used as a default value.

If the port number is not specified, 7276 is used as the default value.

If the protocol is not specified, a predefined chain such as BootstrapBasicMessaging is used as the default value.

-authenticationAlias

The name of a J2C authentication alias used for component-managed authentication of connections to the service integration bus.

A Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JMS provider.

-maxBatchSize

The maximum number of messages in a single batch delivered serially to a single message-driven bean instance. Batching of messages can improve performance particularly when used with Acknowledge mode set to Duplicates-ok auto-acknowledge. If message-ordering must be retained across failed deliveries, set the batch size to 1

-maxConcurrency

The maximum number of endpoints to which messages are delivered concurrently.

Increasing this number can improve performance but can increase the number of threads that are in use at any one time. If message ordering must be retained across failed deliveries, set the maximum concurrent endpoints to 1. Message ordering applies only if the destination that the message-driven bean is consuming from is not a partitioned destination. Partitioned destinations are used in a workload sharing scenario in a cluster.

-subscriptionDurability

Whether a JMS topic subscription is durable or nondurable

Usually, only one application at a time can have a consumer for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers. Select one of the following values:

Durable

The messaging provider stores messages while the message-driven bean is not available, and delivers the messages when the message-driven bean becomes available again.

Nondurable

The messaging provider does not store and redeliver messages if a message-driven bean is not available.

-subscriptionName

The subscription name needed for durable topic subscriptions. Required field when using a durable topic subscription.

Each JMS durable subscription is identified by a subscription name (specified on this property). A JMS connection also has an associated client identifier (specified on the Client identifier property), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client.

This subscription name must be unique within a given client identifier.

-clientId

The JMS client identifier needed for durable topic subscriptions on all connections created using this activation specification.

The value specified is a unique identifier for a client (message-driven bean). The client identifier is used to associate a client connection with the list of messages (on a durable subscription) that the messaging provider keeps for the client. When a client becomes available again, after a being unavailable, the messaging provider uses the client identifier to redeliver stored messages to the correct client.

-durableSubscriptionHome

The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS activation specification. This is a required field when using a durable topic subscription.

Administrators can manage the runtime state of durable subscriptions through publication points for this messaging engine.

-shareDurableSubscriptions

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Usually, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers, one on each application server in the server cluster.

Select one of the following values:

In cluster

Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared

Durable subscriptions can be shared across connections.

Never shared

Durable subscriptions are never shared across connections.

-shareDataSourceWithCmp

Allow sharing of connections between JMS and container-managed persistence (CMP) entity beans.

True | False

This option is used as part of the task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. This has been estimated as a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

For more information about using this option, see [Enabling CMP entity beans and messaging engine data stores to share database connections](#).

-readAhead

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

You can override this property for individual JMS destinations by setting the **Read ahead** property on the JMS destination.

Select one of the following values:

Enabled

The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Disabled

The messaging provider does not preemptively assign messages to consumers.

Default

The message provider preemptively assigns messages to consumers on nondurable subscriptions and unshared durable subscriptions. That is, read ahead optimization is turned on only when there can only be a single consumer.

The “pass message payload by reference” properties:

-forwarderDoesNotModifyPayloadAfterSet

true | false (default false)

Applications resending messages that were originally received using this activation specification must obey the following rules:

- The application can replace the data object in a JMS object message, provided that the data object has not yet been set in the message. The application does not modify or replace the data object after it is set in the message.
- The application can replace the byte array in a JMS bytes message, but only by using a single call to `writeBytes(byte[])`, and provided that the byte array has not yet been set in the message. The application does not modify or replace the byte array after it is set in the message.

-consumerDoesNotModifyPayloadAfterGet

true | false (default false)

Applications that use this activation specification to receive messages must obey the following rule: The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION: The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic *Why and when to pass the JMS message payload by reference*, or you risk losing data integrity.

-alwaysActivateAllMDBs

True | False

This property is only used when the MDB application is running on a server that is a member of the bus that the application is targeting. It has no effect when the MDB is running on a server that is not a member of the target bus.

If the MDB application is running on a server that is a member of the target bus, enabling this option allows the MDB application to process messages whether or not the server also hosts a running messaging engine. If this option is not enabled, then MDB applications on servers that do not have a local ME running do not process messages.

For MDB applications connecting to a cluster bus member, you can also use this option to enable either of the following additional configurations:

- All servers in the cluster can receive messages from the MDB application, to make full use of the processing power in the cluster.
- Just one server at a time can receive messages from the MDB application, to ensure sequential processing of the messages.

To enable all servers in the cluster to receive messages from the MDB application, select this option. To enable just one server at a time to receive messages from the MDB application, check that this option is not selected and select the **receive exclusive** option on the destination.

For more information, see `./ae/cjn_mdb_endpt_overview.dita`.

-retryInterval

The delay (in seconds) between attempts to connect to a messaging engine, both for the initial connection, and any subsequent attempts to establish a better connection.

-userName

The user identity for Java 2 connector security to use.

-password

The password for Java 2 connector security to use.

-WAS_EndpointInitialState

This property determines whether the endpoint is activated when the endpoint is registered. If the property is set to active, message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

The value of this parameter must be ACTIVE or INACTIVE.

Example

- The following example shows an activation specification being modified using Jython:

```
wsadmin>AdminTask.modifySIBJMSActivationSpec("myjmsas(cells/
9994GKCNODE01Cell/nodes/
9994GKCNODE01|resources.xml#J2CActivationSpec_1098726667851)",
["-jndiName", "jms/jmsas4q1",
"-description", "JMS activation specification for myqueue1",
"-destinationJndiName", "jms/myqueue1"])
'myjmsas(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098726667851)'
```

- The following example shows an activation specification being modified using Jacl:

```
wsadmin>$AdminTask modifySIBJMSActivationSpec
myjmsas(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098726667851)
{-jndiName jms/jmsas4q1 -description "JMS activation specification
for myqueue1" -destinationJndiName jms/myqueue1}
myjmsas(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098726667851)
```

- The following example modifies an activation specification by activating the WAS_EndpointInitialState optional parameter, using Jython:

```
wsadmin>attrs = '[[name "WAS_EndpointInitialState"] [required "false"] [type "java.lang.String"] [value "ACTIVE"]]'
wsadmin>AdminConfig.getid("/Node:myNode01")
'myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)'
wsadmin>wsadmin>AdminTask.listSIBJMSActivationSpecs("myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)")
'newas(cells/myCell01/nodes/myNode01|resources.xml#J2CActivationSpec_1298546034140)'
wsadmin>wsadmin>AdminConfig.create('J2EEResourceProperty', "testas(cells/myCell01/nodes/myNode01|resources.xml#J2CActi
'WAS_EndpointInitialState(cells/myCell01/nodes/myNode01|resources.xml#J2EEResourceProperty_1298546239332)'
```

showSIBJMSActivationSpec command

Use the showSIBJMSActivationSpec command to show properties of a JMS activation specification for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command returns a set of property-value pairs for the specified JMS activation specification.

Target object

A JMS activation specification.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01" )
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.listSIBJMSActivationSpecs("9994GKCNODE01(cells/
9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml)")
'myjmsas(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098726667851)'
```

```
wsadmin>AdminTask.showSIBJMSActivationSpec("myjmsas(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|resources.xml#J2CActivationSpec_1098726667851)")
myjmsas(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098726667851)
'{busName=abus, subscriptionDurability=Nondurable, description=,
destinationType=, password=, targetTransportChain=,
acknowledgeMode=Auto-acknowledge, readAhead=Default, clientId=,
authenticationAlias=, name=myjmsas, maxConcurrency=10, maxBatchSize=1,
durableSubscriptionHome=, userName=, messageSelector=,
shareDurableSubscriptions=InCluster, jndiName=jms/myjmsas,
shareDataSourceWithCMP=false, destination=, destinationJndiName=jms/mqueue,
subscriptionName=}'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listSIBJMSActivationSpecs
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
myjmsas(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098726667851)
```

```
wsadmin>$AdminTask showSIBJMSActivationSpec
myjmsas(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098726667851)
{busName=abus, subscriptionDurability=Nondurable, description=,
destinationType=, password=, targetTransportChain=,
acknowledgeMode=Auto-acknowledge, readAhead=Default, clientId=,
authenticationAlias=, name=myjmsas, maxConcurrency=10, maxBatchSize=1,
```

```
    durableSubscriptionHome=, userName=, messageSelector=,
    shareDurableSubscriptions=InCluster, jndiName=jms/myjmsas,
    shareDataSourceWithCMP=false, destination=, destinationJndiName=jms/mqueue,
    subscriptionName=}
```

createSIBJMSConnectionFactory command

Use the createSIBJMSConnectionFactory command to create a new JMS connection factory for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates a new JMS connection factory at a specific scope.

Target object

Scope of the default messaging provider at which the JMS connection factory is to be created.

Required parameters

-name

The administrative name assigned to this connection factory.

-jndiName

The JNDI name that is specified in the bindings for message-driven beans associated with this connection factory.

-busName

Enter the name of the service integration bus to which connections are made. This must be the name of the bus on which the destination identified by the **-destinationJndiName** property is defined.

Optional parameters

-type

queue | topic

The **type** parameter is used to specify the type of connection factory to create. To create a queue connection factory, set this parameter to queue. To create a topic connection factory, set this parameter to topic. Leave this parameter unset to create a generic connection factory.

-category

An optional category string to use when classifying or grouping the resource.

-description

text

-logMissingTransactionContext

True | False

-manageCachedHandles

True | False

-clientID

id

-userName

name

-password

password

-target

The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property.

Before the connection proximity search is performed to select a suitable messaging engine, the set of messaging engines that are members of the specified target group are selected. The connection proximity search is then restricted to these messaging engines. If a target group is not specified (the default), then all messaging engines in the bus are considered during the connection proximity search. For example, if the Target type property is set to Bus member name, the Target property specifies the name of the bus member from which suitable messaging engines can be chosen.

-targetType

The type of target named in the Target property.

Select one of the following values:

Bus member name

The name of a bus member. This option retrieves the active messaging engines that are hosted by the named bus member (an application server or server cluster).

To specify a non-clustered bus member the **-target** property must be set to *node_name.server_name*, for example Node01.server1. For a cluster bus member the **-target** property must be set to the cluster name.

Custom messaging engine group name

The name of a custom group of messaging engines (that form a self-declaring cluster). This option retrieves the active messaging engines that have registered with the named custom group.

Messaging engine name

The name of a messaging engine. This option retrieves the available endpoints that can be used to reach the named messaging engine.

-targetSignificance

This property specifies the significance of the target group.

This property defines whether the connection proximity search is restricted to only the messaging engines in the target group.

Select one of the following values:

Preferred

It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Note: A connection to a non-preferred target might be returned even if a preferred one is available. This can happen when connection pooling is enabled for a `ConnectionFactory`, which it is by default when you use a `JMS ConnectionFactory` in a server environment:

- When a preferred messaging engine is not available, a connection to a non-preferred one can be created and stored in the connection pool.
- The next time the application requests a connection it receives this pooled connection even if the preferred messaging engine has subsequently become available.

You can modify the connection pool settings to regularly discard all unused connections in the pool. After the connection pool is emptied, connections are made to the preferred messaging engine if one is available. For example, set the **ReapTime**, **AgedTimeout** and **UnusedTimeout** to 300 seconds, and the **PurgePolicy** to `EntirePool`. This refreshes the connection pool every 5 minutes, after which time the application selects a preferred messaging engine if one is available.

Required

It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

-targetTransportChain

The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

These transport chains specify the communication protocols that can be used to communicate with the application server to which the client application is connected.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> server_name -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging

This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging

This is the `InboundBasicMessaging` protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

-providerEndpoints

A comma-separated list of endpoint triplets, with the syntax `hostName:portNumber:chainName`, used to connect to a bootstrap server. For example `Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging`. If `hostName` is not

specified, the default is localhost. If portNumber is not specified, the default is 7276. If chainName is not specified, the default is BootstrapBasicMessaging. Refer to the information center for more information.

-connectionProximity

Bus | Host | Cluster | Server

-durableSubscriptionHome

me_name

-nonPersistentMapping

BestEffortNonPersistent | ExpressNonPersistent | ReliableNonPersistent | ReliablePersistent | AssuredPersistent | AsSIBDestination | None

-persistentMapping

BestEffortNonPersistent | ExpressNonPersistent | ReliableNonPersistent | ReliablePersistent | AssuredPersistent | AsSIBDestination | None

-readAhead

-tempQueueNamePrefix

prefix

-tempTopicNamePrefix

prefix

-shareDurableSubscriptions

AsCluster | AlwaysShared | NeverShared

The “pass message payload by reference” properties:

-producerDoesNotModifyPayloadAfterSet

true | false (default false)

Applications that use this connection factory to send messages must obey the following rules:

- The application does not modify the data object contained in a JMS object message.
- The application populates a JMS bytes message by using a single call to writeBytes(byte[]) and does not modify the byte array after it is set in the message.

-consumerDoesNotModifyPayloadAfterGet

true | false (default false)

Applications that use this connection factory to receive messages must obey the following rule: The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION: The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic *Why and when to pass the JMS message payload by reference*, or you risk losing data integrity.

-authDataAlias

alias_name

-shareDataSourceWithCMP

True | False

-xaRecoveryAuthAlias

alias_name

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01" )
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.createSIBJMSConnectionFactory("9994GKCNODE01(cells/
9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml)", ["-name", "jmscf1",
"-jndiName", "jms/jmscf1", "-busName", "abus"])
'jmscf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CConnectionFactory_1098733325084)'
```

```
wsadmin>AdminTask.createSIBJMSConnectionFactory("9994GKCNODE01(cells/
9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml)", ["-name", "jmsqcf2",
"-jndiName", "jms/jmsqcf1", "-busName", "abus", "-type", "queue"])
'jmsqcf2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CConnectionFactory_1098733675578)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask createSIBJMSConnectionFactory
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name jmscf1 -jndiName jms/jmscf1 -busName abus}
jmscf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CConnectionFactory_1098733325084)
```

```
wsadmin>$AdminTask createSIBJMSConnectionFactory
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name jmsqcf2 -jndiName jms/jmsqcf1 -busName abus -type queue}
jmsqcf2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CConnectionFactory_1098733675578)
```

deleteSIBJMSConnectionFactory command

Use the deleteSIBJMSConnectionFactory command to delete a JMS connection factory for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes the specified JMS connection factory.

Target object

A JMS connection factory.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01" )
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.deleteSIBJMSConnectionFactory("jmsqcf2(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|resources.xml#J2CConnectionFactory_1098736176544)")
'jmsqcf2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CConnectionFactory_1098736176544)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask deleteSIBJMSConnectionFactory
jmsqcf2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CConnectionFactory_1098736176544)
jmsqcf2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CConnectionFactory_1098736176544)
```

listSIBJMSConnectionFactories command

Use the listSIBJMSConnectionFactories command to list all JMS connection factories for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command lists all JMS connection factories for the default messaging provider at a specific scope

Target object

Scope of the default messaging provider at which the JMS connection factories were created.

Required parameters

None.

Optional parameters

-type

The **-type** parameter is used to filter the list of connection factories.

Select one of the following values:

- all** List all JMS connection factories (generic, queue, and topic) at the specified scope.
- queue** List all JMS queue connection factories at the specified scope.
- topic** List all JMS topic connection factories at the specified scope.

If the **-type** parameter is not supplied, then only generic JMS connection factories at the scope are listed.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01" )
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'

AdminTask.listSIBJMSConnectionFactory("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)")
'qcf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CConnectionFactory_1098730054140)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask listSIBJMSConnectionFactory
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
qcf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CConnectionFactory_1098730054140)
```

modifySIBJMSConnectionFactory command

Use the `modifySIBJMSConnectionFactory` command to modify the properties of a JMS connection factory for the default messaging provider at a specific scope.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```
- For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command changes the properties of a JMS connection factory.

```

showSIBJMSConnectionFactory command

Use the showSIBJMSConnectionFactory command to show the properties of a JMS connection factory for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command returns a set of property-value pairs for the specified JMS connection factory.

Target object

A JMS connection factory.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.showSIBJMSConnectionFactory("jmsqcf2(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|resources.xml#J2CConnectionFactory_1098733675578)")
'{target=, targetTransportChain=, readAhead=Default, password=,
targetType=BusMember, tempQueueNamePrefix=, connectionProximity=Bus,
nonPersistentMapping=ExpressNonPersistent, name=jmsqcf2,
targetSignificance=Preferred, shareDurableSubscriptions=InCluster,
```

```
providerEndpoints=, shareDataSourceWithCMP=false, userName=,
logMissingTransactionContext=false, busName=abus,
persistentMapping=ReliablePersistent, clientID=,
jndiName=jms/jmsqcf1, manageCachedHandles=false}'
```

- **Using Jacl:**

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask showSIBJMSConnectionFactory
jmsqcf2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CConnectionFactory_1098733675578)
{target=, targetTransportChain=, readAhead=Default, password=,
targetType=BusMember, tempQueueNamePrefix=, connectionProximity=Bus,
nonPersistentMapping=ExpressNonPersistent, name=jmsqcf2,
targetSignificance=Preferred, shareDurableSubscriptions=InCluster,
providerEndpoints=, shareDataSourceWithCMP=false, userName=,
logMissingTransactionContext=false, busName=abus,
persistentMapping=ReliablePersistent, clientID=,
jndiName=jms/jmsqcf1, manageCachedHandles=false}
```

createSIBJMSQueue command

Use the createSIBJMSQueue command to create a new JMS queue for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The createSIBJMSQueue command creates a JMS queue for the default messaging provider at a specific scope.

Target object

The scope of the default messaging provider at which the JMS queue is to be created.

Required parameters

-name

The identifier by which this JMS queue is known for administrative purposes.

-jndiName

The JNDI name that is used to bind the queue into the application server namespace.

-queueName

The name of the service integration bus destination to which the JMS queue maps.

Optional parameters

-description

An optional description for the bus, for administrative purposes.

-deliveryMode **Application** | **NonPersistent** | **Persistent**

The delivery mode to be used by MessageProducers for messages sent to this queue.

-timeToLive

The default length of time from its dispatch time that a message sent to this queue should be retained by the system, where 0 indicates that time to live value does not expire. The value from the producer is used if the **Time to Live** parameter is not supplied.

-priority

The priority for messages sent to this queue. The value from the producer is used if not completed. In the range 0 to 9 where 0 is the lowest priority and 9 is the highest priority

-readAhead **AsConnection** | **AlwaysOn** | **AlwaysOff**

Used to control read-ahead optimization during message delivery. The default is AsConnection.

-busName

The name of the service integration bus that the service integration bus destination, identified by **queueName**, is configured on. If not set, the bus that the application is connected to is used.

-scopeToLocalQP **TRUE** | **FALSE**

Indicates whether the underlying service integration bus queue destination is scoped to a local queue point when addressed using this JMS queue. A local queue point is a queue point that is configured on the messaging engine to which the JMS application is connected. The option applies when using this JMS queue to send and receive messages and when setting a reply queue in a request message. When a reply queue is set in a request message, the local queue point is on the messaging engine to which the application setting the reply queue is connected, not the messaging engine to which the application that uses the reply queue sends the reply message. If the connected messaging engine does not have a queue point for the destination this option is ignored. The default value is FALSE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

-producerBind **TRUE** | **FALSE**

Indicates how JMS producers bind to queue points of the clustered queue. The default value is FALSE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

TRUE The messaging system selects a queue point when the session is opened. All messages produced by the session are sent to the chosen queue point. The messaging system uses the **producerPreferLocal** setting when selecting the queue point.

FALSE

The messaging system selects a queue point each time a message is sent, potentially workload balancing the messages across all available queue points. The messaging system uses the **producerPreferLocal** setting when selecting the queue point.

-producerPreferLocal **TRUE** | **FALSE**

Indicates whether a queue point local to the producer is preferred to other available queue points

when the messaging system selects a queue point to produce messages to. A local queue point is a queue point that is configured on the messaging engine to which the JMS application is connected. The default value is TRUE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

-consumerGatherMessages TRUE | FALSE

A JMS consumer or browser is attached to a single queue point of the service integration bus destination by the messaging system. This parameter indicates whether a JMS consumer or browser take messages from any available queue points of the service integration bus destination (TRUE), or the single queue point to which it is attached (FALSE). The default value is FALSE. Gathering messages from multiple queue points results in an increased performance cost and message order cannot be maintained.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Examples

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01" )
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.createSIBJMSQueue("WASINSTALL2Node01(cells/WASINSTALL2Cell101/
nodes/WASINSTALL2Node01|node.xml#Node_1)", ["-name", "jmsq2", "-jndiName",
"jms/jnmsq2", "-queueName", "busq4jmsq2"])
'jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
#J2CAdminObject_1098737234986)'
```

```
wsadmin>AdminTask.listSIBJMSQueues("WASINSTALL2Node01(cells/WASINSTALL2Cell101
/nodes/WASINSTALL2Node01|node.xml#Node_1)")
'queue1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098711838691)
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098737234986)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask createSIBJMSQueue
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name jmsq2 -jndiName jms/jnmsq2 -queueName busq4jmsq2}
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098737234986)
```

```
wsadmin>$AdminTask listSIBJMSQueues
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
queue1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098711838691)
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098737234986)
```

The following example shows how to create a default messaging provider JMS queue that selects a queue point when a session is opened and never changes:

- Using Jython:

```
wsadmin>AdminTask.createSIBJMSQueue("9994GKCN01(cells/9994GKCN01Cell/
nodes/9994GKCN01|node.xml#Node_1)", ["-name", "MyJMSQueue", "-jndiName",
"MyJMSQueue", "-busName bus1", "-queueName", "MyExistingQueue", "-deliveryMode",
"Application", "-readAhead", "AsConnection", "-producerBind", "TRUE"])
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBJMSQueue 9994GKCN01(cells/9994GKCN01Cell/
nodes/9994GKCN01|node.xml#Node_1 {-name MyJMSQueue -jndiName MyJMSQueue
-busName bus1 -queueName MyExistingQueue -deliveryMode Application
-readAhead AsConnection -producerBind TRUE }
```

The following example shows how to create a default messaging provider JMS queue that selects a queue point every time a message is sent. There is no preference over which queue point is selected and the consumers take messages from any queue point:

- Using Jython:

```
wsadmin>AdminTask.createSIBJMSQueue("9994GKCN01(cells/9994GKCN01Cell/
nodes/9994GKCN01|node.xml#Node_1)", ["-name", "MyJMSQueue", "-jndiName",
"MyJMSQueue", "-busName bus1", "-queueName", "MyExistingQueue", "-deliveryMode",
"Application", "-readAhead", "AsConnection", "-producerBind", "FALSE",
"-producerPreferLocal", "FALSE", "-gatherMessages", "TRUE"])
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBJMSQueue 9994GKCN01(cells/9994GKCN01Cell/
nodes/9994GKCN01|node.xml#Node_1 {-name MyJMSQueue -jndiName MyJMSQueue
-busName bus1 -queueName MyExistingQueue -deliveryMode Application
-readAhead AsConnection -producerBind FALSE -producerPreferLocal FALSE
-gatherMessages TRUE}
```

The following example shows how to create a default messaging provider JMS queue that scopes all operations on it down to the queue point local to the user of the JMS queue:

- Using Jython:

```
wsadmin>AdminTask.createSIBJMSQueue("9994GKCN01(cells/9994GKCN01Cell/
nodes/9994GKCN01|node.xml#Node_1)", ["-name", "MyJMSQueue", "-jndiName",
"MyJMSQueue", "-busName bus1", "-queueName", "MyExistingQueue", "-deliveryMode",
"Application", "-readAhead", "AsConnection", "-scopeToLocalQP", "TRUE"])
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBJMSQueue 9994GKCN01(cells/9994GKCN01Cell/
nodes/9994GKCN01|node.xml#Node_1 {-name MyJMSQueue -jndiName MyJMSQueue
-busName bus1 -queueName MyExistingQueue -deliveryMode Application
-readAhead AsConnection -scopeToLocalQP TRUE}
```

deleteSIBJMSQueue command

Use the deleteSIBJMSQueue command to delete a JMS queue for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes the specified JMS queue.

Target object

A JMS queue.

The JMS queue is deleted at the specified scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01" )
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.deleteSIBJMSQueue("jmsq2(cells/9994GKCNODE01Cell/nodes/
9994GKCNODE01|resources.xml#J2CAdminObject_1098737234986)")
'jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098737234986)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask deleteSIBJMSQueue
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098737234986)
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098737234986)
```

listSIBJMSQueues command

Use the listSIBJMSQueues command to list all JMS queues for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command returns a list of all JMS queues for the default messaging provider at a specific scope.

Target object

Scope of the default messaging provider at which the JMS queues were created.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01" )
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.listSIBJMSQueues("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)")
'queue1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098711838691)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listSIBJMSQueues
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
queue1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098711838691)
```

modifySIBJMSQueue command

Use the modifySIBJMSQueue command to change the properties of a JMS queue for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The modifySIBJMSQueue command changes the properties of a JMS queue for the default messaging provider at a specific scope.

Target object

A JMS queue.

Required parameters

None.

Optional parameters

-name

The identifier by which this JMS queue is known for administrative purposes.

-jndiName

The JNDI name that is used to bind the queue into the application server namespace.

-queueName

The name of the service integration bus destination to which the JMS queue maps.

-description

An optional description for the bus, for administrative purposes.

-deliveryMode Application | NonPersistent | Persistent

The delivery mode to be used by MessageProducers for messages sent to this queue.

-timeToLive

The default length of time from its dispatch time that a message sent to this queue should be retained by the system, where 0 indicates that time to live value does not expire. Value from the producer is used if this parameter is not supplied.

-priority

The priority for messages sent to this queue. The value from the producer is used if not completed. In the range 0 to 9 where 0 is the lowest priority and 9 is the highest priority

-readAhead AsConnection | AlwaysOn | AlwaysOff

Used to control read-ahead optimization during message delivery. The default is AsConnection.

-busName

The name of the service integration bus that the bus destination, identified by **queueName**, is configured on. If not set, the bus that the application is connected to is used.

-scopeToLocalQP TRUE | FALSE

Indicates whether the underlying service integration bus queue destination is scoped to a local queue point when addressed using this JMS queue. A local queue point is a queue point that is configured on the messaging engine to which the JMS application is connected. The option applies when using this JMS queue to send and receive messages and when setting a reply queue in a request message. When a reply queue is set in a request message, the local queue point is on the messaging engine to which the application setting the reply queue is connected, not the messaging engine to which the application using the reply queue sends the reply message. If the connected messaging engine does not have a queue point for the destination this option is ignored. The default value is FALSE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server results in an exception to the application.

-producerBind TRUE | FALSE

Indicates how JMS producers bind to queue points of the clustered queue. The default value is FALSE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server results in an exception to the application.

TRUE The messaging system selects a queue point when the session is opened. All messages produced by the session are sent to the chosen queue point. The messaging system uses the **producerPreferLocal** setting when selecting the queue point.

FALSE

The messaging system selects a queue point each time a message is sent, potentially workload balancing the messages across all available queue points. The messaging system uses the **producerPreferLocal** setting when selecting the queue point.

-producerPreferLocal TRUE | FALSE

Indicates whether a queue point local to the producer is preferred to other available queue points when the messaging system selects a queue point to produce messages to. A local queue point is a queue point that is configured on the messaging engine to which the JMS application is connected. The default value is TRUE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server results in an exception to the application.

-consumerGatherMessages TRUE | FALSE

A JMS consumer or browser is attached to a single queue point of the service integration bus destination by the messaging system. This parameter indicates whether a JMS consumer or browser take messages from any available queue points of the service integration bus destination (TRUE), or the single queue point to which it is attached (FALSE). The default value is FALSE. Gathering messages from multiple queue points results in an increased performance cost and message order cannot be maintained.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server results in an exception to the application.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01 ")
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.modifySIBJMSQueue("jmsq2(cells/9994GKCNODE01Cell/nodes/
9994GKCNODE01|resources.xml#J2CAdminObject_1098737234986)",
["-queueName", "q2forjms"])
'jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098737234986)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask modifySIBJMSQueue
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098737234986)
{-queueName q2forjms}
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098737234986)
```

showSIBJMSQueue command

Use the showSIBJMSQueue command to show properties of a JMS queue for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command returns a set of property-value pairs for the specified JMS queue.

Target object

A JMS queue.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01" )
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.showSIBJMSQueue("jmsq2(cells/9994GKCNODE01Cell/nodes/
9994GKCNODE01|resources.xml#J2CAdminObject_1098737234986)")
'{jndiName=jms/jnmsq2, deliveryMode=Application, busName=, name=jmsq2,
readAhead=AsConnection, timeToLive=, priority=, queueName=busq4jmsq2}'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask showSIBJMSQueue
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098737234986)
{jndiName=jms/jnmsq2, deliveryMode=Application, busName=, name=jmsq2,
readAhead=AsConnection, timeToLive=, priority=, queueName=busq4jmsq2}
```

createSIBJMSTopic command

Use the createSIBJMSTopic command to create a new JMS topic for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates a JMS topic for the default messaging provider at a specific scope.

Target object

Scope of the default messaging provider at which the JMS topic is to be created.

Required parameters

```
-name jmstopic_name  
-jndiName jndi_name
```

Optional parameters

```
-description text  
-topicName topic_name  
-topicSpace topicspace_name  
-deliveryMode Application | NonPersistent | Persistent  
-timeToLive time  
-priority priority  
-readAhead AsConnection | AlwaysOn | AlwaysOff  
-busName name
```

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01" )  
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.createSIBJMSTopic("9994GKCNODE01(cells/9994GKCNODE01Cell/  
nodes/9994GKCNODE01|node.xml#Node_1)", ["-name", "jmstopic2", "-jndiName",  
"jms/jmstopic2", "-topicSpace", "sportshall"])  
'jmstopic2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#  
J2CAdminObject_1098738992263)'
```

```
wsadmin>AdminTask.listSIBJMSTopics("9994GKCNODE01(cells/9994GKCNODE01Cell/  
nodes/9994GKCNODE01|node.xml#Node_1)")  
'topic1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#  
J2CAdminObject_1098738449292)  
jmstopic2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#  
J2CAdminObject_1098738992263)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask createSIBJMSTopic
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name jmstopic2 -jndiName jms/jnmstopic2 -topicSpace sportshall}
jmstopic2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098738992263)

wsadmin>$AdminTask listSIBJMSTopics
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
topic1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098738449292)
jmstopic2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098738992263)
```

deleteSIBJMSTopic command

Use the deleteSIBJMSTopics command to delete a JMS topic for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes the specified JMS topic.

Target object

A JMS topic.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.deleteSIBJMSTopic("jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#J2CAdminObject_1098738992263)")
'jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#J2CAdminObject_1098738992263)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
```

```
wsadmin>$AdminTask deleteSIBJMSTopic
jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)
jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)
```

listSIBJMSTopics command

Use the listSIBJMSTopics command to list all JMS topics for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command returns a list of all JMS topics for the default messaging provider at a specific scope.

Target object

Scope of the default messaging provider at which the JMS topics were created.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.listSIBJMSTopics("9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)")
'topic1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738449292)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listSIBJMSTopics
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
topic1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738449292)
```

modifySIBJMSTopic command

Use the modifySIBJMSTopic command to change the properties of a JMS topic for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command changes the properties of a JMS topic for the default messaging provider at a specific scope.

Target object

A JMS topic.

Required parameters

None.

Optional parameters

```
-name jmstopic_name
-jndiName jndi_name
-description text
-topicName topic_name
-topicSpace topicspace_name
-deliveryMode Application | NonPersistent | Persistent
-timeToLive time
-priority priority
-readAhead AsConnection | AlwaysOn | AlwaysOff
-busName name
```

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.modifySIBJMSTopic("jmstopic2(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#J2CAdminObject_1098738992263)", ["-jndiName",
"jms/jmstopic2", "-topicName", "archery", "-readAhead", "AlwaysOn"])
```

```
'jmsopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)'
```

```
wsadmin>AdminTask.showSIBJMSTopic("jmsopic2(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#J2CAdminObject_1098738992263)")
'{topicSpace=sportshall, deliveryMode=Application, jndiName=jms/jmsopic2,
busName=, readAhead=AlwaysOn, name=jmsopic2, timeToLive=, priority=,
topicName=archery}'
```

- **Using Jacl:**

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
```

```
wsadmin>$AdminTask modifySIBJMSTopic
jmsopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)
{-jndiName jms/jmsopic2 -topicName archery -readAhead AlwaysOn}
jmsopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)
```

```
wsadmin>$AdminTask showSIBJMSTopic
jmsopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)
{topicSpace=sportshall, deliveryMode=Application, jndiName=jms/jmsopic2,
busName=, readAhead=AlwaysOn, name=jmsopic2, timeToLive=, priority=,
topicName=archery}
```

showSIBJMSTopic command

Use the showSIBJMSTopic command to show properties of a JMS topic for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command returns a set of property-value pairs for the specified JMS topic.

Target object

A JMS topic.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01" )
'9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)'
```

```
wsadmin>AdminTask.showSIBJMSTopic("jmstopic2(cells/9994GKCNODE01Cell/nodes/
9994GKCNODE01|resources.xml#J2CAdminObject_1098738992263)")
'{topicSpace=sportshall, deliveryMode=Application, jndiName=jms/jmstopic2,
busName=, readAhead=AsConnection, name=jmstopic2, timeToLive=, priority=,
topicName=jmstopic2}'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask showSIBJMSTopic
jmstopic2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CAdminObject_1098738992263)
{topicSpace=sportshall, deliveryMode=Application, jndiName=jms/jmstopic2,
busName=, readAhead=AsConnection, name=jmstopic2, timeToLive=, priority=,
topicName=jmstopic2}
```

Chapter 13. Managing messaging with the WebSphere MQ messaging provider

Through the WebSphere MQ messaging provider in WebSphere Application Server, Java Message Service (JMS) messaging applications can use your WebSphere MQ system as an external provider of JMS messaging resources. To enable this approach, you configure the WebSphere MQ messaging provider in WebSphere Application Server to define JMS resources for connecting to any queue manager on the WebSphere MQ network.

Before you begin

If your business uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominantly WebSphere MQ network, the WebSphere MQ messaging provider is a logical choice. However, there can be benefits in using another provider. If you are not sure which provider combination is best suited to your requirements, see *Choosing messaging providers for a mixed environment*.

The preferred solution for publish and subscribe messaging with WebSphere MQ as an external JMS messaging provider is to use a message broker such as WebSphere MQ Event Broker.

About this task

The WebSphere MQ messaging provider supports JMS 1.1 domain-independent interfaces (sometimes referred to as “unified” or “common” interfaces), and also supports the Java EE Connector Architecture (JCA) 1.5 activation specification mechanism for message-driven beans (MDBs) across all platforms supported by WebSphere Application Server.

You can use WebSphere Application Server to configure WebSphere MQ resources for applications (for example queue connection factories) and to manage messages and subscriptions associated with JMS destinations. You administer security through WebSphere MQ.

You can use WebSphere Application Server to coordinate global transactions including WebSphere MQ without configuring the extended transactional client.

In a mixed-version WebSphere Application Server cell, you can administer WebSphere MQ resources on nodes of all versions. However, some properties are not available on all versions. In this situation, only the properties of that particular node are displayed in the administrative console.

For publish and subscribe messaging with WebSphere MQ as an external JMS messaging provider you have several options:

- With WebSphere MQ Version 6 on z/OS, you can use a message broker such as WebSphere MQ Event Broker.
- With WebSphere MQ Version 6 on distributed platforms, you can use either a message broker such as WebSphere MQ Message Broker or the built-in publish and subscribe capability of WebSphere MQ.
- With WebSphere MQ Version 7 on any platform you can use the built-in publish and subscribe capability of WebSphere MQ. Note that you cannot use WebSphere MQ Message Broker Version 7 for this because it no longer provides a publish and subscribe capability.

Procedure

- Learn about the WebSphere MQ messaging provider.
- Configure JMS resources for the WebSphere MQ messaging provider.

You can do this through the WebSphere Application Server administrative console, or through the WebSphere Application Server set of WebSphere MQ administrative commands.

- List JMS resources for the WebSphere MQ messaging provider.

JMS provider settings

Use this panel to view the configuration properties of a selected JMS provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->JMS providers**. This displays a list of JMS providers in the content pane. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.
2. (optional) If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.
3. In the Providers column of the list displayed, click the name of a JMS provider.

If you want to browse or change JMS resources of the JMS provider, click the link for the type of resource under Additional Properties. For more information about the administrative console panels for the types of JMS resources, see the related topics.

For the default messaging provider (which is based on service integration technologies) and the WebSphere MQ messaging provider, the scope, name, and description properties are displayed for information only. You cannot change these properties.

For a third-party non-JCA provider that you have defined yourself, the properties of that provider are displayed.

Scope

The level (cell, node, or server level) at which this resource definition is available.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes. For more information about the scope setting, see Scope settings.

Name

The name by which the JMS provider is known for administrative purposes.

Data type String

Default

- Default messaging provider.
For JMS resources to be provided by a service integration bus, as part of WebSphere Application Server.
- *My JMSprovider*
For JMS resources to be provided by a third-party JMS provider that you specify, rather than by the default messaging provider or the WebSphere MQ messaging provider that are available as part of WebSphere Application Server. You assign the name, for example “My JMSprovider”, when you define the third-party JMS provider to WebSphere Application Server. You must also have installed and configured the third-party JMS provider before applications can use its JMS resources.
- WebSphere MQ messaging provider
For JMS resources to be provided by WebSphere MQ. You must have installed and configured WebSphere MQ before applications can use its JMS resources.
- V5 default messaging provider.
For JMS resources to be provided by a WebSphere Application Server Version 5 node in a deployment manager cell.

Description

A description of the JMS provider, for administrative purposes within WebSphere Application Server.

Data type String

Classpath

A list of paths or JAR file names that together form the location for the JMS provider classes. Each class path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Class paths can contain variable (symbolic) names to be substituted by using a variable map. Check your driver installation notes for specific JAR file names that are required.

Note: This property is only available for third-party messaging providers.

Data type String

Native library path

An optional path to any native libraries (*.dll, *.so). Each native path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Native paths can contain variable (symbolic) names to be substituted by using a variable map.

Note: This property is only available for the WebSphere MQ messaging provider and third-party messaging providers.

Data type String

Enable JCA based inbound message delivery

Specifies that WebSphere MQ messaging provider will support inbound delivering of messages using the JCA defined interfaces.

Note: This property is only available for the WebSphere MQ messaging provider, at the server scope.

When using WebSphere MQ messaging provider activation specifications on the z/OS operating system, you must enable the control region adjunct (CRA) process to allow messages to be delivered. Selecting this option starts the control region adjunct process on the next server restart.

Data type	Check box
Default	Cleared
Range	Cleared Do not start the control region adjunct process.
	Selected Start the control region adjunct process.

Update resource adapter

This button can be used to update the WebSphere MQ resource adapter that provides the function made available by the WebSphere MQ messaging provider. This button must only be used as directed by a member of IBM service, otherwise it may result in the use of an unsupported level of the WebSphere MQ resource adapter.

Normally the WebSphere MQ resource adapter is automatically updated by applying WebSphere Application Server fix packs. It is important to note that use of the **Update resource adapter** button prevents these automatic updates from happening for future fix packs for any node on which the button is used. If, in the future, you require the WebSphere MQ resource adapter used by the node to receive updates when a fix pack is applied then you must re-establish the recommended resource adapter configuration. For more information see “Maintaining the WebSphere MQ resource adapter” on page 807.

Note: This property is only available for the WebSphere MQ messaging provider.

Data type	Button
------------------	--------

External initial context factory

The Java classname of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: com.sun.jndi.ldap.LdapCtxFactory.

Note: This property is only available for third-party messaging providers.

Data type	String
Default	Null

External provider URL

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a messaging provider has the form: ldap://hostname.company.com/contextName.

Note: This property is only available for third-party messaging providers.

Data type	String
Default	Null

Disable WebSphere MQ

This check box is only valid for the WebSphere MQ messaging provider. When selected, this check box disables all WebSphere MQ functionality on affected application servers. Note that you must restart the affected application server processes for this change to take effect.

In a single server environment this check box is only available on the WebSphere MQ messaging provider panel where the scope is set to server, and has the effect of disabling all WebSphere MQ functionality in that application server.

In a network deployment environment this check box is available on all WebSphere MQ messaging provider panels. The effect of selecting the check box depends on the scope at which you select it:

- At the cell scope, all WebSphere MQ functionality is disabled on all application servers in the cell.
- At the node scope, all WebSphere MQ functionality is disabled on all application servers that are part of that node.
- At the cluster scope, all WebSphere MQ functionality is disabled on all application servers in that cluster.
- At the server scope, all WebSphere MQ functionality is disabled in that particular application server.

The value of the check box at a higher scope takes precedence over the value at a lower scope. For example, if you do not select the check box for a WebSphere MQ messaging provider at the server scope, but do select it for a WebSphere MQ messaging provider at a higher scope (such as the cell scope), the value of the check box at the cell scope takes precedence and WebSphere MQ functionality is therefore disabled in all application servers in the cell, regardless of whether the check box is selected at the server scope.

An informational message indicating that WebSphere MQ has been disabled is added to all WebSphere MQ messaging provider panels that are at affected scopes, but this message does not appear on those panels where the check box is selected. In a single server environment this informational message is only displayed after a server restart is performed. In a network deployment environment the informational message is displayed immediately.

For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

Data type	Check box
Default	Not selected

Additional properties

Connection factories

A connection factory is used to create connections to the associated JMS provider. These connection factories can be used for accessing JMS Queue and JMS Topic destinations.

Queue connection factories

A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

Topic connection factories

A topic connection factory is used to create connections to the associated JMS provider of JMS topic destinations, for publish and subscribe messaging.

Queues

A JMS queue is used as a destination for point-to-point messaging.

Topics

A JMS topic is used as a destination for publish/subscribe messaging.

Activation specifications

A JMS activation specification is associated with one or more message-driven beans and provides configuration necessary for them to receive messages.

Resource adapter properties

These properties are used to configure the WebSphere MQ resource adapter, which is used by the WebSphere MQ messaging provider. In particular most of these settings affect the behavior of WebSphere MQ messaging provider activation specifications.

Resource adapter properties

Use this page to configure the WebSphere MQ resource adapter that underlies the WebSphere MQ messaging provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->JMS providers** to display a list of JMS providers in the content pane.
2. (optional) If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.
3. In the Providers column of the displayed list of JMS providers, click the name of the WebSphere MQ messaging provider that you want to work with.
4. In the content pane under Additional properties, click **Resource adapter properties** to view the configuration page for the properties.

The resource adapter properties are used to configure the WebSphere MQ resource adapter, which is used by the WebSphere MQ messaging provider. These properties affect the connection pool, which is used by the WebSphere MQ messaging provider activation specifications. They do not affect the WebSphere MQ messaging provider queues, topics, or connection factories.

These properties only have an effect on the WebSphere MQ messaging provider objects that are defined at the same scope as the messaging provider and resource adapter on which they are set. So, for example, if you set the max connections property to a particular setting at the server scope, only the server scoped WebSphere MQ messaging provider activation specifications are affected by this setting.

For further information about these properties, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

If you want to configure a WebSphere MQ resource adapter custom property that is not exposed in WebSphere Application Server, click **Custom properties** under Additional properties.

Connection pool properties

Max connections

The maximum number of connections to a WebSphere MQ queue manager.

Data type	String
Default	10

Connection concurrency

The maximum number of message-driven beans that can be supplied by each connection.

Data type	String
Default	5

Reconnection retry count

The maximum number of attempts made by a WebSphere MQ messaging provider activation specification to reconnect to a WebSphere MQ queue manager if a connection fails.

Data type	String
Default	5

Reconnection retry interval

The time, in milliseconds, that a WebSphere MQ messaging provider activation specification waits before making another attempt to reconnect to a WebSphere MQ queue manager.

Data type	String
Default	300000

Additional properties

Custom properties

The full set of custom properties that are used to configure the WebSphere MQ resource adapter. Use this page to configure custom properties that are not exposed in WebSphere Application Server.

Installing WebSphere MQ to interoperate with WebSphere Application Server

When you install a new WebSphere MQ network, you can tune the installation for working with WebSphere Application Server. If you have an established WebSphere MQ network, you can choose whether to modify some of the settings for better interoperation.

About this task

This topic provides installation instructions for setting up a new WebSphere MQ installation to interoperate with WebSphere Application Server. If you have an established WebSphere MQ network, treat this task as a source of tips to tune your existing WebSphere MQ installation.

Procedure

1. Install a supported version of WebSphere MQ, as described in the installation instructions provided with WebSphere MQ.

To identify the supported version of WebSphere MQ, see the following article: Detailed system requirements page.

You should not install Rational Application Developer and WebSphere Application Server on the same machine when using WebSphere MQ.

For other installation prerequisites, see the *Quick Beginnings* section for your platform, in the WebSphere MQ information center.

2. Follow the WebSphere MQ instructions for verifying your installation setup.
3. Configure WebSphere Application Server and WebSphere MQ to interoperate effectively.
For information about the prerequisites and requirements for effective interoperation, see the following technote: Information about using the WebSphere MQ messaging provider for WebSphere Application Server Version 7.0.
4. Configure the WebSphere MQ messaging provider with native libraries information.

To connect to a WebSphere MQ queue manager or queue-sharing group in bindings mode, the WebSphere MQ messaging provider needs to know where to load native libraries from. For more information, see “Configuring the WebSphere MQ messaging provider with native libraries information.”

Note: For migration purposes only, you can also specify native path information, when in an application server environment, by setting the `MQ_INSTALL_ROOT` WebSphere Application Server environment variable. For more information see, Installing WebSphere MQ to interoperate with WebSphere Application Server.

5. Optional: At Cell scope or Node scope, set the WebSphere Application Server `MQ_CLEAR_MQ_FROM_OSGI_CACHE_ON_SHUTDOWN` environment variable to `True`. This allows application server startup to automatically take account of changes that are made to the `MQ_INSTALL_ROOT` environment variable and WebSphere MQ JMS client libraries while the application server is stopped.

If you do not set this variable, you must restart the application server a second time after any changes of this type, to enable the application to perform messaging by using the WebSphere MQ messaging provider.

Note: If you set the `MQ_CLEAR_MQ_FROM_OSGI_CACHE_ON_SHUTDOWN` environment variable, the startup time might increase because, on startup, each application server needs to initialize an additional state associated with WebSphere MQ installation.

What to do next

You are now ready to configure a messaging provider. If your business uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominantly WebSphere MQ network, the WebSphere MQ messaging provider is the natural choice. However, there can be benefits in using another provider. If you are not sure which provider combination is best suited to your needs, see Choosing messaging providers for a mixed environment.

To create WebSphere MQ messaging provider resources, see “Configuring JMS resources for the WebSphere MQ messaging provider” on page 818.

Configuring the WebSphere MQ messaging provider with native libraries information

To connect to a WebSphere MQ queue manager or queue-sharing group in bindings mode, the WebSphere MQ messaging provider needs to know where to load native libraries from. This information is known as native path information. The way native path information is set depends on whether the connection is established in an application client or in an application server environment.

About this task

If you are running in a client environment, use `launchClient` to start a client application. In the system property `MQ_INSTALL_ROOT` enter the name of a directory that contains the WebSphere MQ native libraries, in a subdirectory of `java/lib` or `java/lib64` depending on whether you are using 32 bit or 64 bit native libraries. For example, on Linux specify `./launchClient.sh myappclient.ear -CCDMQ_INSTALL_ROOT=/opt/mqm/`.

If you are running in an application server environment, you can configure the WebSphere MQ messaging provider with native path information by using the command line, as described in “WMQAdminCommands command group for the AdminTask object” on page 954, or you can use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, expand **Resources > JMS > JMS providers**.

2. Select the WebSphere MQ messaging provider that is at the correct **Scope** for the connection factory or activation specification that will create the bindings mode connection.

Note:

- Native path information at **Server** scope is used in preference to native path information at all other scopes.
- Native path information at **Cluster** scope is used in preference to native path information at **Node** and **Cell** scopes.
- Native path information at **Node** scope is used in preference to native path information at **Cell** scope.

Note: When using WebSphere MQ messaging provider connection factories or activation specifications that create bindings mode connections to a WebSphere MQ for z/OS queue manager, ensure that the IDBACK parameter is large enough. Otherwise, MQExceptions with a completion code of 2, and a reason code of 2025 (MQRC_MAX_CONNS_LIMIT_REACHED) can occur. For more information on how to set the IDBACK parameter, refer to the CSQ6SYSP macro section in the following the WebSphere MQ information centre pages:

WebSphere MQ Version 7.0: Task 17: Tailor your system parameter module

WebSphere MQ Version 6.0: Task 17: Tailor your system parameter module.

3. Under General Properties, in the **Native library path** property, enter the full name of the directory that contains the WebSphere MQ native libraries. For example, on Linux enter `/opt/mqm/java/lib`. Enter only one directory name.
4. Click **OK**.
5. Save any changes to the master configuration.
6. If you are running in an application server environment, you must restart all affected servers twice when you have changed the native path information. Otherwise, a WMSG1623E message is produced, indicating that the WebSphere MQ messaging provider is not available.

If you are running in a client environment, you must rerun the client program twice. Otherwise, a WMSG2013E message is produced.

Whichever environment you are running in, until you perform these restarts any attempt to use a WebSphere MQ messaging provider resource (for example, a connection factory) from one of the affected servers causes a `javax.naming.NamingException` and a WMSG2003E message.

What to do next

Note: For migration purposes only, you can also specify native path information, when in an application server environment, by setting the `MQ_INSTALL_ROOT` WebSphere Application Server environment variable. For more information, see the following topic in the WebSphere Application Server Version 6.1 information center: [Installing WebSphere MQ to interoperate with WebSphere Application Server \(Version 6.1\)](#).

Maintaining the WebSphere MQ resource adapter

The WebSphere MQ resource adapter is used by all applications that perform JMS messaging with the WebSphere MQ messaging provider. The WebSphere MQ resource adapter is usually updated automatically when you apply WebSphere Application Server fix packs, but if you have previously manually updated the resource adapter you must manually update your configuration to ensure that maintenance is applied correctly.

About this task

Applying a WebSphere Application Server fix pack does not automatically update the version of the WebSphere MQ resource adapter used by servers on nodes where the WebSphere MQ resource adapter has previously been manually updated.

Procedure

- To migrate the configuration of all servers in the cell to use the latest version of the WebSphere MQ resource adapter contained in the WebSphere Application Server installation, see “Ensuring that servers use the latest available WebSphere MQ resource adapter maintenance level.”
- If you want a specific version of the WebSphere MQ resource adapter to be installed, and the version you require is not available in a WebSphere Application Server fix pack, or an interim fix, see “Installing a specific maintenance level of the WebSphere MQ resource adapter” on page 809.

Ensuring that servers use the latest available WebSphere MQ resource adapter maintenance level

To ensure that the WebSphere MQ resource adapter is automatically updated to the latest available maintenance level when you apply WebSphere Application Server fix packs, you can configure all servers in your environment to use the latest version of the resource adapter contained in the WebSphere Application Server fix pack that you have applied to the installation of each node.

About this task

Use this task if any of the following circumstances apply to your configuration, and you want to configure all servers in your environment to use the latest version of the WebSphere MQ resource adapter:

- The JVM logs of any application server in your environment contain the following entry:
WMSG1625E: It was not possible to detect
the WebSphere MQ messaging provider code at the specified path <null>
- One or more nodes has previously been manually updated to use a specific maintenance level of the WebSphere MQ resource adapter that is now superseded by the latest version of the resource adapter contained in the current WebSphere Application Server maintenance level.

When you have performed the following steps for all cells and single server installations in your environment, your servers will automatically receive maintenance to the WebSphere MQ resource adapter when a new WebSphere Application Server fix pack is applied.

Procedure

1. Start the application server. If the profile is part of a network deployment configuration, start the deployment manager and all node agents. If the profile contains an administrative agent, start the administrative agent.
2. Copy the following Jython script into a file called `convertWMQRA.py`, then save it into the `profile_root/bin` directory.

```
ras = AdminUtilities.convertToList(AdminConfig.list('J2CResourceAdapter'))

for ra in ras :
    desc = AdminConfig.showAttribute(ra, "description")
    if (desc == "WAS 7.0 Built In WebSphere MQ Resource Adapter") or (desc == "WAS 7.0.0.1 Built In WebSphere MQ Reso
        print "Updating archivePath and classpath of " + ra
        AdminConfig.modify(ra, [['archivePath', "${WAS_INSTALL_ROOT}/installedConnectors/wmq.jmsra.rar"]])
        AdminConfig.unsetAttributes(ra, ['classpath'])
        AdminConfig.modify(ra, [['classpath', "${WAS_INSTALL_ROOT}/installedConnectors/wmq.jmsra.rar"]])
        AdminConfig.save()
    #end if
#end for
```

3. Use the `wsadmin` tool to run the Jython script that you have just created.

Open a command prompt and navigate to the *profile_root/bin* directory, then enter the following command:

```
wsadmin -lang jython -f convertWMQRA.py
```

Note: If you run the script against a profile that is part of a network deployment configuration, the script updates all profiles that need updating in that configuration.

4. If you are running in a network deployment configuration, ensure that the node agents are fully re-synchronized.

For more information, see Synchronizing nodes using the wsadmin scripting tool or Adding, managing, and removing nodes.

5. Stop all servers in the profile. If the profile is part of a network deployment configuration, also stop any cluster members in the configuration, stop all node agents in the configuration, and stop the deployment manager. If the profile contains an administrative agent, stop the administrative agent.
6. Run the `osgiCfgInit` command from the *profile_root/bin* directory. If the profile is part of a network deployment configuration, run the `osgiCfgInit` command from the *profile_root/bin* directory of every profile that is part of the configuration.

Note: The `osgiCfgInit` command resets the class cache used by the OSGi runtime environment.

7. Restart all servers in the profile. If the profile is part of a network deployment configuration, also restart any cluster members in the configuration, restart all node agents in the configuration, and restart the deployment manager. If the profile contains an administrative agent, restart the administrative agent.

What to do next

If you continue to experience problems after performing the steps described in this topic, and you have previously used the **Update resource adapter...** button on the JMS Provider Settings panel in the administrative console to update the WebSphere MQ resource adapter on any nodes in your environment, it is possible that you are experiencing the issue described in APAR PM10308.

Installing a specific maintenance level of the WebSphere MQ resource adapter

If you require a specific version of the WebSphere MQ resource adapter to be installed and the version you require is unavailable in a WebSphere Application Server fix pack, or an interim fix, you can install the resource adapter using the administrative console.

Before you begin

The minimum version of the WebSphere MQ resource adapter required for this version of WebSphere Application Server is WebSphere MQ Version 7.0.

About this task

Use this task only if you have a requirement to use a specific maintenance level of the WebSphere MQ resource adapter that is unavailable in a WebSphere Application Server fix pack, or an interim fix.

You do not need to use this task if you want to restore the configuration of all servers in your cell to use the latest version of the WebSphere MQ resource adapter contained in the WebSphere Application Server installation. In this case, see “Ensuring that servers use the latest available WebSphere MQ resource adapter maintenance level” on page 808 for further information.

In a network deployment environment, you must perform the following steps individually for each node where you require to install the specific maintenance level.

Procedure

1. Start the administrative console.

2. In the navigation pane, click **Resources > JMS->JMS providers** The JMS providers collection panel opens.
3. Change the scope to the node that you want to update.
4. Select the WebSphere MQ messaging provider entry in the list. The settings panel for this provider opens.
5. Click **Update resource adapter...**

Note: **Update resource adapter...** is only available for the WebSphere MQ messaging provider at node scope.

6. Specify the installation path for the resource adapter archive (RAR) file, then click **Next**:
 - If your RAR file is located on the same workstation as your browser, select **Local file system**, and browse to find the file.
 - If your RAR file is located on the server workstation where the application server is installed, select **Remote file system**, and specify the fully qualified path to the file.
7. Review the configuration information that is provided for the RAR file then, when you have finished your review, click **Next**. The following information is displayed for the RAR file:
 - Name
 - Current RAR version
 - New RAR version
 - Scope
 - Any existing copies of the resource adapter. The resource adapters shown with an asterisk (*) are copies of the resource adapter and must also be updated at the same time.
8. Optional: Edit any properties that were added by the new version of the resource adapter. You can also edit these properties after you have completed the update.
 - a. From the displayed list, select the resource for which you want to edit the new properties. Only resources with new properties are included in the list.
 - b. Edit the resource properties. Use the table that is provided to set the values for new properties of the selected resource.
 - Select **Set for all** to apply the property value to all resources of the same type.
 - Click **Reset to Default** to reset all the properties to the default values that are defined in the RAR file. This resetting of property values only affects the selected resource.
 - c. Click **Next**.
9. Review the summary panel and then, when you are satisfied with the configuration settings, click **Finish**. When you click **Finish**, all the configuration changes are saved automatically. To revert to an older version of the resource adapter you must perform the update process again, and specify the older version of the RAR file that you want to revert to.
10. Restart the servers that contain the updated RAR file.

Listing JMS resources for the WebSphere MQ messaging provider

Use the WebSphere Application Server administrative console to list JMS resources for the WebSphere MQ provider, for administrative purposes.

About this task

You use the WebSphere Application Server administrative console to list JMS resources, if you want to view, modify or delete any of the following resources:

- Activation specifications
- Unified connection factories
- Queue connection factories

- Topic connection factories
- Queues
- Topics

When you use the administrative console to locate these resources, two different navigation pathways are available:

- **Provider-centric navigation** lets you view all providers, or just those for a specified scope, then navigate to a specific resource for a specific provider. This is the traditional way of navigating to a resource when you know which provider supports it. Any navigation that starts with **Resources > JMS->JMS providers** is provider-centric.
- **Resource-centric navigation** lets you view all resources of a specified type, then navigate to a resource. This is useful if you want to find a resource, but you do not know which provider supports it (you can list all resources of a given type across all scopes, for all providers, in a single panel). Any navigation that follows the pattern **Resources > JMS > resource_type** is resource-centric, where *resource_type* is one of the resource types previously listed.

You can use either of these navigation pathways to locate JMS resources of any type.

Procedure

- Use provider-centric navigation, for example to navigate to a specified queue connection factory.
 1. Start the administrative console.
 2. In the navigation pane, click **Resources > JMS->JMS providers**.
The JMS providers collection panel is displayed. This lists all currently configured messaging providers across all scopes (you can modify the scope if required).
 3. Select the required JMS provider.
The settings panel for this provider is displayed. The configuration tab contains a set of links to all the JMS resources owned by this provider.
 4. Click the link for a JMS resource type. For example, click **Queue connection factories**.
The queue connection factories collection panel is displayed. This panel lists all the queue connection factories for this provider.
 5. Select the required queue connection factory.
- Use resource-centric navigation, for example to navigate to a specified queue connection factory.
 1. Start the administrative console..
 2. In the navigation pane, click **Resources > JMS->Queue connection factories**.
The queue connection factories collection panel is displayed. This panel lists all the queue connection factories across all messaging providers.
 3. Select the required queue connection factory.

Results

You can now view and work with the resource properties.

JMS providers collection

Use this panel to list JMS providers, or to select a JMS provider to view or change its configuration properties.

To view this administrative console page, click **Resources > JMS->JMS providers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS providers that are available to WebSphere applications. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.

If you want to manage existing JMS resource definitions, or create a new JMS resource definition, you can select the name of one of the JMS providers in the list.

If you want to define a new third-party JMS provider (that is, a provider other than the default messaging provider or the WebSphere MQ messaging provider), select the Scope setting at which JMS resource definitions are to be visible for that provider, then click **New**.

Name The name by which this JMS provider is known for administrative purposes.

Description

A description of this JMS provider for administrative purposes.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Activation specification collection

A JMS activation specification is associated with one or more message-driven beans and provides the configuration necessary for them to receive messages. The default messaging provider and the WebSphere MQ messaging provider both support use of activation specifications.

In the administrative console, to view this page click **Resources > JMS->Activation specifications**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

This page lists the JMS activation specifications that are available to WebSphere applications at the scope indicated by the **Scope** field.

Name The display name of each activation specification instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each activation specification instance.

Provider

The messaging provider that supports each activation specification instance. This is either the default messaging provider (service integration) or the WebSphere MQ messaging provider.

Description

An optional description of each activation specification instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Connection factory collection

A JMS connection factory is used to create connections to the associated messaging provider of JMS destinations, for both point-to-point and publish/subscribe messaging. Use connection factory administrative objects to manage JMS connection factories for the default messaging provider, the WebSphere MQ messaging provider or a third-party messaging provider.

In the administrative console, to view this page click **Resources > JMS->Connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory of the messaging provider named in the **Provider** column of the list.

This type of connection factory is for applications that use the JMS 1.1 domain-independent interfaces (referred to as the “common interfaces” in the JMS specification).

This type of JMS connection factory can also be used by the domain-specific (queue and topic) interfaces, as used in JMS 1.0.2, so applications can still use those interfaces without the need for you to create a domain-specific connection factory, such as a queue connection factory.

In a mixed release cell, these connection factories are only available for Version 7 and later nodes.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the

scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

Name The display name of each connection factory instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each connection factory instance.

Provider

The messaging provider that supports each connection factory instance. This is the default messaging provider (service integration), the WebSphere MQ messaging provider or a third-party messaging provider.

Description

An optional description of each connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue connection factory collection

A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

In the administrative console, to view this page click **Resources > JMS->Queue connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS queue connection factory is used to create connections to JMS destinations. When an application needs a JMS queue connection, an instance can be created by the factory for the JMS provider that is named in the **Provider** column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 queue-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server

environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

Name The display name of each queue connection factory instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each queue connection factory instance.

Provider

The messaging provider that supports each queue connection factory instance.

Description

An optional description of each queue connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic connection factory collection

A JMS topic connection factory is used to create connections to the associated messaging provider of JMS topic destinations, for publish and subscribe messaging.

In the administrative console, to view this page click **Resources > JMS->Topic connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory for the JMS provider that is named in the Provider column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 topic-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

General properties

Name The display name of each topic connection factory instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each topic connection factory instance.

Provider

The messaging provider that supports each topic connection factory instance.

Description

An optional description of each topic connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue collection

A JMS queue destination is used for point-to-point messaging. Use this panel to create or delete queue destinations, or to select a queue destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources > JMS->Queues**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a queue destination to manage JMS queues for the JMS provider that is named in the **Provider** column of the list. Connections to the queue are created by a unified connection factory or queue connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

General properties

Name The display name of each queue destination instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each queue destination instance.

Provider

The messaging provider that supports each queue destination instance.

Description

An optional description of each queue destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic collection

A JMS topic destination is used for publish and subscribe messaging. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources > JMS->Topics**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a topic destination to manage JMS topics for the JMS provider that is named in the **Provider** column of the list. Connections to the topic are created by a unified connection factory or topic connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

General properties

Name The display name of each topic destination instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each topic destination instance.

Provider

The messaging provider that supports each topic destination instance.

Description

An optional description of each topic destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Configuring JMS resources for the WebSphere MQ messaging provider

Use the WebSphere Application Server administrative console to configure activation specifications, connection factories and destinations for the WebSphere MQ JMS provider.

Before you begin

This task assumes that you are working in a mixed WebSphere Application Server and WebSphere MQ environment, and that you have decided to use the WebSphere MQ messaging provider to handle JMS messaging between the two systems. If your business uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominately WebSphere MQ network, the WebSphere MQ messaging provider is the natural choice. However, there can be benefits in using another provider. If you are not sure which provider combination is best suited to your needs, see [Choosing messaging providers for a mixed environment](#).

You can configure JMS resources for the WebSphere MQ messaging provider through the administrative console as described in this task, or you can configure JMS resources for the WebSphere MQ messaging provider through the WebSphere MQ administrative commands.

About this task

Using the administrative console, you can set the scope of the WebSphere MQ messaging provider to restrict the range of resources that are displayed:

- If you set the scope to contain only WebSphere Application Server Version 6 or Version 7.0 or later nodes, you can configure JMS 1.1 resources and properties. This includes unified JMS connection factories for use by both point-to-point and publish/subscribe JMS 1.1 applications. With JMS 1.1, this approach is preferred to the domain-specific queue connection factory and topic connection factory.
- If you set the scope to contain only WebSphere Application Server Version 7.0 or later nodes, you can also configure JMS activation specifications.
- If you set the scope to a WebSphere Application Server Version 5 node, you can only configure domain-specific JMS resources, and the subset of properties that apply to WebSphere Application Server Version 5.

Note:

There are two ways of specifying the information needed by WebSphere MQ messaging provider messaging resources so that they can connect to a WebSphere MQ queue manager. It can either be specified manually, or by providing the WebSphere MQ messaging provider resource with a uniform resource locator (URL) that points to a client channel definition table (CCDT).

A CCDT is a binary file that contains information about how to create a client connection channel to one or more queue managers. The file contains information such as the hostname, port, and name of the target queue manager, as well as more advanced configuration information like the SSL attributes that should be used.

Creating WebSphere MQ messaging provider resources using CCDTs provides the following benefits:

- Flexibility, because client connection channel information is contained in a single place. If any of the information changes, such as the host name of the machine on which the WebSphere MQ queue manager resides, only the CCDT needs to be updated. When it is updated, all WebSphere MQ messaging provider resources that make use of the CCDT pick up the change.
- Reliability, because less information is needed for a CCDT there is a reduced chance of configuration errors. When using a CCDT to enter connection information, all that is required are the CCDT URL and an optional queue manager name. If you configure a WebSphere MQ messaging provider resource manually, much more information is required -- especially if you are configuring SSL.

For further information about generating a CCDT, see the WebSphere MQ information center.

Maintenance note: The WebSphere MQ messaging provider uses code provided by the WebSphere MQ resource adapter, which is automatically installed as part of the product.

Procedure

- “Creating an activation specification for the WebSphere MQ messaging provider”
- “Configuring an activation specification for the WebSphere MQ messaging provider” on page 822
- “Migrating a listener port to an activation specification for use with the WebSphere MQ messaging provider” on page 842

- “Configuring a topic connection factory for the WebSphere MQ messaging provider” on page 897
- “Configuring a queue for the WebSphere MQ messaging provider” on page 924
- “Configuring a topic for the WebSphere MQ messaging provider” on page 936
- “Configuring custom properties for WebSphere MQ messaging provider JMS resources” on page 946

Creating an activation specification for the WebSphere MQ messaging provider

Use this task to create an activation specification for use with the WebSphere MQ messaging provider.

About this task

To create an activation specification for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps. You can choose either to enter all the required connection information using the Create WebSphere MQ JMS resource wizard or to use a client channel definition table (CCDT) to establish a connection to the WebSphere MQ messaging provider.

For information about modifying an existing activation specification, see the related tasks.

Procedure

1. In the navigation pane, click **Resources > JMS > Activation specifications**.
2. Select the **Scope** setting corresponding to the scope of the activation specification that you want to create.
3. Click **New** in the content pane.
4. Select **WebSphere MQ messaging provider**, then click **OK** to start the Create WebSphere MQ JMS resource wizard.
5. On the “Configure basic attributes” page, enter the following information, then click **Next**.

Name The name by which this activation specification is known for administrative purposes within WebSphere Application Server.

JNDI name

The name that is used to bind this activation specification into the JNDI namespace.

Description

Optional. A description of this activation specification for administrative purposes within WebSphere Application Server.

6. On the “Specify MDB destination data” page, enter the following information, then click **Next**.

Destination JNDI name

The JNDI name for the JMS destination from which messages are delivered to a message-driven bean (MDB) that is configured to use this activation specification.

Message selector

Optional. A message selector expression specifying which messages are to be delivered.

Destination type

The type of destination (queue or topic) from which to consume messages.

7. On the “Select connection method” page, choose how you want to specify the connection details for to the WebSphere MQ messaging provider by selecting one of the following options, then click **Next**.

Enter all the required information into this wizard

Choosing this option takes you to the “Supply queue manager details” page (see step 8), where you can start entering the connection details using the Create WebSphere MQ JMS resource wizard.

Use a client channel definition table

Choosing this option takes you to the “Specify client channel definition table” page (see step 9), where you can enter details of the client channel definition table that you want to use.

8. If you have chosen to enter all the required information using the wizard, complete the following steps:
 - a. On the “Supply queue manager details” page, enter the name of the queue manager or queue-sharing group that you want to connect to then click **Next**.
 - b. On the “Enter connection details” page, specify the details for the connection, then click **Next** to continue to the “Test connection” page. You can choose either to enter host and port information separately, or enter host and port information in the form of a connection name list. You must only choose the option to use a connection name list if you are creating a connection to a multi-instance queue manager. You must not use this option for connections to non-multi-instance queue managers as that can result in transaction integrity issues.

Transport

Optional. The WebSphere MQ transport type for the connection. The option that you select is used to determine the exact mechanisms used to connect to WebSphere MQ. If you are configuring a transport type of *bindings*, *then client* or *bindings*, see “Configuring the WebSphere MQ messaging provider with native libraries information” on page 806 for more information.

Enter host and port information in the form of separate hostname and port values

This radio button is selected by default and enables the **Hostname** and **Port** fields and disables the **Connection name list** field. Leave this radio button selected if you want to enter host and port information in the form of separate hostname and port values.

Hostname

The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to. Complete this field if you have selected **Enter host and port information in the form of separate hostname and port values**.

Port Optional. The port number on which WebSphere MQ is listening. If you do not specify a

value for the port number, the default value of 1414 is used. Complete this field if you have selected **Enter host and port information in the form of separate hostname and port values**.

Enter host and port information in the form of a connection name list

This radio button is cleared by default and, if selected, disables the **Hostname** and **Port** fields and enables the **Connection name list** field.

- Click this radio button to select it if you want to enter host and port information in the form of a connection name list.
- Leave this radio button cleared if you want to enter host and port information in the form of separate host name and port values.

Connection name list

The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager. Complete this field if you have selected **Enter host and port information in the form of a connection name list**. Enter the host name and port details in the following form:

host [(*port*)] [, *host* (*port*)]

host must be a valid TCP/IP host name or IPv4 or IPv6 address.

port must be an integer value in the range 1 - 65536 (inclusive). The port information is optional, and if not specified, defaults to 1414.

For example: localhost(1234), remotehost1(1234), remotehost2

Server connection channel

Optional. The WebSphere MQ server connection channel name used when connecting to WebSphere MQ queue manager or queue-sharing group.

9. If you are using a channel client definition table to establish a connection to the WebSphere MQ messaging provider, complete the following fields on the “Specify client channel definition table” page, then click **Next** to continue to the “Test connection” page.

Client channel definition table URL

The URL to the client channel definition table that you want to use when connecting to WebSphere MQ.

Queue manager

Optional. The name of the queue manager to be used to select one or more entries from the CCDT.

10. Optional: On the “Test connection” page, if you want to test establishing the connection, click **Test connection**. This test can take several seconds to perform.
11. On the “Summary” page, complete the creation of the new activation specification by clicking **Finish**.
12. Stop then restart the application server.

JMS resource provider selection panel

Select the messaging provider with which to create this JMS activation specification, connection factory or destination.

You select the scope setting on an earlier page. The choice of JMS provider depends on the scope that you selected. You might see a choice such as the following list:

- Default messaging provider.
Select this option if you want the JMS resource to be provided by the service integration bus, as part of WebSphere Application Server.
- WebSphere MQ messaging provider
Select this option if you want the JMS resource to be provided by WebSphere MQ. You must have installed and configured a WebSphere MQ network in order to use this provider.

- “My JMS provider”

Select this option if you want the JMS resource to be provided by a third-party JMS provider. This option is only available if you have installed and configured a third-party provider. The name that is displayed (for example “My JMS provider”) is the name you gave to the provider when you installed and configured it.

- V5 default messaging provider

Select this option if you want to manage the JMS connection factories and destinations for JMS applications that were designed to work with WebSphere Application Server Version 5.1, and are still running on a Version 5.1 or Version 6 node that is part of a Version 7.0 or later mixed cell.

Configuring an activation specification for the WebSphere MQ messaging provider

Configure a JMS activation specification to enable a message-driven bean (MDB) to communicate with the WebSphere MQ messaging provider.

About this task

To view or change the configuration of an activation specification for use with WebSphere MQ, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources > JMS->Activation specifications**. A list of existing activation specifications, with a summary of their properties, is displayed in an “Activation specification collection” on page 812 form.
2. Select the **Scope** setting corresponding to the scope of the activation specifications that you want to view or change.
3. Select the name of the activation specification that you want to view or change. Configuration details for the activation specification are displayed in an “WebSphere MQ messaging provider activation specification settings” on page 823 form.
4. Under **General Properties** make modifications as necessary.

For information about each of the available fields, see “WebSphere MQ messaging provider activation specification settings” on page 823.

Note: There are four WebSphere MQ connection properties that are used to configure the WebSphere MQ resource adapter used by the WebSphere MQ messaging provider. These properties affect the connection pool that is used by activation specifications:

- maxConnections
- connectionConcurrency
- reconnectionRetryCount
- reconnectionRetryInterval

For more information about these four properties, and how to configure them, see “Resource adapter properties” on page 804.

5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your activation specification.
7. Optional: Click **Broker properties** to display or change the list of broker properties of your activation specification.
8. Optional: Click **Custom properties** to display or change the list of custom properties of your activation specification. For example, you would use this option to set the custom property `WAS_EndpointInitialState` for an activation specification. `WAS_EndpointInitialState` determines

whether or not message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

9. Optional: Click **Client transport properties** to display or change the list of client transport properties of your activation specification. This link is only present on the explicitly-defined variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
10. Click **OK**.
11. Save your changes to the master configuration.
12. If you use activation specifications with WebSphere MQ message-driven beans (MDBs) on the z/OS platform, you must enable the control region adjunct (CRA) process of the application server. Either select **Enable JCA based inbound message delivery** on the JMS provider settings panel, or by use the manageWMQ command to include starting the CRA as part of the process for starting an application server.
13. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider activation specification settings

Use this panel to view or change the configuration properties of the selected activation specification for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to associated queues and topics.

To view WebSphere MQ activation specification settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Select the name of the activation specification that you want to work with.

Under General Properties there are five groups of properties:

- “Administration” on page 824
- “Connection” on page 825
- “Destination” on page 831
- “Advanced” on page 832
- “Security settings” on page 832

Make any required changes to the Administration, Connection, Destination, Advanced, and Security settings groups of properties, and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click any of the following links:

- **Advanced properties** to display or change the advanced properties of your WebSphere MQ activation specification.
- **Broker properties** to display or change the broker properties of your WebSphere MQ activation specification.
- **Custom properties** to display or change the custom properties of your WebSphere MQ activation specification. For example, you would use this option to set the custom property `WAS_EndpointInitialState` for an activation specification. `WAS_EndpointInitialState` determines whether or not message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.
- **Client transport properties** to display or change the client transport properties of your WebSphere MQ activation specification. If the selected activation specification was not created using a Client Channel Definition Table (CCDT), follow this link to enter all the information required to connect to WebSphere MQ. If the selected activation specification was created using a CCDT, you do not need to supply the client transport properties, and so the link is absent.

Under Related Items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the activation specification.

You can also specify the **-localAddress** property by using the createWMQActivationSpec WebSphere MQ administrative command.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information, see the *Using Java* and *System Administration* sections of the WebSphere MQ information center.

If WebSphere MQ functionality has been disabled at a scope that affects this WebSphere MQ messaging provider resource, then an informational message indicating that WebSphere MQ has been disabled appears. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

A WebSphere MQ activation specification has the following properties.

Administration:

Scope:

The level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the WebSphere MQ activation specification collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the activation specification is created.

For all activation specifications created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which this activation specification is known for administrative purposes within WebSphere Application Server.

Data type	String
Range	The name must be unique within the set of activation specifications defined to the cell.

JNDI name:

The JNDI name that is used to bind the activation specification into the JNDI namespace.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

Data type	String
------------------	--------

Description:

A description of this activation specification for administrative purposes within WebSphere Application Server.

Data type	String
Default	Null

Connection:

The information required to configure a connection depends on whether the selected activation specification was created using a Client Channel Definition Table (CCDT).

If the selected activation specification was created using a CCDT, only the following properties are displayed:

- Client channel definition table URL
- Queue manager
- SSL configuration

If the selected activation specification was not created using a CCDT, the following properties are displayed:

- Queue manager
- Transport
- If **Enter host and port information in the form of separate host and port values** is selected, the connection name list property cannot be used and the following properties can be used:
 - Host name
 - Port
- If **Enter host and port information in the form of a connection name list** is selected, the connection name list property can be used and the following properties cannot be used:
 - Host name
 - Port
- Server connection channel
- If you clear the check box for the **Use SSL to secure communication with Websphere MQ** property, the following properties cannot be used:
 - Centrally managed
 - Specific configuration
 - SSL configuration

For more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *WebSphere MQ Using Java* section of the WebSphere MQ information center.

Note: There are four WebSphere MQ connection properties that are used to configure the WebSphere MQ resource adapter used by the WebSphere MQ messaging provider. These properties affect the connection pool that is used by activation specifications:

- maxConnections
- connectionConcurrency
- reconnectionRetryCount
- reconnectionRetryInterval

For more information about these four properties, and how to configure them, see “Resource adapter properties” on page 804.

Client channel definition table URL:

A URL that specifies the location of a WebSphere MQ CCDT.

Data type String

Queue manager:

If the specified activation specification is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, this property specifies the name of the queue manager or queue-sharing group to connect to. A connection is established to the specified WebSphere MQ resource to receive messages.

Data type String

Range

If this activation specification is not based on a CCDT, the value must be a valid queue manager name.

If this activation specification is based on a CCDT, the value must be one of the following:

- A valid queue manager name
- An asterisk (*) followed by the name of a queue manager group¹
- An asterisk (*)
- Blank¹

¹When you specify the value of the Queue manager property in this form in combination with a CCDT, individual connections established by using the activation specification might connect to different queue managers. Selection from multiple queue managers occurs when the CCDT contains multiple client connection channel definitions with a matching queue manager name (QMNAME) parameter, and these connection channel definitions define the network connection details of different queue managers.

If the specified connection factory is based on a CCDT, and the CCDT can select from more than one queue manager, you might not be able to recover global transactions. Therefore, for connection factories that specify a CCDT, you have two alternatives:

- Avoid any ambiguity about the target queue manager when specifying the Queue manager property, which means that the specified value of this property must not include an asterisk (*).
- Avoid using the resources with applications that enlist in global transactions.

Transport:

The WebSphere MQ transport type for the connection. The transport type is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type

Drop-down list

Default**Bindings, then client**

Range

Client Use a TCP/IP-based network connection to communicate with the WebSphere MQ queue manager.

Bindings, then client

Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport.

Bindings

Establish a cross-memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled:

- Host name
- Port
- Connection name list
- Server connection channel

For more information about configuring a transport type of *Bindings, then client* or *Bindings*, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 806.

Enter host and port information in the form of separate host and port values:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the host name and port properties.

Selecting this option enables the host name and port properties, and disables the connection name list property. To enter connection name list information, click **Enter host and port information in the form of a connection name list**.

This radio button is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Hostname:

The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type String

Port:

The port number on which WebSphere MQ is listening.

Data type Integer

Default 1414

Range The value must be in the range 1 to 65536 (inclusive).

Enter host and port information in the form of a connection name list:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the connection name list property.

Connection name lists can be used to connect to a single queue manager or to a multi-instance queue manager. For more information on using a multi-instance queue manager, see the WebSphere MQ information centre. Selecting this option enables the connection name list property and disables the host name and port properties. To enter separate host and port information, click **Enter host and port information in the form of separate host and port values**.

This radio button is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Connection name list:

The connection name list specifying the host name and port details to use when you want the activation specification to connect to a multi-instance queue manager.

This property must only be used to allow connection to a multi-instance queue manager. It must not be used to allow connections to non-multi-instance queue managers as that can result in transaction integrity issues.

Data type String
Default Unset
Range This field must be set to a string in the following form:

host[(*port*)][,*host*(*port*)]

The port information is optional, and if not specified, defaults to 1414.

host must be a valid TCP/IP host name or IPv4 or IPv6 address.

port must be an integer value in the range 1 to 65536 (inclusive).

For example:
localhost(1234),remotehost1(1234),remotehost2

When the connection name list property is specified, the host name or port properties are automatically set to the host name and port number of the first entry in the connection name list. So if you specified localhost(1234),remotehost1(1234),remotehost2, the host name would be set to localhost and port would be set to 1234.

This property is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

When used in a mixed cell environment, the information in the connection name list property, for cluster or cell scope activation specifications, is available to WebSphere Application Server Version 7.0 nodes. The exact behaviour depends on the fix pack level of the node:

- For nodes running at a fix pack level of WebSphere Application Server Version 7.0 Fix Pack 7 or later, the connection name list property can be used to connect to multi-instance queue managers.
- For nodes running at a fix pack level earlier than Version 7.0, the connection name list property is not recognized, and a warning message similar to the following example is output:

```
[29/09/10 12:15:27:468 BST] 00000018 J2CUtilityCla W J2CA0008W: Class com.ibm.mq.connector.inbound.ActivationSp
```

In this case the information in the host name and port properties are used to connect to a queue manager.

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type	String
Default	SYSTEM.DEF.SVRCONN
Range	The value must be a server connection channel defined to the WebSphere MQ queue manager that is being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

When using a WebSphere MQ messaging provider activation specification in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security > SSL certificate and key management** panel.

You can only use one cipher suite in the SSL configuration for a WebSphere MQ messaging provider activation specification . If you specify more than one cipher suite, only the first one is used.

Data type	Check box. If this check box is cleared, the following SSL properties are disabled: <ul style="list-style-type: none">• Centrally managed• Specific configuration• SSL configuration
------------------	--

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the host name and port attributes from the WebSphere MQ messaging provider activation specification are used to select an appropriate SSL configuration. If host and port information has been supplied to the activation specification by a connection name list this means that the host name and port information of the first element in the list are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the activation specification, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type	Radio button
------------------	--------------

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

Data type	Radio button
------------------	--------------

SSL configuration:

The SSL configuration to use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if an SSL configuration of none is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Destination:

Note: The property WAS_EndpointInitialState is a custom property. This property determines whether or not message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination. To set custom properties, when you have completed your changes in this content pane and clicked **Apply** to save the configuration, then click the link **Custom properties** in the content pane under Additional Properties.

Destination JNDI name:

The JNDI name for the JMS destination from which messages are consumed for delivery to a message-driven bean (MDB) that is configured to use this activation specification.

Data type String

Message selector:

A message selector expression specifying which messages are to be delivered.

Data type String

Destination type:

The type of destination (queue or topic) from which to consume messages.

Data type Drop-down list
Range **Queue** The Destination JNDI name refers to a JMS destination that is a queue.
Topic The Destination JNDI name refers to a JMS destination that is a topic.

Durable subscription:

An option to specify whether a durable or nondurable subscription is used to deliver messages to an MDB subscribing to the topic.

Data type Check box
Default Cleared (nondurable)

Range

Cleared

Nondurable.

Selected

Durable.

Subscription name:

The name of a durable subscription. This is available only when the **Durable subscription** check box is selected.

Data type

String

Advanced:

Client ID:

The client identifier to specify when connecting to the WebSphere MQ messaging provider.

Data type

String

Allow cloned durable subscriptions:

An option that determines whether multiple instances of a durable subscription can be accessed concurrently by different servers.

Data type

Check box

Default

Cleared

Range

Selected

Multiple instances of a durable subscription can be accessed concurrently by different servers.

Cleared

Multiple instances of a durable subscription cannot be accessed concurrently by different servers.

Provider version:

The WebSphere MQ messaging provider version. This is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functions required by the client.

Data type

String

Range

The value entered must either be the empty string or be in one of the following formats:

n.n.n.n

n.n.n

n.n

n

where n is a numeric value greater than or equal to zero.

For example 6.0.0.0.

Security settings:

Authentication alias:

The user name and password to use when connecting to WebSphere MQ.

Data type	Drop-down list
Default	(none)
Range	All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

WebSphere MQ messaging provider activation specification advanced properties:

Use this panel to view or change the advanced properties of the selected activation specification for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ activation specification advanced properties, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Select the name of the activation specification that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ activation specification.

Under General Properties there are four groups of properties:

- Message compression
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the activation specification.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* section of the WebSphere MQ library.

A WebSphere MQ activation specification has the following advanced properties.

Compress message headers:

An option that enables the compression of message headers.

Data type	Check box
Default	Cleared
Range	Cleared Do not compress message headers. Selected Compress message headers.

Compression algorithm for message payloads:

The compression algorithm that is used to compress message payloads.

Data type	Drop-down list
Default	NONE
Range	RLE Message data compression is performed using run-length encoding. ZLIBFAST Message data compression is performed using ZLIB encoding with speed prioritized. ZLIBHIGH Message data compression is performed using ZLIB encoding with compression prioritized. NONE No message data compression is performed.

Retain messages, even if no matching consumer is available:

An option that determines whether messages for which there is no matching consumer are retained on the input queue or dealt with according with their disposition options.

Data type	Check box
Default	Selected
Range	Cleared Do not retain messages. Selected Retain messages.

Rescan interval:

When using a WebSphere MQ version 6 queue manager (or WebSphere MQ version 5.3 for z/OS), this setting configures the mechanism that is used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread retrieves messages from a WebSphere MQ queue before switching to consume messages from another WebSphere MQ queue in the set.

Data type	Integer
Units	Milliseconds
Default	5000
Range	A value greater than zero.

Maximum server sessions:

The maximum number of server sessions in the server session pool that is used by the connection consumer.

Data type	Integer
Default	10
Range	A value greater than zero.

Server session pool timeout:

The period of time, in milliseconds, that an unused server session is held open in the server session pool before being closed due to inactivity.

Data type	Integer
Units	Milliseconds
Default	300,000
Range	A value greater than zero.

Start timeout:

The period of time, in milliseconds, within which delivery of a message to a message-driven bean (MDB) must start after the work to deliver the message has been scheduled. If this period of time elapses, the message is rolled back onto the queue.

Data type	Integer
Units	Milliseconds
Default	10,000
Range	A value greater than zero.

Coded character set identifier:

The character set to use when you are encoding strings in the message.

Data type	Integer
Default	819
Range	A value greater than zero. The value must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* sections of the WebSphere MQ library.

Fail JMS method calls if the WebSphere MQ queue manager is quiescing:

An option that enables selected JMS operations to fail when the queue manager is put into a quiescing state. Selecting this option enables the queue manager to quiesce successfully and shut down.

Data type	Check box
Default	Selected
Range	Cleared Do not fail JMS operations if the queue manager is quiescing. Selected Fail JMS operations if the queue manager is quiescing.

Stop endpoint if message delivery fails:

An option that determines whether message delivery is suspended to a failing endpoint.

Data type	Check box
Default	Selected

Range**Cleared**

Message delivery is not suspended to a failing endpoint.

Selected

Message delivery is suspended to a failing endpoint when the value for the **Number of sequential delivery failures before suspending endpoint** is exceeded.

Number of sequential delivery failures before suspending endpoint:

The number of sequential message delivery failures to an endpoint that are allowed before message delivery to that endpoint is suspended. This property is enabled only when **Suspend message delivery to failing endpoints** is selected.

Data type

Integer

Default

0

Range

A value greater than or equal to zero.

WebSphere MQ messaging provider activation specification broker properties:

Use this panel to view or change the broker settings of the selected activation specification for use with the WebSphere MQ messaging provider. These broker settings determine how the WebSphere MQ messaging provider interacts with a broker for the purposes of publishing messages and subscribing to topics. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ activation specification broker properties, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Select the name of the activation specification that you want to work with.
4. In the content pane under Additional properties, click **Broker properties** to view a list of the broker properties of the WebSphere MQ activation specification.

Under General Properties there are four groups of properties:

- Queues
- Capabilities
- Tuning
- Additional

Make any required changes to these groups and then click **Apply** to return to the activation specification.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* section of the WebSphere MQ library.

A WebSphere MQ activation specification has the following broker properties.

Broker control queue:

The queue to which broker control messages are sent.

Data type String
Default SYSTEM.BROKER.CONTROL.QUEUE

Broker subscriber queue:

The queue from which subscription messages are received.

Data type String
Default SYSTEM.JMS.ND.SUBSCRIBER.QUEUE

Broker connection consumer subscription queue:

The queue to receive subscription messages for connection consumers from.

Data type String
Default SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE

Broker connection consumer durable subscription queue:

The queue to receive subscription messages for durable connection consumers from.

Data type String
Default SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE

Version:

The version of the broker that is used. This determines some of the capabilities that the broker is assumed to have. For example, whether to use an RFH version 1 or version 2 header in publications.

Data type Radio button
Default Version 1 broker
Range

Version 1 broker
Message selection cannot be specified.

Version 2 broker
Message selection can be specified. If you select this option, you must also complete **Specify where message selection occurs**.

Specify where message selection occurs:

The process in which message selection is performed. This property is enabled only if **Version 2 broker** was selected.

Data type Drop-down list
Default CLIENT

Range

CLIENT

Message selection is performed in the application server process.

BROKER

Message selection is performed in the broker process.

Subscription store:

The process for tracking subscriptions.

Data type

Default

Range

Drop-down list

MIGRATE

MIGRATE

Any information that is held on queues is migrated to the broker mechanism for persisting subscription information. If subscription information is already persisted using the broker mechanism then specifying a value of Migrate is equivalent to specifying a value of Broker.

BROKER

Internal broker mechanisms are used to track subscription information.

QUEUE

A designated WebSphere MQ queue is used to record information about current subscriptions.

Durable subscription state refresh interval:

How often a long running transaction is recreated and used to clean up durable subscriptions, for some versions of the queue manager.

Data type

Default

Range

Integer

60000

Any positive integer

Subscription cleanup level:

How aggressively messages are cleaned up if the subscriber that is expected to consume the messages terminates unexpectedly.

Data type

Default

Drop-down list

SAFE

Range**SAFE** A conservative algorithm is used to clean up subscriptions.**ASPROP**

The cleanup algorithm is determined by a system property.

NONE No cleanup of subscriptions is performed.**STRONG**

An aggressive algorithm is used to clean up subscriptions.

Subscription cleanup interval:

How often to check for orphaned subscriptions and clean up messages.

Data type	Integer
Default	3600000
Range	Any positive integer

Subscription wildcard format:

The wildcard format used for subscribing to more than one topic in a topic hierarchy.

Data type	Drop-down list
Default	character wildcards
Range	<p>character wildcards</p> <p>You can use an asterisk (*) or question mark (?) to represent characters, or strings of characters, in a topic name.</p> <p>* is interpreted as matching many characters.</p> <p>? is interpreted as matching a single character.</p> <p>topic level wildcards</p> <p>You can use a plus sign (+) or number sign (#) to represent topics in a multilevel topic hierarchy.</p> <p>+ is interpreted as matching a single topic name.</p> <p># is interpreted as matching many topics in the hierarchy. / is used to delimit topics.</p>

Optimize for sparse subscription patterns:

An option to specify whether this activation specification is anticipated to receive a high proportion of messages that match its selection criteria. This information can be used to optimize message delivery.

Data type	Check box
Default	Cleared
Range	<p>Cleared</p> <p>Subscriptions frequently receive matching messages.</p> <p>Selected</p> <p>Subscriptions do not frequently receive matching messages.</p>

Broker queue manager:

The name of the queue manager that is running the broker, if it is not the same as the queue manager to which the activation specification connects.

Data type	String
Default	The queue manager name that was specified in the activation specification.

WebSphere MQ messaging provider activation specification client transport properties:

Use this panel to view or change the client transport properties of an activation specification for use with the WebSphere MQ messaging provider. These properties affect how a client connection is established with a WebSphere MQ queue manager or queue-sharing group. Updates to the properties take effect when the server is restarted.

To view WebSphere MQ activation specification client transport properties, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Select the name of the activation specification that you want to work with.
4. In the content pane, under Additional properties, click **Client transport properties** to display a list of the client transport properties of the WebSphere MQ activation specification.

Under General Properties there are two groups of properties:

- Additional SSL settings (for more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center)
- Channel exits

Make any required changes to these groups and then click **Apply** to return to the activation specification.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ activation specification has the following client transport properties:

Certificate revocation list:

A list of LDAP URLs pointing to LDAP repositories of SSL certificates that might have been revoked.

Data type	String
Default	No certificate revocation list
Range	The value must be a space-separated list of LDAP URLs.

Reset count:

The total number of bytes to transfer over an SSL connection before renegotiating the symmetric encryption keys used to secure the connection.

Data type	Integer
Default	0 (do not renegotiate)
Range	The value must be in the range 0 through 999,999,999 (inclusive).

Peer name:

A name (possibly including wildcards) that must match the distinguished name of the peer SSL certificate for a connection to be established.

Data type	String
Default	Do not check the distinguished name of the peer certificate.
Range	Validated using the rules for a WebSphere MQ SSLPEER channel parameter.

Receive exit or exits:

A comma-separated list of Java class names corresponding to receive exits to be loaded.

Data type	String
------------------	--------

Receive exit initialization data:

Initialization data to be passed to the receive exit.

Data type	String
------------------	--------

Send exit or exits:

A comma-separated list of Java class names corresponding to send exits to be loaded.

Data type	String
------------------	--------

Send exit initialization data:

Initialization data to be passed to the send exit.

Data type	String
------------------	--------

Security exit:

A Java class name corresponding to the security exit to be loaded.

Data type	String
------------------	--------

Security exit initialization data:

Initialization data to be passed to the security exit.

Data type	String
------------------	--------

Migrating a listener port to an activation specification for use with the WebSphere MQ messaging provider

For WebSphere Application Server Version 7 and later, listener ports are stabilized. You must therefore plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications.

Before you begin

EJB 2.0 message-driven beans cannot be configured against JCA 1.5-compliant resources. If your bean is an EJB 2.0 application, upgrade it to EJB 3 or EJB 2.1 before you complete this task.

Note: You can continue to configure EJB 3, EJB 2.1, and EJB 2.0 message-driven beans against a listener port. You might want to do this for compatibility with existing message-driven bean applications. However, listener ports are stabilized, and you should plan to migrate all your message-driven beans to use JCA 1.5-compliant resources. For more information about when to use listener ports rather than activation specifications, see *Message-driven beans, activation specifications, and listener ports*.

About this task

For WebSphere Application Server Version 7 and later, listener ports are stabilized. For more information, read the article on stabilized features. You should plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications. However, you should not begin this migration until you are sure the application does not have to work on application servers earlier than WebSphere Application Server Version 7. For example, if you have an application server cluster with some members at Version 6.1 and some at Version 7, you should not migrate applications on that cluster to use activation specifications until after you migrate all the application servers in the cluster to Version 7. Also, when you migrate to activation specifications on the z/OS platform, you must enable the Control Region Adjunct (CRA) process of the application server (either by selecting **Enable JCA based inbound message delivery** on the JMS provider settings panel, or by using the `manageWMQ` command to include starting the CRA process as part of starting an application server).

Note that the **Maximum retries** listener port setting is not migrated to the new activation specification as there is no exact equivalent.

When you are migrating a listener port associated with a message-driven bean (MDB) that has the `subscriptionDurability` activation configuration property set to `Durable`, and that MDB already has an active durable subscription, the durable subscription is not migrated. This is because listener ports and WebSphere MQ activation specifications use incompatible forms of subscription name. As a result there can be two active durable subscriptions subscribed to the relevant topic for the same MDB. As part of the migration process, you must delete the old durable subscription that was associated with the listener port and manually clean up any messages associated with it. For information on how do to this see the *WebSphere MQ and WebSphere Message Broker information centres*.

Procedure

1. Start the administrative console.
2. In the navigation pane, expand **Servers > Server Types > WebSphere application servers->server_name > [Communications] Messaging > Message listener service > [Additional Properties] Listener Ports**
The "Message listener port collection" on page 504 panel is displayed.
3. Select the listener port that you want to work with by selecting the check box to the left of the listener port name.
4. Click **Convert to activation specification** to start the "Convert listener port to activation specification" wizard.

5. On the "Step1: Supply activation specification name" page, enter the following information then click **Next** to continue:
 - The name of the new activation specification to be created.
 - The JNDI name of the new activation specification.
 - The scope of the new activation specification (Server, Node, Cluster, Cell). Note that Cluster only appears when the server is in a cluster.
6. On the "Step2: Summary" page, click **Finish** to complete the creation of the new activation specification.
7. Stop then restart the application server.
8. To complete the configuration of the activation specification, see "Configuring an activation specification for the WebSphere MQ messaging provider" on page 822.

Creating a connection factory for the WebSphere MQ messaging provider

Use this task to create a connection factory, a queue connection factory, or a topic connection factory for use with the WebSphere MQ messaging provider.

About this task

With JMS 1.1, domain-independent connection factories are preferred to domain-specific queue connection factories and topic connection factories.

To create a connection factory, a queue connection factory, or a topic connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps. You can choose either to enter all the required connection information using the Create WebSphere MQ JMS resource wizard or to use a client channel definition table (CCDT) to establish a connection to the WebSphere MQ messaging provider.

For information about modifying an existing connection factory, see the related tasks.

Procedure

1. In the navigation pane, select the type of connection factory you want to create:
 - To create a connection factory, click **Resources > JMS->Connection factories**.
 - To create a queue connection factory, click **Resources > JMS->Queue connection factories**.
 - To create a topic connection factory, click **Resources > JMS->Topic connection factories**.
2. Select the **Scope** setting corresponding to the scope of the connection factory that you want to create.
3. Click **New** in the content pane to start the Create WebSphere MQ JMS resource wizard.
4. Select **WebSphere MQ messaging provider**, then click **OK**.
5. On the "Configure basic attributes" page, specify the following properties, then click **Next**.

Name The name by which this connection factory is known for administrative purposes within WebSphere Application Server.

JNDI name

The name that is used to bind this connection factory into the Java Naming and Directory Interface (JNDI) namespace.

Description

Optional. A description of this connection factory for administrative purposes within WebSphere Application Server.

6. On the "Select connection method" page, choose how you want to specify the connection details for to the WebSphere MQ messaging provider by selecting one of the following options, then click **Next**.

Enter all the required information into this wizard

Choosing this option takes you to the “Supply queue manager details” page (see step 7), where you can start entering the connection details using the Create WebSphere MQ JMS resource wizard.

Use a client channel definition table

Choosing this option takes you to the “Specify client channel definition table” page (see step 8), where you can enter details of the client channel definition table that you want to use.

7. If you have chosen to enter all the required information using the wizard, complete the following steps:
 - a. On the “Supply queue manager details” page, enter the name of the queue manager or queue-sharing group that you want to connect to then click **Next**.
 - b. On the “Enter connection details” page, specify the details for the connection, then click **Next** to continue to the “Test connection” page. You can choose either to enter host and port information separately, or enter host and port information in the form of a connection name list. You must only choose the option to use a connection name list if you are creating a connection to a multi-instance queue manager. You must not use this option for connections to non-multi-instance queue managers as that can result in transaction integrity issues.

Transport

Optional. The WebSphere MQ transport type for the connection. The option that you select is used to determine the exact mechanisms used to connect to WebSphere MQ. If you are configuring a transport type of *bindings*, *then client* or *bindings*, see “Configuring the WebSphere MQ messaging provider with native libraries information” on page 806 for more information.

Enter host and port information in the form of separate hostname and port values

This radio button is selected by default and enables the **Hostname** and **Port** fields and disables the **Connection name list** field. Leave this radio button selected if you want to enter host and port information in the form of separate host name and port values.

Hostname

The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to. Complete this field if you have selected **Enter host and port information in the form of separate hostname and port values**.

Port Optional. The port number on which WebSphere MQ is listening. Complete this field if you have selected **Enter host and port information in the form of separate hostname and port values**.

Enter host and port information in the form of a connection name list

This radio button is cleared by default and, if selected, disables the **Hostname** and **Port** fields and enables the **Connection name list** field.

- Click this radio button to select it if you want to enter host and port information in the form of a connection list.
- Leave this radio button cleared if you want to enter host and port information in the form of separate hostname and port values.

Connection name list

The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager. Complete this field if you have selected **Enter host and port information in the form of a connection name list**. Enter the host name and port details in the following form:

```
host[(port)][,host(port)]
```

host must be a valid TCP/IP host name or IPv4 or IPv6 address.

port must be an integer value in the range 1 - 65536 (inclusive). The port information is optional, and if not specified, defaults to 1414.

For example: localhost(1234),remotehost1(1234),remotehost2

Server connection channel

Optional. The WebSphere MQ server connection channel name used when connecting to WebSphere MQ queue manager or queue-sharing group.

8. If you are using a channel client definition table to establish a connection to the WebSphere MQ messaging provider, complete the following fields on the “Specify client channel definition table” page, then click **Next** to continue to the “Test connection” page.

Client channel definition table URL

The URL to the client channel definition table that you want to use when connecting to WebSphere MQ.

Queue manager

Optional. The name of the queue manager to be used to select one or more entries from the CCDT.

9. Optional: On the “Test connection” page, if you want to test establishing the connection, click **Test connection**. This test can take several seconds to perform.
10. On the “Summary” page, complete the creation of the new connection factory by clicking **Finish**.
11. Stop then restart the application server.

JMS resource provider selection panel

Select the messaging provider with which to create this JMS activation specification, connection factory or destination.

You select the scope setting on an earlier page. The choice of JMS provider depends on the scope that you selected. You might see a choice such as the following list:

- Default messaging provider.
Select this option if you want the JMS resource to be provided by the service integration bus, as part of WebSphere Application Server.
- WebSphere MQ messaging provider
Select this option if you want the JMS resource to be provided by WebSphere MQ. You must have installed and configured a WebSphere MQ network in order to use this provider.
- “My JMS provider”
Select this option if you want the JMS resource to be provided by a third-party JMS provider. This option is only available if you have installed and configured a third-party provider. The name that is displayed (for example “My JMS provider”) is the name you gave to the provider when you installed and configured it.
- V5 default messaging provider
Select this option if you want to manage the JMS connection factories and destinations for JMS applications that were designed to work with WebSphere Application Server Version 5.1, and are still running on a Version 5.1 or Version 6 node that is part of a Version 7.0 or later mixed cell.

Configuring a unified connection factory for the WebSphere MQ messaging provider

Use this task to view or change the configuration of an existing domain-independent connection factory for the WebSphere MQ messaging provider on a WebSphere Application Server node.

About this task

This task applies to unified connection factories. With JMS 1.1, domain-independent (unified) connection factories are preferred to domain-specific queue connection factories and topic connection factories. If you want to view or change a queue connection factory or topic connection factory, see the related tasks.

To view or change the configuration of an existing connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources > JMS->Connection factories**. A list of existing unified connection factories, with a summary of their properties, is displayed.
2. Select the **Scope** corresponding to the scope at which the connection factory is visible to applications.
3. Click the name of the connection factory that you want to view or change. Configuration details for the unified connection factory are displayed.
4. Under **General Properties** make any required changes.
For information about each of the available fields, see “WebSphere MQ messaging provider connection factory settings.”
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your connection factory.
7. Optional: Click **Broker properties** to display or change the list of broker properties of your connection factory.
8. Optional: Click **Custom properties** to display or change the list of custom properties of your connection factory.
9. Optional: Click **Client transport properties** to display or change the list of client transport properties of your connection factory. This link is only appears if, when you created the connection factory, you chose to enter all the information required to connect to WebSphere MQ. This link does not appear if you have chosen to use a client channel definition table (CCDT) to establish a connection to WebSphere MQ.
10. Optional: Click **Connection pools** to display or change the connection pools detail of your connection factory.
11. Optional: Click **Session pools** to display or change the session pools detail of your connection factory.
There is a mechanism (session.sharing.scope custom property) to make JMS sessions unshareable. This means that whenever an application calls Session.close(), the JMS session is automatically released from any transaction that is associated with and returned to the session pool. This means that sessions can be cleaned up and removed from the session pool even if the servlet or asynchronous bean that created it is still running.
12. Click **OK**.
13. Save your changes to the master configuration.
14. To make the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider connection factory settings

Use this panel to view or change the configuration properties of the selected connection factory for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to associated JMS queues and topics.

The WebSphere MQ messaging provider supports JMS 1.1 domain-independent interfaces, such as the unified JMS connection factory. A domain-independent application can use the same interface for both point-to-point and publish/subscribe messaging, and can support both point-to-point and publish/subscribe messaging within the same transaction. With JMS 1.1, you are recommended to use domain-independent unified JMS connection factories for new applications. A domain-specific interface extends the domain-independent equivalent, so an application that uses domain-specific queue and topic connection factories can choose to use either interface.

To view WebSphere MQ connection factory settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Connection factories** to display existing connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. This restricts the set of connection factories displayed.
3. Select the name of the connection factory that you want to work with.

Under General Properties there are four groups of properties:

- “Administration” on page 848
- “Connection” on page 849
- “Advanced” on page 854
- “Security settings” on page 855

Make any required changes to the Administration, Connection, Advanced, and Security settings groups of properties, and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click any of the following links:

- **Advanced properties** to display or change the advanced properties of your WebSphere MQ connection factory.
- **Broker properties** to display or change the broker properties of your WebSphere MQ connection factory.
- **Custom properties** to display or change the custom properties of your WebSphere MQ connection factory.
- **Client transport properties** to display or change the client transport properties of your WebSphere MQ connection factory. If the selected connection factory was not created using a Client Channel Definition Table (CCDT), follow this link to enter all the information required to connect to WebSphere MQ. If the selected connection factory was created using a CCDT, you do not need to supply the client transport properties, and so the link is absent.
- **Connection pools** to display or change the connection pools detail of your WebSphere MQ connection factory.
- **Session pools** to display or change the session pools detail of your WebSphere MQ connection factory.

Under Related Items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the connection factory.

You can specify the following additional properties by using WebSphere MQ administrative commands:

- **-localAddress**
- **-clonedSubs**
- **-componentAuthAlias**

For more information about these properties, refer to the “createWMQConnectionFactory command” on page 971.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *Using Java* and *WebSphere MQ System Administration* sections of the WebSphere MQ information center.

If WebSphere MQ functionality has been disabled at a scope that affects this WebSphere MQ messaging provider resource, then an informational message indicating that WebSphere MQ has been disabled appears. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

A WebSphere MQ unified connection factory has the following properties.

Administration:

Scope:

The level at which this connection factory definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change other resources at a different scope, change the scope on the WebSphere MQ connection factory collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the queue connection factory is created.

For all connection factories that use this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which this connection factory is known for administrative purposes within WebSphere Application Server.

Data type String
Range The name must be unique within the set of connection factories defined to the cell.

JNDI name:

The JNDI name that is used to bind the connection factory into the JNDI namespace.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

Data type String

Description:

A description of this connection factory for administrative purposes within WebSphere Application Server.

Data type	String
Default	Null

Connection:

The information required to configure a connection depends on whether the selected queue connection factory was created using a Client Channel Definition Table (CCDT).

If the selected connection factory was created using a CCDT, only the following properties are displayed:

- Client channel definition table URL
- Queue manager
- SSL configuration

If the selected connection factory was not created using a CCDT, the following properties are displayed:

- Queue manager
- Transport
- If **Enter host and port information in the form of separate host and port values** is selected, the connection name list property cannot be used and the following properties can be used:
 - Host name
 - Port
- If **Enter host and port information in the form of a connection name list** is selected, the connection name list property can be used and the following properties cannot be used:
 - Host name
 - Port
- Server connection channel
- If you clear the check box for the **Use SSL to secure communication with Websphere MQ** property, the following properties cannot be used:
 - Centrally managed
 - Specific configuration
 - SSL configuration

For more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center.

Client channel definition table URL:

A URL that specifies the location of a WebSphere MQ CCDT.

Data type	String
------------------	--------

Queue manager:

If the specified connection factory is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, this property specifies the name of the queue manager or queue-sharing group to connect to. A connection is established to the specified WebSphere MQ resource to send or receive messages.

Data type	String
------------------	--------

Range

If this connection factory is not based on a CCDT, the value must be a valid queue manager name.

If this connection factory is based on a CCDT, the value must be one of the following:

- A valid queue manager name
- An asterisk (*) followed by the name of a queue manager group¹
- An asterisk (*)
- Blank¹

¹When you specify the value of the Queue manager property in this form in combination with a CCDT, individual connections established by using the connection factory might connect to different queue managers. Selection from multiple queue managers occurs when the CCDT contains multiple client connection channel definitions with a matching queue manager name (QMNAME) parameter, and these connection channel definitions define the network connection details of different queue managers.

If the specified connection factory is based on a CCDT, and the CCDT can select from more than one queue manager, you might not be able to recover global transactions. Therefore, for connection factories that specify a CCDT, you have two alternatives:

- Avoid any ambiguity about the target queue manager when specifying the Queue manager property, which means that the specified value of this property must not include an asterisk (*).
- Avoid using the resources with applications that enlist in global transactions.

Transport:

The WebSphere MQ transport type for the connection. The transport type is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type

Drop-down list

Default**Bindings, then client**

Range

Client Use a TCP/IP-based network connection to communicate with the WebSphere MQ queue manager.

Bindings, then client

Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport.

Bindings

Establish a cross-memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled:

- Host name
- Port
- Connection name list
- Server connection channel

For more information about configuring a transport type of *Bindings, then client* or *Bindings*, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 806.

Enter host and port information in the form of separate host and port values:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the host name and port properties.

Selecting this option enables the host name and port properties, and disables the connection name list property. To enter connection name list information, click **Enter host and port information in the form of a connection name list**.

This radio button is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Hostname:

The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type String

Port:

The port number on which WebSphere MQ is listening.

Data type Integer

Default 1414

Range The value must be in the range 1 to 65536 (inclusive).

Enter host and port information in the form of a connection name list:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the connection name list property.

Connection name lists can be used to connect to a single queue manager or to a multi-instance queue manager. For more information on using a multi-instance queue manager, see the WebSphere MQ information centre. Selecting this option enables the connection name list property and disables the host name and port properties. To enter separate host and port information, click **Enter host and port information in the form of separate host and port values**.

This radio button is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Connection name list:

The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager.

This property must only be used to allow connection to a multi-instance queue manager. It must not be used to allow connections to non-multi-instance queue managers as that can result in transaction integrity issues.

Data type String
Default Unset
Range This field must be set to a string in the following form:

host[(*port*)][,*host*(*port*)]

The port information is optional, and if not specified, defaults to 1414.

host must be a valid TCP/IP host name or IPv4 or IPv6 address.

port must be an integer value in the range 1 to 65536 (inclusive).

For example:
localhost(1234),remotehost1(1234),remotehost2

When the connection name list property is specified, the host name or port properties are automatically set to the host name and port number of the first entry in the connection name list. So if you specified localhost(1234),remotehost1(1234),remotehost2, the host name would be set to localhost and port would be set to 1234.

This property is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

When used in a mixed cell environment, the information in the connection name list property is not available to versions of WebSphere Application Server earlier than Version 8.0. In this case, the information in the host name and port name fields, based on the first element in the connection name list, is used instead.

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type String
Default SYSTEM.DEF.SVRCONN

Range

The value must be a server connection channel defined to the WebSphere MQ queue manager that is being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

When using a WebSphere MQ messaging provider connection factory in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security > SSL certificate and key management** panel.

When using a WebSphere MQ messaging provider connection factory in the client environment, the client takes SSL configuration information from the `ssl.client.props` file. Use of this file is detailed in the related reference information for this topic.

You can only use one cipher suite in the SSL configuration for a WebSphere MQ messaging provider connection factory. If you specify more than one cipher suite, only the first one is used.

Data type

Check box. If this check box is cleared, the following SSL properties are disabled:

- Centrally managed
- Specific configuration
- SSL configuration

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the host name and port attributes from the WebSphere MQ messaging provider connection factory are used to select an appropriate SSL configuration. If host and port information has been supplied by a connection name list this means that the host name and port information of the first element in the list are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the connection factory, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type

Radio button

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

Data type

Radio button

SSL configuration:

The SSL configuration to use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if an SSL configuration of none is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Advanced:

Client ID:

The client identifier to specify when connecting to the WebSphere MQ messaging provider.

The client identity is not a user ID in the conventional sense, and is not related to security. It is used by durable subscriptions in publish-subscribe messaging. A durable subscription continues to collect up messages while the subscriber is "away" (for example, not running or failed) and delivers those messages when the subscriber reconnects. The client identity is the token that says which subscriber you are when you reconnect so that you get the messages that have been saved up for you in your absence.

Data type String

Allow cloned durable subscriptions:

An option that determines whether multiple instances of a durable subscription can be accessed concurrently by different servers.

Data type	Check box
Default	Cleared
Range	Selected Multiple instances of a durable subscription can be accessed concurrently by different servers.
	Cleared Multiple instances of a durable subscription cannot be accessed concurrently by different servers.

Provider version:

The WebSphere MQ messaging provider version. This value is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functions required by the client.

Data type String

Range

The value entered must either be the empty string or be in one of the following formats:

n.n.n.n
 n.n.n
 n.n
 n

where n is a numeric value greater than or equal to zero.

For example 6.0.0.0.

Support distributed two-phase commit protocol:

An option that specifies whether the connection factory supports XA coordination of messaging transactions. Enable this option if multiple resources, including this connection factory, are to be used in the same transaction.

If you clear this property, you disable support for distributed two-phase commit protocol. The JMS session can still be enlisted in a transaction, but it uses the resource manager local transaction calls `session.commit` and `session.rollback`, instead of XA calls. This can lead to an improvement in performance. However, only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type

Check box

Default

Selected

Range**Selected**

The connection factory supports the use of distributed two-phase commit protocols for the coordination of transacted work.

Cleared

The connection factory does not support the use of distributed two-phase commit protocols for the coordination of transacted work.

Keep this option selected if transactions involve other resources, including other queues or topics. Clear this option only when you are certain that the queue manager that is the target for this queue connection is the only resource in the transaction.

Security settings:***Authentication alias for XA recovery:***

The user name and password to use when connecting to WebSphere MQ during XA recovery.

Data type

Drop-down list

Default

(none)

Range

All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ during XA recovery.

Mapping-configuration alias:

This field is used only in the absence of a login configuration on the component resource reference.

When the resource authority value is "container", the preferred way to define the authentication strategy is by specifying a login configuration and associated properties on the component resource reference.

If the **DefaultPrincipalMapping** login configuration is specified, the associated property is a JAAS - J2C authentication data entry alias. To configure authentication information for use with the connection factory, under Related Items, click **JAAS - J2C authentication data** .

Data type	Drop-down list
Default	(none)
Range	The following options are available: ClientContainer WSLogin WSKRB5Login DefaultPrincipalMapping TrustedConnectionMapping KerberosMapping

Container-managed authentication alias:

The authentication alias which specifies the user name and password to use when connecting to the WebSphere MQ messaging provider.

Data type	Drop-down list
Default	(none)
Range	All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

WebSphere MQ messaging provider connection factory advanced properties:

Use this panel to view or change the advanced properties of the selected connection factory for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ connection factory advanced properties, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Connection factories** to display existing connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. Setting the scope in this way restricts the set of queue connection factories displayed.
3. Select the name of the connection factory that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ connection factory.

Under General Properties there are six groups of advanced properties:

- Client reconnect
- Message compression
- Temporary destinations
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, except for channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ connection factory has the following advanced properties:

Client reconnect options:

This property specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment.

Data type	Drop-down list
Default	DISABLED
Range	DISABLED Client reconnection does not automatically occur.
ASDEF	The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified in the client configuration file, ASDEF has the same effect as DISABLED.
QMGR	Reconnection occurs only to the queue manager to which the connection was originally connected.
RECONNECT	Reconnection occurs to any queue manager that is consistent with the value of the queue manager attribute. This queue manager might be a different queue manager from the one to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Client reconnect timeout:

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

Data type	Integer
Units	Seconds
Default	1800 (30 minutes)
Range	A value greater than zero and up to 2147483647

For more information about automatic client reconnection, see the WebSphere MQ information center.

Compress message headers:

An option that enables the compression of message headers.

Data type	Check box
------------------	-----------

Default	Cleared
Range	Cleared Do not compress message headers. Selected Compress message headers.

Compression algorithm for message payloads:

The compression algorithm that is used to compress message payloads.

Data type	Drop-down list
Default	NONE
Range	RLE Message data compression is performed using run-length encoding. ZLIBFAST Message data compression is performed using ZLIB encoding with speed prioritized. ZLIBHIGH Message data compression is performed using ZLIB encoding with compression prioritized. NONE No message data compression is performed.

WebSphere MQ model queue name:

The model queue that is used as a basis for temporary queue creation.

Data type	String
Default	SYSTEM.DEFAULT.MODEL.QUEUE

Temporary queue prefix:

The prefix that is appended to the beginning of the names generated for temporary queues.

Data type	String
------------------	--------

Temporary topic prefix:

The prefix that is appended to the beginning of the names generated for temporary topics.

Data type	String
------------------	--------

Retain messages, even if no matching consumer is available:

An option that determines whether messages for which there is no matching consumer are retained on the input queue or dealt with according with their disposition options.

Data type	Check box
Default	Selected
Range	Cleared Do not retain messages. Selected Retain messages.

Polling interval:

This setting is applicable in the client container only. When using a WebSphere MQ Version 6 queue manager (or WebSphere MQ Version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread waits for a message to arrive at a WebSphere MQ queue before polling another WebSphere MQ queue in the set.

Data type	Integer
Units	Milliseconds
Default	5000
Range	A value greater than zero.

Rescan interval:

When using a WebSphere MQ Version 6 queue manager (or WebSphere MQ Version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread retrieves messages from a WebSphere MQ queue before switching to use messages from another WebSphere MQ queue in the set.

Data type	Integer
Units	Milliseconds
Default	5000
Range	A value greater than zero.

Maximum batch size:

The maximum number of messages that can be removed from a queue before at least one must be delivered to an asynchronous consumer.

Data type	Integer
Default	10
Range	A value greater than zero.

Coded character set identifier:

The character set to use when you are encoding strings in the message.

Data type	Integer
Default	819
Range	A value greater than zero. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration* and *Application Programming Reference* sections of the WebSphere MQ information center.

Append an RFH version 2 header to reply messages:

The action required when sending a reply message to the reply-to queue obtained from a message that does not include an RFH version 2 header.

Data type	Check box
Default	Cleared
Range	Selected Append an RFH version 2 header to reply messages regardless of whether the original message had an RFH version 2 header.
	Cleared Append an RFH version 2 header to reply messages only if the original message had an RFH version 2 header.

Fail JMS method calls if the WebSphere MQ queue manager is quiescing:

An option that enables selected JMS operations to fail when the queue manager is put into a quiescing state. Selecting this option enables the queue manager to quiesce successfully and shut down.

Data type	Check box
Default	Selected
Range	Cleared Do not fail JMS operations if the queue manager is quiescing.
	Selected Fail JMS operations if the queue manager is quiescing.

WebSphere MQ messaging provider connection factory broker properties:

Use this panel to view or change the broker settings of the selected connection factory, or topic connection factory, for use with the WebSphere MQ messaging provider. These broker settings determine how the WebSphere MQ messaging provider interacts with a broker for the purposes of publishing messages and subscribing to topics. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory, or topic connection factory, broker properties use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Connection factories** to display existing connection factories, or click **Resources > JMS->Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. This restricts the set of connection factories displayed.
3. Select the name of the connection factory, or topic connection factory, that you want to work with.
4. In the content pane, under Additional Properties, click **Broker properties** to display the broker properties of the WebSphere MQ connection factory, or topic connection factory.

Under General Properties there are four groups of properties:

- Queues
- Capabilities
- Tuning
- Additional

Make any required changes to these groups and then click **Apply** to return to the connection factory, or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* section of the WebSphere MQ library.

A WebSphere MQ connection factory, or topic connection factory, has the following broker properties:

Broker control queue:

The queue to which broker control messages are sent.

Data type	String
Default	SYSTEM.BROKER.CONTROL.QUEUE

Broker publication queue:

The queue to which publication messages are sent.

Data type	String
Default	SYSTEM.BROKER.DEFAULT.STREAM

Broker subscriber queue:

The queue to which subscription messages are sent.

Data type	String
Default	SYSTEM.JMS.ND.SUBSCRIBER.QUEUE

Broker connection consumer subscription queue:

The queue to which subscription messages that are destined for a connection consumer are sent.

Data type	String
Default	SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE

Version:

The version of the broker that is used. This determines some of the capabilities that the broker is assumed to have. For example, whether to use an RFH version 1 or version 2 header in publications.

Data type	Radio button
Default	Version 1 broker
Range	Version 1 broker Message selection cannot be specified. Version 2 broker Message selection can be specified. If you select this option, you must also complete Specify where message selection occurs .

Specify where message selection occurs:

The process in which message selection is performed. This property is enabled only if **Version 2 broker** was selected.

Data type	Drop-down list
Default	CLIENT
Range	CLIENT Message selection is performed in the application server process. BROKER Message selection is performed in the broker process.

Subscription store:

The process for tracking subscriptions.

Data type	Drop-down list
Default	MIGRATE
Range	MIGRATE Any information that is held on queues is migrated to the broker mechanism for persisting subscription information. If subscription information is already persisted using the broker mechanism then specifying a value of Migrate is equivalent to specifying a value of Broker. BROKER Internal broker mechanisms are used to track subscription information. QUEUE A designated WebSphere MQ queue is used to record information about current subscriptions.

Durable subscription state refresh interval:

How often a long running transaction is recreated and used to clean up durable subscriptions, for some versions of the queue manager.

Data type	Integer
Default	60000
Range	Any positive integer

Subscription cleanup level:

How aggressively messages are cleaned up if the subscriber that is expected to consume the messages terminates unexpectedly.

Data type	Drop-down list
Default	SAFE

Range**SAFE** A conservative algorithm is used to clean up subscriptions.**ASPROP**

The cleanup algorithm is determined by a system property.

NONE No cleanup of subscriptions is performed.**STRONG**

An aggressive algorithm is used to clean up subscriptions.

Subscription cleanup interval:

How often to check for orphaned subscriptions and clean up messages.

Data type	Integer
Default	3600000
Range	Any positive integer

Subscription wildcard format:

The wildcard format used for subscribing to more than one topic in a topic hierarchy.

Data type	Drop-down list
Default	character wildcards
Range	<p>character wildcards</p> <p>You can use an asterisk (*) or question mark (?) to represent characters, or strings of characters, in a topic name.</p> <p>* is interpreted as matching many characters.</p> <p>? is interpreted as matching a single character.</p> <p>topic level wildcards</p> <p>You can use a plus sign (+) or number sign (#) to represent topics in a multilevel topic hierarchy.</p> <p>+ is interpreted as matching a single topic name.</p> <p># is interpreted as matching many topics in the hierarchy. / is used to delimit topics.</p>

Publish acknowledgement window:

The number of messages to publish before publishing a message that requires broker acknowledgement

Data type	Integer
Default	25
Range	Any positive integer

Optimize for sparse subscription patterns:

An option to specify whether this connection factory is anticipated to receive a high proportion of messages that match its selection criteria. This information can be used to optimize message delivery.

Data type	Check box
Default	Cleared
Range	<p>Cleared Subscriptions frequently receive matching messages.</p> <p>Selected Subscriptions do not frequently receive matching messages.</p>

Broker queue manager:

The name of the queue manager that is running the broker, if it is not the same as the queue manager to which the connection factory connects.

Data type	String
Default	The queue manager name that was specified in the connection factory.

WebSphere MQ messaging provider connection factory client transport settings:

Use this panel to view or change the client transport settings of a connection factory, queue connection factory, or topic connection factory for use with the WebSphere MQ messaging provider. Client transport properties affect how a client connection is established with a WebSphere MQ queue manager or queue-sharing group. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory, queue connection factory, or topic connection factory client transport settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS**.
2. Click **Connection factories**, **Queue connection factories**, or **Topic connection factories** to display existing connection factories, queue connection factories or topic connection factories.
3. Select the name of the connection factory, queue connection factory, or topic connection factory that you want to work with.
4. In the content pane under Additional Properties, click **Client transport properties** to view a list of the client transport settings of the WebSphere MQ connection factory, queue connection factory, or topic connection factory.

Under General Properties there are two groups of properties:

- Additional SSL settings (for more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center)
- Channel exits

Make any required changes to these groups and then click **Apply** to return to the connection factory, queue connection factory or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ connection factory, queue connection factory, or topic connection factory has the following client transport settings properties:

Certificate revocation list:

A list of LDAP URLs pointing to LDAP repositories of SSL certificates that might have been revoked.

Data type	String
Default	No certificate revocation list
Range	The value must be a space-separated list of LDAP URLs.

Peer name:

A name (possibly including wildcards) that must match the distinguished name of the peer SSL certificate for a connection to be established.

Data type	String
Default	Do not check the distinguished name of the peer certificate.
Range	Validated according to the rules for a WebSphere MQ SSLPEER channel parameter.

Reset count:

The total number of bytes to transfer over an SSL connection before renegotiating the symmetric encryption keys used to secure the connection.

Data type	Integer
Default	0 (do not renegotiate)
Range	The value must be in the range 0 through 999,999,999 (inclusive).

Receive exits:

A comma-separated list of Java class names corresponding to receive exits to be loaded.

Data type	String
------------------	--------

Receive exit initialization data:

Initialization data to be passed to the receive exit.

Data type	String
------------------	--------

Send exits:

A comma-separated list of Java class names corresponding to send exits to be loaded.

Data type	String
------------------	--------

Send exit initialization data:

Initialization data to be passed to the send exit.

Data type	String
------------------	--------

Security exit:

A Java class name corresponding to the security exit to be loaded.

Data type String

Security exit initialization data:

Initialization data to be passed to the security exit.

Data type String

Connection pool settings:

Use this page to configure connection pool settings.

This administrative console page is common to JDBC data sources and JMS connection factories (unified, queue, or topic connection factories). To view this page, the path depends on the type of resource, but generally you select an instance of the resource type then click **Connection Pool**. For example:

- Click **Resources > JDBC > Data Sources > data_source > [Additional Properties] Connection pool properties**
- Click **Resources > JMS->Queue connection factories->queue_connection_factory->[Additional Properties] Connection pool**

Note: Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the `getConnection()` request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

Connection timeout:

Specifies the interval, in seconds, after which a connection request times out and a `ConnectionWaitTimeoutException` is thrown.

This value indicates the number of seconds that a connection request waits when there are no connections available in the free pool and no new connections can be created. This usually occurs because the maximum value of connections in the particular connection pool has been reached.

For example, if Connection timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. In most cases, you should not retry the `getConnection()` method; if a longer wait time is required you should increase the Connection timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, and a new physical connection is created.

If Maximum Connections is set to 0, an infinite number of physical connections are enabled, and the Connection timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Maximum connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. When this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` error displays. For example, if the Max Connections value is set to 5, and there are 5 physical connections in use, the pool manager waits for the amount of time specified in Connection timeout for a physical connection to become free.

Knowing the number of connection pools that can potentially request connections from the backend, such as a DB2 database or a CICS server, helps you determine a value for the Maximum Connections property.

Consider the number of servants that access the same resource; at run time, this number essentially multiplies your Maximum Connections setting. When servants start the same JDBC data source or J2C connection factory configuration, WebSphere Application Server (base) implements a corresponding physical connection pool for every servant. Therefore the same connection pool exists, independently, in each servant. Your Maximum Connections setting applies to each one of these pools.

Potentially, every application that requires the data source or connection factory in these servants can attempt to use the resource simultaneously. Therefore the corresponding connection pools require connections from the same backend, at the same time. Do not set a Maximum Connections value that might cause the load of connection requests to overwhelm your database or other enterprise information system (EIS).

Data type	Integer
Default	10
Range	0 to maximum integer

If Max Connections is set to 0, the Connection timeout value is ignored.

Tip: For better performance, set the value for the connection pool lower than the value for the maximum thread pool connections of the web container. To configure this setting click **Servers > Server types > WebSphere application servers > server > Thread Pools**, and modify the web container property. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the processor load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Minimum connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the Unused timeout thread does not discard physical connections. However, the pool does not create connections solely to

ensure that the minimum connection pool size is maintained. Also, if you set a value for Aged timeout, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example, if the Minimum Connections value is set to 3, and one physical connection is created, the Unused timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Minimum Connections setting.

Data type	Integer
Default	1
Range	0 to max int

Reap time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the Unused timeout and Aged timeout settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused timeout and Aged timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused timeout, until it reaches the number of connections specified in Minimum Connections. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread, set Reap Time to 0, or set both Unused timeout and Aged timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, and Unused timeout and Aged timeout are ignored. However, if Unused timeout and Aged timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout, because of non-zero timeout values, are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused timeout value higher than the Reap timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for 2 minutes is discarded.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 218 for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting Aged timeout to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged timeout value higher than the Reap timeout value for optimal performance.

For example, if the Aged timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. The only exception is if the connection is involved in a transaction when the aged timeout is reached, the application server will not discard the connection until after the transaction is completed and the connection is closed.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 218 for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**.

Data type	String
Defaults	<ul style="list-style-type: none">• EntirePool for J2C connection factories and JMS-related connection factories• EntirePool for WebSphere Version 4.0 data sources• EntirePool for current version data sources that you create through the administrative console• EntirePool for current version data sources that you script through wsadmin AdminConfig commands, starting JDBC templates that are built into WebSphere Application Server. For information about the command createUsingTemplate, see the topic, Commands for the AdminConfig object.• FailingConnectionOnly for data sources that you script in wsadmin tool without starting JDBC templates
	:

Range

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this closure is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a possibility that the next getConnection() request from the application can return a connection from the pool that is also stale. The result is more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to JMS unified connection factories, queue connection factories and topic connection factories. To view this page, you select an instance of the resource type then click **Session pools**. For example, click **Resources > JMS->Queue connection factories->queue_connection_factory->[Additional Properties] Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached . For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a ConnectionWaitTimeoutException. It usually does not make sense to retry the getConnection() method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher

value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. Java EE Connector Architecture (JCA) data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type
Default
Range

String
FailingConnectionOnly

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Configuring a queue connection factory for the WebSphere MQ messaging provider

Use this task to view or change the configuration of an existing JMS queue connection factory for point-to-point messaging with the WebSphere MQ messaging provider.

About this task

This task applies to queue connection factories. With JMS 1.1, domain-independent (unified) connection factories are preferred to domain-specific queue connection factories and topic connection factories. To configure a unified connection factory, see “Configuring a unified connection factory for the WebSphere MQ messaging provider” on page 845.

To view or change the configuration of an existing queue connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources > JMS->Queue connection factories**. A list of existing queue connection factories, with a summary of their properties, is displayed.

2. Select the **Scope** setting corresponding to the scope at which the queue connection factory is visible to applications.
3. Click the name of the queue connection factory that you want to view or change. Configuration details for the queue connection factory are displayed.
4. Under **General Properties** make any required changes.
For information about each of the available fields, see “WebSphere MQ messaging provider queue connection factory settings.”
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your queue connection factory.
7. Optional: Click **Custom properties** to display or change the list of custom properties of your queue connection factory.
8. Optional: Click **Client transport properties** to display or change the list of client transport properties of your queue connection factory. This link is only appears if, when you created the connection factory, you chose to enter all the information required to connect to WebSphere MQ. This link does not appear if you have chosen to use a client channel definition table (CCDT) to establish a connection to WebSphere MQ.
9. Optional: Click **Connection pools** to display or change the connection pools detail of your queue connection factory.
10. Optional: Click **Session pools** to display or change the session pools detail of your queue connection factory.
There is a mechanism (session.sharing.scope custom property) to make JMS sessions unshareable. This means that whenever an application calls Session.close(), the JMS session is automatically released from any transaction that is associated with and returned to the session pool. This means that sessions can be cleaned up and removed from the session pool even if the servlet or asynchronous bean that created it is still running.
11. Click **OK**.
12. Save your changes to the master configuration.
13. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider queue connection factory settings

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to associated JMS queue destinations.

A WebSphere MQ queue connection factory is used to create JMS connections to queues provided by WebSphere MQ for point-to-point messaging.

To view WebSphere MQ queue connection factory settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Queue connection factories** to display existing queue connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the queue connection factories are defined. This restricts the set of queue connection factories displayed.
3. Select the name of the queue connection factory that you want to work with.

Under General Properties there are four groups of properties:

- “Administration” on page 875
- “Connection” on page 876
- “Advanced” on page 882
- “Security settings” on page 883

Make any required changes to the Administration, Connection, Advanced, and Security settings groups of properties, and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you select any of the following links:

- **Advanced properties** to display the advanced properties of your WebSphere MQ queue connection factory.
- **Custom properties** to display the custom properties of your WebSphere MQ queue connection factory.
- **Client transport properties** to display or change the client transport properties of your WebSphere MQ queue connection factory. If the selected queue connection factory was not created using a Client Channel Definition Table (CCDT), follow this link to enter all the information required to connect to WebSphere MQ. If the selected queue connection factory was created using a CCDT, you do not need to supply the client transport properties, and so the link is absent.
- **Connection pools** to display the connection pool detail of your WebSphere MQ queue connection factory.
- **Session pools** to display the session pools detail of your WebSphere MQ queue connection factory.

Under Related Items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the queue connection factory.

You can specify the following additional properties by using WebSphere MQ administrative commands:

- **-localAddress**
- **-componentAuthAlias**

For more information about these properties, refer to the “createWMQConnectionFactory command” on page 971.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *Using Java* and *System Administration* sections of the WebSphere MQ information center.

A WebSphere MQ queue connection factory has the following properties.

Administration:

Scope:

The level at which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the WebSphere MQ queue connection factory collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the queue connection factory is created.

For all queue connection factories created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server.

Data type String
Range The name must be unique within the set of queue connection factories defined to the cell.

JNDI name:

The JNDI name that is used to bind the queue connection factory into the namespace.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

Data type String

Description:

A description of this queue connection factory for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Connection:

The information required to configure a connection depends on whether the selected queue connection factory was created using a Client Channel Definition Table (CCDT).

If the selected queue connection factory was created using a CCDT, only the following properties are displayed:

- Client channel definition table URL
- Queue manager
- SSL configuration

If the selected queue connection factory was not created using a CCDT, the following properties are displayed:

- Queue manager
- Transport
- If **Enter host and port information in the form of separate host and port values** is selected, the connection name list property cannot be used and the following properties can be used:

- Host name
- Port
- If **Enter host and port information in the form of a connection name list** is selected, the connection name list property can be used and the following properties cannot be used:
 - Host name
 - Port
- Host name
- Port
- Server connection channel
- If you clear the check box for the **Use SSL to secure communication with Websphere MQ** property, the following properties cannot be used:
 - Centrally managed
 - Specific configuration
 - SSL configuration

For more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center.

Client channel definition table URL:

A URL that specifies the location of a WebSphere MQ CCDT.

Data type String

Queue manager:

If the specified queue connection factory is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, this property specifies the name of the queue manager or queue-sharing group to connect to. A connection is established to the specified WebSphere MQ resource to send or receive messages.

Data type String

Range

If this queue connection factory is not based on a CCDT, the value must be a valid queue manager name.

If this queue connection factory is based on a CCDT, the value must be one of the following:

- A valid queue manager name
- An asterisk (*) followed by the name of a queue manager group¹
- An asterisk (*)
- Blank¹

¹When you specify the value of the Queue manager property in this form in combination with a CCDT, individual connections established by using the queue connection factory might connect to different queue managers. Selection from multiple queue managers occurs when the CCDT contains multiple client connection channel definitions with a matching queue manager name (QMNAME) parameter, and these connection channel definitions define the network connection details of different queue managers.

If the specified connection factory is based on a CCDT, and the CCDT can select from more than one queue manager, you might not be able to recover global transactions. Therefore, for connection factories that specify a CCDT, you have two alternatives:

- Avoid any ambiguity about the target queue manager when specifying the Queue manager property, which means that the specified value of this property must not include an asterisk (*).
- Avoid using the resources with applications that enlist in global transactions.

Transport:

The WebSphere MQ transport type for the connection. The transport type is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type

Drop-down list

Default**Bindings, then client**

Range

Client Use a TCP/IP-based network connection to communicate with the WebSphere MQ queue manager.

Bindings, then client

Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport.

Bindings

Establish a cross-memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled:

- Hostname
- Port
- Connection name list
- Server connection channel

For more information about configuring a transport type of *Bindings, then client* or *Bindings*, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 806.

Enter host and port information in the form of separate host and port values:

If this radio is button selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the host name and port properties.

Selecting this option enables the host name and port properties, and disables the connection name list property. To enter connection name list information, click **Enter host and port information in the form of a connection name list**.

This radio button is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Hostname:

The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type String

Port:

The port number on which WebSphere MQ is listening.

Data type Integer

Default 1414

Range The value must be in the range 1 to 65536 (inclusive).

Enter host and port information in the form of a connection name list:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the connection name list property.

Connection name lists can be used to connect to a single queue manager or to a multi-instance queue manager. For more information on using a multi-instance queue manager, see the WebSphere MQ information centre. Selecting this option enables the connection name list property and disables the host name and port properties. To enter separate host and port information, click **Enter host and port information in the form of separate host and port values**.

This radio button is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Connection name list:

The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager.

This property must only be used to allow connection to a multi-instance queue manager. It must not be used to allow connections to non-multi-instance queue managers as that can result in transaction integrity issues.

Data type String
Default Unset
Range This field must be set to a string in the following form:

host[(*port*)][,*host*(*port*)]

The port information is optional, and if not specified, defaults to 1414.

host must be a valid TCP/IP host name or IPv4 or IPv6 address.

port must be an integer value in the range 1 to 65536 (inclusive).

For example:
localhost(1234),remotehost1(1234),remotehost2

When the connection name list property is specified, the host name or port properties are automatically set to the host name and port number of the first entry in the connection name list. So if you specified localhost(1234),remotehost1(1234),remotehost2, the host name would be set to localhost and port would be set to 1234.

This property is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

When used in a mixed cell environment, the information in the connection name list property is not available to versions of WebSphere Application Server earlier than Version 8.0. In this case, the information in the host name and port name fields, based on the first element in the connection name list, is used instead.

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type String
Default SYSTEM.DEF.SVRCONN

Range

The value must be a server connection channel defined to the WebSphere MQ queue manager that is being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

When using a WebSphere MQ messaging provider queue connection factory in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security > SSL certificate and key management** panel.

When using a WebSphere MQ messaging provider queue connection factory in the client environment, the client takes SSL configuration information from the `ssl.client.props` file. Use of this file is detailed in the related reference information for this topic.

You can only use one cipher suite in the SSL configuration for a WebSphere MQ messaging provider queue connection factory. If you specify more than one cipher suite, only the first one is used.

Data type

Check box. If this check box is cleared, the following SSL properties are disabled:

- Centrally managed
- Specific configuration
- SSL configuration

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the host name and port attributes from the WebSphere MQ messaging provider connection factory are used to select an appropriate SSL configuration. If host and port information has been supplied by a connection name list this means that the host name and port information of the first element in the list are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the connection factory, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type

Radio button

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

Data type

Radio button

SSL configuration:

The SSL configuration to use when SSL is to be used to secure network communications with the WebSphere queue manager or queue-sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if an SSL configuration of none is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Advanced:

Client ID:

The client identifier to specify when connecting to the WebSphere MQ messaging provider.

Data type String

Provider version:

The WebSphere MQ messaging provider version. This is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functions required by the client.

Data type String
Range The value entered must either be the empty string or be in one of the following formats:
n.n.n.n
n.n.n
n.n
n
where n is a numeric value greater than or equal to zero.
For example 6.0.0.0.

Support distributed two-phase commit protocol:

An option that specifies whether the queue connection factory supports XA coordination of messaging transactions. Enable this option if multiple resources, including this queue connection factory, are to be used in the same transaction.

If you clear this property, you disable support for distributed two-phase commit protocol. The JMS session can still be enlisted in a transaction, but it uses the resource manager local transaction calls session.commit and session.rollback, instead of XA calls. This can lead to an improvement in performance. However, only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type Check box
Default Selected

Range**Selected**

The queue connection factory supports the use of distributed two-phase commit protocols for the coordination of transacted work.

Cleared

The queue connection factory does not support the use of distributed two-phase commit protocols for the coordination of transacted work.

Keep this option selected if transactions involve other resources, including other queues or topics. Clear this option only when you are certain that the queue manager that is the target for this queue connection factory is the only resource in the transaction.

Security settings:**Authentication alias for XA recovery:**

The user name and password to use when connecting to WebSphere MQ during XA recovery.

Data type

Drop-down list

Default

(none)

Range

All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ during XA recovery.

Mapping-configuration alias:

This field is used only in the absence of a login configuration on the component resource reference.

When the resource authority value is "container", the preferred way to define the authentication strategy is by specifying a login configuration and associated properties on the component resource reference.

If the **DefaultPrincipalMapping** login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. To configure authentication information for use with the queue connection factory, under Related Items, click **JAAS - J2C authentication data** .

Data type

Drop-down list

Default

(none)

Range

The following options are available:

ClientContainer

WSLogin

WSKRB5Login

DefaultPrincipalMapping

TrustedConnectionMapping

KerberosMapping

Container-managed authentication alias:

The authentication alias which specifies the user name and password to use when connecting to the WebSphere MQ messaging provider.

Data type

Drop-down list

Default

(none)

Range

All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

WebSphere MQ messaging provider queue connection factory advanced properties:

Use this panel to view or change the advanced properties of the selected queue connection factory for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ queue connection factory advanced properties, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Queue connection factories** to display existing queue connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the queue connection factories are defined. Setting the scope in this way restricts the set of queue connection factories displayed.
3. Select the name of the queue connection factory that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ queue connection factory.

Under General Properties there are six groups of advanced properties:

- Client reconnect
- Message compression
- Temporary destinations
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the queue connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, except for channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ queue connection factory has the following advanced properties:

Client reconnect options:

This property specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment.

Data type

Drop-down list

Default

DISABLED

Range**DISABLED**

Client reconnection does not automatically occur.

ASDEF

The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified in the client configuration file, ASDEF has the same effect as DISABLED.

QMGR

Reconnection occurs only to the queue manager to which the connection was originally connected.

RECONNECT

Reconnection occurs to any queue manager that is consistent with the value of the queue manager attribute. This queue manager might be a different queue manager from the one to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Client reconnect timeout:

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

Data type

Integer

Units

Seconds

Default

1800 (30 minutes)

Range

A value greater than zero and up to 2147483647

For more information about automatic client reconnection, see the WebSphere MQ information center.

Compress message headers:

An option that enables the compression of message headers.

Data type

Check box

Default

Cleared

Range**Cleared**

Do not compress message headers.

Selected

Compress message headers.

Compression algorithm for message payloads:

The compression algorithm that is used to compress message payloads.

Data type

Drop-down list

Default

NONE

Range	<p>RLE Message data compression is performed using run-length encoding.</p> <p>ZLIBFAST Message data compression is performed using ZLIB encoding with speed prioritized.</p> <p>ZLIBHIGH Message data compression is performed using ZLIB encoding with compression prioritized.</p> <p>NONE No message data compression is performed.</p>
--------------	---

WebSphere MQ model queue name:

The model queue that is used as a basis for temporary queue definitions.

Data type	String
Default	SYSTEM.DEFAULT.MODEL.QUEUE

Temporary queue prefix:

The prefix that is attached to the beginning of the names generated for temporary queues.

Data type	String
------------------	--------

Retain messages, even if no matching consumer is available:

An option that determines whether messages for which there is no matching consumer are retained on the input queue or dealt with according with their disposition options.

Data type	Check box
Default	Selected
Range	<p>Cleared Do not retain messages.</p> <p>Selected Retain messages.</p>

Polling interval:

This setting is applicable in the client container only. When using a WebSphere MQ Version 6 queue manager (or WebSphere MQ Version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread waits for a message to arrive at a WebSphere MQ queue before polling another WebSphere MQ queue in the set.

Data type	Integer
Units	Milliseconds
Default	5000
Range	A value greater than zero.

Rescan interval:

When using a WebSphere MQ Version 6 queue manager (or WebSphere MQ Version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread retrieves messages from a WebSphere MQ queue before switching to use messages from another WebSphere MQ queue in the set.

Data type	Integer
Units	Milliseconds
Default	5000
Range	A value greater than zero.

Maximum batch size:

The maximum number of messages that can be removed from a queue before at least one must be delivered to an asynchronous consumer.

Data type	Integer
Default	10
Range	A value greater than zero.

Coded character set identifier:

The character set to use when you are encoding strings in the message.

Data type	Integer
Default	819
Range	A value greater than zero. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration* and the *Application Programming Reference* sections of the WebSphere MQ information center.

Append an RFH version 2 header to reply messages:

The action required when sending a reply message to the reply-to queue obtained from a message that does not include an RFH version 2 header.

Data type	Check box
Default	Cleared
Range	Selected Append an RFH version 2 header to reply messages regardless of whether the original message had an RFH version 2 header. Cleared Append an RFH version 2 header to reply messages only if the original message had an RFH version 2 header.

Fail JMS method calls if the WebSphere MQ queue manager is quiescing:

An option that enables selected JMS operations to fail when the queue manager is put into a quiescing state. Selecting this option enables the queue manager to quiesce successfully and shut down.

Data type	Check box
Default	Selected
Range	<p>Cleared Do not fail JMS operations if the queue manager is quiescing.</p> <p>Selected Fail JMS operations if the queue manager is quiescing.</p>

WebSphere MQ messaging provider connection factory client transport settings:

Use this panel to view or change the client transport settings of a connection factory, queue connection factory, or topic connection factory for use with the WebSphere MQ messaging provider. Client transport properties affect how a client connection is established with a WebSphere MQ queue manager or queue-sharing group. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory, queue connection factory, or topic connection factory client transport settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS**.
2. Click **Connection factories**, **Queue connection factories**, or **Topic connection factories** to display existing connection factories, queue connection factories or topic connection factories.
3. Select the name of the connection factory, queue connection factory, or topic connection factory that you want to work with.
4. In the content pane under Additional Properties, click **Client transport properties** to view a list of the client transport settings of the WebSphere MQ connection factory, queue connection factory, or topic connection factory.

Under General Properties there are two groups of properties:

- Additional SSL settings (for more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center)
- Channel exits

Make any required changes to these groups and then click **Apply** to return to the connection factory, queue connection factory or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ connection factory, queue connection factory, or topic connection factory has the following client transport settings properties:

Certificate revocation list:

A list of LDAP URLs pointing to LDAP repositories of SSL certificates that might have been revoked.

Data type	String
Default	No certificate revocation list
Range	The value must be a space-separated list of LDAP URLs.

Peer name:

A name (possibly including wildcards) that must match the distinguished name of the peer SSL certificate for a connection to be established.

Data type	String
Default	Do not check the distinguished name of the peer certificate.
Range	Validated according to the rules for a WebSphere MQ SSLPEER channel parameter.

Reset count:

The total number of bytes to transfer over an SSL connection before renegotiating the symmetric encryption keys used to secure the connection.

Data type	Integer
Default	0 (do not renegotiate)
Range	The value must be in the range 0 through 999,999,999 (inclusive).

Receive exits:

A comma-separated list of Java class names corresponding to receive exits to be loaded.

Data type	String
------------------	--------

Receive exit initialization data:

Initialization data to be passed to the receive exit.

Data type	String
------------------	--------

Send exits:

A comma-separated list of Java class names corresponding to send exits to be loaded.

Data type	String
------------------	--------

Send exit initialization data:

Initialization data to be passed to the send exit.

Data type	String
------------------	--------

Security exit:

A Java class name corresponding to the security exit to be loaded.

Data type	String
------------------	--------

Security exit initialization data:

Initialization data to be passed to the security exit.

Data type String

Connection pool settings:

Use this page to configure connection pool settings.

This administrative console page is common to JDBC data sources and JMS connection factories (unified, queue, or topic connection factories). To view this page, the path depends on the type of resource, but generally you select an instance of the resource type then click **Connection Pool**. For example:

- Click **Resources > JDBC > Data Sources > data_source > [Additional Properties] Connection pool properties**
- Click **Resources > JMS->Queue connection factories->queue_connection_factory->[Additional Properties] Connection pool**

Note: Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the `getConnection()` request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

Connection timeout:

Specifies the interval, in seconds, after which a connection request times out and a `ConnectionWaitTimeoutException` is thrown.

This value indicates the number of seconds that a connection request waits when there are no connections available in the free pool and no new connections can be created. This usually occurs because the maximum value of connections in the particular connection pool has been reached.

For example, if Connection timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. In most cases, you should not retry the `getConnection()` method; if a longer wait time is required you should increase the Connection timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, and a new physical connection is created.

If Maximum Connections is set to 0, an infinite number of physical connections are enabled, and the Connection timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Maximum connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. When this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` error displays. For example, if the `Max Connections` value is set to 5, and there are 5 physical connections in use, the pool manager waits for the amount of time specified in `Connection timeout` for a physical connection to become free.

Knowing the number of connection pools that can potentially request connections from the backend, such as a DB2 database or a CICS server, helps you determine a value for the `Maximum Connections` property.

Consider the number of servants that access the same resource; at run time, this number essentially multiplies your `Maximum Connections` setting. When servants start the same JDBC data source or J2C connection factory configuration, WebSphere Application Server (base) implements a corresponding physical connection pool for every servant. Therefore the same connection pool exists, independently, in each servant. Your `Maximum Connections` setting applies to each one of these pools.

Potentially, every application that requires the data source or connection factory in these servants can attempt to use the resource simultaneously. Therefore the corresponding connection pools require connections from the same backend, at the same time. Do not set a `Maximum Connections` value that might cause the load of connection requests to overwhelm your database or other enterprise information system (EIS).

Data type	Integer
Default	10
Range	0 to maximum integer
	If <code>Max Connections</code> is set to 0, the <code>Connection timeout</code> value is ignored.

Tip: For better performance, set the value for the connection pool lower than the value for the maximum thread pool connections of the web container. To configure this setting click **Servers > Server types > WebSphere application servers > server > Thread Pools**, and modify the web container property. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the processor load is not close to 100%, consider increasing the connection pool size. If the `Percent Used` value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Minimum connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the `Unused timeout` thread does not discard physical connections. However, the pool does not create connections solely to ensure that the minimum connection pool size is maintained. Also, if you set a value for `Aged timeout`, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example, if the `Minimum Connections` value is set to 3, and one physical connection is created, the `Unused timeout` thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the `Minimum Connections` setting.

Data type	Integer
Default	1

Range 0 to max int

Reap time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the Unused timeout and Aged timeout settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused timeout and Aged timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused timeout, until it reaches the number of connections specified in Minimum Connections. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread, set Reap Time to 0, or set both Unused timeout and Aged timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, and Unused timeout and Aged timeout are ignored. However, if Unused timeout and Aged timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout, because of non-zero timeout values, are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused timeout value higher than the Reap timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for 2 minutes is discarded.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 218 for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting Aged timeout to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged timeout value higher than the Reap timeout value for optimal performance.

For example, if the Aged timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. The only exception is if the connection is involved in a transaction when the aged timeout is reached, the application server will not discard the connection until after the transaction is completed and the connection is closed.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 218 for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**.

Data type	String
Defaults	<ul style="list-style-type: none"> • EntirePool for J2C connection factories and JMS-related connection factories • EntirePool for WebSphere Version 4.0 data sources • EntirePool for current version data sources that you create through the administrative console • EntirePool for current version data sources that you script through wsadmin AdminConfig commands, starting JDBC templates that are built into WebSphere Application Server. For information about the command createUsingTemplate, see the topic, Commands for the AdminConfig object. • FailingConnectionOnly for data sources that you script in wsadmin tool without starting JDBC templates
	:

Range

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this closure is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a possibility that the next getConnection() request from the application can return a connection from the pool that is also stale. The result is more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to JMS unified connection factories, queue connection factories and topic connection factories. To view this page, you select an instance of the resource type then click **Session pools**. For example, click **Resources > JMS->Queue connection factories->queue_connection_factory->[Additional Properties] Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached . For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a ConnectionWaitTimeoutException. It usually does not make sense to retry the getConnection() method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher

value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. Java EE Connector Architecture (JCA) data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type
Default
Range

String
FailingConnectionOnly

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Configuring a topic connection factory for the WebSphere MQ messaging provider

Use this task to view or change the configuration of a JMS topic connection factory for publish/subscribe messaging with the WebSphere MQ messaging provider.

About this task

This task applies to topic connection factories. With JMS 1.1, domain-independent (unified) connection factories are preferred to domain-specific queue connection factories and topic connection factories. To view or configure a unified connection factory, see “Configuring a unified connection factory for the WebSphere MQ messaging provider” on page 845.

To view or change the configuration of an existing topic connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources > JMS->Topic connection factories**. A list of existing topic connection factories, with a summary of their properties, is displayed.

2. Select the **Scope** corresponding to the scope at which the topic connection factory is visible to applications.
3. Click the name of the topic connection factory that you want to view or change. Configuration details for the topic connection factory are displayed.
4. Under **General properties** make any required changes.
For information about each of the available fields, see “WebSphere MQ messaging provider topic connection factory settings.”
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your topic connection factory.
7. Optional: Click **Broker properties** to display or change the list of broker properties of your topic connection factory.
8. Optional: Click **Custom properties** to display or change the list of custom properties of your topic connection factory.
9. Optional: Click **Client transport properties** to display or change the list of client transport properties of your topic connection factory. This link is only appears if, when you created the connection factory, you chose to enter all the information required to connect to WebSphere MQ. This link does not appear if you have chosen to use a client channel definition table (CCDT) to establish a connection to WebSphere MQ
10. Optional: Click **Connection pools** to display or change the connection pools detail of your topic connection factory.
11. Optional: Click **Session pools** to display or change the session pools detail of your topic connection factory.
There is a mechanism (session.sharing.scope custom property) to make JMS sessions unshareable. This means that whenever an application calls Session.close(), the JMS session is automatically released from any transaction that is associated with and returned to the session pool. This means that sessions can be cleaned up and removed from the session pool even if the servlet or asynchronous bean that created it is still running.
12. Click **OK**.
13. Save your changes to the master configuration.
14. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider topic connection factory settings

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to the associated JMS topic destination.

A WebSphere MQ topic connection factory is used to create JMS connections to topic destinations provided by WebSphere MQ for publish/subscribe messaging.

To view WebSphere MQ topic connection factory settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the topic connection factories are defined. This restricts the set of topic connection factories displayed.
3. Select the name of the topic connection factory that you want to work with.

Under General Properties there are four groups of properties:

- “Administration” on page 899
- “Connection” on page 900
- “Advanced” on page 906

- “Security settings” on page 907

Make any required changes to the Administration, Connection, Advanced and Security settings groups of properties, and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click any of the following links:

- **Advanced properties** to display the advanced properties of your WebSphere MQ topic connection factory.
- **Broker properties** to display the broker properties of your WebSphere MQ topic connection factory.
- **Custom properties** to display the custom properties of your WebSphere MQ topic connection factory.
- **Client transport properties** to display or change the client transport properties of your WebSphere MQ topic connection factory. If the selected topic connection factory was not created using a Client Channel Definition Table (CCDT), follow this link to enter all the information required to connect to WebSphere MQ. If the selected topic connection factory was created using a CCDT, you do not need to supply the client transport properties, and so the link is absent.
- **Connection pools** to display the connection pools detail of your WebSphere MQ topic connection factory
- **Session pools** to display the session pools detail of your WebSphere MQ topic connection factory.

Under Related Items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the topic connection factory.

You can specify the following additional properties by using WebSphere MQ administrative commands:

- **-localAddress**
- **-clonedSubs**
- **-componentAuthAlias**

For more information about these properties, refer to the “createWMQConnectionFactory command” on page 971.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when you configured the JMS resources in WebSphere MQ. For more information about configuring JMS resources in WebSphere MQ, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ topic connection factory has the following properties.

Administration:

Scope:

The level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource at a different scope, change the scope on the WebSphere MQ topic connection factory collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String
------------------	--------

Provider:

The JMS provider assigned when the topic connection factory is created.

For all topic connection factories created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which this topic connection factory is known for administrative purposes within WebSphere Application Server.

Data type String
Range The name must be unique within the set of JMS topic connection factories defined to the cell.

JNDI name:

The JNDI name that is used to bind the topic connection factory into the JNDI namespace.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

Data type String

Description:

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Connection:

The information required to configure a connection depends on whether the selected topic connection factory was created using a Client Channel Definition Table (CCDT).

If the selected topic connection factory was created using a CCDT, only the following properties are displayed:

- Client channel definition table URL
- Queue manager
- SSL configuration

If the selected topic connection factory was not created using a CCDT, the following properties are displayed:

- Queue manager

- Transport
- If **Enter host and port information in the form of separate host and port values** is selected, the connection name list property cannot be used and the following properties can be used:
 - Host name
 - Port
- If **Enter host and port information in the form of a connection name list** is selected, the connection name list property can be used and the following properties cannot be used:
 - Host name
 - Port
- Server connection channel
- If you clear the check box for the **Use SSL to secure communication with Websphere MQ** property, the following properties cannot be used:
 - Centrally managed
 - Specific configuration
 - SSL configuration

For more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center.

Client channel definition table URL:

A URL that specifies the location of a WebSphere MQ CCDT.

Data type String

Queue manager:

If the specified topic connection factory is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, it is the name of the queue manager or queue-sharing group to connect to. A connection is established to this WebSphere MQ resource to send or receive messages.

Data type String

Range

If this topic connection factory is not based on a CCDT, the value must be a valid queue manager name.

If this topic connection factory is based on a CCDT, the value must be one of the following:

- A valid queue manager name
- An asterisk (*) followed by the name of a queue manager group¹
- An asterisk (*)
- Blank¹

¹When you specify the value of the Queue manager property in this form in combination with a CCDT, individual connections established by using the topic connection factory might connect to different queue managers. Selection from multiple queue managers occurs when the CCDT contains multiple client connection channel definitions with a matching queue manager name (QMNAME) parameter, and these connection channel definitions define the network connection details of different queue managers.

If the specified connection factory is based on a CCDT, and the CCDT can select from more than one queue manager, you might not be able to recover global transactions. Therefore, for connection factories that specify a CCDT, you have two alternatives:

- Avoid any ambiguity about the target queue manager when specifying the Queue manager property, which means that the specified value of this property must not include an asterisk (*).
- Avoid using the resources with applications that enlist in global transactions.

Transport:

The WebSphere MQ transport type for the connection. The transport type is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type

Drop-down list

Default**Bindings, then client**

Range

Client Use a TCP/IP-based network connection to communicate with the WebSphere MQ queue manager

Bindings, then client

Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport.

Bindings

Establish a cross-memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled:

- Hostname
- Port
- Connection name list
- Server connection channel

For more information about configuring a transport type of *Bindings, then client* or *Bindings*, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 806.

Enter host and port information in the form of separate host and port values:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the host name and port properties.

Selecting this option enables the host name and port properties, and disables the connection name list property. To enter connection name list information, click **Enter host and port information in the form of a connection name list**.

This radio button is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Hostname:

The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type String

Port:

The port number on which WebSphere MQ is listening.

Data type Integer

Default 1414

Range The value must be in the range 1 to 65536 (inclusive).

Enter host and port information in the form of a connection name list:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the connection name list property.

Connection name lists can be used to connect to a single queue manager or to a multi-instance queue manager. For more information on using a multi-instance queue manager, see the WebSphere MQ information centre. Selecting this option enables the connection name list property and disables the host name and port properties. To enter separate host and port information, click **Enter host and port information in the form of separate host and port values**.

This radio button is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Connection name list:

The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager.

This property must only be used to allow connection to a multi-instance queue manager. It must not be used to allow connections to non-multi-instance queue managers as that can result in transaction integrity issues.

Data type String
Default Unset
Range This field must be set to a string in the following form:

host[(*port*)][,*host*(*port*)]

The port information is optional, and if not specified, defaults to 1414.

host must be a valid TCP/IP host name or IPv4 or IPv6 address.

port must be an integer value in the range 1 to 65536 (inclusive).

For example:
localhost(1234),remotehost1(1234),remotehost2

When the connection name list property is specified, the host name or port properties are automatically set to the host name and port number of the first entry in the connection name list. So if you specified localhost(1234),remotehost1(1234),remotehost2, the host name would be set to localhost and port would be set to 1234.

This property is only available if the scope property specifies a cell or cluster, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

When used in a mixed cell environment, the information in the connection name list property is not available to versions of WebSphere Application Server earlier than Version 8.0. In this case, the information in the host name and port name fields, based on the first element in the connection name list, is used instead.

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type String
Default SYSTEM.DEF.SVRCONN

Range

The value must be a server connection channel defined to the WebSphere MQ queue manager that is being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

When using a WebSphere MQ messaging provider topic connection factory in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security > SSL certificate and key management** panel.

When using a WebSphere MQ messaging provider topic connection factory in the client environment, the client takes SSL configuration information from the `ssl.client.props` file. Use of this file is detailed in the related reference information for this topic.

You can only use one cipher suite in the SSL configuration for a WebSphere MQ messaging provider topic connection factory. If you specify more than one cipher suite, only the first one is used.

Data type

Check box. If this check box is cleared, the following SSL properties are disabled:

- Centrally managed
- Specific configuration
- SSL configuration

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the host name and port attributes from the WebSphere MQ messaging provider connection factory are used to select an appropriate SSL configuration. If host and port information has been supplied by a connection name list this means that the host name and port information of the first element in the list are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the connection factory, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type

Radio button

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

Data type

Radio button

SSL configuration:

The SSL configuration to use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if an SSL configuration of none is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Advanced:

Client ID:

The client identifier to specify when connecting to WebSphere MQ messaging provider.

Data type String

Allow cloned durable subscriptions:

An option that determines whether multiple instances of a durable subscription can be accessed concurrently by different servers.

Data type Check box
Default Cleared
Range **Selected** Multiple instances of a durable subscription can be accessed concurrently by different servers.
Cleared Multiple instances of a durable subscription cannot be accessed concurrently by different servers.

Provider version:

The WebSphere MQ messaging provider version. This is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functions required by the client.

Data type String
Range The value entered must either be the empty string or be in one of the following formats:
n.n.n.n
n.n.n
n.n
n
where n is a numeric value greater than or equal to zero.
For example 6.0.0.0.

Support distributed two-phase commit protocol:

An option that specifies whether the topic connection factory supports XA coordination of messaging transactions. Enable this option if multiple resources, including this topic connection factory, are to be used in the same transaction.

If you clear this property, you disable support for distributed two-phase commit protocol. The JMS session can still be enlisted in a transaction, but it uses the resource manager local transaction calls `session.commit` and `session.rollback`, instead of XA calls. This can lead to an improvement in performance. However, only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type	Check box
Default	Selected
Range	<p>Selected</p> <p>The connection factory supports the use of distributed two-phase commit protocols for the coordination of transacted work.</p> <p>Cleared</p> <p>The connection factory does not support the use of distributed two-phase commit protocols for the coordination of transacted work.</p>

Do not enable XA when the queue manager specified by the topic connection factory is the only resource in the transaction. Enable XA if transactions involve other resources, including other queues or topics.

Security settings:

Authentication alias for XA recovery:

The user name and password to use when connecting to WebSphere MQ during XA recovery.

Data type	Drop-down list
Default	(none)
Range	All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ during XA recovery.

Mapping-configuration alias:

This field is used only in the absence of a login configuration on the component resource reference.

When the resource authority value is "container", the preferred way to define the authentication strategy is by specifying a login configuration and associated properties on the component resource reference.

If the **DefaultPrincipalMapping** login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. To configure authentication information for use with the topic connection factory, under Related Items, click **JAAS - J2C authentication data** .

Data type	Drop-down list
Default	(none)

Range

The following options are available:

- ClientContainer
- WSLogin
- WSKRB5Login
- DefaultPrincipalMapping
- TrustedConnectionMapping
- KerberosMapping

Container-managed authentication alias:

The authentication alias which specifies the user name and password to use when connecting to the WebSphere MQ messaging provider.

Data type

Drop-down list

Default

(none)

Range

All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

WebSphere MQ messaging provider topic connection factory advanced properties:

Use this panel to view or change the advanced properties of the selected topic connection factory for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ topic connection factory advanced properties, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the topic connection factories are defined. Setting the scope in this way restricts the set of queue connection factories displayed.
3. Select the name of the topic connection factory that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ topic connection factory.

Under General Properties there are six groups of advanced properties:

- Client reconnect
- Message compression
- Temporary destinations
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, except for channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ topic connection factory has the following advanced properties.

Client reconnect options:

This property specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment.

Data type	Drop-down list
Default	DISABLED
Range	DISABLED Client reconnection does not automatically occur.
ASDEF	The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified in the client configuration file, ASDEF has the same effect as DISABLED.
QMGR	Reconnection occurs only to the queue manager to which the connection was originally connected.
RECONNECT	Reconnection occurs to any queue manager that is consistent with the value of the queue manager attribute. This queue manager might be a different queue manager from the one to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Client reconnect timeout:

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

Data type	Integer
Units	Seconds
Default	1800 (30 minutes)
Range	A value greater than zero and up to 2147483647

For more information about automatic client reconnection, see the WebSphere MQ information center.

Compress message headers:

An option that enables the compression of message headers.

Data type	Check box
Default	Cleared
Range	Cleared Do not compress message headers. Selected Compress message headers.

Compression algorithm for message payloads:

The compression algorithm to use to compress message payloads.

Data type	Drop-down list
Default	NONE
Range	<p>RLE Message data compression is performed using run-length encoding.</p> <p>ZLIBFAST Message data compression is performed using ZLIB encoding with speed prioritized.</p> <p>ZLIBHIGH Message data compression is performed using ZLIB encoding with compression prioritized.</p> <p>NONE No message data compression is performed.</p>

Temporary topic prefix:

The prefix to append to the beginning of the names generated for temporary topics.

Data type	String
------------------	--------

Polling interval:

This setting is applicable in the client container only. When using a WebSphere MQ Version 6 queue manager (or WebSphere MQ Version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread waits for a message to arrive at a WebSphere MQ queue before polling another WebSphere MQ queue in the set.

Data type	Integer
Units	Milliseconds
Default	5000
Range	A value greater than zero.

Maximum batch size:

The maximum number of messages that can be removed from a queue before at least one must be delivered to an asynchronous consumer.

Data type	Integer
Default	10
Range	A value greater than zero.

Coded character set identifier:

The character set to use when you are encoding strings in the message.

Data type	Integer
Default	819
Range	A value greater than zero. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration* and the *Application Programming Reference* sections of the WebSphere MQ information center.

Fail JMS method calls if the WebSphere MQ messaging provider queue manager is quiescing:

An option that enables selected JMS operations to fail when the queue manager is put into a quiescing state. Selecting this option enables the queue manager to quiesce successfully and shut down.

Data type	Check box
Default	Selected
Range	Cleared Do not fail JMS operations if the queue manager is quiescing.
	Selected Fail JMS operations if the queue manager is quiescing.

WebSphere MQ messaging provider connection factory broker properties:

Use this panel to view or change the broker settings of the selected connection factory, or topic connection factory, for use with the WebSphere MQ messaging provider. These broker settings determine how the WebSphere MQ messaging provider interacts with a broker for the purposes of publishing messages and subscribing to topics. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory, or topic connection factory, broker properties use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Connection factories** to display existing connection factories, or click **Resources > JMS->Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. This restricts the set of connection factories displayed.
3. Select the name of the connection factory, or topic connection factory, that you want to work with.
4. In the content pane, under Additional Properties, click **Broker properties** to display the broker properties of the WebSphere MQ connection factory, or topic connection factory.

Under General Properties there are four groups of properties:

- Queues
- Capabilities
- Tuning
- Additional

Make any required changes to these groups and then click **Apply** to return to the connection factory, or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* section of the WebSphere MQ library.

A WebSphere MQ connection factory, or topic connection factory, has the following broker properties:

Broker control queue:

The queue to which broker control messages are sent.

Data type String
Default SYSTEM.BROKER.CONTROL.QUEUE

Broker publication queue:

The queue to which publication messages are sent.

Data type String
Default SYSTEM.BROKER.DEFAULT.STREAM

Broker subscriber queue:

The queue to which subscription messages are sent.

Data type String
Default SYSTEM.JMS.ND.SUBSCRIBER.QUEUE

Broker connection consumer subscription queue:

The queue to which subscription messages that are destined for a connection consumer are sent.

Data type String
Default SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE

Version:

The version of the broker that is used. This determines some of the capabilities that the broker is assumed to have. For example, whether to use an RFH version 1 or version 2 header in publications.

Data type Radio button
Default Version 1 broker
Range

Version 1 broker
Message selection cannot be specified.

Version 2 broker
Message selection can be specified. If you select this option, you must also complete **Specify where message selection occurs**.

Specify where message selection occurs:

The process in which message selection is performed. This property is enabled only if **Version 2 broker** was selected.

Data type Drop-down list
Default CLIENT

Range

CLIENT

Message selection is performed in the application server process.

BROKER

Message selection is performed in the broker process.

Subscription store:

The process for tracking subscriptions.

Data type

Drop-down list

Default

MIGRATE

Range

MIGRATE

Any information that is held on queues is migrated to the broker mechanism for persisting subscription information. If subscription information is already persisted using the broker mechanism then specifying a value of Migrate is equivalent to specifying a value of Broker.

BROKER

Internal broker mechanisms are used to track subscription information.

QUEUE

A designated WebSphere MQ queue is used to record information about current subscriptions.

Durable subscription state refresh interval:

How often a long running transaction is recreated and used to clean up durable subscriptions, for some versions of the queue manager.

Data type

Integer

Default

60000

Range

Any positive integer

Subscription cleanup level:

How aggressively messages are cleaned up if the subscriber that is expected to consume the messages terminates unexpectedly.

Data type

Drop-down list

Default

SAFE

Range

SAFE A conservative algorithm is used to clean up subscriptions.

ASPROP

The cleanup algorithm is determined by a system property.

NONE No cleanup of subscriptions is performed.

STRONG

An aggressive algorithm is used to clean up subscriptions.

Subscription cleanup interval:

How often to check for orphaned subscriptions and clean up messages.

Data type	Integer
Default	3600000
Range	Any positive integer

Subscription wildcard format:

The wildcard format used for subscribing to more than one topic in a topic hierarchy.

Data type	Drop-down list
Default	character wildcards
Range	character wildcards You can use an asterisk (*) or question mark (?) to represent characters, or strings of characters, in a topic name. * is interpreted as matching many characters. ? is interpreted as matching a single character. topic level wildcards You can use a plus sign (+) or number sign (#) to represent topics in a multilevel topic hierarchy. + is interpreted as matching a single topic name. # is interpreted as matching many topics in the hierarchy. / is used to delimit topics.

Publish acknowledgement window:

The number of messages to publish before publishing a message that requires broker acknowledgement

Data type	Integer
Default	25
Range	Any positive integer

Optimize for sparse subscription patterns:

An option to specify whether this connection factory is anticipated to receive a high proportion of messages that match its selection criteria. This information can be used to optimize message delivery.

Data type	Check box
Default	Cleared
Range	<p>Cleared Subscriptions frequently receive matching messages.</p> <p>Selected Subscriptions do not frequently receive matching messages.</p>

Broker queue manager:

The name of the queue manager that is running the broker, if it is not the same as the queue manager to which the connection factory connects.

Data type	String
Default	The queue manager name that was specified in the connection factory.

WebSphere MQ messaging provider connection factory client transport settings:

Use this panel to view or change the client transport settings of a connection factory, queue connection factory, or topic connection factory for use with the WebSphere MQ messaging provider. Client transport properties affect how a client connection is established with a WebSphere MQ queue manager or queue-sharing group. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory, queue connection factory, or topic connection factory client transport settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS**.
2. Click **Connection factories**, **Queue connection factories**, or **Topic connection factories** to display existing connection factories, queue connection factories or topic connection factories.
3. Select the name of the connection factory, queue connection factory, or topic connection factory that you want to work with.
4. In the content pane under Additional Properties, click **Client transport properties** to view a list of the client transport settings of the WebSphere MQ connection factory, queue connection factory, or topic connection factory.

Under General Properties there are two groups of properties:

- Additional SSL settings (for more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center)
- Channel exits

Make any required changes to these groups and then click **Apply** to return to the connection factory, queue connection factory or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ connection factory, queue connection factory, or topic connection factory has the following client transport settings properties:

Certificate revocation list:

A list of LDAP URLs pointing to LDAP repositories of SSL certificates that might have been revoked.

Data type	String
Default	No certificate revocation list
Range	The value must be a space-separated list of LDAP URLs.

Peer name:

A name (possibly including wildcards) that must match the distinguished name of the peer SSL certificate for a connection to be established.

Data type	String
Default	Do not check the distinguished name of the peer certificate.
Range	Validated according to the rules for a WebSphere MQ SSLPEER channel parameter.

Reset count:

The total number of bytes to transfer over an SSL connection before renegotiating the symmetric encryption keys used to secure the connection.

Data type	Integer
Default	0 (do not renegotiate)
Range	The value must be in the range 0 through 999,999,999 (inclusive).

Receive exits:

A comma-separated list of Java class names corresponding to receive exits to be loaded.

Data type	String
------------------	--------

Receive exit initialization data:

Initialization data to be passed to the receive exit.

Data type	String
------------------	--------

Send exits:

A comma-separated list of Java class names corresponding to send exits to be loaded.

Data type	String
------------------	--------

Send exit initialization data:

Initialization data to be passed to the send exit.

Data type	String
------------------	--------

Security exit:

A Java class name corresponding to the security exit to be loaded.

Data type String

Security exit initialization data:

Initialization data to be passed to the security exit.

Data type String

Connection pool settings:

Use this page to configure connection pool settings.

This administrative console page is common to JDBC data sources and JMS connection factories (unified, queue, or topic connection factories). To view this page, the path depends on the type of resource, but generally you select an instance of the resource type then click **Connection Pool**. For example:

- Click **Resources > JDBC > Data Sources > data_source > [Additional Properties] Connection pool properties**
- Click **Resources > JMS->Queue connection factories->queue_connection_factory->[Additional Properties] Connection pool**

Note: Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the `getConnection()` request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

Connection timeout:

Specifies the interval, in seconds, after which a connection request times out and a `ConnectionWaitTimeoutException` is thrown.

This value indicates the number of seconds that a connection request waits when there are no connections available in the free pool and no new connections can be created. This usually occurs because the maximum value of connections in the particular connection pool has been reached.

For example, if Connection timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. In most cases, you should not retry the `getConnection()` method; if a longer wait time is required you should increase the Connection timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, and a new physical connection is created.

If Maximum Connections is set to 0, an infinite number of physical connections are enabled, and the Connection timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Maximum connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. When this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` error displays. For example, if the `Max Connections` value is set to 5, and there are 5 physical connections in use, the pool manager waits for the amount of time specified in `Connection timeout` for a physical connection to become free.

Knowing the number of connection pools that can potentially request connections from the backend, such as a DB2 database or a CICS server, helps you determine a value for the `Maximum Connections` property.

Consider the number of servants that access the same resource; at run time, this number essentially multiplies your `Maximum Connections` setting. When servants start the same JDBC data source or J2C connection factory configuration, WebSphere Application Server (base) implements a corresponding physical connection pool for every servant. Therefore the same connection pool exists, independently, in each servant. Your `Maximum Connections` setting applies to each one of these pools.

Potentially, every application that requires the data source or connection factory in these servants can attempt to use the resource simultaneously. Therefore the corresponding connection pools require connections from the same backend, at the same time. Do not set a `Maximum Connections` value that might cause the load of connection requests to overwhelm your database or other enterprise information system (EIS).

Data type	Integer
Default	10
Range	0 to maximum integer

If `Max Connections` is set to 0, the `Connection timeout` value is ignored.

Tip: For better performance, set the value for the connection pool lower than the value for the maximum thread pool connections of the web container. To configure this setting click **Servers > Server types > WebSphere application servers > server > Thread Pools**, and modify the web container property. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the processor load is not close to 100%, consider increasing the connection pool size. If the `Percent Used` value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Minimum connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the `Unused timeout` thread does not discard physical connections. However, the pool does not create connections solely to

ensure that the minimum connection pool size is maintained. Also, if you set a value for Aged timeout, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example, if the Minimum Connections value is set to 3, and one physical connection is created, the Unused timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Minimum Connections setting.

Data type	Integer
Default	1
Range	0 to max int

Reap time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the Unused timeout and Aged timeout settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused timeout and Aged timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused timeout, until it reaches the number of connections specified in Minimum Connections. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread, set Reap Time to 0, or set both Unused timeout and Aged timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, and Unused timeout and Aged timeout are ignored. However, if Unused timeout and Aged timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout, because of non-zero timeout values, are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused timeout value higher than the Reap timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for 2 minutes is discarded.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 218 for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting Aged timeout to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged timeout value higher than the Reap timeout value for optimal performance.

For example, if the Aged timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. The only exception is if the connection is involved in a transaction when the aged timeout is reached, the application server will not discard the connection until after the transaction is completed and the connection is closed.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 218 for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**.

Data type	String
Defaults	<ul style="list-style-type: none">• EntirePool for J2C connection factories and JMS-related connection factories• EntirePool for WebSphere Version 4.0 data sources• EntirePool for current version data sources that you create through the administrative console• EntirePool for current version data sources that you script through wsadmin AdminConfig commands, starting JDBC templates that are built into WebSphere Application Server. For information about the command createUsingTemplate, see the topic, Commands for the AdminConfig object.• FailingConnectionOnly for data sources that you script in wsadmin tool without starting JDBC templates
	:

Range

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this closure is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a possibility that the next getConnection() request from the application can return a connection from the pool that is also stale. The result is more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to JMS unified connection factories, queue connection factories and topic connection factories. To view this page, you select an instance of the resource type then click **Session pools**. For example, click **Resources > JMS->Queue connection factories->queue_connection_factory->[Additional Properties] Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached . For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a ConnectionWaitTimeoutException. It usually does not make sense to retry the getConnection() method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher

value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a ConnectionWaitTimeoutException is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. Java EE Connector Architecture (JCA) data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type
Default
Range

String
FailingConnectionOnly

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Configuring a queue for the WebSphere MQ messaging provider

Use this task to view or change the configuration of a JMS queue destination for point-to-point messaging with the WebSphere MQ messaging provider. This task contains an optional step for you to create a new JMS queue destination.

About this task

To optimize performance, configure the queue destination properties to best fit your message-driven beans or other applications that use the queue destinations. For more information about performance, see Performance for WebSphere MQ queues.

To view or change the configuration of a queue destination for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources > JMS->Queues** to view existing queue destinations, with a summary of their properties.

2. Select the **Scope** corresponding to the scope of the queue destinations that you want to view or change.
3. To view or change the properties of an existing queue destination, click its name in the list. Otherwise, to create a new queue, complete the following steps:
 - a. Click **New** in the content pane. Select **WebSphere MQ messaging provider** then click **OK**.
 - b. Specify the following required properties.

Name The name by which this queue destination is known for administrative purposes within WebSphere Application Server.

JNDI name
The JNDI name that is used to bind the queue destination into the namespace.

Queue name
The name of the WebSphere MQ queue to which messages are sent.
 - c. Click **Apply**. This defines the queue destination to WebSphere Application Server, and enables you to browse or change additional properties.
4. Optional: Change WebSphere MQ queue settings, according to your needs.
5. Click **OK**.
6. Save any changes to the master configuration.
7. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider queue settings

Use this panel to view or change the configuration properties of the selected queue destination for point-to-point messaging with WebSphere MQ as a messaging provider.

A WebSphere MQ queue destination is used to configure the properties of a queue for the WebSphere MQ messaging provider. Connections to the queue are created using an associated WebSphere MQ queue connection factory or connection factory.

To view WebSphere MQ queue settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Queues** to display existing queue destinations.
2. Select the name of the queue destination that you want to work with.
3. Optional: To create a new queue destination, click **New**.
4. Optional: To view or change the queue destination settings, select its name in the list displayed.

Under General Properties there are two groups of properties:

- Administration
- WebSphere MQ Queue

Make any required changes to the Administration and WebSphere MQ Queue groups of properties and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click one of the following links:

- **Advanced properties** to display or change the advanced properties of your WebSphere MQ queue destination
- **WebSphere MQ queue connection properties** to display or change the connection properties of your WebSphere MQ queue destination
- **Custom properties** to display or change the custom properties of your WebSphere MQ queue destination

Under Related items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the queue destination.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *Using Java* and *System Administration* sections of the WebSphere MQ information center.

If WebSphere MQ functionality has been disabled at a scope that affects this WebSphere MQ messaging provider resource, then an informational message indicating that WebSphere MQ has been disabled appears. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

A queue destination for use with the WebSphere MQ messaging provider has the following properties.

Scope:

The scope assigned to the queue when it is created. The scope specifies the level to which this queue definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource at a different scope, change the scope on WebSphere MQ queue destination collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the queue is created.

For all queues created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

JNDI name:

The name that is used to bind the queue into the JNDI namespace.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

Data type String

Description:

A description of the queue for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Queue name:

The WebSphere MQ name for the queue that holds the messages for the JMS destination.

Data type String

Queue manager or queue-sharing group name:

The name of the WebSphere MQ queue manager or queue-sharing group that hosts the queue.

Data type String

WebSphere MQ queue connection properties:

Use this panel to specify how to connect to the queue manager that hosts the queue.

The system uses these connection properties to retrieve, display and update the queue configuration details that are shown on the **WebSphere MQ queue settings** panel.

To set of change the queue connection properties, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Queues** to display existing queue destinations.
2. Click the name of the queue destination that you want to work with.
3. To view or change the queue destination settings, click its name in the list displayed.

Under General Properties there are two groups of properties:

- Administration
- WebSphere MQ Queue

Make any required changes to the Administration and WebSphere MQ Queue groups of properties and then click **Apply** before, in the content pane under Additional Properties, you click the **WebSphere MQ queue connection properties** link to display or change the connection properties of your WebSphere MQ queue destination.

Make any required changes to the General properties and then click **Apply** before, in the content pane under Additional Properties, you click **WebSphere MQ configuration** to return to the **WebSphere MQ queue settings** panel.

A queue destination for use with the WebSphere MQ messaging provider has the following WebSphere MQ queue connection properties.

Note:

- The property values that you specify must match the values that you specified when you configured the JMS resources in WebSphere MQ. For more information about configuring JMS resources in WebSphere MQ, see the *Using Java* section of the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Note: You cannot use this panel when WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

Queue Manager Host:

The name of host for the queue manager on which the queue destination is created.

Data type String

Queue Manager Port:

The number of the port used by the queue manager on which this queue is defined.

Data type Integer
Range A valid TCP/IP port number. This port must be configured on the WebSphere MQ queue manager.
Default 1414

Server Connection Channel Name:

The name of the channel used for connection to the WebSphere MQ queue manager.

Data type String
Range 1 through 20 ASCII characters

User ID:

The user ID used, with the **Password** property, for authentication when connecting to the queue manager to define the queue destination.

*If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.*

Data type String

Password:

The password, used with the **User ID** property, for authentication when connecting to the queue manager to define the queue destination.

*If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.*

Data type String

WebSphere MQ messaging provider queue and topic advanced properties settings:

Use this panel to view or change the advanced properties for the selected queue or topic destination for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ queue or topic advanced properties settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS**.
2. Click **Queues** or **Topics** to display existing queue or topic destinations.
3. If appropriate, in the content pane, change the **Scope** setting to the level at which the queue or topic destinations are defined. This restricts the set of queue or topic destinations displayed.
4. Click the name of the queue or topic destination that you want to work with.
5. In the content pane, under Additional properties, click **Advanced properties** to display a list of the advanced properties of the WebSphere MQ queue or topic destination.

Under General Properties there are five groups of properties:

- Delivery
- Message format
- Optimizations
- Message descriptor
- Additional

Make any required changes to these groups and then click **Apply** to return to the queue or topic.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see *Using Java* section of the WebSphere MQ information center.

A queue or topic for use with the WebSphere MQ messaging provider has the following advanced properties.

Persistence:

The level of persistence used to store messages sent to this destination.

Data type	Drop-down list
Default	As set by application
Range	<p>As set by application Messages on the destination have their persistence defined by the application that put them onto the queue.</p> <p>As for WebSphere MQ queue definition Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.</p> <p>WebSphere MQ Persistent Messages on the destination are persistent.</p> <p>WebSphere MQ Non-persistent Messages on the destination are not persistent.</p> <p>WebSphere MQ High Permit persistent messages to be sent as non-persistent messages when you use an underlying WebSphere MQ queue with a NPMCLASS of 'HIGH'.</p>

Priority:

The priority assigned to messages sent to this destination.

Data type	Drop-down list
Default	As set by application
Range	As set by application The priority of messages on this destination is defined by the application that put them onto the destination. As for WebSphere MQ queue definition Messages on the destination have their persistence defined by the WebSphere MQ destination definition properties. Specified The priority of messages on this destination is defined by the Specified priority property. If you select this option, you must define a priority on the Specified priority property.

Specified priority:

If the **Priority** property was set to Specified, select the priority assigned to messages sent to this queue type destination.

Data type	Drop-down list
Units	Message priority level
Default	As set by application
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

An option that specifies the expiry timeout for this destination.

Data type	Drop-down list
Default	As set by application
Range	As set by application The expiry timeout for messages on this destination is defined by the application that put them onto the destination. Specified The expiry timeout for messages on this destination is defined by the Specified expiry property. If you select this option, you must define a timeout on the Specified expiry property. Unlimited Messages on this destination have no expiry timeout, so these messages never expire.

Specified expiry:

If the **Expiry** property is set to Specified, enter the number of milliseconds after which messages expire and are removed from this destination.

Data type	Integer
Units	Milliseconds
Default	0
Range	Greater than or equal to 0 <ul style="list-style-type: none"> • 0 indicates that messages never timeout • Other values are an integer number of milliseconds

Coded character set identifier:

The character set to use when encoding strings in the message.

Data type	Integer
Default	1208
Range	1 through 65535. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ. Blank. Leaving this field empty indicates that the default value must be used.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration Guide* and *Application Programming Reference* sections of the WebSphere MQ information center.

Use native encoding:

An option that specifies whether the destination should use native encoding to provide appropriate encoding values for the Java platform.

Data type	Check box
Default	Selected
Range	Selected Native encoding is used. Cleared Native encoding is not used, so specify the properties for Integer encoding , Decimal encoding , and Floating point encoding .

Integer encoding:

If the **Use native encoding** check box is cleared, select the type of integer encoding to be used.

Data type	Drop-down list
Default	Normal
Range	Normal Normal integer encoding is used. Reversed Reversed integer encoding is used.

Decimal encoding:

If the **Use native encoding** check box is cleared, select the type of decimal encoding to be used.

Data type	Drop-down list
Units	Not applicable
Default	Normal

Range**Normal**

Normal decimal encoding is used.

Reversed

Reversed decimal encoding is used.

Floating point encoding:

If the **Use native encoding** check box is cleared, select the type of floating point encoding to be used.

Data type

Drop-down list

Default

IEEENORMAL

Range**IEEENORMAL**

IEEE normal floating point encoding is used.

IEEEVERSED

IEEE reversed floating point encoding is used.

z/OS

z/OS floating point encoding is used.

Append RFH version 2 headers to messages sent to this destination:

The action to take when replying to a message that is sent to this destination.

Data type

Check box

Default

Selected

Range**Cleared**

Do not append RFH version 2 headers to messages sent to this destination.

Selected

Append RFH version 2 headers to messages sent to this destination.

Message body:

Specifies whether an application processes the RFH version 2 header of a WebSphere MQ message as part of the JMS message body.

Data type

Drop-down list

Default

UNSPECIFIED

Range**UNSPECIFIED**

When sending messages, the WebSphere MQ messaging provider does or does not generate and include an RFH version 2 header, depending on the value of the Append RFH version 2 headers to messages sent to this destination property. When receiving messages, the WebSphere MQ messaging provider acts as if the value is set to JMS.

JMS

When sending messages, the WebSphere MQ messaging provider automatically generates an RFH version 2 header and includes it in the WebSphere MQ message. When receiving messages, the WebSphere MQ messaging provider sets the JMS message properties according to values in the RFH version 2 header (if these value are present); it does not present the RFH version 2 header as part of the JMS message body.

MQ

When sending messages, the WebSphere MQ messaging provider does not generate an RFH version 2 header. When receiving messages, the WebSphere MQ messaging provider presents the RFH version 2 header as part of the JMS message body.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Data type

Drop-down list

Default

DEFAULT

Range**DEFAULT**

The default value is equivalent to the information in the RFH version 2 header.

MQMD

Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.

RFH2

Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

Asynchronously send messages to the queue manager:

An option that enables the queue manager to acknowledge receipt of messages sent to it. Asynchronously sending messages to the queue manager is faster, but messages can be lost if the messaging infrastructure fails.

Data type

Drop-down list

Default	The default value depends on whether you are working with a queue or topic destination. As for queue definition The default value if you are working with a queue destination. As for topic definition The default value if you are working with a topic destination.
Range	As for queue definition Messages are acknowledged according to the WebSphere MQ queue definition properties. As for topic definition Messages are acknowledged according to the WebSphere MQ topic definition properties. Yes The queue manager acknowledges receipt of messages sent to it. No The queue manager does not acknowledge receipt of messages sent to it.

Read ahead and cache non-persistent messages for consumers:

An option that determines whether messages for non-persistent consumers are sent to the client speculatively. Selecting this option results in faster message delivery but messages can be lost in the event of a failure in the messaging infrastructure.

Data type	Drop-down list
Default	The default value depends on whether you are working with a queue or topic destination. As for queue definition This is the default value if you are working with a queue destination. As for topic definition This is the default value if you are working with a topic destination.
Range	As for queue definition Messages are sent to the client according to the WebSphere MQ queue definition properties. As for topic definition Messages are sent to the client according to the WebSphere MQ topic definition properties. Yes Messages are sent to the client speculatively. No Messages are not sent to the client speculatively.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Data type	Drop-down list
Default	DEFAULT

Range**DEFAULT**

The default value is equivalent to the information in the RFH version 2 header.

MQMD Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.

RFH2 Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Read ahead consumer close method:

If **Read ahead and cache non-persistent messages for consumers** is set to Yes or As for queue definition this property is enabled. This property determines what happens to messages in the internal read ahead buffer when the message consumer is closed.

Data type

Drop-down list

Default

Close method waits for all cached messages to be delivered

Range**Wait for all cached messages to be delivered**

All messages in the internal read ahead buffer are delivered to the application's message listener before returning.

Wait for the current message to be delivered

Only the current message listener invocation completes before returning, potentially leaving messages in the internal read ahead buffer, which are then discarded.

MQMD read enabled:

Specifies whether an application can read the values of MQMD fields from JMS messages that have been sent or received using the WebSphere MQ messaging provider.

Data type

Check box

Default

Cleared

Range**Cleared**

Applications cannot read the values of the MQMD fields.

Selected

Applications can read the values of the MQMD fields.

MQMD write enabled:

Specifies whether an application can write the values of MQMD fields to JMS messages that will be sent or received using the WebSphere MQ messaging provider.

Data type

Check box

Default

Cleared

Range**Cleared**

Applications cannot write the values of the MQMD fields.

Selected

Applications can write the values of the MQMD fields.

MQMD message context:

Defines the message context options specified when sending messages to a destination.

Data type

Drop-down list

Default

DEFAULT

Range**DEFAULT**

The MQOPEN API call and the MQPMO structure specify no explicit message context options.

SET_IDENTITY_CONTEXT

The MQOPEN API call specifies the message context option MQOO_SET_IDENTITY_CONTEXT, and the MQPMO structure specifies MQPMO_SET_IDENTITY_CONTEXT.

SET_ALL_CONTEXT

The MQOPEN API call specifies the message context option MQOO_SET_ALL_CONTEXT, and the MQPMO structure specifies MQPMO_SET_ALL_CONTEXT.

Configuring a topic for the WebSphere MQ messaging provider

Use this task to view or change the configuration of a JMS topic destination for publish/subscribe messaging with the WebSphere MQ messaging provider. This task contains an optional step for you to create a new JMS topic destination.

About this task

To optimize performance, configure the properties of a topic destination to best fit your applications. For more information, see Performance for WebSphere MQ topics.

To view or change the configuration of a topic destination for use with the WebSphere MQ messaging provider, or to create a new topic destination, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources > JMS->Topics** to view existing topic destinations, with a summary of their properties.
2. Select the **Scope** corresponding to the scope of the topic destinations that you want to view or change.
3. To view or change the properties of an existing topic destination, click its name in the list. Otherwise, to create a new topic destination, complete the following steps:
 - a. Click **New** in the content pane. Select **WebSphere MQ messaging provider** then click **OK**.
 - b. Specify the following required properties.

Name The name by which this topic destination is known for administrative purposes within WebSphere Application Server.

JNDI name

The Java Naming and Directory Interface (JNDI) name that is used to bind the topic destination into the namespace.

Topic name

The name of the WebSphere MQ topic to which messages are sent.

- c. Click **Apply**. This defines the topic destination to WebSphere Application Server, and enables you to browse or change additional properties.
4. Optional: Change WebSphere MQ topics settings according to your needs.
5. Click **OK**.
6. Save any changes to the master configuration.
7. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider topic settings

Use this panel to view or change the configuration properties of the selected JMS topic destination for publish/subscribe messaging with WebSphere MQ as a messaging provider.

A WebSphere MQ topic destination is used to configure the properties of a topic for the WebSphere MQ messaging provider. Connections to the topic are created using an associated WebSphere MQ topic connection factory or connection factory.

To view WebSphere MQ topic settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->Topics** to display existing topic destinations.
2. Select the name of the topic destination that you want to work with.
3. Optional: To create a new topic destination, click **New**.
4. Optional: To view or change the topic destination settings, select its name in the list displayed.

Under General Properties there are two groups of properties:

- Administration
- WebSphere MQ topic

Make any required changes to the Administration and WebSphere MQ topic groups of properties, and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click either of the following links:

- **Advanced properties** to display or change the advanced properties of your WebSphere MQ topic.
- **Custom properties** to display or change the custom properties of your WebSphere MQ topic.

Under Related items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the topic.

You can specify the following additional properties by using WebSphere MQ administrative commands:

- **wildcardFormat**
- **brokerVersion**

For more information about these properties, refer to the “createWMQTopic command” on page 987.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *Using Java and MQ System Administration* sections of the WebSphere MQ information center.

If WebSphere MQ functionality has been disabled at a scope that affects this WebSphere MQ messaging provider resource, then an informational message indicating that WebSphere MQ has been disabled appears. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

Scope:

The scope assigned to the topic when it is created. The scope specifies the level to which this topic definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource at a different scope, change the scope on the WebSphere MQ topic destination collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the topic is created.

For all topics created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which the topic is known for administrative purposes within WebSphere Application Server.

Data type String

JNDI name:

The name that is used to bind the topic into the JNDI namespace.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

Data type String

Description:

A description of the topic for administrative purposes within WebSphere Application Server.

Data type String

Topic name:

The WebSphere MQ name for the topic.

Data type String

Broker durable subscriber queue:

The queue to use for durable subscribers.

If this property is blank then the default WebSphere MQ value SYSTEM.JMS.D.SUBSCRIBER.QUEUE is used.

Data type String

Broker durable subscription connection consumer queue:

The queue to use for durable subscribers that use a connection consumer.

If this property is blank then the default WebSphere MQ value SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE is used.

Data type String

Broker publication queue:

The queue to use for publishing messages.

Data type Drop-down list
Default As connection
Range **As connection** The connection factory values are used.
Override connection Enter the name of a queue in the associated text box.

Broker publication queue manager:

The queue manager that hosts the topic.

Data type String

WebSphere MQ messaging provider queue and topic advanced properties settings:

Use this panel to view or change the advanced properties for the selected queue or topic destination for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ queue or topic advanced properties settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS**.
2. Click **Queues** or **Topics** to display existing queue or topic destinations.
3. If appropriate, in the content pane, change the **Scope** setting to the level at which the queue or topic destinations are defined. This restricts the set of queue or topic destinations displayed.
4. Click the name of the queue or topic destination that you want to work with.

- In the content pane, under Additional properties, click **Advanced properties** to display a list of the advanced properties of the WebSphere MQ queue or topic destination.

Under General Properties there are five groups of properties:

- Delivery
- Message format
- Optimizations
- Message descriptor
- Additional

Make any required changes to these groups and then click **Apply** to return to the queue or topic.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see *Using Java* section of the WebSphere MQ information center.

A queue or topic for use with the WebSphere MQ messaging provider has the following advanced properties.

Persistence:

The level of persistence used to store messages sent to this destination.

Data type	Drop-down list
Default	As set by application
Range	<p>As set by application Messages on the destination have their persistence defined by the application that put them onto the queue.</p> <p>As for WebSphere MQ queue definition Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.</p> <p>WebSphere MQ Persistent Messages on the destination are persistent.</p> <p>WebSphere MQ Non-persistent Messages on the destination are not persistent.</p> <p>WebSphere MQ High Permit persistent messages to be sent as non-persistent messages when you use an underlying WebSphere MQ queue with a NPMCLASS of 'HIGH'.</p>

Priority:

The priority assigned to messages sent to this destination.

Data type	Drop-down list
Default	As set by application

Range**As set by application**

The priority of messages on this destination is defined by the application that put them onto the destination.

As for WebSphere MQ queue definition

Messages on the destination have their persistence defined by the WebSphere MQ destination definition properties.

Specified

The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority on the **Specified priority** property.

Specified priority:

If the **Priority** property was set to Specified, select the priority assigned to messages sent to this queue type destination.

Data type	Drop-down list
Units	Message priority level
Default	As set by application
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

An option that specifies the expiry timeout for this destination.

Data type	Drop-down list
Default	As set by application
Range	As set by application The expiry timeout for messages on this destination is defined by the application that put them onto the destination. Specified The expiry timeout for messages on this destination is defined by the Specified expiry property. If you select this option, you must define a timeout on the Specified expiry property. Unlimited Messages on this destination have no expiry timeout, so these messages never expire.

Specified expiry:

If the **Expiry** property is set to Specified, enter the number of milliseconds after which messages expire and are removed from this destination.

Data type	Integer
Units	Milliseconds
Default	0
Range	Greater than or equal to 0 <ul style="list-style-type: none"> • 0 indicates that messages never timeout • Other values are an integer number of milliseconds

Coded character set identifier:

The character set to use when encoding strings in the message.

Data type	Integer
Default	1208
Range	1 through 65535. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ. Blank. Leaving this field empty indicates that the default value must be used.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration Guide* and *Application Programming Reference* sections of the WebSphere MQ information center.

Use native encoding:

An option that specifies whether the destination should use native encoding to provide appropriate encoding values for the Java platform.

Data type	Check box
Default	Selected
Range	Selected Native encoding is used. Cleared Native encoding is not used, so specify the properties for Integer encoding , Decimal encoding , and Floating point encoding .

Integer encoding:

If the **Use native encoding** check box is cleared, select the type of integer encoding to be used.

Data type	Drop-down list
Default	Normal
Range	Normal Normal integer encoding is used. Reversed Reversed integer encoding is used.

Decimal encoding:

If the **Use native encoding** check box is cleared, select the type of decimal encoding to be used.

Data type	Drop-down list
Units	Not applicable
Default	Normal
Range	Normal Normal decimal encoding is used. Reversed Reversed decimal encoding is used.

Floating point encoding:

If the **Use native encoding** check box is cleared, select the type of floating point encoding to be used.

Data type	Drop-down list
Default	IEEENORMAL
Range	IEEENORMAL IEEE normal floating point encoding is used. IEEEVERSED IEEE reversed floating point encoding is used. z/OS z/OS floating point encoding is used.

Append RFH version 2 headers to messages sent to this destination:

The action to take when replying to a message that is sent to this destination.

Data type	Check box
Default	Selected
Range	Cleared Do not append RFH version 2 headers to messages sent to this destination. Selected Append RFH version 2 headers to messages sent to this destination.

Message body:

Specifies whether an application processes the RFH version 2 header of a WebSphere MQ message as part of the JMS message body.

Data type	Drop-down list
Default	UNSPECIFIED
Range	UNSPECIFIED When sending messages, the WebSphere MQ messaging provider does or does not generate and include an RFH version 2 header, depending on the value of the Append RFH version 2 headers to messages sent to this destination property. When receiving messages, the WebSphere MQ messaging provider acts as if the value is set to JMS. JMS When sending messages, the WebSphere MQ messaging provider automatically generates an RFH version 2 header and includes it in the WebSphere MQ message. When receiving messages, the WebSphere MQ messaging provider sets the JMS message properties according to values in the RFH version 2 header (if these value are present); it does not present the RFH version 2 header as part of the JMS message body. MQ When sending messages, the WebSphere MQ messaging provider does not generate an RFH version 2 header. When receiving messages, the WebSphere MQ messaging provider presents the RFH version 2 header as part of the JMS message body.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Data type
Default
Range

Drop-down list
DEFAULT
DEFAULT

The default value is equivalent to the information in the RFH version 2 header.

MQMD Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.

RFH2 Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

Asynchronously send messages to the queue manager:

An option that enables the queue manager to acknowledge receipt of messages sent to it. Asynchronously sending messages to the queue manager is faster, but messages can be lost if the messaging infrastructure fails.

Data type
Default

Drop-down list
The default value depends on whether you are working with a queue or topic destination.

As for queue definition

The default value if you are working with a queue destination.

As for topic definition

The default value if you are working with a topic destination.

Range

As for queue definition

Messages are acknowledged according to the WebSphere MQ queue definition properties.

As for topic definition

Messages are acknowledged according to the WebSphere MQ topic definition properties.

Yes The queue manager acknowledges receipt of messages sent to it.

No The queue manager does not acknowledge receipt of messages sent to it.

Read ahead and cache non-persistent messages for consumers:

An option that determines whether messages for non-persistent consumers are sent to the client speculatively. Selecting this option results in faster message delivery but messages can be lost in the event of a failure in the messaging infrastructure.

Data type
Default

Drop-down list
The default value depends on whether you are working with a queue or topic destination.

As for queue definition

This is the default value if you are working with a queue destination.

As for topic definition

This is the default value if you are working with a topic destination.

Range**As for queue definition**

Messages are sent to the client according to the WebSphere MQ queue definition properties.

As for topic definition

Messages are sent to the client according to the WebSphere MQ topic definition properties.

Yes Messages are sent to the client speculatively.

No Messages are not sent to the client speculatively.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Data type

Drop-down list

Default

DEFAULT

Range**DEFAULT**

The default value is equivalent to the information in the RFH version 2 header.

MQMD Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.

RFH2 Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Read ahead consumer close method:

If **Read ahead and cache non-persistent messages for consumers** is set to Yes or As for queue definition this property is enabled. This property determines what happens to messages in the internal read ahead buffer when the message consumer is closed.

Data type

Drop-down list

Default

Close method waits for all cached messages to be delivered

Range**Wait for all cached messages to be delivered**

All messages in the internal read ahead buffer are delivered to the application's message listener before returning.

Wait for the current message to be delivered

Only the current message listener invocation completes before returning, potentially leaving messages in the internal read ahead buffer, which are then discarded.

MQMD read enabled:

Specifies whether an application can read the values of MQMD fields from JMS messages that have been sent or received using the WebSphere MQ messaging provider.

Data type

Check box

Default

Cleared

Range

Cleared

Applications cannot read the values of the MQMD fields.

Selected

Applications can read the values of the MQMD fields.

MQMD write enabled:

Specifies whether an application can write the values of MQMD fields to JMS messages that will be sent or received using the WebSphere MQ messaging provider.

Data type

Check box

Default

Cleared

Range

Cleared

Applications cannot write the values of the MQMD fields.

Selected

Applications can write the values of the MQMD fields.

MQMD message context:

Defines the message context options specified when sending messages to a destination.

Data type

Drop-down list

Default

DEFAULT

Range

DEFAULT

The MQOPEN API call and the MQPMO structure specify no explicit message context options.

SET_IDENTITY_CONTEXT

The MQOPEN API call specifies the message context option MQOO_SET_IDENTITY_CONTEXT, and the MQPMO structure specifies MQPMO_SET_IDENTITY_CONTEXT.

SET_ALL_CONTEXT

The MQOPEN API call specifies the message context option MQOO_SET_ALL_CONTEXT, and the MQPMO structure specifies MQPMO_SET_ALL_CONTEXT.

Configuring custom properties for WebSphere MQ messaging provider JMS resources

In addition to the standard properties that you can define for WebSphere MQ messaging provider JMS resources, you can configure further WebSphere MQ properties as custom properties. You can configure custom properties for activation specifications, connection factories, and JMS destinations for the WebSphere MQ messaging provider.

About this task

WebSphere Application Server supports the use of custom properties to define WebSphere MQ properties. This is useful because it enables WebSphere Application Server to work with later versions of WebSphere MQ that might have properties that are not exposed in WebSphere Application Server.

You can use this task to set custom properties for JMS destinations, connection factories, and activation specifications for the WebSphere MQ messaging provider. For example, you would use this task to set the custom property `WAS_EndpointInitialState` for an activation specification. `WAS_EndpointInitialState` determines whether or not message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

To specify custom properties for WebSphere MQ messaging provider JMS resources, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources > JMS**.
2. Select the type of JMS resource for which you want create custom properties (JMS destinations, connection factories, or activation specifications).
3. Optional: Change the **Scope** setting to the level at which the resource definition is visible to applications.
4. In the contents pane, select the specific WebSphere MQ messaging provider JMS resource name for which you want to specify the custom property. This displays information about the resource.
5. To create a custom property, select **[Additional Properties] Custom properties**.
6. Click **New** in the content pane.
7. Specify the following attributes for the new custom property:

Name

The name of the custom property. A property name is required.

Value The value for the custom property.

Type The type of the custom property. Select the custom property type from the list.

8. Click **Apply**. This defines the custom property to WebSphere Application Server, and enables you to browse or change additional properties.
9. Save any changes to the master configuration.
10. To have the changed configuration take effect, stop then restart the application server.

Example

To set the custom property `WAS_EndpointInitialState` for an activation specification, specify the following attributes:

- For **Name**, specify `WAS_EndpointInitialState`.
- For **Value**, specify one of the following options:

ACTIVE Specify a value of `ACTIVE` if message consumption is to begin as soon as the message-driven bean connects with the JMS destination.

INACTIVE

Specify a value of `INACTIVE` if message consumption is not to begin until you use the `wsadmin` tool or the administrative console to activate message consumption for the message-driven bean.

- For **Type**, select `String`.

WebSphere MQ messaging provider custom properties

WebSphere MQ messaging provider custom properties can be specified in the administrative console. Click **Resources > JMS**. Select the type of JMS resource for which you want create custom properties (JMS destinations, connection factories, or activation specifications). In the contents pane, select the specific WebSphere MQ messaging provider JMS resource name. Information about the resource is displayed. To create custom properties, select **[Additional Properties] Custom properties**.

You can define the following WebSphere MQ messaging provider custom properties:

- “WAS_EndpointInitialState”

WAS_EndpointInitialState

This custom property is for use with activation specifications.

This parameter determines whether the endpoint is activated when the endpoint is registered.

This parameter should be ignored for subsequent activation or deactivation via the J2CMessageEndpoint.

Table 58. WAS_EndpointInitialState custom property. The table includes the data type and acceptable values for the property.

Data type	String
Acceptable values	ACTIVE, INACTIVE

Configuring custom properties for WebSphere MQ messaging provider JMS resources

In addition to the standard properties that you can define for WebSphere MQ messaging provider JMS resources, you can configure further WebSphere MQ properties as custom properties. You can configure custom properties for activation specifications, connection factories, and JMS destinations for the WebSphere MQ messaging provider.

About this task

WebSphere Application Server supports the use of custom properties to define WebSphere MQ properties. This is useful because it enables WebSphere Application Server to work with later versions of WebSphere MQ that might have properties that are not exposed in WebSphere Application Server.

You can use this task to set custom properties for JMS destinations, connection factories, and activation specifications for the WebSphere MQ messaging provider. For example, you would use this task to set the custom property WAS_EndpointInitialState for an activation specification. WAS_EndpointInitialState determines whether or not message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

To specify custom properties for WebSphere MQ messaging provider JMS resources, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources > JMS**.
2. Select the type of JMS resource for which you want create custom properties (JMS destinations, connection factories, or activation specifications).
3. Optional: Change the **Scope** setting to the level at which the resource definition is visible to applications.
4. In the contents pane, select the specific WebSphere MQ messaging provider JMS resource name for which you want to specify the custom property. This displays information about the resource.
5. To create a custom property, select **[Additional Properties] Custom properties**.
6. Click **New** in the content pane.
7. Specify the following attributes for the new custom property:

Name

The name of the custom property. A property name is required.

Value The value for the custom property.

Type The type of the custom property. Select the custom property type from the list.

8. Click **Apply**. This defines the custom property to WebSphere Application Server, and enables you to browse or change additional properties.
9. Save any changes to the master configuration.
10. To have the changed configuration take effect, stop then restart the application server.

Example

To set the custom property `WAS_EndpointInitialState` for an activation specification, specify the following attributes:

- For **Name**, specify `WAS_EndpointInitialState`.
- For **Value**, specify one of the following options:

ACTIVE Specify a value of `ACTIVE` if message consumption is to begin as soon as the message-driven bean connects with the JMS destination.

INACTIVE

Specify a value of `INACTIVE` if message consumption is not to begin until you use the `wsadmin` tool or the administrative console to activate message consumption for the message-driven bean.

- For **Type**, select `String`.

WebSphere MQ resource custom properties settings

Use this page to specify custom properties that your enterprise information system (EIS) requires for the resource providers and resource factories that you configure. For example, most database vendors require additional custom properties for data sources that access the database.

To view this administrative console page, complete the following steps:

1. In the navigation pane, click **Resources > JMS->JMS providers**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider.
3. In the content pane, click the **WebSphere MQ messaging provider** that you want to support the JMS destination.
4. In the content pane, under Additional Properties, click the type of resource that you want to change, for example **Queues**.
5. Click the name of the resource that you want to work with.
6. In the content pane, under General Properties, complete the groups of fields, for example **Administration** and **WebSphere MQ Queue**.
7. In the content pane, under Additional Properties, click **Custom properties** to display a list of the custom properties of a WebSphere MQ resource.

A resource for use with the WebSphere MQ messaging provider has the following custom properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.

Name:

The name by which the resource is known for administrative purposes within WebSphere Application Server.

Data type String

Value:

The value of the resource.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the resource, for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Required:

Whether the resource is required, for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Configuring properties for the WebSphere MQ resource adapter

You can configure the WebSphere MQ resource adapter properties that affect the connection pool, which is used by WebSphere MQ messaging provider activation specifications.

About this task

There are four properties that are used to configure the WebSphere MQ resource adapter used by the WebSphere MQ messaging provider:

- **maxConnections**
- **connectionConcurrency**
- **reconnectionRetryCount**
- **reconnectionRetryInterval**

These four properties affect the connection pool, which is used by the WebSphere MQ messaging provider activation specifications. They do not affect the WebSphere MQ messaging provider queues, topics, or connection factories.

For further information about these properties, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

To configure the WebSphere MQ resource adapter properties, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources > JMS->JMS providers** to display a list of JMS providers in the content pane.
2. If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.

Note: These properties only have an effect on the WebSphere MQ messaging provider objects that are defined at the same scope as the messaging provider and resource adapter on which they are set. So, for example, if you set the **max connections** property to a particular setting at the server scope, only the server scoped WebSphere MQ messaging provider activation specifications are affected by this setting.

3. In the Providers column of the displayed list of JMS providers, click the name of the WebSphere MQ messaging provider that you want to work with.
4. In the content pane under Additional properties, click **Resource adapter properties** to view the configuration page for the properties.
5. Specify the required values for the properties:

Max connections

The maximum number of connections to a WebSphere MQ queue manager.

Connection concurrency

The maximum number of message-driven beans that can be supplied by each connection.

Reconnection retry count

The maximum number of attempts made by a WebSphere MQ messaging provider activation specification to reconnect to a WebSphere MQ queue manager if a connection fails.

Reconnection retry interval

The time, in milliseconds, that a WebSphere MQ messaging provider activation specification waits before making another attempt to reconnect to a WebSphere MQ queue manager.

6. Click **Apply**. This defines the property to WebSphere Application Server, and enables you to browse or change additional properties.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring custom properties for the WebSphere MQ resource adapter

In addition to the standard properties that you can specify for the WebSphere MQ resource adapter, you can configure custom properties for WebSphere MQ resource adapter.

About this task

WebSphere Application Server supports the definition of custom properties for the WebSphere MQ resource adapter. This is useful because it enables WebSphere Application Server to work with later versions of WebSphere MQ that might have properties that are not exposed in WebSphere Application Server.

To specify custom properties for the WebSphere MQ resource adapter, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources > JMS->JMS providers** to display a list of JMS providers in the content pane.
2. If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.

3. In the Providers column of the displayed list of JMS providers, click the name of the WebSphere MQ messaging provider that you want to work with.
4. In the content pane under Additional properties, click **Resource adapter properties** to view the configuration page for the properties.
5. In the content pane under Additional properties, click **Custom properties** to view the configuration page for the properties.
6. Click the name of the property that you want to configure then make any required changes.
7. Click **Apply**. This defines the custom property to WebSphere Application Server, and enables you to browse or change additional properties.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Disabling WebSphere MQ functionality in WebSphere Application Server

If you do not need to use WebSphere MQ functionality in an application server you can disable it by using either the administrative console or an administrative command. You can also disable WebSphere MQ functionality in a client process by specifying a custom property.

About this task

Note: When a WebSphere Application Server process or an application client process starts, and while this process is running, an amount of processing is performed to allow it to support WebSphere MQ-related functionality such as the WebSphere MQ messaging provider. By default this processing is performed regardless of whether any WebSphere MQ-related functionality is ever used. If you do not need to take advantage of any WebSphere MQ functionality, it is possible to disable all WebSphere MQ functionality in an application server or client process to give increased performance.

Disabling WebSphere MQ functionality in a WebSphere Application Server process has the following effects:

- No WebSphere MQ messaging provider functionality is available on that particular server:
 - Any defined WebSphere MQ messaging provider resources are not bound into JNDI, and so are unavailable to look up from inside the affected application server process, from other application server processes or application clients.
 - It is still possible to define WebSphere MQ messaging provider resources. However the **test connection** button on either the create connection factory or create activation specification wizard, depending on the scope at which WebSphere MQ has been disabled, does not work.
 - Any message driven beans that use message listener ports configured with WebSphere MQ messaging provider resources do not start.
 - Any message driven beans that use WebSphere MQ messaging provider activation specifications do not start.
 - It is not possible to recover any indoubt XA transactions involving WebSphere MQ messaging provider resources.
 - Any attempt to look up a WebSphere MQ messaging provider resource from a remote server that does not have WebSphere MQ functionality disabled fails.
 - It is not possible to use the WebSphere MQ queue connection properties function.
- No WebSphere MQ link functionality is available on that particular server:
 - It is not possible to stop or start any WebSphere MQ links.
 - It is not possible to stop or start any WebSphere MQ receiver channels.
 - It is not possible to stop, start, or reset any WebSphere MQ sender channels.

- It is not possible to send messages to a WebSphere MQ queue manager. Any messages that are sent to a foreign bus based on a WebSphere MQ link remain on the transmission item stream for that WebSphere MQ link.
- It is not possible to receive messages from a WebSphere MQ queue manager.
- The inbound channel chains used by the WebSphere MQ link do not start.
- It is not possible to resolve indoubt sender channels.
- Attempts to use the **Test connection** functionality of the foreign bus connection that uses the WebSphere MQ link fail.
- It is not possible to fully delete a WebSphere MQ link, as any stored state about indoubt messages cannot be processed.
- No WebSphere MQ server functionality is available on that particular server:
 - It is not possible to send messages to WebSphere MQ.
 - It is not possible to receive messages from WebSphere MQ.
 - The **Test connection** button does not work.
- No WebSphere MQ client link functionality works:
 - It is not possible to stop or start any WebSphere MQ client links.
 - It is not possible to send messages using a WebSphere MQ client link.
 - It is not possible to receive messages using a WebSphere MQ client link.
 - The inbound channel chains used by the WebSphere MQ link do not start.
- WebSphere MQ resource adapters do not start.
- WebSphere MQ Base Java functionality is unavailable.
- Any attempt to use any classes provided by WebSphere MQ fails.

Disabling WebSphere MQ functionality in a WebSphere Application Server client process has the following effects:

- Any attempt to look up a WebSphere MQ messaging provider resource from a remote server that does not have WebSphere MQ functionality disabled fails.
- WebSphere MQ Base Java functionality is not available.
- Any attempt to make use of any classes provided by WebSphere MQ fails.

Procedure

- To disable WebSphere MQ functionality in a WebSphere Application Server process, complete one of the following steps:
 - Using the administrative console, select the **Disable WebSphere MQ** check box on the required WebSphere MQ messaging provider panel.
 - Use the manageWMQ administrative command with the disableWMQ flag.

In a single server environment, you can only disable WebSphere MQ at the server scope. When you have saved your changes and restarted the application server, all WebSphere MQ functionality is disabled on that server.

In a network deployment environment, you can disable WebSphere MQ at all scopes in order to give fine grained configuration flexibility:

- At the cell scope, all WebSphere MQ functionality is disabled on all application servers in the cell.
- At the node scope, all WebSphere MQ functionality is disabled on all application servers that are part of that node.
- At the cluster scope, all WebSphere MQ functionality is disabled on all application servers in that cluster.
- At the server scope, all WebSphere MQ functionality is disabled in that particular application server.

The value of the **Disable WebSphere MQ** check box at a higher scope takes precedence over the value at a lower scope. For example, if you do not select the check box at the server scope but do select it for a higher (for example, cell) scoped WebSphere MQ messaging provider, the value at the cell scope takes precedence and WebSphere MQ functionality is therefore disabled in all application servers in the cell, regardless of whether the check box is selected at the server scope. The changes take effect when you have saved them and restarted all affected processes in the cell.

- To disable WebSphere MQ functionality in a WebSphere Application Server client process, specify the custom property `com.ibm.ejs.jms.disableWMQSupport=true`.

Example

Consider the following example: A network deployment configuration with two nodes: node1 and node2. Node1 has two servers on it, server1 and server2. Node2 has a single server on it, server3. Server3 and server1 are part of a cluster, cluster1. The WebSphere MQ messaging provider panel at cluster1 scope has the **WebSphere MQ disabled** check box selected and the changes saved. When cluster1 has been restarted, all WebSphere MQ functionality is disabled on server3 and server1.

It is worth noting that it is possible to have WebSphere MQ functionality disabled on all processes in a network deployment configuration without all scopes having WebSphere MQ functionality disabled. Using the scenario in the previous example, if all nodes in the topology (deployment manager node, node1 and node2) have WebSphere MQ functionality disabled, then all the processes in the topology also have WebSphere MQ functionality disabled.

What to do next

When the server starts, it is possible to detect whether WebSphere MQ functionality has been disabled on that server because messages with the following ids are output:

- WMSG2016I is output when the server starts if WebSphere MQ has been disabled.
- CWSIC3650I is output once for any configured WebSphere MQ links that are running on the server.
- CWSIC3713I is output once for any configured WebSphere MQ client links that are running on the server.

WMQAdminCommands command group for the AdminTask object

You can use the WebSphere MQ administrative commands to manage JMS resources for the WebSphere MQ messaging provider.

You can configure JMS resources for the WebSphere MQ messaging provider through the WebSphere MQ administrative commands, or you can configure JMS resources for the WebSphere MQ messaging provider through the administrative console.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

These commands are valid only when they are used with WebSphere Application Server Version 7 and later application servers. Do not use them with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using these commands, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

The following commands are available for the WMQAdminCommands group of the AdminTask object:

- createWMQActivationSpec command
- deleteWMQActivationSpec command
- listWMQActivationSpec command
- modifyWMQActivationSpec command
- showWMQActivationSpec command
- createWMQConnectionFactory command
- deleteWMQConnectionFactory command
- listWMQConnectionFactory command
- modifyWMQConnectionFactory command
- showWMQConnectionFactory command
- createWMQTopic command
- deleteWMQTopic command
- listWMQTopic command
- modifyWMQTopic command
- showWMQTopic command
- manageWMQ command
- migrateWMQMLP command
- createWMQQueue command
- deleteWMQQueue command
- listWMQQueue command
- modifyWMQQueue command
- showWMQQueue command

createWMQActivationSpec command

Use the createWMQActivationSpec command to create an activation specification for the WebSphere MQ messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the `createWMQActivationSpec` command to create a WebSphere MQ messaging provider activation specification at a specific scope.

You cannot create a WebSphere MQ messaging provider activation specification under either of the following conditions:

- A WebSphere MQ messaging provider activation specification already exists with the same name, at the same scope.
- The JNDI name clashes with another entry in WebSphere Application Server JNDI.

You create a CCDT based activation specification by specifying any of the following parameters:

- **-ccdtUrl**
- **-ccdtQmgrName**

If you do not specify any of the following parameters, you create a generic activation specification :

- **-ccdtUrl**
- **-ccdtQmgrName**

Target object

The scope of the WebSphere MQ messaging provider at which the WebSphere MQ messaging provider activation specification is to be created.

Required parameters

-name

The administrative name assigned to this WebSphere MQ messaging provider activation specification.

-jndiName

The name and location used to bind this object into WebSphere Application Server JNDI.

-destinationJndiName

The JNDI name of a WebSphere MQ messaging provider queue or topic type destination. When an MDB is deployed with this activation specification, messages for the MDB are consumed from this destination.

-destinationType

The type of the destination specified by using the **-destinationJndiName** parameter.

Enter one of the following values:

- `javax.jms.Queue`
- `javax.jms.Topic`

There is no default value.

Optional parameters

-description

An administrative description assigned to the activation specification.

-ccdtUrl

A URL to a client channel definition table to use, for this activation specification, when contacting WebSphere MQ.

Use this parameter to create ccdtURL activation specifications

Do not specify this parameter in conjunction with the following parameters: **-qmgrName**, **-qmgrType**, **-qmgrHostname**, **-qmgrPortNumber**, **-qmgrSvrconnChannel**, or **-localAddress**.

-ccdtQmgrName

A queue manager name, used to select one or more entries from a client channel definition table.

You must specify this parameter if the **-transportType** has been specified as client or bindingsThenClient.

Do not specify this parameter in conjunction with the following parameters: **-qmgrName**, **-qmgrType**, **-qmgrHostname**, **-qmgrPortNumber**, **-qmgrSvrconnChannel**, or **-localAddress**.

-qmgrName

The name of the queue manager to use, for this activation specification, when contacting WebSphere MQ.

Use this parameter to create generic activation specifications.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-wmqTransportType

This parameter determines the way in which a connection is established to WebSphere MQ for this activation specification.

Use this parameter to create generic activation specifications.

Enter one of the following case-sensitive values:

- BINDINGS
- BINDINGS_THEN_CLIENT
- CLIENT

BINDINGS_THEN_CLIENT is the default value.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For more information about configuring a transport type of bindings then client or bindings, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 806.

-qmgrHostname

The host name to use, for this activation specification, when attempting a client mode connection to WebSphere MQ. It must be a valid TCP/IP host name or IPv4 or IPv6 address.

The default value is the local host.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For information on setting the **-qmgrHostname** parameter in conjunction with the **-connectionNameList** parameter, see the description of the **-connectionNameList** parameter.

-qmgrPortNumber

The port number to use, for this activation specification, when attempting a client mode connection to WebSphere MQ.

Enter an integer value in the range 1 - 65536 (inclusive).

The default value is 1414.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For information on setting the **-qmgrPortNumber** parameter in conjunction with the **-connectionNameList** parameter, see the description of the **-connectionNameList** parameter.

-connectionNameList

The connection name list specifying the host name and port details to use when you want the activation specification to connect to a multi-instance queue manager.

Note: You must only use the **-connectionNameList** parameter to allow a connection to a multi-instance queue manager. Using the **-connectionNameList** parameter to connect to a non-multi-instance queue manager can jeopardize transaction integrity.

The **-connectionNameList** parameter must be entered as a comma separated list of host names and ports in the following format:

host(port),host(port)

For *host* enter a valid TCP/IP host name, IPv4 or IPv6 address.

For *port* enter an integer value between 1 and 65536 (inclusive). Specifying a value for *port* is optional. When you do not specify a value, *port* defaults to 1414.

For example: localhost(1234),remotehost(1234),remotehost2

When you specify the **-connectionNameList** parameter, the **-qmgrHostname** and **-qmgrPortNumber** parameters are automatically set to the host name and port number of the first entry in the connection name list. This overrides any values that you previously specified in the **-qmgrHostname** and **-qmgrPortNumber** parameters.

In the preceding example this would mean that **-qmgrHostname** would be localhost and **-qmgrPortNumber** would be 1234.

The **-connectionNameList** parameter is only valid for use in WebSphere Application Server Version 8.0.

Attempting to specify the **-connectionNameList** parameter on a WebSphere MQ messaging provider activation specification which is defined at a server or node scope that is running on a version of WebSphere Application Server earlier than Version 8.0 results in an error message when you run the following commands:

- createWMQActivationSpec
- modifyWMQActivationSpec

If you specify the **-connectionNameList** parameter on a cell or cluster-scoped WebSphere MQ activation specification, you can use it for nodes that are running WebSphere Application Server Version 7.0. The exact behaviour is determined by the fix pack level of the node:

- For nodes running at WebSphere Application Server Version 7.0 Fix Pack 7 or later, the activation specification uses the **-connectionNameList** parameter to connect to a multi-instance queue manager.
- For nodes running at a fix pack level earlier than WebSphere Application Server Version 7.0 Fix Pack 7, a warning message similar to the one in the following example is output:

```
[29/09/10 12:15:27:468 BST] 00000018 J2CUtilityCla W J2CA0008W: Class com.ibm.mq.connector.inbound.ActivationSpecIn
```

You can ignore this message.

You must not specify the **-connectionNameList** parameter in conjunction with the **-ccdtUrl** or **-ccdtQmgrName** parameters.

Note: If you use the **-connectionNameList** parameter with a centrally managed SSL configuration the host name and port number information used to select the appropriate SSL configuration is

based on the first entry in the **-connectionNameList**, regardless of which entry in the list is actually used to connect to the queue manager. This is because each instance of a multi-instance queue manager should be using the same SSL configuration, for a given server connection channel, regardless of which instance is actually running.

For more information on using multi-instance queue managers, see the WebSphere MQ information center.

-authAlias

The authentication alias used to obtain the credentials specified when this activation specification needs to establish a connection to WebSphere MQ.

-clientId

The client identifier used for connections started by using this activation specification.

-providerVersion

This parameter determines the minimum version, and capabilities of the queue manager.

Enter values in one of the following formats:

- *n*
- *n.n*
- *n.n.n*
- *n.n.n.n*

where *n* is an integer greater than or equal to zero.

For example 6.0.0.0

-sslCr1

This parameter specifies a list of LDAP servers that are used to provide certificate revocation information if this activation specification establishes an SSL based connection to WebSphere MQ.

-sslResetCount

This parameter is used when the activation specification establishes an SSL connection to the queue manager. This parameter determines how many bytes to transfer before resetting the symmetric encryption key that is used for the SSL session.

Enter a value in the range 0 through 999,999,999.

The default value is 0.

-sslPeerName

This parameter is used when the activation specification establishes an SSL connection to the queue manager. The value is compared with the distinguished name present in the peer's certificate.

-rcvExit

A comma-separated list of receive exit class names.

-rcvExitInitData

Initialization data to pass to the receive exit.

Do not specify this parameter unless you specify the **-rcvExit** parameter.

-sendExit

A comma-separated list of send exit class names.

-sendExitInitData

Initialization data to pass to the send exit.

Do not specify this parameter unless you specify the **-sendExit** parameter.

-secExit

A security exit class name.

-secExitInitData

Initialization data to pass to the security exit.

Do not specify this parameter unless you specify the **-secExit** parameter.

-compressHeaders

This parameter determines if message headers are compressed.

Enter one of the following values:

- NONE
- SYSTEM

The default value is NONE.

-compressPayload

This parameter determines if message payloads are compressed.

Enter one of the following values:

- NONE
- RLE
- ZLIBFAST
- ZLIBHIGH

The default value is NONE.

-msgRetention

This parameter determines if the connection consumer keeps unwanted messages on the input queue.

Enter one of the following values:

- YES
- NO

where YES specifies that the connection consumer keeps unwanted messages on the input queue, and NO specifies that the messages are disposed of according to their disposition options.

The default value is YES.

-rescanInterval

When a message consumer in the point-to-point domain uses a message selector to select which messages it is to receive, the JMS client searches the WebSphere MQ queue for suitable messages in the sequence determined by the `MsgDeliverySequence` attribute of the queue. When the client finds a suitable message and delivers it to the consumer, the client resumes the search for the next suitable message from its current position in the queue. The client continues to search the queue in this way until it reaches the end of the queue, or until the interval of time in milliseconds, as determined by the value of this **-rescanInterval** parameter has expired. In each case, the client returns to the beginning of the queue to continue its search, and a new time interval commences.

This parameter must be a positive integer value.

The default value is 5000.

-ccsid

The coded character set identifier (CCSID) to be used on connections.

The value of this parameter must be a positive integer and must be one of the CCSIDs supported by WebSphere MQ. See the "WebSphere MQ messaging provider activation specification advanced properties" on page 833 for more details.

The default value is 819.

-failIfQuiescing

This parameter determines the behavior of certain calls to the queue manager when the queue manager is put into quiescing state.

The value of this parameter must be true or false.

true specifies that calls to certain methods fail if the queue manager is in a quiescing state. If an application detects that the queue manager is quiescing, the application can complete its immediate task and close the connection, allowing the queue manager to stop.

false specifies that no methods fail if the queue manager is in a quiescing state. If you specify this value, an application cannot detect that the queue manager is quiescing. The application might continue to perform operations against the queue manager, and therefore prevent the queue manager from stopping.

The default value is true.

-brokerCtrlQueue

The name of the broker control queue to use if this activation specification is to subscribe to a topic.

The default value is SYSTEM.BROKER.CONTROL.QUEUE.

-brokerSubQueue

The name of the queue to use for obtaining subscription messages if this activation specification is to subscribe to a topic.

The default value is SYSTEM.JMS.ND.SUBSCRIBER.QUEUE.

-brokerCCSubQueue

The name of the queue from which non-durable subscription messages are retrieved for a ConnectionConsumer.

The default value is SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE.

-brokerVersion

The value of this parameter determines the level of functionality required for publish/subscribe operations.

Valid values are 1 and 2.

The default value is 1.

-msgSelection

This parameter determines where message selection occurs.

Valid values are CLIENT and BROKER.

The default value is CLIENT.

-subStore

This parameter determines where WebSphere MQ messaging provider stores persistent data relating to active subscriptions.

Valid values are MIGRATE, QUEUE and BROKER.

The default value is MIGRATE.

-stateRefreshInt

The interval, in milliseconds, between refreshes of the long running transaction that detects when a subscriber loses its connection to the queue manager. This parameter is relevant only if **-subStore** parameter has the value QUEUE.

The value of this parameter must be a positive integer.

The default value is 60,000.

-cleanupLevel

The cleanup level for BROKER or MIGRATE subscription stores.

Valid values are SAFE, NONE, ASPROP, and STRONG.

The default value is SAFE.

-cleanupInterval

The interval between background executions of the publish/subscribe cleanup utility.

The value of this parameter must be a positive integer.

The default value is 3,600,000.

-wildcardFormat

This parameter determines which sets of characters are interpreted as topic wildcards.

Valid values are Topic or Char.

The default value is Char.

-sparseSubs

This parameter controls the message retrieval policy of a TopicSubscriber object.

The value of this parameter must be true or false

The default value is false.

-brokerQmgr

The name of the queue manager on which the broker is running.

-clonedSubs

This parameter determines whether two or more instances of the same durable topic subscriber can run simultaneously.

The value of this parameter must be ENABLED or DISABLED

The default value is DISABLED.

-qmgrSvrconnChannel

The SVRCONN channel to use when connecting to WebSphere MQ.

Use this parameter to create **explicitly defined** activation specifications.

The default value is SYSTEM.DEF.SVRCONN.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-brokerCCDurSubQueue

The name of the queue from which a connection consumer receives durable subscription messages.

The default value is SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE.

-maxPoolSize

The maximum number of server sessions in the server session pool used by the connection consumer.

The value of this parameter must be a positive integer.

The default value is 10.

-messageSelector

A message selector expression specifying which messages are to be delivered.

The value of this parameter must be either the empty string or a valid SQL 92 statement.

-poolTimeout

The period of time, in milliseconds, that an unused server session is held open in the server session pool before being closed due to inactivity.

The value of this parameter must be a positive integer.

The default value is 300,000.

-startTimeout

The period of time, in milliseconds, within which delivery of a message to an MDB must start after the work to deliver the message has been scheduled. If this period of time elapses, the message is rolled back onto the queue.

The value of this parameter must be a positive integer.

The default value is 10,000.

-subscriptionDurability

This parameter determines whether a durable or nondurable subscription is used to deliver messages to an MDB that is subscribing to the topic.

The value of this parameter must be Durable or Nondurable

The default value is Nondurable.

-subscriptionName

The name of the durable subscription.

-customProperties

This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider activation specification implementation. Typically, custom properties are used to set attributes of the activation specification which are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:

- In Jython: [*name value*]
- In Jacl: {*name value*}

For example, **-WAS_EndpointInitialState** is a custom property that can be used with the **-customProperties** parameter. The value of **-WAS_EndpointInitialState** must be ACTIVE or INACTIVE. **-WAS_EndpointInitialState** determines whether the endpoint is activated when the endpoint is registered. If the parameter is set to active, message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

This parameter should be ignored for subsequent activation or deactivation via the J2CMessageEndpoint MBean.

-localAddress

This parameter specifies either or both of the following:

- the local network interface
- the local port, or range of local ports

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-sslType

This parameter determines the configuration, if any, to use when applying SSL encryption to the network connection to the queue manager.

The value of this parameter must be CENTRAL, SPECIFIC or NONE

The **-sslConfiguration** parameter is not valid unless this parameter is set to SPECIFIC.

The default value is NONE.

-sslConfiguration

The name of the SSL configuration to use when using SSL to secure network connections to the queue manager.

Do not specify this parameter unless the parameter **-sslType** is assigned the value SPECIFIC.

The value of this parameter must correspond to an SSL configuration.

There is no default value.

-stopEndpointIfDeliveryFails

This parameter indicates whether the endpoint should be stopped if message delivery fails the number of times specified by the **failureDeliveryCount** property.

The value of this parameter must be true or false.

The default value is true.

-failureDeliveryCount

This parameter specifies the number of sequential delivery failures that are allowed before the endpoint is suspended. This value is only used if **stopEndpointIfDeliveryFails** is true.

The value of this parameter must be a non-negative integer.

The default value is 0, which means that the endpoint is stopped the first time it fails.

Minimal activation specification definition

The following example creates an activation specification, specifying the minimum number of parameters. Due to the default values assumed for the unspecified parameters, MDBs deployed by using this activation specification are co-located with a generic queue manager installed on the same node.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>AdminTask.createWMQActivationSpec("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)", ["-name spec1 -jndiName jms/as/spec1
-destinationJndiName jms/queues/q1 -destinationType javax.jms.Queue"])
spec1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask createWMQActivationSpec
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name spec1 -jndiName jms/as/spec1 -destinationJndiName jms/queues/q1
-destinationType javax.jms.Queue}
spec1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)
```

Explicit activation specification definition

The following example creates an activation specification for which the user must specify and maintain all the parameters used for establishing a connection to WebSphere MQ.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>AdminTask.createWMQActivationSpec("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)", ["-name spec2 -jndiName 'jms/as/spec2'
-destinationJndiName 'jms/topics/t2' -destinationType javax.jms.Topic
-description 'Must remember to keep each of these activation specifications in
```

```

sync with the WebSphere MQ queue manager to which they refer' -qmgrName QM1
-qmgrHostname 192.168.0.22 -qmgrPort 1415 -qmgrSvrconnChannel QM1.SVRCONN"])
spec2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234987)

```

- Using Jacl:

```

wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask createWMQActivationSpec
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name spec2 -jndiName "jms/as/spec2" -destinationJndiName "jms/topics/t2"
-destinationType javax.jms.Topic -description "Must remember to keep each
of these activation specifications in sync with the WebSphere MQ queue manager
to which they refer" -qmgrName QM1 -qmgrHostname 192.168.0.22 -qmgrPort 1415
-qmgrSvrconnChannel QM1.SVRCONN}
spec2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234987)

```

Activation specification definition specifying a CCDT

The following example creates an activation specification that uses a CCDT to locate the queue manager to connect to.

- Using Jython:

```

wsadmin>AdminConfig.getid("/Node:9994GKCNODE019994GKCNODE01(cells/
9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)")

wsadmin>AdminTask.createWMQActivationSpec("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)", ["-name spec3 -jndiName 'jms/as/spec3'
-destinationJndiName 'jms/queue/q3' -destinationType javax.jms.Queue
-ccdtUrl 'http://gorillaaction:9080/ccdt/amqclchl.tab' -ccdtQmgrName QM3"])
spec3(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234988)

```

- Using Jacl:

```

wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask createWMQActivationSpec
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name spec3 -jndiName "jms/as/spec3" -destinationJndiName "jms/queue/q3"
-destinationType javax.jms.Queue -ccdtUrl "http://gorillaaction:9080/ccdt/
amqclchl.tab" -ccdtQmgrName QM3}
spec3(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234988)

```

Creating an activation specification with the -WAS_EndpointInitialState custom property set to ACTIVE

- The following example creates an activation specification with the WAS_EndpointInitialState custom property activated, using Jython:

```

wsadmin>attrs = '[[name "WAS_EndpointInitialState"] [required "false"] [type "java.lang.String"] [value "ACTIVE"]]'
wsadmin>AdminConfig.getid("/Node:myNode01")
myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)'
wsadmin>theActSpec = AdminTask.createWMQActivationSpec("myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)",

```

deleteWMQActivationSpec command

Use this command to delete a WebSphere MQ messaging provider activation specification at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the `deleteWMQActivationSpec` command to delete a WebSphere MQ messaging provider activation specification defined at the scope at which the command is issued.

Target object

A WebSphere MQ messaging provider activation specification at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>AdminTask.listWMQActivationSpecs("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)")
unwantedSpec(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)

wsadmin>AdminTask.deleteWMQActivationSpec("unwantedSpec(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|resources.xml#J2CActivationSpec_1098737234986)")
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask listWMQActivationSpecs
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
unwantedSpec(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)

wsadmin>$AdminTask deleteWMQActivationSpec
unwantedSpec(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)
```

listWMQActivationSpecs command

Use the listWMQActivationSpecs command to list WebSphere MQ messaging provider activation specifications.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the listWMQActivationSpecs command to list all of the WebSphere MQ messaging provider activation specifications defined at the scope at which the command is issued.

Target object

WebSphere MQ messaging provider activation specifications at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCN01")
9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQActivationSpecs("9994GKCN01(cells/9994GKCN01Cell/
nodes/9994GKCN01|node.xml#Node_1)")
spec1(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCN01
9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listWMQActivationSpecs
9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)
spec1(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
J2CActivationSpec_1098737234986)
```

modifyWMQActivationSpec command

Use the modifyWMQActivationSpec command to change certain parameters of a WebSphere MQ messaging provider activation specification.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the modifyWMQActivationSpec command to modify a WebSphere MQ messaging provider activation specification defined at the scope at which the command is issued.

Note: You cannot change the type of an activation specification. For example, you cannot create an activation specification where you enter all the configuration information manually and then modify it to use a CCDT.

For a CCDT-based activation specification, you cannot modify any of the following parameters:

- **qmgrName**
- **qmgrHostname**
- **qmgrPortNumber**
- **qmgrSrvconnChannel**
- **transportChain**
- **wmqTransportType**

For a generic activation specification, you cannot modify any of the following parameters:

- **ccdtUrl**
- **ccdtQmgrName**

Target object

A WebSphere MQ messaging provider activation specification at the specific scope.

Required parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider activation specification.

Optional parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider activation specification.

Note: If either the **-qmgrHostname** or **-qmgrPortNumber** parameters are specified without the **-connectionNameList** parameter being specified, then it is assumed that a connection name list should no longer be used to connect to WebSphere MQ and that the specified host name and port number information should be used instead. As a result of this the **-connectionNameList** parameter is set to blank.

Note the behavior of this command on the **-customProperties** parameter.

-customProperties

This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider activation specification implementation. Typically, custom properties are used to set attributes of the activation specification which are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:

- In Jython: [*name value*]
- In Jacl: {*name value*}

For example, **-WAS_EndpointInitialState** is a custom property that can be used with the **-customProperties** parameter. The value of **-WAS_EndpointInitialState** must be ACTIVE or INACTIVE. **-WAS_EndpointInitialState** determines whether the endpoint is activated when the endpoint is registered. If the parameter is set to active, message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

This parameter should be ignored for subsequent activation or deactivation via the J2CMessageEndpoint MBean.

New name/value pairs are added to the existing set of custom properties using the following rules:

- If the existing set of properties does not contain a property with the same name as that supplied as part of a modify command, the supplied property is added to the set of custom properties, unless the custom property has no value specified, when it is disregarded.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, and the modify command also specifies a value for the property, the existing value is replaced by the supplied value.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, but the modify command does not specify a value for the property, the property with the same name is deleted from the existing set of custom properties.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQActivationSpecs("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)")
spec1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)
```

```
wsadmin>AdminTask.modifyWMQActivationSpec("spec1(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|resources.xml#J2CActivationSpec_1098737234986)",
["-destinationJndiName jms/topics/t5 -destinationType javax.jms.Topic"])
spec1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listWMQActivationSpecs
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
spec1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)
```

```
wsadmin>$AdminTask modifyWMQActivationSpec
spec1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)
{-destinationJndiName jms/topics/t5 -destinationType javax.jms.Topic}
spec1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)
```

- The following example modifies an activation specification by activating the `WAS_EndpointInitialState` custom property, using Jython:

```
wsadmin>AdminConfig.getid("/Node:myNode01")
'myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)'
wsadmin>wsadmin>AdminTask.listWMQActivationSpecs("myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)")
'newas(cells/myCell01/nodes/myNode01|resources.xml#J2CActivationSpec_1298546034140)'
wsadmin>AdminTask.modifyWMQActivationSpec("newas(cells/myCell01/nodes/myNode01|resources.xml#J2CActivationSpec_1298546034140)")
```

showWMQActivationSpec command

Use the `showWMQActivationSpec` command to display information about a specific WebSphere MQ messaging provider activation specification.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the `showWMQActivationSpec` command to display all the parameters, and their values, associated with a particular WebSphere MQ messaging provider activation specification.

Target object

A WebSphere MQ messaging provider activation specification at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>AdminTask.listWMQActivationSpecs("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)")
spec1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)

wsadmin>AdminTask.showWMQActivationSpec("spec1(cells/9994GKCNODE01Cell/nodes/
9994GKCNODE01|resources.xml#J2CActivationSpec_1098737234986)")
{cleanupLevel=SAFE, useConnectionPooling=true, port=1414, maxPoolDepth=10,
channel=channel1, transportType=CLIENT, subscriptionStore=MIGRATE,
messageSelection=CLIENT, cleanupInterval=3600000,
brokerCCSubQueue=SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE, name=spec1, CCSID=819,
useJNDI=true, hostName=localhost, rescanInterval=5000, headerCompression=NONE,
brokerCCDurSubQueue=SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE, queueManager=QMGR1,
messageCompression=NONE, startTimeout=10000, destinationJndiName=jms/q1,
poolTimeout=300000, sslType=NONE,
destinationType=javax.jms.Queue, brokerSubQueue=SYSTEM.JMS.ND.SUBSCRIBER.QUEUE,
sslResetCount=0, brokerControlQueue=SYSTEM.BROKER.CONTROL.QUEUE,
stateRefreshInt=60000, cloneSupport=DISABLED, jndiName=jms/as1,
sparseSubscriptions=false, authenticationAlias=null, failIfQuiesce=true,
description=, brokerVersion=1}
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask listWMQActivationSpecs
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
spec1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)

wsadmin>$AdminTask showWMQActivationSpec
spec1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
J2CActivationSpec_1098737234986)
{cleanupLevel=SAFE, useConnectionPooling=true, port=1414, maxPoolDepth=10,
channel=channel1, transportType=CLIENT, subscriptionStore=MIGRATE,
messageSelection=CLIENT, cleanupInterval=3600000,
brokerCCSubQueue=SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE, name=spec1, CCSID=819,
useJNDI=true, hostName=localhost, rescanInterval=5000, headerCompression=NONE,
brokerCCDurSubQueue=SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE, queueManager=QMGR1,
messageCompression=NONE, startTimeout=10000, destinationJndiName=jms/q1,
poolTimeout=300000, sslType=NONE,
destinationType=javax.jms.Queue, brokerSubQueue=SYSTEM.JMS.ND.SUBSCRIBER.QUEUE,
sslResetCount=0, brokerControlQueue=SYSTEM.BROKER.CONTROL.QUEUE,
stateRefreshInt=60000, cloneSupport=DISABLED, jndiName=jms/as1,
sparseSubscriptions=false, authenticationAlias=null, failIfQuiesce=true,
description=, brokerVersion=1}
```

createWMQConnectionFactory command

Use the createWMQConnectionFactory command to create a connection factory for the WebSphere MQ messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the `createWMQConnectionFactory` command to create a WebSphere MQ messaging provider connection factory at a specific scope.

You cannot create a WebSphere MQ messaging provider connection factory under either of the following conditions:

- A WebSphere MQ messaging provider connection factory already exists with the same name, at the same scope.
- The JNDI name clashes with another entry in WebSphere Application Server JNDI.

Target object

The scope of the WebSphere MQ messaging provider at which the WebSphere MQ messaging provider connection factory is to be created.

Required parameters

-name

The administrative name assigned to this WebSphere MQ messaging provider connection factory.

-jndiName

The name and location used to bind this object into WebSphere Application Server JNDI.

-type

Use this parameter to determine whether a unified connection factory, a queue connection factory or a topic connection factory is to be created.

Enter one of the following values:

- CF
- QCF
- TCF

CF is the default value.

If you specify QCF, you cannot specify any of the following parameters:

- **-brokerCtrlQueue**
- **-brokerSubQueue**
- **-brokerCCSubQueue**
- **-brokerVersion**

- **-brokerPubQueue**
- **-tempTopicPrefix**
- **-pubAckWindow**
- **-subStore**
- **-stateRefreshInt**
- **-cleanupLevel**
- **-sparesSubs**
- **-wildcardFormat**
- **-brokerQmgr**
- **-clonedSubs**
- **-msgSelection**

If you specify TCF, you cannot specify any of the following parameters:

- **-msgRetention**
- **-rescanInterval**
- **-tempQueuePrefix**
- **-modelQueue**
- **-replyWithRFH2**

Optional parameters

-description

An administrative description assigned to the connection factory.

-ccdtUrl

A URL to a client channel definition table to use, for this connection factory, when contacting WebSphere MQ.

Use this parameter to create a ccdtURL connection factory

Do not specify this parameter in conjunction with the following parameters: **-qmgrName**, **-qmgrHostname**, **-qmgrPortNumber**, **-qmgrSvrconnChannel**, **-wmqTransportType** or **-localAddress**.

-ccdtQmgrName

A queue manager name, used to select one or more entries from a client channel definition table.

Do not specify this parameter in conjunction with the following parameters: **-qmgrName**, **-qmgrHostname**, **-qmgrPortNumber**, **-qmgrSvrconnChannel**, **-wmqTransportType**, or **-localAddress**.

-qmgrName

The name of the queue manager to use, for this connection factory, when contacting WebSphere MQ.

Use this parameter to create a generic connection factory.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-wmqTransportType

This parameter determines the way in which a connection is established to WebSphere MQ for this connection factory.

Use this parameter to create a generic connection factory.

Enter one of the following values:

- BINDINGS
- BINDINGS_THEN_CLIENT

- CLIENT

The default value is BINDINGS_THEN_CLIENT.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For more information about configuring a transport type of BINDINGS_THEN_CLIENT or BINDINGS, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 806.

-qmgrHostname

The host name to use, for this connection factory, when attempting a client mode connection to WebSphere MQ. It must be a valid TCP/IP host name or IPv4 or IPv6 address.

The default value is the local host.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For information on setting the **-qmgrHostname** parameter in conjunction with the **-connectionNameList** parameter, see the description of the **-connectionNameList** parameter.

-qmgrPortNumber

The port number to use, for this connection factory, when attempting a client mode connection to WebSphere MQ.

Enter an integer value in the range 1 - 65536 (inclusive).

The default value is 1414.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For information on setting the **-qmgrPortNumber** parameter in conjunction with the **-connectionNameList** parameter, see the description of the **-connectionNameList** parameter.

-connectionNameList

The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager.

Note: You must only use the **-connectionNameList** parameter to allow a connection to a multi-instance queue manager. Using the **-connectionNameList** parameter to connect to a non-multi-instance queue manager can jeopardize transaction integrity.

The **-connectionNameList** parameter must be entered as a comma separated list of host names and ports in the following format:

host(port),host(port)

For *host* enter a valid TCP/IP host name, IPv4 or IPv6 address.

For *port* enter an integer value between 1 and 65536 (inclusive). Specifying a value for *port* is optional. When you do not specify a value, *port* defaults to 1414.

For example: localhost(1234),remotehost1(1234),remotehost2

When you specify the **-connectionNameList** parameter, the **-qmgrHostname** and **-qmgrPortNumber** parameters are automatically set to the host name and port number of the first entry in the connection name list. This overrides any values that you previously specified in the **-qmgrHostname** and **-qmgrPortNumber** parameters.

In the preceding example this would mean that **-qmgrHostname** would be localhost and **-qmgrPortNumber** would be 1234.

The **-connectionNameList** parameter is only valid for use in WebSphere Application Server Version 8.0. Attempting to specify the **-connectionNameList** parameter on a WebSphere MQ messaging provider connection factory which is defined at a server or node scope that is running on a version of WebSphere Application Server earlier than Version 8.0 results in an error message when you run the following commands:

- createWMQConnectionFactory
- modifyWMQConnectionFactory

If a WebSphere MQ messaging provider connection factory that is based on a connection name list is used by an application client or server that is running a version of WebSphere Application Server earlier than Version 8.0, the **-connectionNameList** information is not used. Instead, the values specified in the **-qmgrHostname** and **-qmgrPortNumber** are used, and are set to the relevant values from the first entry in the **connectionNameList** parameter.

You must not specify the **connectionNameList** parameter in conjunction with the **-ccdtUrl** or **-ccdtQmgrName** parameters.

Note: If you use the **-connectionNameList** parameter with a centrally managed SSL configuration, the host name and port number information used to select the appropriate SSL configuration is based on the first entry in the connection name list, regardless of which entry in the list is actually used to connect to the queue manager. This is because each instance of a multi-instance queue manager should be using the same SSL configuration, for a given server connection channel, regardless of which instance is actually running.

For more information on using multi-instance queue managers see the WebSphere MQ information center.

-containerAuthAlias

The container-managed authentication alias, defined to the cell, from which security credentials are used to establish a connection to WebSphere MQ.

-componentAuthAlias

The component-managed authentication alias, defined to the cell, from which security credentials are used to establish a connection to WebSphere MQ.

-clientId

The client identifier used for connections started by using this connection factory.

-providerVersion

This parameter determines the minimum version, and capabilities of the queue manager.

Enter values in one of the following formats:

- *n*
- *n.n*
- *n.n.n*
- *n.n.n.n*

where *n* is an integer greater than or equal to zero.

For example 6.0.0.0

-sslCr1

This parameter specifies a list of LDAP servers that are used to provide certificate revocation information if this connection factory establishes an SSL based connection to WebSphere MQ.

-sslResetCount

This parameter is used when the connection factory establishes an SSL connection to the queue manager. This parameter determines how many bytes to transfer before resetting the symmetric encryption key that is used for the SSL session.

Enter a value in the range 0 through 999,999,999.

The default value is 0.

-sslPeerName

This parameter is used when the connection factory establishes an SSL connection to the queue manager. The value is compared with the distinguished name present in the peer's certificate.

-rcvExit

A comma-separated list of receive exit class names.

-rcvExitInitData

Initialization data to pass to the receive exit.

Do not specify this parameter unless you specify the **-rcvExit** parameter.

-sendExit

A comma-separated list of send exit class names.

-sendExitInitData

Initialization data to pass to the send exit.

Do not specify this parameter unless you specify the **-sendExit** parameter.

-secExit

A security exit class name.

-secExitInitData

Initialization data to pass to the security exit.

Do not specify this parameter unless you specify the **-secExit** parameter.

-compressHeaders

This parameter determines if message headers are compressed.

Enter one of the following values:

- NONE
- SYSTEM

The default value is NONE.

-compressPayload

This parameter determines if message payloads are compressed.

Enter one of the following values:

- NONE
- RLE
- ZLIBFAST
- ZLIBHIGH

The default value is NONE.

-msgRetention

This parameter determines if the connection consumer keeps unwanted messages on the input queue.

Enter one of the following values:

- YES
- NO

where YES specifies that the connection consumer keeps unwanted messages on the input queue, and NO specifies that the messages are disposed of according to their disposition options.

The default value is YES.

-pollingInterval

This property is applicable in the client container only.

If each message listener within a session has no suitable message on its queue, this parameter is the maximum interval, in milliseconds, that elapses before each message listener tries again to get a message from its queue. If it frequently happens that no suitable message is available for any of the message listeners in a session, consider increasing the value of this parameter. The default value is 5000.

-rescanInterval

When a message consumer in the point-to-point domain uses a message selector to select which messages it is to receive, the JMS client searches the WebSphere MQ queue for suitable messages in the sequence determined by the `MsgDeliverySequence` attribute of the queue. When the client finds a suitable message and delivers it to the consumer, the client resumes the search for the next suitable message from its current position in the queue. The client continues to search the queue in this way until it reaches the end of the queue, or until the interval of time in milliseconds, as determined by the value of this **-rescanInterval** parameter has expired. In each case, the client returns to the beginning of the queue to continue its search, and a new time interval commences

This parameter must be a positive integer value.

The default value is 5000.

-ccsid

The coded character set identifier (CCSID) to be used on connections.

The value of this parameter must be a positive integer. See the “WebSphere MQ messaging provider connection factory advanced properties” on page 856 for more details.

The default value is 819.

-failIfQuiescing

This parameter determines the behavior of certain calls to the queue manager when the queue manager is put into quiescing state.

The value of this parameter must be true or false.

true specifies that calls to certain methods fail if the queue manager is in a quiescing state. If an application detects that the queue manager is quiescing, the application can complete its immediate task and close the connection, allowing the queue manager to stop.

false specifies that no methods fail if the queue manager is in a quiescing state. If you specify this value, an application cannot detect that the queue manager is quiescing. The application might continue to perform operations against the queue manager, and therefore prevent the queue manager from stopping.

The default value is true.

-brokerCtrlQueue

The name of the broker control queue to use if this connection factory is to subscribe to a topic.

The default value is `SYSTEM.BROKER.CONTROL.QUEUE`.

-brokerSubQueue

The name of the queue to use for obtaining subscription messages if this connection factory is to subscribe to a topic.

The default value is `SYSTEM.JMS.ND.SUBSCRIBER.QUEUE`.

-brokerCCSubQueue

The name of the queue from which non-durable subscription messages are retrieved for a `ConnectionConsumer`.

The default value is `SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE`.

-brokerVersion

The value of this parameter determines the level of functionality required for publish/subscribe operations.

Valid values are 1 and 2.

The default value is 1.

-msgSelection

This parameter determines where message selection occurs.

Valid values are CLIENT and BROKER.

The default value is CLIENT.

-subStore

This parameter determines where WebSphere MQ messaging provider stores persistent data relating to active subscriptions.

Valid values are MIGRATE, QUEUE and BROKER.

The default value is MIGRATE.

-stateRefreshInt

The interval, in milliseconds, between refreshes of the long running transaction that detects when a subscriber loses its connection to the queue manager. This parameter is relevant only if **-subStore** parameter has the value QUEUE.

The value of this parameter must be a positive integer.

The default value is 60,000.

-cleanupLevel

The cleanup level for BROKER or MIGRATE subscription stores

Valid values are SAFE, NONE, ASPROP, and STRONG.

The default value is SAFE.

-cleanupInterval

The interval between background executions of the publish/subscribe cleanup utility.

The value of this parameter must be a positive integer.

The default value is 3,600,000.

-wildcardFormat

This parameter determines which sets of characters are interpreted as topic wildcards.

Valid values are Topic or Char.

The default value is Topic.

-sparseSubs

This parameter controls the message retrieval policy of a TopicSubscriber object.

The value of this parameter must be true or false

The default value is false.

-brokerQmgr

The name of the queue manager that is running the broker, if it is not the same as the queue manager to which the connection factory connects.

There is no default value.

-clonedSubs

This parameter determines whether two or more instances of the same durable topic subscriber can run simultaneously

The value of this parameter must be ENABLED or DISABLED

The default value is DISABLED.

-customProperties

This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider connection factory implementation. Typically, custom properties are used to set attributes of the connection factory that are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:

- In Jython: [*name value*]
- In Jacl: {*name value*}

-qmgrSvrconnChannel

The SVRCONN channel to use when connecting to WebSphere MQ.

Use this parameter to create an **explicitly defined** connection factory.

The default value is SYSTEM.DEF.SVRCONN.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-support2PCProtocol

This parameter determines if the connection factory acts as a resource that is capable of participation in distributed two-phase commit processing.

The value of this parameter must be True or False.

The default value True specifies that the connection factory acts as a resource that is capable of participation in distributed two-phase commit processing.

-modelQueue

The name of the WebSphere MQ model queue whose definition is used as a basis when creating JMS temporary destinations.

The default value is SYSTEM.DEFAULT.MODEL.QUEUE.

-tempQueuePrefix

The prefix to apply to WebSphere MQ temporary queues that are used to represent JMS temporary queue type destinations.

There is no default value.

-tempTopicPrefix

The prefix to apply to the names generated for temporary topics. This parameter is only valid for connection factories or topic connection factories.

There is no default value.

-replyWithRFH2

This parameter determines whether, when sending a reply message to the reply-to queue obtained from a message that does not include an RFH version 2 header, a RFH version 2 header is included in the reply message.

The value of this parameter must be ALWAYS or AS_REPLY_DEST

The default value is AS_REPLY_DEST.

-brokerPubQueue

The name of the queue to which to send publication messages when using queue based brokering.

The default value is SYSTEM.BROKER.DEFAULT.STREAM.

-pubAckInterval

The number of publications to send to a queue based broker before sending a publication that solicits an acknowledgement.

The value of this parameter must be a positive integer greater than zero.

The default value is 25.

-sslType

This parameter determines the configuration, if any, to use when applying SSL encryption to the network connection to the queue manager.

The value of this parameter must be CENTRAL, SPECIFIC or NONE

The default value is NONE.

The **sslConfiguration** parameter is not valid unless this parameter is set to the value SPECIFIC.

-sslConfiguration

The name of the SSL configuration to use when using SSL to secure network connections to the queue manager.

The value of this parameter must correspond to an SSL configuration.

Do not specify this parameter unless the parameter **-sslType** is assigned the value SPECIFIC.

-localAddress

This parameter specifies either or both of the following:

- the local network interface
- the local port, or range of local ports

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-mappingAlias

The JAAS mapping alias used when determining which security credentials to use when establishing a connection to WebSphere MQ.

The default value is DefaultPrincipleMapping.

-xaRecoveryAuthAlias

The authentication alias from which credentials are taken and used to connect to WebSphere MQ for XA recovery.

There is no default value.

Minimal connection factory definition

The following example creates an connection factory, specifying the minimum number of parameters. Due to the default values assumed for the unspecified parameters, applications using this connection factory expect to be co-located with a queue manager installed on the same node.

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask createWMQConnectionFactory
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name cf1 -jndiName "jms/cf/cf1" -type CF}
cf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1205322636000)
```

Explicitly defined connection factory

The following example creates an connection factory for which the user must specify and maintain all the parameters used for establishing a connection to WebSphere MQ.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>AdminTask.createWMQConnectionFactory("9994GKCNODE01(cells/
9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)", ["-name cf2
-jndiName 'jms/cf/cf2' -type CF -description 'Must remember to keep each
of these connection factories in sync with the WebSphere MQ queue manager
to which they refer' -qmgrName QM1 -qmgrHostname 192.168.0.22 -qmgrPort 1415
-qmgrSvrconnChannel QM1.SVRCONN"])
cf2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_120532263601)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask createWMQConnectionFactory
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name cf2 -jndiName "jms/cf/cf2" -type CF -description "Must remember to
keep each of these connection factories in sync with the WebSphere MQ queue
manager to which they refer" -qmgrName QM1 -qmgrHostname 192.168.0.22
-qmgrPort 1415 -qmgrSvrconnChannel QM1.SVRCONN}
cf2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_120532263601)
```

Connection factory definition specifying a CCDT

The following example creates a connection factory that uses a CCDT to locate the queue manager to connect to.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>AdminTask.createWMQConnectionFactory("9994GKCNODE01(cells/
9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)", ["-name cf3 -jndiName
'jms/cf/cf3' -type CF -ccdtUrl 'http://gorillaaction:9080/ccdt/amqclchl.tab'
-ccdtQmgrName QM3"])
cf3(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_120532263606)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask createWMQConnectionFactory
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name cf3 -jndiName "jms/cf/cf3" -type CF -ccdtUrl
"http://gorillaaction:9080/ccdt/amqclchl.tab" -ccdtQmgrName QM3}
cf3(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_120532263606)
```

deleteWMQConnectionFactory command

Use the `deleteWMQConnectionFactory` command to delete a WebSphere MQ messaging provider connection factory at a specific scope.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the `deleteWMQConnectionFactory` command to delete a WebSphere MQ messaging provider connection factory defined at the scope at which the command is issued.

Target object

A WebSphere MQ messaging provider connection factory at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQConnectionFactory("9994GKCNODE01(cells/
9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)")
unwantedCF(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1098737234986)
```

```
wsadmin>AdminTask.deleteWMQConnectionFactory("unwantedCF(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|resources.xml#MQConnectionFactory_1098737234986)")
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listWMQConnectionFactory
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
unwantedCF(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1098737234986)
```

```
wsadmin>$AdminTask deleteWMQConnectionFactory
unwantedCF(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1098737234986)
```

listWMQConnectionFactoryFactories command

Use the listWMQConnectionFactoryFactories command to list WebSphere MQ messaging provider connection factories.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the listWMQConnectionFactoryFactories command to list all of the WebSphere MQ messaging provider connection factories defined at the scope at which the command is issued.

Target object

WebSphere MQ messaging provider connection factories at the specific scope.

Required parameters

None.

Optional parameters

-type

Use this parameter to determine which type of connection factory is listed. If it is omitted all connection factories are shown at the appropriate scope.

Valid values are:

- CF to list only common connection factories
- QCF to list only queue connection factories
- TCF to list only topic connection factories

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQConnectionFactoryFactories("9994GKCNODE01(cells/
9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)")
cf2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listWMQConnectionFactoryes
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
cf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986)
```

modifyWMQConnectionFactory command

Use the modifyWMQConnectionFactory command to change certain parameters of a WebSphere MQ messaging provider connection factory.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the modifyWMQConnectionFactory command to modify a WebSphere MQ messaging provider connection factory defined at the scope at which the command is issued.

Note: When modifying a WebSphere MQ messaging provider connection factory, there is an interaction between the **mappingAlias** and **containerAuthAlias** parameters. This interaction occurs if the **containerAuthAlias** parameter is specified but the **mappingAlias** is not specified. In this situation, the **mappingAlias** parameter is automatically set to the value DefaultPrincipleMapping.

Target object

A WebSphere MQ messaging provider connection factory at the specific scope.

Required parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider connection factory.

Optional parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider connection factory.

Note: If either the **-qmgrHostname** or **-qmgrPortNumber** parameters are specified without the **-connectionNameList** parameter being specified, then it is assumed that a connection name list

should no longer be used to connect to WebSphere MQ and that the specified host name and port number information should be used instead. As a result of this the **-connectionNameList** parameter is set to blank.

Note the behavior of this command on the **-customProperties** parameter.

-customProperties

This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider connection factory implementation. Typically, custom properties are used to set attributes of the connection factory that are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:

- In Jython: *[name value]*
- In Jacl: *{name value}*

New name/value pairs are added to the existing set of custom properties using the following rules:

- If the existing set of properties does not contain a property with the same name as that supplied as part of a modify command, the supplied property is added to the set of custom properties, unless the custom property has no value specified, when it is disregarded.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, and the modify command also specifies a value for the property, the existing value is replaced by the supplied value.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command but the modify command does not specify a value for the property, the property with the same name is deleted from the existing set of custom properties.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>AdminTask.listWMQConnectionFactory("9994GKCNODE01(cells/
9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)")
cf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1098737234986)

wsadmin>AdminTask.modifyWMQConnectionFactory("cf1(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|resources.xml#MQConnectionFactory_1098737234986)", ["-description
'My new description'"])
cf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask listWMQConnectionFactory
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
cf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1098737234986)

wsadmin>$AdminTask modifyWMQConnectionFactory
cf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1098737234986) {-description "My new description"}
cf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1098737234986)
```

showWMQConnectionFactory command

Use the showWMQConnectionFactory command to display information about a specific WebSphere MQ messaging provider connection factory.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the showWMQConnectionFactory command to display all the parameters, and their values, associated with a particular WebSphere MQ messaging provider connection factory.

Target object

A WebSphere MQ messaging provider connection factory at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQConnectionFactory("9994GKCNODE01(cells/
9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)")
cf1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQConnectionFactory_1098737234986)
```

```
wsadmin>AdminTask.showWMQConnectionFactory("cf1(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|resources.xml#MQConnectionFactory_1098737234986)")
{ name=cf1 jndiName=jms/cf/cf1 description= qmgrName=QMGR1

```

createWMQTopic command

Use the createWMQTopic command to create a JMS topic destination for the WebSphere MQ messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the createWMQTopic command to create a WebSphere MQ messaging provider topic type destination at a specific scope.

You cannot create a WebSphere MQ messaging provider topic type destination under either of the following conditions:

- A WebSphere MQ messaging provider topic type destination already exists with the same name, at the same scope.
- The JNDI name clashes with another entry in WebSphere Application Server JNDI.

Target object

The scope of the WebSphere MQ messaging provider at which the WebSphere MQ messaging provider topic type destination is to be created.

Required parameters

-name

The administrative name assigned to this WebSphere MQ messaging provider topic type destination.

-jndiName

The name used to bind this object into WebSphere Application Server JNDI.

-topicName

The name of the WebSphere MQ topic where publications are received from, or sent to, when this destination definition is used.

Optional parameters

-description

An administrative description assigned to the topic type destination.

-persistence

This parameter determines the level of persistence used to store messages sent to this destination.

Enter one of the following case-sensitive values:

- APP
- TDEF
- PERS
- NON
- HIGHT

APP is the default value.

-priority

The priority level to assign to messages sent to this destination.

Enter one of the following case-sensitive values:

- APP
- TDEF

or enter a positive integer in the range 0 to 9 (inclusive).

The default value is APP .

-expiry

The length of time after which messages that are sent to this destination expire and are dealt with according to their disposition options.

Enter one of the following case-sensitive values:

- APP
- UNLIM

or enter any positive integer.

The default value is APP.

-ccsid

The coded character set identifier (CCSID).

The value of this parameter must be a positive integer or blank. See the “WebSphere MQ messaging provider queue and topic advanced properties settings” on page 928 for more details.

The default value is 1208.

Leaving this field empty indicates that the default value must be used.

-useNativeEncoding

This parameter specifies whether to use native encoding or not. It can take a value true or false.

If it is set to true, the values of the **-integerEncoding**, **-decimalEncoding** and **-floatingPointEncoding** attributes are ignored.

If it is set to false, the encoding is specified by the **-integerEncoding**, **-decimalEncoding** and **-floatingPointEncoding** attributes.

-integerEncoding

The integer encoding setting for this queue.

Enter one of the following case-sensitive values: Normal, Reversed.

Normal is the default value.

-decimalEncoding

The decimal encoding setting for this queue.

Enter one of the following case-sensitive values: Normal, Reversed.

The default value is Normal.

-floatingPointEncoding

The floating point encoding setting for this queue.

Enter one of the following case-sensitive values: IEEENormal, IEEEReversed, z/OS

The default value is IEEENormal.

-useRFH2

This parameter determines whether an RFH version 2 header is appended to messages sent to this destination.

Enter one of the following case-sensitive values: true or false.

The default value is true.

-sendAsync

This parameter determines whether messages can be sent to this destination without queue manager acknowledging that they have arrived.

Enter one of the following case-sensitive values: YES, NO or TDEF.

The default value is YES.

-readAhead

This parameter determines whether messages for non-persistent consumers can be read ahead and cached.

Enter one of the following case-sensitive values: YES, NO or TDEF.

The default value is YES.

-readAheadClose

This property determines the behavior that occurs when closing a message consumer that is receiving messages asynchronously by using a message listener from a destination that has the **readAhead** parameter set to True.

When a value of `deliverAll` is specified, all read-ahead messages are delivered before closing the consumer.

When a value of `deliverCurrent` is specified, only in-progress messages are delivered before closing the consumer.

The default value is `deliverCurrent`.

-wildcardFormat

This parameter determines which sets of characters are interpreted as topic wildcards.

Valid values are `Topic` or `Char`.

The default value is `Topic`.

-brokerDurSubQueue

The name of the queue, defined to the queue manager, from which a connection consumer receives non-durable subscription messages.

The value of this parameter must be a valid queue name or left blank

The default value is `SYSTEM.JMS.D.SUBSCRIBER.QUEUE`.

-brokerCDurSubQueue

The name of the queue, defined to the queue manager, from which a connection consumer receives durable subscription messages.

The value of this parameter must be a valid queue name or left blank

The default value is `SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE`.

-brokerPubQueue

The name of the queue, defined to the queue manager, to which publication messages are sent.

The value of this parameter must be a valid queue name or left blank

The default value is `SYSTEM.BROKER.DEFAULT.STREAM`.

-brokerPubQmgr

The name of the queue manager on which the broker is running.

The value of this parameter must be a valid queue manager name or left blank

There is no default value.

-brokerVersion

This parameter determines the level of functionality required for publish/subscribe operations.

The value of this parameter must be `V1` or `V2`.

The default value is `V1`.

-customProperties

This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider topic type destination implementation. Typically, custom properties are used to set attributes of the topic type destination that are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:

- In Jython: `[name value]`
- In JACL: `{name value}`

The following example creates a topic definition by specifying the minimum number of parameters.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>AdminTask.createWMQTopic("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)", [{"-name T1 -jndiName jms/topic/t1
-topicName woodland/creatures/badger"}])
T1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)

wsadmin>$AdminTask createWMQTopic
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
{-name T1 -jndiName jms/topic/t1 -topicName woodland/creatures/badger}
T1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234986)
```

deleteWMQTopic command

Use this command to delete a WebSphere MQ messaging provider topic at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the deleteWMQTopic command to delete a WebSphere MQ messaging provider topic defined at the scope at which the command is issued.

Target object

A WebSphere MQ messaging provider topic at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQTopics("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)")
unwantedTopic(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234986)
```

```
wsadmin>$AdminTask.deleteWMQTopic
unwantedTopic(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig.getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask.listWMQTopics
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
unwantedTopic(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234986)
```

```
wsadmin>$AdminTask.deleteWMQTopic
unwantedTopic(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234986)
```

listWMQTopics command

Use the listWMQTopics command to list WebSphere MQ messaging provider topics.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the listWMQTopics command to list all of the WebSphere MQ messaging provider topics defined at the scope at which the command is issued.

Target object

WebSphere MQ messaging provider topics at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQTopics("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)")
aaaTopic(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234986)
bbbTopic(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234987)
cccTopic(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234988)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listWMQTopics
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
aaaTopic(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234986)
bbbTopic(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234987)
cccTopic(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234988)
```

modifyWMQTopic command

Use the `modifyWMQTopic` command to change certain parameters of a WebSphere MQ messaging provider topic.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the `modifyWMQTopic` command to modify a WebSphere MQ messaging provider topic defined at the scope at which the command is issued.

Note: You cannot change the name of an topic.

Target object

A WebSphere MQ messaging provider topic at the specific scope.

Required parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider topic.

Optional parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider topic.

Note the behavior of this command on the **-customProperties** parameter.

-customProperties

This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider topic implementation. Typically, custom properties are used to set attributes of the topic that are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:

- In Jython: [*name value*]
- In Jacl: {*name value*}

New name/value pairs are added to the existing set of custom properties using the following rules:

- If the existing set of properties does not contain a property with the same name as that supplied as part of a modify command, the supplied property is added to the set of custom properties, unless the custom property has no value specified, when it is disregarded.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, and the modify command also specifies a value for the property, the existing value is replaced by the supplied value.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, but the modify command does not specify a value for the property, the property with the same name is deleted from the existing set of custom properties.

Example

- Using Jython:

```
wsadmin>AdminTask.modifyWMQTopic("t1(cells/L3A3316Node04Cell/
nodes/L3A3316Node05|resources.xml#MQTopic_1204538835312)", ["-priority 7"])
t1(cells/L3A3316Node04Cell/nodes/L3A3316Node05|resources.xml#
MQTopic_1204538835312)
```

- Using Jacl:

```
wsadmin>$AdminTask modifyWMQTopic
t1(cells/L3A3316Node04Cell/nodes/L3A3316Node05|resources.xml#
MQTopic_1204538835312) {-priority 7}
t1(cells/L3A3316Node04Cell/nodes/L3A3316Node05|resources.xml#
MQTopic_1204538835312)
```

showWMQTopic command

Use the showWMQTopic command to display information about a specific WebSphere MQ messaging provider topic.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the showWMQTopic command to display all the parameters, and their values, associated with a particular WebSphere MQ messaging provider topic.

Target object

A WebSphere MQ messaging provider topic at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQTopics("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)")
topic1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234986)
```

```
wsadmin>AdminTask.showWMQTopic("topic1(cells/9994GKCNODE01Cell/nodes/
9994GKCNODE01|resources.xml#MQTopic_1098737234986)")
{specifiedExpiry=0, priority=APPLICATION_DEFINED, decimalEncoding=Normal,
baseTopicName=topic1, name=topic1, readAhead=NO, brokerPubQmgr=null,
readAheadClose=DELIVERCURRENT, brokerPubQueue=SYSTEM.BROKER.DEFAULT.STREAM,
ccsid=1208, integerEncoding=Normal, useNativeEncoding=true,
wildcardFormat=charWildcards, expiry=APP, specifiedPriority=0,
jndiName=jms/t1, sendAsync=NO,
brokerDurSubQueue=SYSTEM.JMS.D.SUBSCRIBER.QUEUE, brokerCCDurSubQueue=null,
description=null, targetClient=JMS, floatingPointEncoding=IEEENormal,
persistence=APP, brokerVersion=V1}
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listWMQTopics
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
topic1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234986)
```

```
wsadmin>$AdminTask showWMQTopic
topic1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQTopic_1098737234986)
{specifiedExpiry=0, priority=APPLICATION_DEFINED, decimalEncoding=Normal,
baseTopicName=topic1, name=topic1, readAhead=NO, brokerPubQmgr=null,
readAheadClose=DELIVERCURRENT, brokerPubQueue=SYSTEM.BROKER.DEFAULT.STREAM,
ccsid=1208, integerEncoding=Normal, useNativeEncoding=true,
wildcardFormat=charWildcards, expiry=APP, specifiedPriority=0,
jndiName=jms/t1, sendAsync=NO,
brokerDurSubQueue=SYSTEM.JMS.D.SUBSCRIBER.QUEUE, brokerCCDurSubQueue=null,
description=null, targetClient=JMS, floatingPointEncoding=IEEENormal,
persistence=APP, brokerVersion=V1}
```

manageWMQ command

Use the manageWMQ command to manage the settings of the WebSphere MQ resource adapter that is installed at a particular scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the manageWMQ command to manage the settings associated with the WebSphere MQ resource adapter that is installed at a particular scope.

You can use the manageWMQ command to manage the native library path and query the metadata of the specified WebSphere MQ resource adapter.

Target object

A WebSphere MQ resource adapter.

Required parameters

None.

Optional parameters

-nativePath

This parameter specifies the path to the WebSphere MQ messaging provider native libraries that are used by the WebSphere MQ resource adapter to establish a bindings mode connection to the queue manager. This parameter can be specified on a WebSphere MQ adapter at any scope.

-query

This parameter provides information about the level of WebSphere MQ resource adapter that is used by the WebSphere MQ messaging provider. This parameter can be specified on a WebSphere MQ resource adapter at any scope.

-enableInbound

This parameter enables inbound Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) message delivery to WebSphere MQ resource adapter activation specifications on the z/OS platform. This value can only be specified if the target WebSphere MQ resource adapter is at server scope. An application server restart is required for these changes to take effect.

The value of this parameter must be true or false.

The default value is false.

-disableWMQ

This parameter specifies whether or not to disable WebSphere MQ functionality at the scope of the specified resource adapter, and at all scopes beneath it.

The value of this parameter must be true or false.

The default value is false.

In a single server environment this parameter is valid only at the server scope. In a network deployment environment this parameter is valid at all scopes. The affect of setting this parameter to true depends on the scope at which you set it:

- For a cell scoped WebSphere MQ resource adapter, all WebSphere MQ functionality on all application servers in the cell is disabled.
- For a node scoped WebSphere MQ resource adapter, all WebSphere MQ functionality on all application servers that are part of that node is disabled.
- For a cluster scoped WebSphere MQ resource adapter, all WebSphere MQ functionality on all application servers in that cluster are disabled.
- For a server scoped WebSphere MQ resource adapter, all WebSphere MQ functionality in that particular application server is disabled.

In all cases, all affected processes must be restarted for the changes to take effect.

The value of the parameter at a higher scope takes precedence over the value at a lower scope. For example, if you set the parameter to false at the server scope but a higher (for example, cell) scoped WebSphere MQ messaging provider has the parameter set to true, the value at the cell scope takes precedence and WebSphere MQ functionality is therefore disabled in all application servers in the cell, regardless of the parameter value at the server scope.

-maxConnections

This parameter specifies the maximum number of connections to a WebSphere MQ queue manager.

The default value is 10.

For further information, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

-connectionConcurrency

This parameter specifies the maximum number of message-driven beans that can be supplied by each connection.

The default value is 5.

For further information, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

-reconnectionRetryCount

This parameter specifies the maximum number of attempts made by a WebSphere MQ messaging provider activation specification to reconnect to a WebSphere MQ queue manager if a connection fails.

The default value is 5.

For further information, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

-reconnectionRetryInterval

This parameter specifies the time, in milliseconds, that a WebSphere MQ messaging provider activation specification waits before making another attempt to reconnect to a WebSphere MQ queue manager.

The default value is 300000.

For further information, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

-customProperties

This parameter specifies custom properties to be passed to the WebSphere MQ resource adapter. Typically, custom properties are used to set attributes of the WebSphere MQ resource adapter that are not directly supported through the WebSphere Application Server administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:

- In Jython: [*name value*]
- In Jacl: {*name value*}

New name/value pairs are added to the existing set of custom properties using the following rules:

- If the existing set of properties does not contain a property with the same name as that which is supplied, the supplied property is added to the set of custom properties, unless the custom property has no value specified, when it is disregarded.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, and the modify command also specifies a value for the property, the existing value is replaced by the supplied value.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, but the modify command does not specify a value for the property, the property with the same name is deleted from the existing set of custom properties.

Examples

The following example shows how to enable inbound JCA message delivery on the z/OS platform.

- Using Jython:

```
wsadmin>AdminTask.manageWMQ("WebSphere MQ Resource Adapter
(ce11s/L3A3316Node04Cell/nodes/L3A3316Node05/servers/server1|resources.xml#
J2CResourceAdapter_1201601803796)", ["-enableInbound true"])
```

- Using Jacl:

```
wsadmin>$AdminTask manageWMQ "WebSphere MQ Resource Adapter
(cells/L3A3316Node04Cell/nodes/L3A3316Node05/servers/Server1/resources.xml#
J2CResourceAdapter_1201601803796)" {-enableInbound true}
```

The following example sets the value of **-maxConnections** to 100 and adds a custom property with name `name1` and value `value1`.

- Using Jython:

```
AdminTask.manageWMQ("WebSphere MQ Resource Adapter(
cells/L3A3316Node01Cell/resources.xml#J2CResourceAdapter_1284547647859)",
["-maxConnections 100 -customProperties [[name1 value1]]"])
```

- Using Jacl:

```
wsadmin>$AdminTask manageWMQ "WebSphere MQ Resource Adapter(
cells/L3A3316Node01Cell/resources.xml#J2CResourceAdapter_1284547647859)"
{-maxConnections 100 -customProperties {{name1 value1}}}
```

showWMQ command

Use the `showWMQ` command to show the settings which can be set by the `manageWMQ` command.

To run the command, use the `AdminTask` object of the `wsadmin` scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the `wsadmin` prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the `showWMQ` command to display all the parameters, and their values that can be set by the `manageWMQ` command. These settings are either related to the WebSphere MQ resource adapter or the WebSphere MQ messaging provider. The command also shows custom properties which are set on the WebSphere MQ resource adapter.

The following settings are expected:

- `maxConnections`
- `connectionConcurrency`
- `reconnectionRetryCount`
- `reconnectionRetryInterval`
- `nativePath`
- `enableInbound`
- `disableWMQ` (this parameter is only visible when setting it is valid, see the description of the `manageWMQ` command for more information)

For a description of these settings, see “manageWMQ command” on page 996.

Any other setting that is shown is either a custom property or a property that is not appropriate in WebSphere Application Server.

Target object

A WebSphere MQ resource adapter.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminTask.showWMQ("WebSphere MQ Resource Adapter
(cells/L3A3316Node01Cell|resources.xml#J2CResourceAdapter_1284547647859)")
'{name1=value1, logWriterEnabled=true, maxConnections=100, startupReconnectionRetryCount=500,
connectionConcurrency=123, reconnectionRetryCount=3, traceEnabled=false,
reconnectionRetryInterval=4, nativePath=[], startupReconnectionRetryInterval=600, traceLevel=3}'
```

- Using Jacl:

```
wsadmin>$AdminTask showWMQ "WebSphere MQ Resource Adapter(
cells/L3A3316Node01Cell|resources.xml#J2CResourceAdapter_1284547647859)"
{name1=value1, logWriterEnabled=true, maxConnections=100, startupReconnectionRetryCount=500,
connectionConcurrency=123, reconnectionRetryCount=3, traceEnabled=false,
reconnectionRetryInterval=4, nativePath=[], startupReconnectionRetryInterval=600, traceLevel=3}
```

migrateWMQMLP command

Use the migrateWMQMLP command to migrate a WebSphere MQ message listener port definition to an activation specification definition.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the `migrateWMQMLP` command to migrate a WebSphere MQ message listener port definition to an activation specification definition. After the activation specification has been created, you can delete the listener port.

Note that the **Maximum retries** listener port setting is not migrated to the new activation specification as there is no exact equivalent.

When you are migrating a listener port associated with a message-driven bean (MDB) that has the `subscriptionDurability` activation configuration property set to `Durable`, and that MDB already has an active durable subscription, the durable subscription is not migrated. This is because listener ports and WebSphere MQ activation specifications use incompatible forms of subscription name. As a result there can be two active durable subscriptions subscribed to the relevant topic for the same MDB. As part of the migration process, you must delete the old durable subscription that was associated with the listener port and manually clean up any messages associated with it. For information on how to do this see the WebSphere MQ and WebSphere Message Broker information centres.

Target object

The message listener port to be migrated.

Required parameters

-asName

The name of the activation specification to be created.

-asJNDIName

The JNDI name of the activation specification to be created.

-asScope

The type of scope at which to create the activation specification (`server`, `node`, `cluster` or `cell`). Note that the `cluster` option is only supported when the server that contains the message listener port is part of a cluster. If not specified this defaults to `server`. The scopes specified are relative to the message listener port, so `node` is the node of the server that contains the message listener port.

Optional parameters

None.

The following example shows how to migrate a message listener port to an activation specification.

- Using Jython:

```
wsadmin>AdminConfig.list("ListenerPort")
lp1(cells/L3A3316Node09Cell/nodes/L3A3316Node10/servers/server1|
server.xml#ListenerPort_1211265363796)

wsadmin>AdminTask.migrateWMQMLP("lp1(cells/L3A3316Node09Cell/nodes/
L3A3316Node10/servers/server1|server.xml#ListenerPort_1211265363796)",
["-asName migratedFromLP -asJNDIName jms/as1 -asScope node"])
migratedFromLP(cells/L3A3316Node09Cell/nodes/L3A3316Node10|
resources.xml#J2CActivationSpec_1211265679078)
```

- Using Jacl:

```
wsadmin>$AdminConfig list ListenerPort
lp1(cells/L3A3316Node09Cell/nodes/L3A3316Node10/servers/server1|
server.xml#ListenerPort_1211265363796)

wsadmin>$AdminTask migrateWMQMLP
lp1(cells/L3A3316Node09Cell/nodes/L3A3316Node10/servers/server1|
```

```
server.xml#ListenerPort_1211265363796)
{-asName migratedFromLP -asJNDIName jms/as1 -asScope node}
migratedFromLP(cells/L3A3316Node09Cell/nodes/L3A3316Node10|
resources.xml#J2CActivationSpec_1211265679078)
```

createWMQQueue command

Use the createWMQQueue command to create a queue type destination for the WebSphere MQ messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the createWMQQueue command to create a WebSphere MQ messaging provider queue type destination at a specific scope.

You cannot create a WebSphere MQ messaging provider queue type destination under either of the following conditions:

- A WebSphere MQ messaging provider queue type destination already exists with the same name, at the same scope.
- The JNDI name clashes with another entry in WebSphere Application Server JNDI.

Target object

The scope of the WebSphere MQ messaging provider at which the WebSphere MQ messaging provider queue type destination is to be created.

Required parameters

-name

The administrative name assigned to this WebSphere MQ messaging provider queue type destination.

-jndiName

The name used to bind this object into WebSphere Application Server JNDI.

Optional parameters

-description

An administrative description assigned to the queue type destination.

-queueName

The name of the WebSphere MQ queue to use to store messages for the WebSphere MQ messaging provider queue type destination definition.

-qmgr

The queue manager that hosts the WebSphere MQ queue.

-persistence

This parameter determines the level of persistence used to store messages sent to this destination.

Enter one of the following case-sensitive values:

- APP
- QDEF
- PERS
- NON
- HIGH

The default value is APP.

-priority

The priority level to assign to messages sent to this destination.

Enter one of the following case-sensitive values:

- APP
- QDEF

or enter a positive integer in the range 0 to 9 (inclusive).

The default value is APP.

-expiry

The length of time after which messages sent to this destination expire and are dealt with according to their disposition options.

Enter one of the following case-sensitive values:

- APP
- UNLIM

or enter any positive integer.

The default value is APP.

-ccsid

The coded character set identifier (CCSID).

The value of this parameter must be a positive integer or blank. See the “WebSphere MQ messaging provider queue and topic advanced properties settings” on page 928 for more details.

The default value is 1208.

Leaving this field empty indicates that the default value must be used.

-useNativeEncoding

This parameter specifies whether to use native encoding or not. It can take a value true or false.

If it is set to true, the values of the **-integerEncoding**, **-decimalEncoding** and **-floatingPointEncoding** attributes are ignored.

If it is set to false, the encoding is specified by the **-integerEncoding**, **-decimalEncoding** and **-floatingPointEncoding** attributes.

-integerEncoding

The integer encoding setting for this queue.

Enter one of the following case-sensitive values: Normal or Reversed.

The default value is Normal.

-decimalEncoding

The decimal encoding setting for this queue.

Enter one of the following case-sensitive values: Normal or Reversed.

The default value is Normal.

-floatingPointEncoding

The floating point encoding setting for this queue.

Enter one of the following case-sensitive values: IEEENormal, IEEEReversed, z/OS

The default value is IEEENormal.

-useRFH2

This parameter determines whether an RFH version 2 header is appended to messages sent to this destination.

Enter one of the following case-sensitive values: true or false.

The default value is true.

-sendAsync

This parameter determines whether messages can be sent to this destination without queue manager acknowledging that they have arrived.

Enter one of the following case-sensitive values: YES, NO or QDEF.

The default value is YES.

-readAhead

This parameter determines whether messages for non-persistent consumers can be read ahead and cached.

Enter one of the following case-sensitive values: YES, NO or QDEF.

The default value is YES.

-readAheadClose

Enter one of the following case-sensitive values: YES, NO or QDEF.

The default value is YES.

-customProperties

This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider queue type destination implementation. Typically, custom properties are used to set attributes of the queue type destination that are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:

- In Jython: [*name value*]
- In JACL: {*name value*}

The following example creates a WebSphere MQ messaging provider queue type destination.

- Using Jython:

```
wsadmin>AdminTask.createWMQueue("9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)", ["-name queue1 -jndiName jms/queues/Q1
-queueName APP1.QUEUE1"])
queue1(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.xml#
MQQueue_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminTask createWMQQueue
9994GKCN0de01(cells/9994GKCN0de01Cell/nodes/9994GKCN0de01|node.xml#Node_1)
{-name queue1 -jndiName jms/queues/Q1 -queueName APP1.QUEUE1}
queue1(cells/9994GKCN0de01Cell/nodes/9994GKCN0de01|resources.xml#
MQQueue_1098737234986)
```

deleteWMQQueue command

Use this command to delete a WebSphere MQ messaging provider queue type destination at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the deleteWMQQueue command to delete a WebSphere MQ messaging provider queue type destination defined at the scope at which the command is issued.

Note: The WebSphere MQ messaging provider queue type destination definition is deleted from WebSphere Application Server JNDI at the specific scope. Any messages present on the underlying WebSphere MQ queue are not affected.

Target object

A WebSphere MQ messaging provider queue type destination at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCN0de01")
9994GKCN0de01(cells/9994GKCN0de01Cell/nodes/9994GKCN0de01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQQueues("9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)")
unwantedQueue(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#MQQueue_1098737234986)
```

```
wsadmin>AdminTask.deleteWMQQueue("unwantedQueue(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#MQQueue_1098737234986)")
```

- **Using Jacl:**

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listWMQQueues
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
unwantedQueue(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#MQQueue_1098737234986)
```

```
wsadmin>$AdminTask deleteWMQQueue
unwantedQueue(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#MQQueue_1098737234986)
```

listWMQQueues command

Use the listWMQQueues command to list WebSphere MQ messaging provider queue type destinations.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the listWMQQueues command to list all of the WebSphere MQ messaging provider queue type destinations defined at the scope at which the command is issued.

Target object

WebSphere MQ messaging provider queue type destinations at the specific scope.

Required parameters

None.

Optional parameters

-type

If this parameter is omitted all connection factories are shown at the appropriate scope.

Enter one of the following case-sensitive values: CF, QCF or TCF. Enter CF to list only common connection factories, QCF to list only queue connection factories or **TCF** to list only topic connection factories.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCN01")
9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQQueues("9994GKCN01(cells/9994GKCN01Cell/
nodes/9994GKCN01|node.xml#Node_1)")
jmsq2(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCN01
9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listWMQQueues
9994GKCN01(cells/9994GKCN01Cell/nodes/9994GKCN01|node.xml#Node_1)
jmsq2(cells/9994GKCN01Cell/nodes/9994GKCN01|resources.
```

modifyWMQQueue command

Use the modifyWMQQueue command to change certain parameters of a WebSphere MQ messaging provider queue type destination.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the modifyWMQQueue command to modify a WebSphere MQ messaging provider queue type destination defined at the scope at which the command is issued.

Target object

A WebSphere MQ messaging provider queue type destination at the specific scope.

Required parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider queue type destination.

Optional parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider queue type destination.

Note the behavior of this command on the **-customProperties** parameter.

-customProperties

This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider queue type destination implementation. Typically, custom properties are used to set attributes of the queue type destination which are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:

- In Jython: [*name value*]
- In Jacl: {*name value*}

New name/value pairs are added to the existing set of custom properties using the following rules:

- If the existing set of properties does not contain a property with the same name as that supplied as part of a modify command, the supplied property is added to the set of custom properties, unless the custom property has no value specified, when it is disregarded.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, and the modify command also specifies a value for the property, the existing value is replaced by the supplied value.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, but the modify command does not specify a value for the property, the property with the same name is deleted from the existing set of custom properties.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQQueues("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)")
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQQueue_1098737234986)
```

```
wsadmin>AdminTask.modifyWMQQueue("jmsq2(cells/9994GKCNODE01Cell/nodes/
9994GKCNODE01|resources.xml#
MQQueue_1098737234986)", ["-ccsid 500"])
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listWMQQueues
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQQueue_1098737234986)
```

```
wsadmin>$AdminTask modifyWMQQueue
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQQueue_1098737234986) {-ccsid 500}
jmsq2(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.
```

showWMQQueue command

Use the showWMQQueue command to display information about a specific WebSphere MQ messaging provider queue type destination.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the showWMQQueue command to display all the parameters, and their values, associated with a particular WebSphere MQ messaging provider queue type destination.

Target object

A WebSphere MQ messaging provider queue type destination at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNODE01")
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQQueues("9994GKCNODE01(cells/9994GKCNODE01Cell/
nodes/9994GKCNODE01|node.xml#Node_1)")
ncq1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQQueue_1098737234986)
```

```
wsadmin>AdminTask.showWMQQueue("ncq1(cells/9994GKCNODE01Cell/nodes/
9994GKCNODE01|resources.xml#MQQueue_1098737234986)")
{expiry=0, priority=9, decimalEncoding=Normal, queueName=TARGETQ, name=q1,
readAhead=YES, readAheadClose=DELIVERALL, ccsid=1208,
useNativeEncoding=true, integerEncoding=Normal, specifiedPriority=0,
jndiName=jms/q1, sendAsync=YES, qmgr=null, description=null,
targetClient=JMS, floatingPointEncoding=IEEENormal, persistence=APP}
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNODE01
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listWMQQueues
```

```
9994GKCNODE01(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|node.xml#Node_1)
ncq1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQQueue_1098737234986)
```

```
wsadmin>$AdminTask showWMQQueue
ncq1(cells/9994GKCNODE01Cell/nodes/9994GKCNODE01|resources.xml#
MQQueue_1098737234986)
{expiry=0, priority=9, decimalEncoding=Normal, queueName=TARGETQ, name=q1,
readAhead=YES, readAheadClose=DELIVERALL, ccsid=1208,
useNativeEncoding=true, integerEncoding=Normal, specifiedPriority=0,
jndiName=jms/q1, sendAsync=YES, qmgr=null, description=null,
targetClient=JMS, floatingPointEncoding=IEEENormal, persistence=APP}
```

Mapping of administrative console panel names to command names and WebSphere MQ names

Use these tables to relate the names used in the administrative console panels to the names in the commands and the names used by WebSphere MQ.

The following tables list property mappings. Use these tables in conjunction with the WebSphere MQ information center to get more information on a particular property.

Note that not every WebSphere Application Server panel or command property maps to a WebSphere MQ property.

Table 59. WebSphere MQ Activation Specification property mappings. The first column of this table shows the property names that appear on a WebSphere Application Server administrative console panel, and the second column shows the corresponding WebSphere Application Server command names. The third column shows the WebSphere MQ activation specification properties that the administrative console panel names and command names map on to.

Name on WebSphere Application Server administrative console panel	WebSphere Application Server command name	WebSphere MQ activation specification property
Basic panel		
Queue manager	qmgrName	queueManager
Queue manager (when used with CCDT)	ccdtQmgrName	queueManager
Transport	wmqTransportType	transportType
Host name	qmgrHostname	hostName
Port	qmgrPortNumber	port
Server connection channel	qmgrSvrconnChannel	channel
Destination JNDI name	destinationJndiName	destination
Message selector	messageSelector	messageSelector
Destination type	destinationType	destinationType
Durable subscription	subscriptionDurability	subscriptionDurability
Subscription name	subscriptionName	subscriptionName
Client ID	clientId	clientId
Provider version	providerVersion	providerVersion
Client channel definition table URL	ccdtUrl	ccdtURL
Allow cloned durable subscriptions	clonedSubs	cloneSupport
Connection name list	connectionNameList	connectionNameList
Advanced properties panel		
Compress message headers	compressHeaders	headerCompression
Compression algorithm for message payloads	compressPayload	messageCompression

Table 59. WebSphere MQ Activation Specification property mappings (continued). The first column of this table shows the property names that appear on a WebSphere Application Server administrative console panel, and the second column shows the corresponding WebSphere Application Server command names. The third column shows the WebSphere MQ activation specification properties that the administrative console panel names and command names map on to.

Name on WebSphere Application Server administrative console panel	WebSphere Application Server command name	WebSphere MQ activation specification property
Retain messages, even if no matching consumer is available	msgRetention	messageRetention
Rescan interval	rescanInterval	rescanInterval
Maximum server sessions	maxPoolSize	maxPoolDepth
Start timeout	startTimeout	startTimeout
Server session pool timeout	poolTimeout	poolTimeout
Coded character set identifier	ccsid	CCSID
Fail JMS method calls if the queue manager is quiescing	failIfQuiescing	failIfQuiesce
Broker properties panel		
Broker control queue	brokerCtrlQueue	brokerControlQueue
Broker durable subscriber connection consumer queue	brokerCCDurSubQueue	brokerCCDurSubQueue
Broker subscriber queue	brokerSubQueue	brokerSubQueue

	brokerVersion	BVER	BROKERVER

Chapter 14. Managing messaging with a third-party or (deprecated) V5 default messaging provider

For messaging between application servers, most requirements are best met by either the default messaging provider or the WebSphere MQ messaging provider. However, you can instead use a third-party messaging provider (that is, use another company's product as the provider). You might want to do this, for example, if you have existing investments. For backwards compatibility with earlier releases, there is also support for the V5 default messaging provider.

Before you begin

If you are not sure which provider combination is best suited to your needs, see [Types of messaging providers](#).

About this task

Enterprise applications in WebSphere Application Server can use asynchronous messaging through services based on Java Message Service (JMS) messaging providers and their related messaging systems. These messaging providers conform to the JMS Version 1.1 specification.

The choice of provider depends on what your JMS application needs to do, and on other factors relating to your business environment and planned changes to that environment.

Procedure

- Choose a third-party messaging provider.

To administer a third-party messaging provider, you use either the resource adaptor (for a Java EE Connector Architecture (JCA) 1.5-compliant messaging provider) or the client (for a non-JCA messaging provider) that is supplied by the third party. You use the WebSphere Application Server administrative console to administer the activation specifications, connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

To use message-driven beans, third-party messaging providers must either provide an inbound JCA 1.5-compliant resource adapter, or (for non-JCA messaging providers) include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification.

To work with a third-party provider, choose one of the following options:

1. Manage messaging with a third-party JCA 1.5-compliant messaging provider.
 2. Manage messaging with a third-party non-JCA messaging provider.
- Choose the (deprecated) V5 default messaging provider.

This deprecated provider is identical to the WebSphere Application Server Version 5 default provider. Only the name has changed. It provides backwards compatibility that enables WebSphere Application Server Version 6 or later applications to connect to WebSphere Application Server Version 5 resources in a mixed cell. It also allows WebSphere Application Server Version 5 applications to connect to WebSphere Application Server Version 6 or later resources in a mixed cell. To configure and manage messaging to interoperate with WebSphere Application Server Version 5, see “Maintaining (deprecated) Version 5 default messaging resources” on page 1044.

Managing messaging with a third-party JCA 1.5-compliant messaging provider

You can configure WebSphere Application Server to use a third-party JCA 1.5-compliant messaging provider. You might want to do this, for example, if you have existing investments.

Before you begin

For messaging between application servers, perhaps with some interaction with a WebSphere MQ system, you can use the default messaging provider. To integrate WebSphere Application Server messaging into a predominately WebSphere MQ network, you can use the WebSphere MQ messaging provider. You can also use a third-party messaging provider as described in this topic. To choose the provider that is best suited to your needs, see [Choosing a messaging provider](#).

About this task

A third-party JCA 1.5-compliant messaging provider takes the form of a resource adapter that you install in WebSphere Application Server. You use the administrative console to administer the activation specifications (for message-driven beans) and other J2C administered objects for the provider.

In a mixed-version WebSphere Application Server deployment manager cell, you can administer third-party messaging resources on Version 7, Version 6 and Version 5 nodes. For Version 5 nodes, the administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.

Procedure

- Install the third-party JCA 1.5-compliant messaging provider.
Install the resource adapter for the third-party provider, as described in [“Installing a resource adapter archive”](#) on page 191.
- Configure an activation specification for a third-party JCA resource adapter.
- Configure an administered object for a third-party JCA resource adapter.

Configuring an activation specification for a third-party JCA resource adapter

You can configure an activation specification that is used to deploy message-driven beans with a Java™ Connector Architecture (JCA), also called J2EE Connector (J2C), resource adapter that is not included as part of the WebSphere Application Server.

Before you begin

For guidance about when to configure your message-driven beans to work with listener ports rather than activation specifications, see [Message-driven beans, activation specifications, and listener ports](#).

This task assumes that you have installed the resource adapter for the third-party provider, as described in [“Installing a resource adapter archive”](#) on page 191.

About this task

Use this task if you want to use a message-driven bean as a listener on a JCA resource adapter other than the default messaging provider or the WebSphere MQ messaging provider.

Procedure

1. Start the administrative console.
2. Display the resource adapter. In the navigation pane, click **Resources > Resource Adapters > *adapter_name***. This displays in the content pane a table of properties for the resource adapter, including links to the types of JCA resource that it provides.
3. Optional: Change the **Scope** setting to the scope level at which the activation specification is to be visible to applications, according to your needs.

4. In the content pane, under the Activation specifications heading, click **J2C Activation Specifications**. This lists any existing activation specifications for the resource adapter.
5. Display the properties of the activation specification.

If you want to display an existing activation specification, click one of the names listed.

Alternatively, if you want to create a new activation specification, click **New**, then specify the following required properties:

Name Type the name by which the activation specification is known for administrative purposes. The JNDI name is automatically generated based on the value for the Name property.

Message listener type

Select the message listener type that this activation specification instance should support. This list is based on the deployment descriptor of the resource adapter.

Depending on the resource adapter, there can be additional required properties that you must supply. To provide values for these properties, click **Custom properties**. When creating a new activation specification, you might have to click **Apply** before this custom property selection is available.

6. Specify properties for the activation specification, according to your needs.
7. Click **OK**.
8. Save your changes to the master configuration.

J2C Activation Specifications collection

This page contains a list of Java 2 Connector (J2C) activation specifications for a resource adapter configuration and is used to create new J2C activation specifications, to select J2C activation specifications for configuration changes, or to delete J2C activation specifications.

Activation specification definitions and classes are provided by a resource adapter when it is installed. Using this information, the administrator can create and configure J2C activation specifications with JNDI names that are then available for applications to use. The resource adapter uses a J2C activation specification to configure a specific endpoint instance. Each application configuring one or more endpoints must specify the resource adapter that sends messages to the endpoint. The application must use the activation specification to provide the configuration properties related to the processing of the inbound messages.

The following guidelines show which scenarios use activation specifications or listener ports:

- If you are using Java 2 Platform, Enterprise Edition (J2EE) 1.2 and EJB 1.1 with WebSphere Application Server v4, message driven beans (MDB) are not used so you do not need listener ports or activation specifications. WebSphere Application Server v4 uses message beans, but these are not MDBs or Enterprise JavaBeans (EJB).
- If you are using J2EE 1.3 and EJB 2.0 with WebSphere Application Server v5, you must use listener ports. The MDBs are JMS MDBs that implement MessageListener, and there is no JCA support. WebSphere Application Server v5 uses listener ports to associate MDB classes with their JMS destinations.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server v6, the decision depends on whether your JMS provider API is implemented with JCA. In J2EE 1.4, the JMS 1.1 API can now be implemented with the JCA 1.5 API. If so, your MDB is a JMS MDB that is implemented as a connector MDB, and must therefore be configured with an activation specification. If not, this is the same JMS situation as for J2EE 1.3, and you must configure this EJB 2.1 MDB in the same way as you would configure an EJB 2.0 MDB, which in WebSphere Application Server is to use a listener port.

You can access this administrative console page in one of two ways:

- **Resources > Resource Adapters > Resource adapters > *resource_adapter* > J2C activation specifications.**
- **Resources > Resource Adapters > J2C activation specifications.**

Name:

Specifies the display name of the J2C activation specification instance.

A string with no spaces meant to be a meaningful text identifier for the J2C activation specification.

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the J2C activation specification instance.

Data type String

Scope:

Specifies the scope of the resource adapter that supports this activation specification. Only applications that are installed within this scope can use this activation specification.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this activation specification.

Description:

A free-form text string to describe the J2C activation specification instance.

Data type String

Message Listener Type:

The Message Listener Type that is used by this activation specification.

The list of available classes is provided by the resource adapter.

Data type String

J2C Activation Specifications settings:

Use this page to specify the settings for a Java 2 Connector (J2C) activation specification.

The resource adapter uses a J2C activation specification to configure a specific endpoint instance. Each application configuring one or more endpoints must specify the resource adapter that sends messages to the endpoint. The application must use the activation specification to provide the configuration properties related to the processing of the inbound messages.

You can access this administrative console page in one of two ways:

- **Resources > Resource Adapters > Resource adapters > *resource_adapter* > J2C activation specifications > *activation_specification*.**
- **Resources > Resource Adapters > J2C activation specifications > *activation_specification*.**

Scope:

Specifies the scope of the resource adapter that supports this activation specification. Only applications that are installed within this scope can use this activation specification.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this activation specification.

For new objects, available resource adapters are listed in a drop-down list. After you create the activation specification, the field is a read only text field.

Data type Drop-down list or text

Name:

Specifies the display name of the J2C activation specification instance.

A string with no spaces meant to be a meaningful text identifier for the J2C activation specification. Name is required

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the J2C activation specification instance.

The JNDI name is required. If you do not specify one, it is created from the Name field. If not specified, the JNDI name defaults to *eis/[name]*

Data type String

Description:

A free-form text string to describe the J2C activation specification instance.

Data type String

Authentication alias:

This optional field is used to bind the J2C activation specification to an authentication alias (configured through the security JAAS screens).

This alias is used to access a user name and password that are set on the configured J2C activation specification. This field is meaningful only if the J2C activation specification that you are configuring has a UserName and Password field.

If you have defined security domains in the application server, you can click **Browse...** to select a J2C authentication alias for the resource that you are configuring. Security domains allow you to isolate J2C authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that is able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

The Browse button is only accessible if at least one security domain is defined and assigned a scope that is applicable to the resource that is being edited. Additionally, that security domain must contain at least one JAAS J2C Authentication alias.

Data type Drop-down list

Message Listener Type:

The Message Listener Type used by this activation specification.

For new objects, the list of available classes is provided by the resource adapter in a drop-down list. After you create the activation specification, the field is a read only text field.

Data type Drop-down list or text

Destination JNDIName:

The destination JNDIName field appears only when a message of type javax.jms.Destination with name *Destination* is received.

Configuring an administered object for a third-party JCA resource adapter

You can configure an administered object for a Java™ Connector Architecture (JCA), also called J2EE Connector (J2C), resource adapter that is not included as part of the WebSphere Application Server.

Before you begin

This task assumes that you have installed the resource adapter for the third-party provider, as described in “Installing a resource adapter archive” on page 191.

About this task

Use this task if you want to configure a JCA administered object for a JCA resource adapter other than the default messaging provider or the WebSphere MQ messaging provider.

Procedure

1. Start the administrative console.
2. Display the resource adapter. In the navigation pane, click **Resources > Resource Adapters > adapter_name**. This displays in the content pane a table of properties for the resource adapter, including links to the types of JCA resource that it provides.
3. Optional: Change the **Scope** setting to the scope level at which the administered object is to be visible to applications, according to your needs.
4. In the content pane, under the Additional Properties heading, click **J2C Administered Objects**. This lists any existing administered objects for the resource adapter.
5. Display the properties of the administered object.

If you want to display an existing administered object, click one of the names listed.

Alternatively, if you want to create a new administered object, click **New**, then specify the following required properties:

Name Type the name by which the administered object is known for administrative purposes. The JNDI name is automatically generated based on the value for the Name property.

Administered object class

Select the administered object class that this instance should support. This list is based on the deployment descriptor of the resource adapter.

Depending on the resource adapter, there can be additional required properties that you must supply. To provide values for these properties, click **Custom properties**. When creating a new administered object, you might have to click **Apply** before this custom property selection is available.

6. Specify properties for the administered object, according to your needs.
7. Click **OK**.
8. Save your changes to the master configuration.

J2C Administered Objects collection

This page contains a list of Java 2 Connector Architecture (JCA) administered objects for a resource adapter configuration. This page is also used to create JCA administered objects, select J2C administered objects for configuration changes, or to delete J2C administered objects.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with JNDI names that are then available for applications to use. Some messaging styles might need applications to use special administered objects for sending and synchronously receiving messages through connection objects with messaging style-specific APIs. Administered objects can also be used to perform transformations on an asynchronously received message in a message provider-specific way. Administered objects can be accessed by a component by using either a resource environment reference or a message destination reference (preferred).

You can access this administrative console page in one of two ways:

- **Resources > Resource Adapters > Resource adapters > *resource_adapter* > J2C administered objects**
- **Resources > Resource Adapters > Resource adapters > J2C administered objects**

Name:

Specifies display name assigned to this administered object.

Data type String

JNDI Name:

Specifies the JNDI name of the administered object.

Data type String

Scope:

Specifies the scope of the resource adapter that supports this administered object. Only applications that are installed within this scope can use this object.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this administrative object.

For new objects, available resource adapters are listed in a drop-down list. After you create the administered object, the field is a read only text field.

Data type Drop-down list or text

Description:

Specifies a description for the administered object.

Data type String

Administered object class:

Specifies the Administered Object class that is associated with this J2C administered object. This class must be one that is provided by the resource adapter.

Data type String

J2C Administered Object settings:

Use this page to specify the settings for a Java 2 Connector (J2C) administered object.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with Java Naming and Directory Interface (JNDI) names that are then available for applications to use. Some messaging styles may need applications to use special administered objects for sending and synchronously receiving messages (through connection objects using messaging style specific APIs). It is also possible that administered objects may be used to perform transformations on an asynchronously received message in a message provider-specific way. Administered objects can be accessed by a component by using either a resource environment reference or a message destination reference (preferred).

You can access this administrative console page in one of two ways:

- **Resources > Resource Adapters > Resource adapters > *resource_adapter* > J2C administered objects > *J2C_administered_object***
- **Resources > Resource Adapters > Resource adapters > J2C administered objects > *J2C_administered_object***

Scope:

Specifies the scope of the resource adapter that supports this administered object. Only applications that are installed within this scope can use this object.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this administrative object.

For new objects, a list of available resource adapters appears in a drop-down list. After you create the administered object, the field is a read only text field.

Data type Drop-down list or text

Name:

Specifies the name of the J2C administered object instance.

A string with no spaces meant to be a meaningful text identifier for the administered object. This name is required.

Data type String

JNDI name:

Specifies the JNDI name that this administered object is bound under.

The JNDI name is required. If you do not specify one, it is created from the Name field. If not specified, the JNDI name defaults to *eis/[name]*

Data type String

Description:

Specifies a text description of the J2C administered object instance.

Data type String

Administered object class:

For new objects, the list of available classes is provided by the resource adapter in a drop-down list. You can only select classes from this list.

After you create the administered object, you cannot modify the administered object class; it is read only.

Data type Class name

Managing messaging with a third-party non-JCA messaging provider

You can configure WebSphere Application Server to use a third-party non-JCA messaging provider. You might want to do this, for example, if you have existing investments. You can configure any third-party non-JCA messaging provider that supports the JMS Version 1.1 unified connection factory.

Before you begin

For messaging between application servers, perhaps with some interaction with a WebSphere MQ system, you can use the default messaging provider. To integrate WebSphere Application Server messaging into a predominately WebSphere MQ network, you can use the WebSphere MQ messaging provider. You can also use a third-party messaging provider as described in this topic. To choose the provider that is best suited to your needs, see *Choosing a messaging provider*.

To work with message-driven beans, the third-party non-JCA messaging provider must include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification.

About this task

To administer a third-party non-JCA messaging provider, you use the client that is supplied by the third party. You use the administrative console to administer the connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

In a mixed-version WebSphere Application Server deployment manager cell, you can administer third-party messaging resources on Version 7, Version 6 and Version 5 nodes. For Version 5 nodes, the

administrative console presents the subset of resources and properties that are applicable to WebSphere Application Server Version 5.

Procedure

- Define a third-party non-JCA messaging provider.
- List JMS resources for a third-party non-JCA messaging provider.
- Configure JMS resources for a third-party non-JCA messaging provider.

Defining a third-party non-JCA messaging provider

Use this task to define a third-party non-JCA messaging provider to WebSphere Application Server. You might want to do this, for example, if you have existing investments.

Before you begin

Before you define a third-party non-JCA messaging provider, you might want to check whether your requirement can be met by the default messaging provider or the WebSphere MQ messaging provider that are supplied with WebSphere Application Server. To choose the provider that is best suited to your needs, see [Choosing a messaging provider](#).

To work with message-driven beans, the third-party non-JCA messaging provider must include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification.

About this task

You can configure any third-party non-JCA messaging provider that supports the JMS Version 1.1 unified connection factory.

To administer a third-party non-JCA messaging provider, you use the client that is supplied by the third party. You use the administrative console to administer the connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Resources > JMS->JMS providers**. The existing messaging providers are displayed, including the default messaging provider and the WebSphere MQ messaging provider.
3. To define a new third-party non-JCA messaging provider, click **New** in the content pane. Otherwise, to change the definition of an existing messaging provider, click the name of the provider.
4. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this messaging provider is known for administrative purposes within WebSphere Application Server.

External initial context factory

The Java classname of the initial context factory for the JMS provider.

External provider URL

The JMS provider URL for external JNDI lookups.

5. Optional: Click **Apply**. This enables you to specify additional properties.
6. Optional: Specify other properties for the messaging provider.
Under Additional Properties, you can use the **Custom Properties** link to specify custom properties for your initial context factory, in the form of standard **javax.naming** properties.
7. Click **OK**.
8. Save the changes to the master configuration.

9. To have the changed configuration take effect, stop then restart the application server.

What to do next

You can now configure JMS resources for your messaging provider, as described in “Configuring JMS resources for a third-party non-JCA messaging provider” on page 1037.

JMS provider settings

Use this panel to view the configuration properties of a selected JMS provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->JMS providers**. This displays a list of JMS providers in the content pane. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.
2. (optional) If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.
3. In the Providers column of the list displayed, click the name of a JMS provider.

If you want to browse or change JMS resources of the JMS provider, click the link for the type of resource under Additional Properties. For more information about the administrative console panels for the types of JMS resources, see the related topics.

For the default messaging provider (which is based on service integration technologies) and the WebSphere MQ messaging provider, the scope, name, and description properties are displayed for information only. You cannot change these properties.

For a third-party non-JCA provider that you have defined yourself, the properties of that provider are displayed.

Scope:

The level (cell, node, or server level) at which this resource definition is available.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes. For more information about the scope setting, see Scope settings.

Name:

The name by which the JMS provider is known for administrative purposes.

Data type	String
------------------	--------

Default

- Default messaging provider.
For JMS resources to be provided by a service integration bus, as part of WebSphere Application Server.
- *My JMSprovider*
For JMS resources to be provided by a third-party JMS provider that you specify, rather than by the default messaging provider or the WebSphere MQ messaging provider that are available as part of WebSphere Application Server. You assign the name, for example “My JMSprovider”, when you define the third-party JMS provider to WebSphere Application Server. You must also have installed and configured the third-party JMS provider before applications can use its JMS resources.
- WebSphere MQ messaging provider
For JMS resources to be provided by WebSphere MQ. You must have installed and configured WebSphere MQ before applications can use its JMS resources.
- V5 default messaging provider.
For JMS resources to be provided by a WebSphere Application Server Version 5 node in a deployment manager cell.

Description:

A description of the JMS provider, for administrative purposes within WebSphere Application Server.

Data type String

Classpath:

A list of paths or JAR file names that together form the location for the JMS provider classes. Each class path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Class paths can contain variable (symbolic) names to be substituted by using a variable map. Check your driver installation notes for specific JAR file names that are required.

Note: This property is only available for third-party messaging providers.

Data type String

Native library path:

An optional path to any native libraries (*.dll, *.so). Each native path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Native paths can contain variable (symbolic) names to be substituted by using a variable map.

Note: This property is only available for the WebSphere MQ messaging provider and third-party messaging providers.

Data type String

Enable JCA based inbound message delivery:

Specifies that WebSphere MQ messaging provider will support inbound delivering of messages using the JCA defined interfaces.

Note: This property is only available for the WebSphere MQ messaging provider, at the server scope.

When using WebSphere MQ messaging provider activation specifications on the z/OS operating system, you must enable the control region adjunct (CRA) process to allow messages to be delivered. Selecting this option starts the control region adjunct process on the next server restart.

Data type	Check box
Default	Cleared
Range	Cleared Do not start the control region adjunct process.
	Selected Start the control region adjunct process.

Update resource adapter:

This button can be used to update the WebSphere MQ resource adapter that provides the function made available by the WebSphere MQ messaging provider. This button must only be used as directed by a member of IBM service, otherwise it may result in the use of an unsupported level of the WebSphere MQ resource adapter.

Normally the WebSphere MQ resource adapter is automatically updated by applying WebSphere Application Server fix packs. It is important to note that use of the **Update resource adapter** button prevents these automatic updates from happening for future fix packs for any node on which the button is used. If, in the future, you require the WebSphere MQ resource adapter used by the node to receive updates when a fix pack is applied then you must re-establish the recommended resource adapter configuration. For more information see “Maintaining the WebSphere MQ resource adapter” on page 807.

Note: This property is only available for the WebSphere MQ messaging provider.

Data type	Button
------------------	--------

External initial context factory:

The Java classname of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: com.sun.jndi.ldap.LdapCtxFactory.

Note: This property is only available for third-party messaging providers.

Data type	String
Default	Null

External provider URL:

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a messaging provider has the form: ldap://hostname.company.com/contextName.

Note: This property is only available for third-party messaging providers.

Data type	String
Default	Null

Disable WebSphere MQ:

This check box is only valid for the WebSphere MQ messaging provider. When selected, this check box disables all WebSphere MQ functionality on affected application servers. Note that you must restart the affected application server processes for this change to take effect.

In a single server environment this check box is only available on the WebSphere MQ messaging provider panel where the scope is set to server, and has the effect of disabling all WebSphere MQ functionality in that application server.

In a network deployment environment this check box is available on all WebSphere MQ messaging provider panels. The effect of selecting the check box depends on the scope at which you select it:

- At the cell scope, all WebSphere MQ functionality is disabled on all application servers in the cell.
- At the node scope, all WebSphere MQ functionality is disabled on all application servers that are part of that node.
- At the cluster scope, all WebSphere MQ functionality is disabled on all application servers in that cluster.
- At the server scope, all WebSphere MQ functionality is disabled in that particular application server.

The value of the check box at a higher scope takes precedence over the value at a lower scope. For example, if you do not select the check box for a WebSphere MQ messaging provider at the server scope, but do select it for a WebSphere MQ messaging provider at a higher scope (such as the cell scope), the value of the check box at the cell scope takes precedence and WebSphere MQ functionality is therefore disabled in all application servers in the cell, regardless of whether the check box is selected at the server scope.

An informational message indicating that WebSphere MQ has been disabled is added to all WebSphere MQ messaging provider panels that are at affected scopes, but this message does not appear on those panels where the check box is selected. In a single server environment this informational message is only displayed after a server restart is performed. In a network deployment environment the informational message is displayed immediately.

For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

Data type	Check box
Default	Not selected

Additional properties:

Connection factories

A connection factory is used to create connections to the associated JMS provider. These connection factories can be used for accessing JMS Queue and JMS Topic destinations.

Queue connection factories

A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

Topic connection factories

A topic connection factory is used to create connections to the associated JMS provider of JMS topic destinations, for publish and subscribe messaging.

Queues

A JMS queue is used as a destination for point-to-point messaging.

Topics

A JMS topic is used as a destination for publish/subscribe messaging.

Activation specifications

A JMS activation specification is associated with one or more message-driven beans and provides configuration necessary for them to receive messages.

Resource adapter properties

These properties are used to configure the WebSphere MQ resource adapter, which is used by the WebSphere MQ messaging provider. In particular most of these settings affect the behavior of WebSphere MQ messaging provider activation specifications.

Listing JMS resources for a third-party non-JCA messaging provider

Use the WebSphere Application Server administrative console to list JMS resources for a third party non-JCA messaging provider.

Before you begin

This topic assumes that you have defined a third-party non-JCA messaging provider.

About this task

You use the WebSphere Application Server administrative console to list JMS resources, if you want to view, modify or delete any of the following resources:

- Unified connection factories
- Queue connection factories
- Topic connection factories
- Queues
- Topics

When you use the administrative console to locate these resources, two different navigation pathways are available:

- **Provider-centric navigation** lets you view all providers, or just those for a specified scope, then navigate to a specific resource for a specific provider. This is the traditional way of navigating to a resource when you know which provider supports it. Any navigation that starts with **Resources > JMS->JMS providers** is provider-centric.
- **Resource-centric navigation** lets you view all resources of a specified type, then navigate to a resource. This is useful if you want to find a resource, but you do not know which provider supports it (you can list all resources of a given type across all scopes, for all providers, in a single panel). Any navigation that follows the pattern **Resources > JMS > resource_type** is resource-centric, where *resource_type* is one of the resource types previously listed.

You can use either of these navigation pathways to locate JMS resources of any type.

Procedure

- Use provider-centric navigation, for example to navigate to a specified queue connection factory.
 1. Start the administrative console.
 2. In the navigation pane, click **Resources > JMS->JMS providers**.

The JMS providers collection panel is displayed. This lists all currently configured messaging providers across all scopes (you can modify the scope if required).
 3. Select the required JMS provider.

The settings panel for this provider is displayed. The configuration tab contains a set of links to all the JMS resources owned by this provider.

4. Click the link for a JMS resource type. For example, click **Queue connection factories**.

The queue connection factories collection panel is displayed. This panel lists all the queue connection factories for this provider.

5. Select the required queue connection factory.

- Use resource-centric navigation, for example to navigate to a specified queue connection factory.

1. Start the administrative console..

2. In the navigation pane, click **Resources > JMS->Queue connection factories**.

The queue connection factories collection panel is displayed. This panel lists all the queue connection factories across all messaging providers.

3. Select the required queue connection factory.

Results

You can now view and work with the resource properties.

JMS providers collection

Use this panel to list JMS providers, or to select a JMS provider to view or change its configuration properties.

To view this administrative console page, click **Resources > JMS->JMS providers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS providers that are available to WebSphere applications. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.

If you want to manage existing JMS resource definitions, or create a new JMS resource definition, you can select the name of one of the JMS providers in the list.

If you want to define a new third-party JMS provider (that is, a provider other than the default messaging provider or the WebSphere MQ messaging provider), select the Scope setting at which JMS resource definitions are to be visible for that provider, then click **New**.

Name The name by which this JMS provider is known for administrative purposes.

Description

A description of this JMS provider for administrative purposes.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Connection factory collection

A JMS connection factory is used to create connections to the associated messaging provider of JMS destinations, for both point-to-point and publish/subscribe messaging. Use connection factory administrative objects to manage JMS connection factories for the default messaging provider, the WebSphere MQ messaging provider or a third-party messaging provider.

In the administrative console, to view this page click **Resources > JMS->Connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory of the messaging provider named in the **Provider** column of the list.

This type of connection factory is for applications that use the JMS 1.1 domain-independent interfaces (referred to as the “common interfaces” in the JMS specification).

This type of JMS connection factory can also be used by the domain-specific (queue and topic) interfaces, as used in JMS 1.0.2, so applications can still use those interfaces without the need for you to create a domain-specific connection factory, such as a queue connection factory.

In a mixed release cell, these connection factories are only available for Version 7 and later nodes.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

Name The display name of each connection factory instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each connection factory instance.

Provider

The messaging provider that supports each connection factory instance. This is the default messaging provider (service integration), the WebSphere MQ messaging provider or a third-party messaging provider.

Description

An optional description of each connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue connection factory collection

A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

In the administrative console, to view this page click **Resources > JMS->Queue connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS queue connection factory is used to create connections to JMS destinations. When an application needs a JMS queue connection, an instance can be created by the factory for the JMS provider that is named in the **Provider** column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 queue-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

Name The display name of each queue connection factory instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each queue connection factory instance.

Provider

The messaging provider that supports each queue connection factory instance.

Description

An optional description of each queue connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic connection factory collection

A JMS topic connection factory is used to create connections to the associated messaging provider of JMS topic destinations, for publish and subscribe messaging.

In the administrative console, to view this page click **Resources > JMS->Topic connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory for the JMS provider that is named in the Provider column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 topic-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

General properties

Name The display name of each topic connection factory instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each topic connection factory instance.

Provider

The messaging provider that supports each topic connection factory instance.

Description

An optional description of each topic connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue collection

A JMS queue destination is used for point-to-point messaging. Use this panel to create or delete queue destinations, or to select a queue destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources > JMS->Queues**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a queue destination to manage JMS queues for the JMS provider that is named in the **Provider** column of the list. Connections to the queue are created by a unified connection factory or queue connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

General properties

Name The display name of each queue destination instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each queue destination instance.

Provider

The messaging provider that supports each queue destination instance.

Description

An optional description of each queue destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic collection

A JMS topic destination is used for publish and subscribe messaging. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources > JMS->Topics**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a topic destination to manage JMS topics for the JMS provider that is named in the **Provider** column of the list. Connections to the topic are created by a unified connection factory or topic connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

General properties

Name The display name of each topic destination instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each topic destination instance.

Provider

The messaging provider that supports each topic destination instance.

Description

An optional description of each topic destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Configuring JMS resources for a third-party non-JCA messaging provider

Use this task to configure the JMS connection factories and destinations for a third-party non-JCA messaging provider.

Before you begin

You only have to complete these tasks if your WebSphere Application Server environment uses a third-party non-JCA messaging provider to support enterprise applications that use JMS.

Before you can configure resources for your third-party non-JCA messaging provider, you must have defined your messaging provider.

About this task

To configure JMS resources for a third-party non-JCA messaging provider, complete the following tasks:

Procedure

- Configure a JMS connection factory for a third-party non-JCA messaging provider.
- Configure a JMS destination for a third-party non-JCA messaging provider.

Configuring a JMS connection factory for a third-party non-JCA messaging provider

Use this task to view or change the properties of a JMS connection factory for use with a third-party non-JCA messaging provider.

About this task

To view or change the configuration of a JMS connection factory for use with a third-party non-JCA messaging provider, use the administrative console to complete the following steps:

Procedure

1. Display the third-party non-JCA messaging provider. In the navigation pane, click **Resources > JMS->JMS providers**.
2. Select the third-party non-JCA messaging provider for which you want to configure a connection factory.
3. Optional: Select the **Scope** setting corresponding to the scope of the connection factories that you want to view or change.
4. In the content pane, under Additional Properties, click **Connection factories**. This displays a table listing any existing JMS connection factories, with a summary of their properties.
5. To browse or change an existing JMS connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server.

Type Select whether the connection factory is for JMS queues (QUEUE) or JMS topics (TOPIC).

JNDI Name
The JNDI name that is used to bind the JMS connection factory into the WebSphere Application Server namespace.

External JNDI Name
The JNDI name that is used to bind the JMS connection factory into the namespace of the messaging provider.
 - c. Click **Apply**. This defines the JMS connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the JMS connection factory, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Third-party JMS connection factory settings:

Use this panel to browse or change the configuration properties of a JMS connection factory configured for use with a third-party non-JCA messaging provider. These configuration properties control how connections are created to the JMS destinations on the provider.

A JMS connection factory is used to create connections to JMS destinations. The JMS connection factory is created by the associated JMS provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->JMS providers**. The JMS providers collection panel is displayed. This lists all currently configured messaging providers across all scopes (you can modify the scope if required).
2. Click the name of the third-party non-JCA messaging provider.
3. Under Additional Properties, click **Connection factories**.
4. Click the name of the JMS connection factory that you want to work with.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated messaging provider.

Data type String

Type:

Whether this connection factory is for creating JMS queue destinations or JMS topic destinations.

Select one of the following options:

QUEUE

A JMS queue connection factory for point-to-point messaging.

TOPIC

A JMS topic connection factory for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the connection factory into the WebSphere Application Server namespace.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String
------------------	--------

External JNDI name:

The JNDI name that is used to bind the connection factory into the namespace of the third-party messaging provider.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String
------------------	--------

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS

provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field provides a list of the modules that have been configured on the **Global Security > JAAS Configuration > Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type	Enum
Default	Null
Range	ClientContainer The client container maps authentication aliases.
	WSLogin The WSLogin module maps authentication aliases.
	DefaultPrincipalMapping The JAAS configuration maps an authentication alias to its userid and password.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Custom properties:

An optional set of name and value pairs for custom properties passed to the messaging provider.

Configuring a JMS destination for a third-party non-JCA messaging provider

Use this task to browse or change the properties of a JMS destination for use with a third-party non-JCA messaging provider.

Before you begin

Before starting this task, you should have defined the messaging provider to WebSphere Application Server.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Resources > JMS->JMS providers**.
3. Click the name of the third-party non-JCA messaging provider.
4. In the content pane, under Additional Properties, click **Queues** for point-to-point messaging or **Topics** for publish/subscribe messaging. This displays a table listing any existing JMS destinations, with a summary of their properties.
5. To browse or change an existing JMS destination, click its name in the list. Otherwise, to create a new destination, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS destination is known for administrative purposes within WebSphere Application Server.

Type Select whether the destination is for JMS queues (QUEUE) or JMS topics (TOPIC).

JNDI Name

The JNDI name that is used to bind the JMS destination into the WebSphere Application Server namespace.

External JNDI Name

The JNDI name that is used to bind the JMS destination into the namespace of the messaging provider.

- c. Click **Apply**. This defines the JMS destination to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the JMS destination, according to your needs.
 7. Click **OK**.
 8. Save any changes to the master configuration.
 9. To have the changed configuration take effect, stop then restart the application server.

Third-party JMS destination settings:

Use this panel to browse or change the configuration properties of the selected JMS destination for use with an associated third-party non-JCA messaging provider.

A JMS destination is used to configure the properties of a JMS destination for the associated third-party non-JCA messaging provider. Connections to the JMS destination are created by the associated JMS connection factory.

To navigate to this panel, complete the following steps:

1. In the navigation pane, click **Resources > JMS->JMS providers**. The JMS providers collection panel is displayed. This lists all currently configured messaging providers across all scopes (you can modify the scope if required).
2. Click the name of the third-party non-JCA messaging provider.
3. Under Additional Properties, click **Queues** for point-to-point messaging or **Topics** for publish/subscribe messaging.
4. Click the name of the JMS destination that you want to work with.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publish/subscribe).

Select one of the following options:

Queue

A JMS queue destination for point-to-point messaging.

Topic A JMS topic destination for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the queue into the application server namespace.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes

Data type String

Category:

A category used to classify or group this queue, for your WebSphere Application Server administrative records.

Data type String

External JNDI name:

The JNDI name that is used to bind the queue into the application server namespace.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Maintaining (deprecated) Version 5 default messaging resources

You can use the WebSphere Application Server administrative console to manage the JMS connection factories and destinations for WebSphere Application Server Version 5.1 applications. JMS connection factories and destinations for the WebSphere Application Server Version 5.1 default messaging provider are not the same as those for the default messaging provider in WebSphere Application Server Version 6 and later. Such JMS resources are maintained as *V5 default messaging* resources.

About this task

In a deployment manager cell, you can use V5 default messaging resources to maintain Version 5 default messaging resources for nodes in the cell that are at later versions.

- V5 default messaging configured against a node in a later version of the product provides a JMS transport to a messaging engine of a service integration bus that supports the default messaging provider in that later version. The messaging engine emulates the service of a JMS server running on WebSphere Application Server Version 5.1.
- V5 default messaging configured against a Version 5.1 node provides a JMS transport to a JMS server running on WebSphere Application Server Version 5.1.

On a WebSphere Application Server Version 5.1 node in a deployment manager cell, a JMS server provides the functions of the JMS provider. You can also use the administrative console to manage a JMS server on a Version 5.1 node.

Procedure

- List Version 5 default messaging resources.
- Configure Version 5 default messaging resources.
- Manage Version 5 JMS servers in a deployment manager cell.

JMS provider settings

Use this panel to view the configuration properties of a selected JMS provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->JMS providers**. This displays a list of JMS providers in the content pane. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.
2. (optional) If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.

3. In the Providers column of the list displayed, click the name of a JMS provider.

If you want to browse or change JMS resources of the JMS provider, click the link for the type of resource under Additional Properties. For more information about the administrative console panels for the types of JMS resources, see the related topics.

For the default messaging provider (which is based on service integration technologies) and the WebSphere MQ messaging provider, the scope, name, and description properties are displayed for information only. You cannot change these properties.

For a third-party non-JCA provider that you have defined yourself, the properties of that provider are displayed.

Scope

The level (cell, node, or server level) at which this resource definition is available.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes. For more information about the scope setting, see Scope settings.

Name

The name by which the JMS provider is known for administrative purposes.

Data type

String

Default

- Default messaging provider.
For JMS resources to be provided by a service integration bus, as part of WebSphere Application Server.
- *My JMSprovider*
For JMS resources to be provided by a third-party JMS provider that you specify, rather than by the default messaging provider or the WebSphere MQ messaging provider that are available as part of WebSphere Application Server. You assign the name, for example "My JMSprovider", when you define the third-party JMS provider to WebSphere Application Server. You must also have installed and configured the third-party JMS provider before applications can use its JMS resources.
- WebSphere MQ messaging provider
For JMS resources to be provided by WebSphere MQ. You must have installed and configured WebSphere MQ before applications can use its JMS resources.
- V5 default messaging provider.
For JMS resources to be provided by a WebSphere Application Server Version 5 node in a deployment manager cell.

Description

A description of the JMS provider, for administrative purposes within WebSphere Application Server.

Data type

String

Classpath

A list of paths or JAR file names that together form the location for the JMS provider classes. Each class path entry is on a separate line (separated by using the Enter key) and must not contain path separator

characters (such as ';' or ': '). Class paths can contain variable (symbolic) names to be substituted by using a variable map. Check your driver installation notes for specific JAR file names that are required.

Note: This property is only available for third-party messaging providers.

Data type String

Native library path

An optional path to any native libraries (*.dll, *.so). Each native path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Native paths can contain variable (symbolic) names to be substituted by using a variable map.

Note: This property is only available for the WebSphere MQ messaging provider and third-party messaging providers.

Data type String

Enable JCA based inbound message delivery

Specifies that WebSphere MQ messaging provider will support inbound delivering of messages using the JCA defined interfaces.

Note: This property is only available for the WebSphere MQ messaging provider, at the server scope.

When using WebSphere MQ messaging provider activation specifications on the z/OS operating system, you must enable the control region adjunct (CRA) process to allow messages to be delivered. Selecting this option starts the control region adjunct process on the next server restart.

Data type	Check box
Default	Cleared
Range	Cleared Do not start the control region adjunct process.
	Selected Start the control region adjunct process.

Update resource adapter

This button can be used to update the WebSphere MQ resource adapter that provides the function made available by the WebSphere MQ messaging provider. This button must only be used as directed by a member of IBM service, otherwise it may result in the use of an unsupported level of the WebSphere MQ resource adapter.

Normally the WebSphere MQ resource adapter is automatically updated by applying WebSphere Application Server fix packs. It is important to note that use of the **Update resource adapter** button prevents these automatic updates from happening for future fix packs for any node on which the button is used. If, in the future, you require the WebSphere MQ resource adapter used by the node to receive updates when a fix pack is applied then you must re-establish the recommended resource adapter configuration. For more information see “Maintaining the WebSphere MQ resource adapter” on page 807.

Note: This property is only available for the WebSphere MQ messaging provider.

Data type Button

External initial context factory

The Java classname of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Note: This property is only available for third-party messaging providers.

Data type	String
Default	Null

External provider URL

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a messaging provider has the form: `ldap://hostname.company.com/contextName`.

Note: This property is only available for third-party messaging providers.

Data type	String
Default	Null

Disable WebSphere MQ

This check box is only valid for the WebSphere MQ messaging provider. When selected, this check box disables all WebSphere MQ functionality on affected application servers. Note that you must restart the affected application server processes for this change to take effect.

In a single server environment this check box is only available on the WebSphere MQ messaging provider panel where the scope is set to server, and has the effect of disabling all WebSphere MQ functionality in that application server.

In a network deployment environment this check box is available on all WebSphere MQ messaging provider panels. The effect of selecting the check box depends on the scope at which you select it:

- At the cell scope, all WebSphere MQ functionality is disabled on all application servers in the cell.
- At the node scope, all WebSphere MQ functionality is disabled on all application servers that are part of that node.
- At the cluster scope, all WebSphere MQ functionality is disabled on all application servers in that cluster.
- At the server scope, all WebSphere MQ functionality is disabled in that particular application server.

The value of the check box at a higher scope takes precedence over the value at a lower scope. For example, if you do not select the check box for a WebSphere MQ messaging provider at the server scope, but do select it for a WebSphere MQ messaging provider at a higher scope (such as the cell scope), the value of the check box at the cell scope takes precedence and WebSphere MQ functionality is therefore disabled in all application servers in the cell, regardless of whether the check box is selected at the server scope.

An informational message indicating that WebSphere MQ has been disabled is added to all WebSphere MQ messaging provider panels that are at affected scopes, but this message does not appear on those panels where the check box is selected. In a single server environment this informational message is only displayed after a server restart is performed. In a network deployment environment the informational message is displayed immediately.

For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

Data type
Default

Check box
Not selected

Additional properties

Connection factories

A connection factory is used to create connections to the associated JMS provider. These connection factories can be used for accessing JMS Queue and JMS Topic destinations.

Queue connection factories

A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

Topic connection factories

A topic connection factory is used to create connections to the associated JMS provider of JMS topic destinations, for publish and subscribe messaging.

Queues

A JMS queue is used as a destination for point-to-point messaging.

Topics

A JMS topic is used as a destination for publish/subscribe messaging.

Activation specifications

A JMS activation specification is associated with one or more message-driven beans and provides configuration necessary for them to receive messages.

Resource adapter properties

These properties are used to configure the WebSphere MQ resource adapter, which is used by the WebSphere MQ messaging provider. In particular most of these settings affect the behavior of WebSphere MQ messaging provider activation specifications.

Listing Version 5 default messaging resources

Use the WebSphere Application Server administrative console to list JMS resources for the V5 default messaging provider, for administrative purposes.

About this task

You use the WebSphere Application Server administrative console to list JMS resources, if you want to view, modify or delete any of the following resources:

- Queue connection factories
- Topic connection factories
- Queues
- Topics

When you use the administrative console to locate these resources, two different navigation pathways are available:

- **Provider-centric navigation** lets you view all providers, or just those for a specified scope, then navigate to a specific resource for a specific provider. This is the traditional way of navigating to a resource when you know which provider supports it. Any navigation that starts with **Resources > JMS->JMS providers** is provider-centric.
- **Resource-centric navigation** lets you view all resources of a specified type, then navigate to a resource. This is useful if you want to find a resource, but you do not know which provider supports it (you can list all resources of a given type across all scopes, for all providers, in a single panel). Any navigation that follows the pattern **Resources > JMS > resource_type** is resource-centric, where *resource_type* is one of the resource types previously listed.

You can use either of these navigation pathways to locate JMS resources of any type.

On a WebSphere Application Server Version 5 node, a JMS server provides the functions of the JMS provider. You can also list JMS servers on WebSphere Application Server Version 5 nodes within the administration domain, or select a JMS server to view or change its configuration properties.

Procedure

- Use provider-centric navigation, for example to navigate to a specified queue connection factory.
 1. Start the administrative console.
 2. In the navigation pane, click **Resources > JMS->JMS providers**.
The JMS providers collection panel is displayed. This lists all currently configured messaging providers across all scopes (you can modify the scope if required).
 3. Select the required JMS provider.
The settings panel for this provider is displayed. The configuration tab contains a set of links to all the JMS resources owned by this provider.
 4. Click the link for a JMS resource type. For example, click **Queue connection factories**.
The queue connection factories collection panel is displayed. This panel lists all the queue connection factories for this provider.
 5. Select the required queue connection factory.
- Use resource-centric navigation, for example to navigate to a specified queue connection factory.
 1. Start the administrative console..
 2. In the navigation pane, click **Resources > JMS->Queue connection factories**.
The queue connection factories collection panel is displayed. This panel lists all the queue connection factories across all messaging providers.
 3. Select the required queue connection factory.
- Navigate to a JMS server on a WebSphere Application Server Version 5 node.
 1. Start the administrative console.
 2. In the navigation pane, click **Servers > Server Types > Version 5 JMS servers**.
The Version 5 JMS server collection panel is displayed. This panel lists all the JMS servers on WebSphere Application Server Version 5 nodes within the administrative domain.
 3. Select the required JMS server.

Results

You can now view and work with the resource properties.

Version 5 JMS server collection

On a WebSphere Application Server Version 5 node, a JMS server provides the functions of the JMS provider. Use this panel to list JMS servers on WebSphere Application Server Version 5 nodes within the administration domain, or to select a JMS server to view or change its configuration properties.

There can be at most one JMS server on each Version 5 node in the administrative domain. Any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

To view this page:

1. Start the administrative console.
2. In the navigation pane, click **Servers > Server Types > Version 5 JMS servers**.

To browse or change the properties of a JMS server, select its name in the list displayed.

To act on one or more of the JMS servers listed, click the check box next to the server name, then use the buttons provided.

JMS providers collection

Use this panel to list JMS providers, or to select a JMS provider to view or change its configuration properties.

To view this administrative console page, click **Resources > JMS->JMS providers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS providers that are available to WebSphere applications. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.

If you want to manage existing JMS resource definitions, or create a new JMS resource definition, you can select the name of one of the JMS providers in the list.

If you want to define a new third-party JMS provider (that is, a provider other than the default messaging provider or the WebSphere MQ messaging provider), select the Scope setting at which JMS resource definitions are to be visible for that provider, then click **New**.

Name The name by which this JMS provider is known for administrative purposes.

Description

A description of this JMS provider for administrative purposes.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue connection factory collection

A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

In the administrative console, to view this page click **Resources > JMS->Queue connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS queue connection factory is used to create connections to JMS destinations. When an application needs a JMS queue connection, an instance can be created by the factory for the JMS provider that is named in the **Provider** column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 queue-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

Name The display name of each queue connection factory instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each queue connection factory instance.

Provider

The messaging provider that supports each queue connection factory instance.

Description

An optional description of each queue connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic connection factory collection

A JMS topic connection factory is used to create connections to the associated messaging provider of JMS topic destinations, for publish and subscribe messaging.

In the administrative console, to view this page click **Resources > JMS->Topic connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory for the JMS provider that is named in the Provider column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 topic-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

General properties

Name The display name of each topic connection factory instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each topic connection factory instance.

Provider

The messaging provider that supports each topic connection factory instance.

Description

An optional description of each topic connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue collection

A JMS queue destination is used for point-to-point messaging. Use this panel to create or delete queue destinations, or to select a queue destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources > JMS->Queues**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a queue destination to manage JMS queues for the JMS provider that is named in the **Provider** column of the list. Connections to the queue are created by a unified connection factory or queue connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that

is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

General properties

Name The display name of each queue destination instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each queue destination instance.

Provider

The messaging provider that supports each queue destination instance.

Description

An optional description of each queue destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic collection

A JMS topic destination is used for publish and subscribe messaging. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources > JMS->Topics**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a topic destination to manage JMS topics for the JMS provider that is named in the **Provider** column of the list. Connections to the topic are created by a unified connection factory or topic connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 952.

General properties

Name The display name of each topic destination instance.

JNDI name

The Java Naming and Directory Interface (JNDI) name of each topic destination instance.

Provider

The messaging provider that supports each topic destination instance.

Description

An optional description of each topic destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Configuring Version 5 default messaging resources

Use the following tasks to configure the JMS connection factories and destinations for WebSphere Application Server Version 5 applications.

About this task

You only have to complete these tasks if you have WebSphere Application Server Version 5 applications that use JMS resources provided by the default messaging provider. Such JMS resources are maintained as *V5 default messaging resources*.

In a deployment manager cell, you can use the V5 default messaging provider to maintain V5 default messaging resources for both Version 6 and Version 5 nodes in the cell.

Procedure

- Configure a connection for Version 5 default messaging
- Configure a queue connection factory for Version 5 default messaging
- Configure a topic connection factory for Version 5 default messaging
- Configure a queue for Version 5 default messaging
- Configure a topic for Version 5 default messaging

Configuring a connection for V5 default messaging

Use this task to configure a connection to V5 default messaging. This task is provided to help you manually migrate nodes from Version 5 to Version 6. If you use the supplied tools to migrate existing Version 5 nodes to Version 6, the jmsserver, application server and port that you create with this task are defined automatically.

About this task

To configure a connection for V5 default messaging, use the administrative console to complete the following steps:

Procedure

1. Create an application server with the name jmsserver (only one of these can exist on each node). In the navigation pane, expand **Servers > Server Types > WebSphere application servers**.

2. On the new server, define a new JMSSERVER_QUEUED_ADDRESS port with the host set to the Version 6 server host, and the port set to the same as the SIB_MQ_ENDPOINT_ADDRESS of the server that is a member of your bus. The appserver called jmsserver does not have to be started; it is only used for looking up the port address.
3. Define a queue connection factory and queue at the Node or Cell scope. In the navigation pane, click **Resources > JMS->JMS providers**.
4. In the content pane, click the name of the V5 default messaging provider.
5. Define a queue destination on your bus with the same name as your queue defined for the V5 default messaging provider.
6. Define an alias destination on your bus with the same name as your queue defined for the V5 default messaging provider but with WQ_ appended to the front the name. For example, if your queue has the name MyV5Queue, your alias should have the name WQ_MyV5Queue.
7. Point the alias at your queue destination with the correct name. The migration process targets the queue with the WQ_ prefix; defining the alias to point to the real queue helps migration.
8. Define the WebSphere MQ Client Link on your messaging engine on the bus. Keep the WebSphere MQ channel name WAS.JMS.SVRCONN and set the queue manager name so that it contains your node name. For example, if your node name is MyNode, you would set the queue manager name to WAS_<MyNode>_jmsserver. Now set the queue manager name to the same; in this example it would be WAS_MyNode_jmsserver. The WebSphere MQ Client Link will show a status of inactive, this is normal.
9. Restart your server so that the new JNDI definitions bind correctly. Your Version 5 client should now be able to connect to Version 6 by using the host and bootstrap address of the Version 6 system in the provider URL component of the initial context. Your client should now also be able to send messages to the destination on the bus.
10. If you open the Client connections view and click the refresh icon, the host name of the connecting system is visible when the client is connected. In the navigation pane, expand **Buses > [bus name] > Messaging engines > [messaging engine name] > WebSphere MQ client links > [client link name] > Runtime > Client connections view**.
11. Click **OK**.
12. Save any changes to the master configuration.
13. To have the changed configuration take effect, stop then restart the application server.

Configuring a queue connection factory for Version 5 default messaging

Use this task to browse or change the properties of a JMS queue connection factory for point-to-point messaging with the default messaging provider on a Version 5 node in a deployment manager cell. This task contains an optional step for you to create a new JMS queue connection factory.

About this task

To configure a JMS queue connection factory for use by WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources > JMS->JMS providers**.
2. Select the V5 default messaging provider for which you want to configure a queue connection factory.
3. Optional: Change the **Scope** setting to the level at which the JMS queue connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Queue connection factories** This displays any existing JMS queue connection factories for the Version 5 messaging provider in the content pane.
5. To browse or change an existing JMS queue connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:

- a. Click **New** in the content pane.
- b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS queue connection factory is known for administrative purposes within WebSphere Application Server.

JNDI Name

The JNDI name that is used to bind the JMS queue connection factory into the namespace.

- c. Click **Apply**. This defines the JMS queue connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the queue connection factory, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Version 5 default messaging queue connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server Version 5 applications.

A WebSphere queue connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server Version 5 applications.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Queue connection factories**. This displays a list of any existing JMS queue connection factories.
5. Click the name of the JMS queue connection factory that you want to work with.

A queue connection factory for the embedded WebSphere JMS provider has the following properties:

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type	String
Default	Null

JNDI name:

The JNDI name that is used to bind the JMS connection factory into the namespace.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String
------------------	--------

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String
------------------	--------

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Default	Null
Range	Drop-down list of Version 5 nodes in the WebSphere administrative domain.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Note: User IDs longer than 12 characters cannot be used for authentication with the V5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere queue connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Note: User IDs longer than 12 characters cannot be used for authentication with the V5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security > JAAS Configuration > Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type	Enum
Default	Null

Range**ClientContainer**

The client container maps authentication aliases.

WSLogin

The WSLogin module maps authentication aliases.

DefaultPrincipalMapping

The JAAS configuration maps an authentication alias to its userid and password.

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are used in the same transaction.

If you clear this check box property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to DIRECT this property does not apply, and always adopts non-XA coordination.

Data type

check box

Default

Selected (enabled for XA coordination)

Range**Selected**

The connection factory is enabled for XA-coordination of messages

Cleared

The connection factory is not enabled for XA coordination of messages

Recommended

Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to JMS unified connection factories, queue connection factories and topic connection factories. To view this page, you select an instance of the resource type then click **Session pools**. For example, click **Resources > JMS->Queue connection factories->queue_connection_factory->[Additional Properties] Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a `ConnectionWaitTimeoutException` is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached. For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a `ConnectionWaitTimeoutException`. It usually does not make sense to retry the `getConnection()` method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If *Connection Timeout* is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If *Max Connections* is set to 0, which enables an infinite number of physical connections, then the *Connection Timeout* value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` is thrown.

For example, if the *Max Connections* value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in *Connection Timeout* for a physical connection to become free.

If *Max Connections* is set to 0, the *Connection Timeout* value is ignored.

For better performance, set the value for the connection pool lower than the value for the *Max Connections* option in the web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. Java EE Connector Architecture (JCA) data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type	String
Default	FailingConnectionOnly

Range

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Configuring a topic connection factory for Version 5 default messaging

Use this task to browse or change a JMS topic connection factory for publish/subscribe messaging by WebSphere Application Server Version 5 applications.

About this task

To configure a JMS topic connection factory for use by WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources > JMS->JMS providers**.
2. Select the V5 default messaging provider for which you want to configure a topic connection factory.
3. Optional: Change the **Scope** setting to the level at which the JMS topic connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Topic connection factories** This displays any existing JMS topic connection factories for the Version 5 messaging provider in the content pane.
5. To browse or change an existing JMS topic connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server.

JNDI Name

The JNDI name that is used to bind the JMS topic connection factory into the namespace.

- c. Click **Apply**. This defines the JMS topic connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the topic connection factory, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Version 5 default messaging topic connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS topic connection factory for publish/subscribe messaging by WebSphere Application Server Version 5 applications.

A WebSphere topic connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server Version 5 applications.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Topic connection factories**. This displays a list of any existing JMS topic connection factories.
5. Click the name of the JMS topic connection factory that you want to work with.

A JMS topic connection factory for use with the V5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String
Default Null

JNDI name:

The JNDI name that is used to bind the topic connection factory into the namespace.

As a convention, use the fully qualified JNDI name; for example, in the form `.jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type	String
------------------	--------

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Category:

A category used to classify or group this topic connection factory, for your IBM WebSphere Application Server administrative records.

Data type	String
------------------	--------

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Default	Null
Range	Drop-down list of nodes in the WebSphere administrative domain.

Port:

Which of the two ports that connections use to connect to the JMS server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for non-persistent, non-transactional, non-durable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish/subscribe support. Therefore, any topic connection factory configured with **Port** set to Direct cannot be used with message-driven beans.

Data type	Enum
Units	Not applicable
Default	QUEUED

Range**QUEUED**

The listener port used for full-function JMS-compliant, publish/subscribe support.

DIRECT

The listener port used for direct TCP/IP connection (non-transactional, non-persistent, and non-durable subscriptions only) for publish/subscribe support.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Note: User IDs longer than 12 characters cannot be used for authentication with the V5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security > JAAS Configuration > Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type	Enum
Default	Null
Range	ClientContainer The client container maps authentication aliases. WSLogin The WSLogin module maps authentication aliases. DefaultPrincipalMapping The JAAS configuration maps an authentication alias to its userid and password.

Clone Support:

Select this check box to enable clone support to allow the same durable subscription across topic clones.

Data type	Enum
Default	Cleared
Range	Selected Clone support is enabled. Cleared Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

Client ID:

The JMS client identifier used for connections to the queue manager.

Data type	String
Range	A valid JMS client ID

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are used in the same transaction.

If you clear this check box property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to DIRECT this property does not apply, and always adopts non-XA coordination.

Data type	check box
Default	Selected (enabled for XA coordination)
Range	Selected The connection factory is enabled for XA-coordination of messages Cleared The connection factory is not enabled for XA coordination of messages
Recommended	Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to JMS unified connection factories, queue connection factories and topic connection factories. To view this page, you select an instance of the resource type then click **Session pools**. For example, click **Resources > JMS->Queue connection factories->queue_connection_factory->[Additional Properties] Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached . For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If

a physical connection is *not* available within this time, the Pool Manager throws a `ConnectionWaitTimeoutException`. It usually does not make sense to retry the `getConnection()` method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. Java EE Connector Architecture (JCA) data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type
Default
Range

String
FailingConnectionOnly

EntirePool

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly

Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Configuring a queue for Version 5 default messaging

Use this task to browse or change the properties of a JMS queue destination for point-to-point messaging by WebSphere Application Server Version 5 applications. This task contains an optional step for you to create a new topic destination.

About this task

To optimize performance, configure the topic destination properties to best fit your applications. For more information, see Performance for Version 5 default messaging queues.

To configure a JMS queue destination for use by WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources > JMS->JMS providers**.
2. Select the V5 default messaging provider for which you want to configure a queue destination.

3. Optional: Change the **Scope** setting to the level at which the JMS destination is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Queues**. This displays any existing queue destinations for the Version 5 default messaging provider in the content pane.
5. To browse or change an existing JMS queue destination, click its name in the list. Otherwise, to create a new queue destination, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this queue destination is known for administrative purposes within IBM WebSphere Application Server.

JNDI Name

The JNDI name that is used to bind the queue destination into the namespace.

- c. Click **Apply**. This defines the queue destination to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the queue destination, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To make a queue destination available to applications, host the queue on a JMS server. To add a new queue to a JMS server or to change an existing queue on a JMS server, you define the administrative name of the queue to the JMS server.
To define the administrative name of the queue to the JMS server, see *Managing Version 5 JMS servers in a deployment manager cell*.
10. To have the changed configuration take effect, stop then restart the application server.

Version 5 default messaging queue settings:

Use this page to view or change the configuration properties of the selected JMS queue destination for point-to-point messaging by WebSphere Application Server Version 5 applications.

A queue destination is used to configure a JMS queue of the default messaging provider for use by WebSphere Application Server Version 5 applications. Connections to the queue are created by the associated V5 default messaging WebSphere queue connection factory.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Queues**. This displays a list of any existing JMS queue destinations.
5. Click the name of the JMS queue destination that you want to work with.

A JMS queue for use with the internal WebSphere JMS provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this page. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the JMS provider settings page, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

To enable applications to use this queue, you must add the queue name to the **Queue Names** field on the Version 5 JMS server settings page for the JMS server that hosts the queue.

Data type String

JNDI name:

The JNDI name that is used to bind the queue into the application server namespace.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes.

Data type String

Default Null

Category:

A category used to classify or group this queue, for your WebSphere Application Server administrative records.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application.

Data type
Default
Range

Enum
APPLICATION DEFINED
APPLICATION DEFINED
Messages on the destination have their persistence defined by the application that put them onto the queue.
NON PERSISTENT
Messages on the destination are not persistent.
PERSISTENT
Messages on the destination are persistent. When a persistent message is put to a queue, all of the message data is written to the messaging log (under the *embedded_messaging_install*log directory) to make recovery of the message possible.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type
Default
Range

Enum
APPLICATION DEFINED
APPLICATION DEFINED
The priority of messages on this destination is defined by the application that put them onto the destination.
QUEUE DEFINED
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
SPECIFIED
The priority of messages on this destination is defined by the **Specified priority** property.
Note: If you select this option, you must define a priority on the **Specified priority** property.

Specified priority:

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

Data type
Units
Default
Range

Integer
Message priority level
0
0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type

Enum

**Default
Range**

APPLICATION DEFINED

APPLICATION DEFINED

The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

UNLIMITED

Messages on this queue have no expiry timeout, so those messages never expire.

SPECIFIED

The expiry timeout for messages on this queue is defined by the **Specified expiry** property.

Note: If you select this option, you must define a timeout on the **Specified expiry** property.

Specified expiry:

If the **Expiry timeout** property is set to Specified, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type

Integer

Units

Milliseconds

Default

0

Range

Greater than or equal to 0

- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Configuring a topic for Version 5 default messaging

Use this task to browse or change the properties of a JMS topic destination for publish/subscribe messaging by WebSphere Application Server Version 5 applications. This task contains an optional step for you to create a new topic destination.

About this task

To optimize performance, configure the topic destination properties to best fit your applications. For more information, see Performance for Version 5 default messaging topics.

To configure a JMS topic destination for use WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources > JMS->JMS providers**.
2. Select the V5 default messaging provider for which you want to configure a topic destination.
3. Optional: Change the **Scope** setting to the level at which the JMS destination is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Topics** This displays any existing JMS topic destinations for the Version 5 default messaging provider in the content pane.
5. To browse or change an existing JMS topic destination, click its name in the list. Otherwise, to create a new topic destination, complete the following steps:
 - a. Click **New** in the content pane.
 - b. Specify the following required properties. You can specify other properties, as described in a later step.

Name The name by which this topic destination is known for administrative purposes within IBM WebSphere Application Server.

JNDI Name

The JNDI name that is used to bind the topic destination into the namespace.

Topic The name of the topic in the default messaging provider, to which messages are sent.

- c. Click **Apply**. This defines the topic destination to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the topic destination, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Version 5 default messaging topic settings:

Use this panel to browse or change the configuration properties of the selected JMS topic destination for publish/subscribe messaging by WebSphere Application Server Version 5 applications.

A WebSphere topic destination is used to configure the properties of a JMS topic for the default messaging provider on a Version 5 node in a deployment manager cell. Connections to the topic are created by the associated topic connection factory.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources > JMS->JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Topics**. This displays a list of any existing JMS topic destinations.
5. Click the name of the JMS topic destination that you want to work with.

A JMS topic destination for use with the V5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI name:

The JNDI name that is used to bind the topic into the application server namespace.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this topic, for your IBM WebSphere Application Server administrative records.

Data type String

Topic:

The name of the topic as defined to the JMS provider.

Data type String
Default Null
Range The topic value can be dot notation and include wildcard characters.

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type Enum
Default APPLICATION_DEFINED

Range

APPLICATION DEFINED

Messages on the destination have their persistence defined by the application that put them onto the queue.

NON-PERSISTENT

Messages on the destination are not persistent.

PERSISTENT

Messages on the destination are persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type

Enum

Units

Not applicable

Default

APPLICATION DEFINED

- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Managing Version 5 JMS servers in a deployment manager cell

Use this task to manage JMS servers on WebSphere Application Server Version 5 nodes in a deployment manager cell.

About this task

The use of JMS servers is only intended to support migration from WebSphere Application Server Version 5 nodes to WebSphere Application Server Version 6.

In a WebSphere Application Server deployment manager cell, each Version 5 node can have at most one JMS server, and any Version 5 application server within the cell can use JMS resources served by any of those JMS servers. Applications on WebSphere Application Server Version 6 can also use JMS resources served by any of those JMS servers.

You can use the WebSphere administrative console to display a list of all Version 5 JMS servers, to show and control their runtime status. You can also configure a general set of JMS server properties, which add to the default values of properties configured automatically for the V5 default messaging provider.

Note: In general, the default values of properties for the V5 default messaging provider are adequate for JMS servers. However, if you are running high messaging loads, you might have to change some WebSphere MQ properties; for example, WebSphere MQ properties for log file locations, file pages, and buffer pages. For more information about configuring WebSphere MQ properties, see the *System administration* section of the WebSphere MQ information center.

To manage a Version 5 JMS server, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, select **Servers > Server Types > Version 5 JMS servers**. This displays a table of the JMS servers, showing their runtime status.

2. Optional: If you want to change the runtime status of a JMS server, complete the following steps:
 - a. In the table of JMS servers, select the JMS servers that you want to act on.
 - To act on one or more specific JMS servers, select the check box next to the JMS server name.
 - To act on all JMS servers, select the check box next to the JMS servers title of the table.
 - b. Click one of the actions displayed to change the status of the JMS servers; for example, click **Stop** to stop a JMS server.

The status of the JMS servers that you have acted on is updated to show the result of your actions.

3. Optional: If you want to change the properties of a JMS server, complete the following steps:
 - a. Click the name of the server
 - b. Set one or more of the following configuration properties:

Initial state

If you want the JMS server to be started automatically when the application server is next started, set this property to Started.

Number of threads

Set the number of concurrent threads to be used by the publish/subscribe matching engine. The number of concurrent threads should only be set to a small number.

4. Optional: If you want the JMS server to host a new JMS queue, add the queue name to the **Queue Names** field.

The name must match the name of a JMS Queue administrative object, including the use of upper- and lowercase.
5. Optional: If you want to stop the JMS server hosting a JMS queue, remove the queue name from the **Queue Names** field.
6. Click **OK**.
7. Save your changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the JMS server.

Version 5 JMS server settings

The JMS functions on a Version 5 node in a deployment manager cell are served by a JMS server. Use this panel to view or change the configuration properties of the selected JMS server.

JMS servers are supported only to aid migration of WebSphere Application Server Version 5 nodes.

You can use this panel to configure a general set of JMS server properties, which add to the default values of properties configured automatically for the Version 5 default messaging provider.

Before you set any of the values on this panel, configure the JMS Server for each node by using the WebSphere Application Server Profile Management Tool described in the topic "Using the Profile Management Tool" or by using the zpmt command described in the topic "Configuring z/OS application-serving environments with the zpmt command".

Name:

The name by which the JMS server is known for administrative purposes within WebSphere Application Server.

This name should not be changed.

Data type	String
Units	Not applicable
Default	WebSphere Internal JMS Server
Range	Not applicable

Description:

A description of the JMS server, for administrative purposes within WebSphere Application Server.

This string should not be changed.

Data type	String
Default	WebSphere Internal JMS Server

Short Name: Specifies the short name of the server. For WebSphere Application Server for z/OS, the server short name must be unique within a cell. The short name is also the default z/OS job name, which identifies the server to the native facilities of the operating system, such as Workload Manager (WLM), Automatic Restart Manager, SAF (for example, RACF), started task control, and others.

The system assigns a default short name that is automatically unique within the cell.

Unique Id: Specifies a unique identifier for this server.

The unique ID property is read only. The system automatically generates the value.

Queue Names:

The names of the queues hosted by this JMS server. Each queue name must be added on a separate line.

Each queue listed in this field must have a separate queue administrative object with the same administrative name. To make a queue available to applications, define a WebSphere queue and add its name to this field on the JMS Server panel for the host on which you want the queue to be hosted.

Data type	String
Units	Queue name
Range	Each entry in this field is a queue name of up to 45 characters, which must match exactly (including use of upper- and lowercase characters) the WebSphere queue administrative object defined for the queue.

Initial State:

The state that you want the JMS server to have when it is next restarted.

Data type	Enum
Default	Started
Range	Started The JMS server is started automatically. Stopped The JMS server is not started automatically. If any deployed enterprise applications are to use JMS server functions provided by the JMS server, the system administrator must start the JMS server manually or select the Started value of this property then restart the JMS server. To restart a JMS server on a Version 5 node, stop then restart that JMS server.

Chapter 15. Managing message-driven beans

You can manage the Java EE Connector Architecture (JCA) Version 1.5-compliant message-driven beans that you deploy as message endpoints, and you can manage the message listener resources for non-JCA message-driven beans that you deploy against listener ports.

Before you begin

For WebSphere Application Server Version 7 and later, listener ports are stabilized. For more information, read the article on stabilized features. You should plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications. However, you should not begin this migration until you are sure the application does not have to work on application servers earlier than WebSphere Application Server Version 7. For example, if you have an application server cluster with some members at Version 6.1 and some at Version 7, you should not migrate applications on that cluster to use activation specifications until after you migrate all the application servers in the cluster to Version 7.

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatibility with existing message-driven bean applications.

For more information about when to use listener ports rather than activation specifications, see [Message-driven beans, activation specifications, and listener ports](#).

About this task

You can manage the following resources for message-driven beans:

- JCA 1.5-compliant message-driven beans that you deploy as message endpoints, and the associated activation specifications.
- The message listener service, listener ports, and listeners for non-JCA message-driven beans that you deploy against listener ports.

Procedure

- Manage JCA 1.5-compliant message-driven beans that are used as message endpoints.

JCA 1.5-compliant message-driven beans, deployed by using activation specifications, can be used as message endpoints. You can start and stop specific endpoints within your applications to ensure that messages are delivered only to listening message-driven beans that are interacting with healthy resources.

- Manage message listener resources for message-driven beans.

The message listener service supports message-driven beans that are used with a non-JCA messaging provider. A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. When you deploy a message-driven bean, you associate the bean with a listener port. When a message arrives on the destination, the listener passes the message to a new instance of a message-driven bean for processing. You can manage the resources used by the message listener service, including being able to start and stop specific listener ports manually.

Managing messages with message endpoints

Manage message delivery for message-driven beans (MDB) that are deployed as message endpoints. The message endpoints are managed beans (MBeans) for inbound resource adapters that are compliant with Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) Version 1.5.

About this task

The application server provides message endpoint MBeans to assist you in managing the delivery of a message to your message-driven beans that are acting as listeners on specific endpoints, which are destinations, and in managing the enterprise information system (EIS) resources that are utilized by these message-driven beans. Message-driven beans that are deployed as message endpoints are not the same as message-driven beans that are configured against a listener port. Message-driven beans that are used as message endpoints must be deployed using an `ActivationSpecification` that is defined within a resource adapter configuration for JCA Version 1.5.

With message endpoint MBeans, you can activate and deactivate specific endpoints within your applications to ensure that messages are delivered only to listening message-driven beans that are interacting with healthy EIS resources. This capability allows you to optimize the performance of your JMS applications in situations where an EIS resource is not behaving as expected. Message delivery to an endpoint typically fails when the message driven bean that is listening invokes an operation against a resource that is not healthy. For example, a messaging provider, which is an inbound resource adapter that is JCA Version 1.5 compliant, might fail to deliver messages to an endpoint when its underlying message-driven bean attempts to commit transactions against a database server that is not responding.

Note: Design your message-driven beans to delegate business processing to other enterprise beans. Do not access the EIS resources directly in the message-driven bean, but do so indirectly through a delegate bean.

Message endpoint MBeans alleviate two problems that are inherent to applications that provide message endpoints that access resources:

- Failed messages require additional processing, such as delivering them to the listening endpoint again or redirecting them to alternate destinations that process failed messages. In addition, a resource adapter might redeliver a message to an endpoint an infinite number of times.
- Message redirection requires the implementation of specialized destinations (queues and listeners) to process failed messages, as well as the logic to detect message failures. Message redirection is potentially error prone and computationally expensive due to its complexity.

The capability to deactivate (pause) and reactivate (resume) a specific message endpoint alleviates these problems by enabling the administrator to deactivate the endpoint from processing messages that are destined to fail. When the message endpoint is deactivated, you can repair the resource that is causing the problems and reactivate the endpoint to resume handling message requests. In the course of troubleshooting, you will not affect the resource adapter or the application that is hosting the endpoint.

If you are connecting to WebSphere MQ, you can also use the `WAS_EndpointInitialState` custom property in the activation specification to make the message endpoint start out in a deactivated state. When you set this property to `Inactive`, the message-driven bean connects with the destination, but does not start receiving messages. Use this setting to automatically deactivate a message endpoint when you know that certain tasks must be completed, services must be started, or checks must be carried out, before message handling begins. You activate the message endpoint in the same way as you would reactivate a message endpoint that you paused during its operation.

Procedure

1. Using the administrative console, navigate to the Message Endpoints panel for the application that is hosting the message endpoint.
 - a. Select the **Applications > Application Types > Websphere enterprise applications > *application_name***.
 - b. Select the **Runtime** panel.
 - c. Select **Message Endpoints**. The panel lists the set of message endpoints that are hosted by the application.

2. Optional: Temporarily disable a message endpoint from handling messages and troubleshoot the problem.
 - a. Deactivate the message endpoint by selecting the appropriate endpoint and clicking **Pause**.
 - b. When the message endpoint is inactive, diagnose and repair the underlying cause of the delivery failures.
 - c. Reactivate the message endpoint by selecting the appropriate endpoint and clicking **Resume**.
3. Optional: Activate a message endpoint that started out in a deactivated state. Select the appropriate endpoint and click **Resume**.

Results

The behavior you will observe when you deactivate (pause) a message endpoint using the message endpoint MBean is dependent upon a variety of factors, including the resource adapter that manages the message endpoint, the configuration of the message endpoint and the application server topology. Some specific examples of interest are as follows:

- **MDB listening on a non-durable topic (dependent on configuration):** The behavior that is implied by the deactivation (pause) of a message endpoint is often dependent upon the function that it is fulfilling. For example, if you have configured a message-driven bean to listen on a non-durable topic on the service integration bus, deactivating the message endpoint is analogous to stopping the application and will cause the subscription to be closed. This means that any messages that are published during the time that the message endpoint is paused will not be received by the message-driven bean.
- **Clustered message-driven bean (dependent on topology):** In this scenario a message-driven bean application has been deployed to a cluster of servers. A given message endpoint MBean controls only the behavior of the MDB in one server from the cluster, so will cause only one server to stop processing messages. Depending upon the messaging configuration and the specific resource adapter in use the messages that would have been consumed by the paused message endpoint may be consumed by the active message endpoints in the cluster, or they may remain unconsumed until the paused message endpoint is resumed.
- **Clustered message-driven bean, a non-clustered queue:** In this scenario, you have a cluster of servers with the same message-driven bean deployed to them. This is similar to the case, in which you have different message-driven beans with the same message selection criteria, except that in this case the message-driven beans are logically the same message-driven bean. Pausing the endpoint will cause only one of the servers to stop receiving messages, and the other message-driven beans will receive all the messages; none of the messages will be orphaned. To stop all of the endpoints, you must direct each server in the cluster to stop the local message endpoint.
- **Clustered message-driven bean, clustered queue:** In this scenario, each message-driven bean is pulling messages from a different partition of the queue. Messaging through WebSphere MQ and the Service Integration Bus have similar, but different, capabilities. If you are using WebSphere MQ, then pausing one endpoint will not allow the other instances of the message-driven bean to receive the messages. In the Service Integration Bus, messages from a paused endpoint will be redirected to the other message-driven beans.

Managing message listener resources for message-driven beans

Manage the resources used by the message listener service to support message-driven beans, typically for use with a messaging provider that does not have a Java EE Connector Architecture (JCA) 1.5 resource adapter.

Before you begin

For WebSphere Application Server Version 7 and later, listener ports are stabilized. For more information, read the article on stabilized features. You should plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications. However, you should not begin this migration until you are sure the application does not have to work on application

servers earlier than WebSphere Application Server Version 7. For example, if you have an application server cluster with some members at Version 6.1 and some at Version 7, you should not migrate applications on that cluster to use activation specifications until after you migrate all the application servers in the cluster to Version 7. Also, when you migrate to activation specifications on the z/OS platform, you must enable the Control Region Adjunct (CRA) process of the application server (either by selecting **Enable JCA based inbound message delivery** on the JMS provider settings panel, or by using the `manageWMQ` command to include starting the CRA process as part of starting an application server).

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatibility with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see [Message-driven beans, activation specifications, and listener ports](#).

About this task

The message listener service is an extension to the JMS functions of the JMS provider and provides a listener manager, which controls and monitors one or more JMS listeners. Each listener monitors either a JMS queue destination (for point-to-point messaging) or a JMS topic destination (for publish/subscribe messaging). A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. When you deploy a message-driven bean, you associate the bean with a listener port. When a message arrives on the destination, the listener passes the message to a new instance of a message-driven bean for processing. For more information, see [Message-driven beans - listener port components](#).

Procedure

1. Configure the message listener service.

Note: Before configuring message listener resources, consider the message listener service implementation on the z/OS platform, which affects how you should configure your listener port. For more information, see [“Message listener service on z/OS”](#) on page 496.

2. Administer listener ports.

You can complete any of the following administrative tasks:

- Create or configure a listener port.
- Start or stop a listener port.
- Delete a listener port.

3. If the message-driven bean uses a queue hosted by WebSphere MQ as a JMS provider, optimize performance by configuring the queue destination properties to best fit your message-driven bean.

For more information about performance, see [Performance for WebSphere MQ queues](#).

4. Configure security for message-driven beans that use listener ports.

Results

You have configured the resources needed by the message listener service to support message-driven beans.

Configuring the message listener service

To support message-driven beans deployed against listener ports, you configure the properties of the message listener service for an application server.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatibility with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see [Message-driven beans, activation specifications, and listener ports](#).

Before configuring message listener resources, consider the message listener service implementation on the z/OS platform, which affects how you should configure your listener port. For more information, see [“Message listener service on z/OS”](#) on page 496.

About this task

The message listener service is an extension to the JMS functions of the JMS provider and provides a listener manager, which controls and monitors one or more JMS listeners. Each listener monitors either a JMS queue destination (for point-to-point messaging) or a JMS topic destination (for publish/subscribe messaging). For more information, see [Message-driven beans - listener port components](#).

When you deploy an enterprise application to use message-driven beans with listener ports, you can browse or change the configuration of the message listener service for a given application server.

Procedure

1. Display the listener service settings page:
 - a. In the navigation pane, select **Servers > Server Types > WebSphere application servers**.
 - b. In the content pane, click the name of the application server.
 - c. Under Communications, click **Messaging > Message Listener Service**.
2. Optional: Browse or change the value of properties for the message-driven bean thread pool.
 - a. Click **Thread Pool**.
 - b. Change the following properties, as required:

Minimum size

The minimum number of threads to allow in the pool.

Maximum size

The maximum number of threads to allow in the pool.

Thread inactivity timeout

The number of milliseconds of inactivity that should elapse before a thread is reclaimed. A value of 0 indicates not to wait and a negative value (less than 0) means to wait forever.

Note: The administrative console does not allow you to set the inactivity timeout to a negative number. To do this you must modify the value directly in the config.xml file.

Allow thread allocation beyond maximum thread size

Select this check box to enable the number of threads to increase beyond the maximum size configured for the thread pool.

- c. Click **OK**.
3. Optional: Specify any message listener service custom properties that you need, as **Custom properties** of the message listener service.
 - a. Click **Custom properties**
 - b. For each custom property, specify the name and value you require.

If you have not specified a property before:

 - 1) Click **New**.
 - 2) Type the name of the property.
 - 3) Type the value of the property.
 - 4) Click **OK**.

For more information about these custom properties, see “Message listener service custom properties” on page 498.

4. Save your changes to the master configuration.
5. To activate the changed configuration, stop then restart the application server.

Results

You have configured the properties of the message listener service for a given application server.

Message listener service on z/OS

On the z/OS platform, the message listener service implementation uses the scalable server architecture to divide the listener port functions between the controller and servant processes.

A single message listener is registered in the controller portion of the ListenerPort, whereas application dispatch (that is, dispatch of the user application onMessage(Message) EJB method) is spread across the various servants comprising the server. This implementation is referred to as “listening in the controller” for the message-driven bean messages.

Note: The WebSphere Application Server for z/OS message listener service implementation does not use the “listening in the controller” internal configuration in all cases, but only when the message-driven bean is mapped to a queue (that is, listening on a queue) or mapped (listening) to a topic through a durable subscription.

If the message-driven bean is listening to a topic through a non-durable subscription, the listener port registers a listener in *each servant*, rather than registering a single listener in the controller. In this case, a single message published to that topic is dispatched once for each servant comprising the server. If a message-driven bean is listening on a queue, or to a topic through a durable subscription, a single message sent is dispatched once only, to a single servant, for the entire server.

The configuration of the listener port, in the “listening in the controller” case, is administered externally through the controls described in Tuning message-driven bean processing on z/OS by using WebSphere MQ as the messaging provider in ASF mode and Message-driven beans and tuning settings on z/OS.

For a non-durable subscription message-driven bean that is listening in each servant as described above, the listener ports are configured in the same manner as they are on distributed platforms. In this case, the single set of settings configured for the listener port are applied identically to each servant.

Message listener service

The message listener service is an extension to the JMS functions of the JMS provider. It provides a listener manager that controls and monitors one or more JMS listeners, which each monitor a JMS destination on behalf of a deployed message-driven bean.

This panel displays links to the Additional Properties pages for Listener Ports and Custom Properties for the message listener service.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > *server_name* > [Communications] Messaging > Message Listener Service**

Custom Properties

You can use the Custom properties page to define the following properties for use by the message listener service.

- “DYNAMIC.CONFIGURATION.ENABLED” on page 498
- “ENABLE.ZOS.LP.RECOVERY” on page 498
- “MAX.RECOVERY.RETRIES” on page 499
- “MQJMS.POOLING.THRESHOLD” on page 499
- “MQJMS.POOLING.TIMEOUT” on page 499
- “NON.ASF.RECEIVE.TIMEOUT” on page 499
- “NON.ASF.BMT.ROLLBACK.ENABLED” on page 500
- “RECOVERY.RETRY.INTERVAL” on page 501
- “SERVER.SESSION.POOL.REAP.TIME” on page 501
- “SERVER.SESSION.POOL.UNUSED.TIMEOUT” on page 501
- “SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*” on page 501

Listener Ports

You can use the Listener Ports page to create and modify listener ports by specifying the following properties:

- Name
- Initial State
- Description
- Connection factory JNDI name
- Destination JNDI name
- Maximum sessions
- Maximum retries
- Maximum messages

Message listener service custom properties:

Use this panel to view or change custom properties of the message listener service.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > *server_name* > [Communications] Messaging > Message Listener Service > Custom Properties.**

You can use the Custom properties page to define the following properties for use by the message listener service.

- “DYNAMIC.CONFIGURATION.ENABLED” on page 498

- “ENABLE.ZOS.LP.RECOVERY” on page 498
- “MAX.RECOVERY.RETRIES” on page 499
- “MQJMS.POOLING.THRESHOLD” on page 499
- “MQJMS.POOLING.TIMEOUT” on page 499
- “NON.ASF.RECEIVE.TIMEOUT” on page 499
- “NON.ASF.BMT.ROLLBACK.ENABLED” on page 500
- “RECOVERY.RETRY.INTERVAL” on page 501
- “SERVER.SESSION.POOL.REAP.TIME” on page 501
- “SERVER.SESSION.POOL.UNUSED.TIMEOUT” on page 501
- “SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*” on page 501

DYNAMIC.CONFIGURATION.ENABLED:

This property controls whether the application server on which a listener port is created requires to be restarted. Set this property to true to enable dynamic configuration.

Data type	Boolean
Default	False (not selected)

ENABLE.ZOS.LP.RECOVERY:

This property controls listener port behavior when an application server connects to WebSphere MQ for z/OS.

Enable this property if your environment requires either of the following capabilities:

- A listener port to attempt to recover if a connection between the application server and WebSphere MQ has been lost, for example if the queue manager has been stopped. If you do not enable this property, the listener port does not attempt to recover after a queue manager has been stopped.
- Multiple workload management classifications to be configured for a listener port. If you do not enable this property, messages remain on the WebSphere MQ queue when multiple workload management classifications are configured for a listener port.

Restart the server after adding the property.

If you are connecting to WebSphere MQ for z/OS through bindings connections, you also need to apply WebSphere MQ APAR PK53912, which is provided in WebSphere MQ Version 6.0.2.4.

Data type	Boolean
Default	True (enabled)

MAX.RECOVERY.RETRIES:

The maximum number of times that a listener port managed by this service tries to recover from a failure before giving up and stopping. When stopped the associated listener port is changed to the stop state. The interval between retry attempts is defined by the **RECOVERY.RETRY.INTERVAL** property.

A failure can be caused by either of the following conditions:

- An unexpected error has occurred when a listener port tries to get a message from the JMS provider.
- The connection between the application server and the JMS provider has been lost, usually due to a network error.

Data type	Integer
------------------	---------

Units	Retry attempts
Default	5
Range	0 (no retries) through 2147483647

MQJMS.POOLING.THRESHOLD:

The maximum number of unused connections in the pool.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if there are more than ten unused connections in the pool.

Data type	Integer
Units	Number of connections
Default	10

MQJMS.POOLING.TIMEOUT:

The number of milliseconds after which a connection in the pool is destroyed if it has not been used.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if it has not been used for five minutes.

Data type	Integer
Units	Milliseconds
Default	5 minutes

NON.ASF.RECEIVE.TIMEOUT:

The timeout in milliseconds for synchronous message receives performed by message-driven bean listener sessions in the non-ASF mode of operation.

Note: The message listener service has two modes of operation, Application Server Facilities (ASF) and non-Application Server Facilities (non-ASF):

- ASF mode provides concurrency and transactional support for applications. For publish/subscribe message-drive beans, ASF mode provides better throughput and concurrency, because in the non-ASF mode the listener is single-threaded.
- Non-ASF mode is mainly for use with third-party messaging providers that do not support JMS ASF, which is an optional extension to the JMS specification. Non-ASF mode is also transactional but, because the path length is shorter than for ASF mode, usually provides improved performance.

To enable the non-ASF mode of operation for all message-driven bean listeners on the application server, set this property to a non-zero value.

Non-ASF mode cannot be selected on z/OS systems, so you should not set a non-zero value for this property.

Data type	Integer
Units	Milliseconds
Default	ASF mode (custom property not created)

Range	0 or greater milliseconds
	0 Non-ASF mode is disabled
	1 or more The timeout in milliseconds for non-ASF message-driven bean listener synchronous session receives
Recommended	If a transaction timeout occurs, the message must recycle causing extra work. If you want to use the non-ASF mode, set this property to less than the transaction timeout, but greater than or equal to the maximum duration of your message-driven bean onMessage() method. For example, if your message-driven bean onMessage() method typically takes a maximum of 10 seconds, and the transaction timeout is set to 120 seconds, you might set the NON.ASF.RECEIVE.TIMEOUT property to no more than 110000 milliseconds (that is, 110 seconds).

NON.ASF.BMT.ROLLBACK.ENABLED:

When the non-Application Server Facilities (non-ASF) mode of operation is in use (because you have set the **NON.ASF.RECEIVE.TIMEOUT** property to a non-zero value), and a message-driven bean that uses bean-managed transactions generates a runtime exception, the **NON.ASF.BMT.ROLLBACK.ENABLED** property determines whether messages are returned to the destination.

Note: The message listener service has two modes of operation, Application Server Facilities (ASF) and non-Application Server Facilities (non-ASF):

- ASF mode provides concurrency and transactional support for applications. For publish/subscribe message-drive beans, ASF mode provides better throughput and concurrency, because in the non-ASF mode the listener is single-threaded.
- Non-ASF mode is mainly for use with third-party messaging providers that do not support JMS ASF, which is an optional extension to the JMS specification. Non-ASF mode is also transactional but, because the path length is shorter than for ASF mode, usually provides improved performance.

Non-ASF mode cannot be selected on z/OS systems.

When this property is set to false (default), the message is automatically acknowledged before it is passed to the message-driven bean.

When this property is set to true, the message listener service sends a message acknowledgement to the client after the message is successfully processed by the message-driven bean, and the message listener service requests recovery of any message for which the bean generates an exception.

Data type	Boolean
Default	False

RECOVERY.RETRY.INTERVAL:

The time in seconds between retry attempts by a listener port to recover from a failure. The maximum number of retry attempts is defined by the **MAX.RECOVERY.RETRIES** property.

A failure can be caused by either of the following conditions:

- An unexpected error has occurred when a listener port tries to get a message from the JMS provider.

- The connection between the application server and the JMS provider has been lost, usually due to a network error.

Data type	Integer
Units	Seconds
Default	60
Range	1 through 2147483647

SERVER.SESSION.POOL.REAP.TIME:

The time in seconds between checks on server session pools. To enable server session pool monitoring, set this property to a non-negative value.

Data type	Integer
Units	Seconds
Default	-1 (disabled)
Range	-2147483648 through 2147483647

SERVER.SESSION.POOL.UNUSED.TIMEOUT:

The default server session pool timeout in seconds.

When this property is set to a non-negative value, it is compared to the time that has elapsed since a server session was used. If the timeout value is less than the elapsed time, the server session is removed from the server session pool and its JMS session is returned to the JMS session pool. For example, if the timeout value is one second and the time that has elapsed since a particular server session was used is two seconds, that server session is removed from the server session pool and its JMS session is returned to the JMS session pool.

Data type	Integer
Units	Seconds
Default	-1 (disabled)
Range	-2147483648 through 2147483647

SERVER.SESSION.POOL.UNUSED.TIMEOUT.lpname:

This property overrides the default **SERVER.SESSION.POOL.UNUSED.TIMEOUT** value for the listener port with the name defined for *lpname*. This value applies to all message-driven beans that use the specified listener port.

If this override is set to a non-negative value, it overrides the **SERVER.SESSION.POOL.UNUSED.TIMEOUT** property, even if the **SERVER.SESSION.POOL.UNUSED.TIMEOUT** property has a negative value.

If this override is set to a negative value, it disables server session pool monitoring for the specified listener port.

Data type	Integer
Units	Seconds
Default	Not set
Range	-2147483648 through 2147483647

Administering listener ports

You can use the WebSphere Application Server administrative console to administer listener ports, which each define the association between a connection factory, a destination, and a message-driven bean.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatibility with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see [Message-driven beans, activation specifications, and listener ports](#).

Before configuring message listener resources, consider the message listener service implementation on the z/OS platform, which affects how you should configure your listener port. For more information, see [“Message listener service on z/OS”](#) on page 496.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. If you set the initial state of a listener port to Started, the listener port is started automatically when a message-driven bean associated with that port is installed.

Listener ports can be manually started and stopped. If a message-driven bean fails to process a message several times, the listener port is automatically stopped by the application server. When a listener port is stopped, the listener manager stops the listeners for all message-driven beans associated with the port. Consequently, the associated message-driven beans can no longer process messages.

Note: You do not usually need to start or stop a listener port manually.

Procedure

- Create a new listener port.
Create a new listener port, to specify a new association between a connection factory, a destination, and a message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination.
- Configure a listener port.
Browse or change the configuration properties of a listener port.
- Start a listener port.
- Stop a listener port.
- Delete a listener port.

Creating a new listener port

You create a new listener port for the message listener service to define the association between a connection factory, a destination, and a deployed message-driven bean. This association enables the message-driven bean to retrieve messages from the associated destination.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatibility with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

Before configuring message listener resources, consider the message listener service implementation on the z/OS platform, which affects how you should configure your listener port. For more information, see “Message listener service on z/OS” on page 496.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination. For more information, see Message-driven beans - listener port components.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers > Server Types > WebSphere application servers->server_name > [Communications] Messaging > Message listener service > [Additional Properties] Listener Ports**. The “Message listener port collection” on page 504 panel is displayed.
3. Click **New**.
4. Specify the following required properties:
 - Name** The name by which the listener port is known for administrative purposes.
 - Connection factory JNDI name**
The JNDI name for the JMS connection factory to be used by the listener port; for example, jms/connFactory1.
 - Destination JNDI name**
The JNDI name for the destination to be used by the listener port; for example, jms/destn1.
5. Optional: Change other properties for the listener port, as required.
6. Click **OK**.
7. Save your changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Results

If you set the initial state of a listener port to Started, the listener port is started automatically when a message-driven bean associated with that port is installed.

Configuring a listener port

Use this task to browse or change the properties of an existing listener port, which is used by message-driven beans associated with the port to retrieve messages.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatibility with existing message-driven bean applications. For more information about when to use listener ports rather than activation specifications, see *Message-driven beans, activation specifications, and listener ports*.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination. For more information, see *Message-driven beans - listener port components*.

When you deploy an enterprise application to use message-driven beans with listener ports, you can browse or change the configuration of a listener port.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers > Server Types > WebSphere application servers->server_name > [Communications] Messaging > Message listener service > [Additional Properties] Listener Ports**
The “Message listener port collection” on page 504 panel is displayed.
3. Select the name of the listener port that you want to work with. This displays the properties of the listener port in the content pane.
4. Optional: Change properties for the listener port, according to your needs.
5. Click **OK**.
6. Save your changes to the master configuration.
7. To have a changed configuration take effect, stop then restart the application server.

Message listener port collection:

The message listener ports configured in the administrative domain

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination.

This panel displays a list of the message listener ports configured in the administrative domain. You can use this panel to add new listener ports or to change the properties of existing listener ports.

To view this administrative console panel, click **Servers > Server Types > WebSphere application servers > server_name > [Messaging] Message Listener Service > Listener Ports**

To manage a listener port, select the check box beside the listener port name in the list and click a button:

Button	Resulting action
Convert to activation specification	Opens a wizard that helps you convert the selected listener port to an activation specification.
New	Accesses the panel to configure a new listener port.
Delete	Deletes the selected listener port or ports.

Button	Resulting action
Start	Starts the selected listener port or ports.
Stop	Stops the selected listener port or ports.

Listener port settings:

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination.

Use this panel to view or change the configuration properties of the selected listener port.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > *server_name* > [Communications] Messaging > Message Listener Service > Listener Ports > *listener_port***.

Name:

The name by which the listener port is known for administrative purposes.

Data type String
Default Null

Initial state:

The state that you want the listener port to have when the application server is next restarted

Data type Enum
Units Not applicable
Default Started
Range **Started**
When the application server is next started, the listener port is started automatically.
Stopped
When the application server is next started, the listener port is not started automatically. If message-driven beans are to use this listener port on the application server, the system administrator must start the port manually or select the Started value of this property then restart the application server.

Description:

A description of the listener port, for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Connection factory JNDI name:

The JNDI name for the JMS connection factory to be used by the listener port; for example, `jms/connFactory1`.

Data type	String
Default	Null

Destination JNDI name:

The JNDI name for the destination to be used by the listener port; for example, jms/destn1.

You cannot use a temporary destination for late responses.

Data type	String
Default	Null

Maximum sessions:

The maximum number of concurrent sessions that a listener can have with the JMS server to process messages.

Each session corresponds to a separate listener thread and therefore controls the number of concurrently processed messages. Adjust this parameter when the server does not fully use the available capacity of the machine.

Data type	Integer
Units	Sessions
Default	1
Range	1 through 2147483647
Recommended	<ul style="list-style-type: none">• For message concurrency, that is to process multiple messages simultaneously, set this property to a value greater than 1. Keep this value as low as possible to prevent overloading client applications. A good starting point for a 100% JMS workload with short transaction times is 2 to 4 sessions per processor. If longer running transactions exist, you might need more sessions, which should be determined by experimentation. <p>The total number of sessions specified in the Maximum Sessions property of all configured listener ports must be less than or equal to the number of threads specified for the Maximum Size property of the message listener service thread pool.</p>

Maximum retries:

The maximum number of times that the listener tries to deliver a message to a message-driven bean instance before the listener is stopped, in the range 0 through 2147483647.

Note: A WebSphere MQ queue has a similar property called the **BackoutThreshold** property. If your listener port is reading from a WebSphere MQ queue, then the retry limit and the behavior when the limit is reached is determined by whichever of these two properties is set to the lower limit:

- If you exceed the WebSphere MQ queue **BackoutThreshold** limit, the message that cannot be delivered is moved to somewhere else by WebSphere MQ (for example, to the WebSphere MQ backout requeue queue or the WebSphere MQ dead letter queue) and the listener port services the next message on the queue. In this case, WebSphere Application Server might not know that the message has not been delivered successfully.

- If you exceed the listener port **maximum retries** limit, the listener port stops. You then manually intervene to investigate the problem, possibly to remove the message from the WebSphere MQ queue then restart the listener port.

Data type	Integer
Units	Retry attempts
Default	0 (no retries)
Range	0 (no retries) through 2147483647

Maximum messages:

The maximum number of messages that the listener can process in one transaction.

If the queue is empty, the listener processes each message when it arrives. Each message is processed within a separate transaction.

For the WebSphere V5 default messaging provider or WebSphere MQ as the JMS provider, if messages start accumulating on the queue then the listener can start processing messages in batches. For third-party messaging providers, this property value is passed to the JMS provider but the effect depends on the JMS provider.

Data type	Integer
Units	Number of messages
Default	1
Range	1 through 2147483647
Recommended	For the WebSphere default messaging providers or WebSphere MQ as the JMS provider, to process multiple messages in a single transaction, set this value to more than 1. If messages start accumulating on the queue, a value greater than 1 enables multiple messages to be batch-processed into a single transaction, and eliminates much of the transaction processing costs for JMS messages. CAUTION: <ul style="list-style-type: none"> • If one message in the batch fails processing with an exception, the entire batch of messages is put back on the queue for processing. • Any resource lock held by any of the interactions for the individual messages are held for the duration of the entire batch. • Depending on the amount of processing that messages need, and if XA transactions are being used, setting a value greater than 1 can cause the transaction to time out. If an XA transaction does time out routinely because processing multiple messages exceeds the transaction timeout, reduce this property to 1 (to limit processing to one message per transaction) or increase your transaction timeout.

Starting a listener port

Use this task to start a listener port on an application server, to enable the listeners for message-driven beans associated with the port to retrieve messages.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. For more information, see [Message-driven beans - listener port components](#).

A listener is active, that is able to receive messages from a destination, if the deployed message-driven bean, listener port, and message listener service are all started. Although you can start these components in any order, they must all be in a started state before the listener can retrieve messages.

If you set the initial state of a listener port to Started, the listener port is started automatically when a message-driven bean associated with that port is installed. You can also start a listener port manually.

When a listener port is started, the listener manager tries to start the listeners for each message-driven bean associated with the port. If a message-driven bean is stopped, the port is started but the listener is not started, and remains stopped. If you start a message-driven bean, the related listener is started.

Procedure

1. Start the administrative console.
2. If you want the listener for a deployed message-driven bean to be able to receive messages at the port, check that the message-driven bean has been started.
3. In the navigation pane, click **Servers > Server Types > WebSphere application servers->server_name > [Communications] Messaging > Message listener service > [Additional Properties] Listener Ports**

The “Message listener port collection” on page 504 panel is displayed.

4. Select the check box for the listener port that you want to start.
5. Click **Start**.
6. Save your changes to the master configuration.

Stopping a listener port

Use this task to stop a listener port on an application server, to prevent the listeners for message-driven beans associated with the port from retrieving messages.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. For more information, see [Message-driven beans - listener port components](#).

If a message-driven bean fails to process a message several times, the listener port is automatically stopped by the application server. You can also stop a listener port manually. When a listener port is stopped, the listener manager stops the listeners for all message-driven beans associated with the port. Consequently, the associated message-driven beans can no longer process messages.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers > Server Types > WebSphere application servers->server_name > [Communications] Messaging > Message listener service > [Additional Properties] Listener Ports**

The “Message listener port collection” on page 504 panel is displayed.

3. Select the check box for the listener port that you want to stop.
4. Click **Stop**.
5. Save your changes to the master configuration.
6. To have the changed configuration take effect, stop then restart the application server.

Deleting a listener port

Use this task to delete a listener port from the message listener service, to prevent message-driven beans associated with the port from retrieving messages.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. For more information, see [Message-driven beans - listener port components](#).

To delete a listener port, use the administrative console to complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers > Server Types > WebSphere application servers->server_name > [Communications] Messaging > Message listener service > [Additional Properties] Listener Ports**

The “Message listener port collection” on page 504 panel is displayed.

3. Select the check box for the listener port that you want to delete.
4. Click **Delete**.
This action stops the port (needed to allow the port to be deleted) then deletes the port.
5. Save your changes to the master configuration.
6. To have the changed configuration take effect, stop then restart the application server.

Monitoring server session pools for listener ports

You can minimize the number of resources that server sessions use by enabling server session pool monitoring and defining the timeout value to be applied to a server session.

About this task

Each listener port uses one or more server sessions, which are held in a server session pool. Each server session is associated with a JMS session, which is taken from the JMS session pool that is associated with the JMS connection factory that the listener port is configured to use.

By default, server session pool monitoring is disabled. When a listener port uses a server session the listener port does not release the server session from the server session pool until the listener port is shut down. This means that the associated JMS session is not released into the JMS session pool until the listener port is shut down, even if the listener port is not processing any messages. Consequently the resources that the JMS session uses, for example TCP/IP connections, can be held for a long time, and this can cause problems for resource-constrained systems.

To minimize the number of resources that server sessions use, you must monitor the server session pools. When you enable server session pool monitoring each server session in each server session pool that a listener port uses is monitored to determine how much time has elapsed since the server session was last used. If the elapsed time is greater than the timeout value that you have configured, the server session is removed from the server session pool and its associated JMS session is returned to the JMS session pool. The returned JMS session can be either reused by another application or closed, depending on your JMS session pool settings. You can also configure additional pooling mechanisms, depending on your JMS provider.

Note: Server session pool monitoring cannot be used if the message listener service is operating in non-Application Server Facilities (non-ASF) mode, that is if the `NON.ASF.RECEIVE.TIMEOUT` message listener service custom property is set to a non-zero value.

Non-ASF mode cannot be selected on z/OS systems.

Procedure

- To enable server session pool monitoring, configure the following message listener service custom properties on each application server as required.

SERVER.SESSION.POOL.REAP.TIME

To enable server session pool monitoring, set this property to the time in seconds between checks on server session pools (this must be a non-negative value).

SERVER.SESSION.POOL.UNUSED.TIMEOUT

To specify the default server session pool timeout, set this property to the required number of seconds for the timeout. When this property is set to a non-negative value, it is compared with the time that has elapsed since a server session was used. If the timeout value is less than the elapsed time, the server session is removed from the server session pool and its JMS session is returned to the JMS session pool. For example, if the timeout value is one second and the time that has elapsed since a particular server session was used is two seconds, that server session is removed from the server session pool and its JMS session is returned to the JMS session pool.

SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*

To override the default SERVER.SESSION.POOL.UNUSED.TIMEOUT value for the listener port with the name *lpname*, set this property to the appropriate value:

- To override the SERVER.SESSION.POOL.UNUSED.TIMEOUT for the specified listener port, set this property to a non-negative value defining the required number of seconds for the server session timeout for this listener port.
- To disable server session pool monitoring for the specified listener port, set this property to a negative value.

The value that you set for this property applies to all message-driven beans that are using the specified listener port.

- Additionally, to enable server session pool monitoring on z/OS systems, perform the following steps:

1. Start the administrative console.
2. In the navigation pane, select one of the following paths:
 - Resources > JMS->Connection factories**
 - Resources > JMS->Queue connection factories**
 - Resources > JMS->Topic connection factories**
3. Select the **Scope** corresponding to the scope of the connection factory that you want to view.
4. From the list of connection factories, select the connection factory used by the listener port. The properties of the connection factory are displayed in the content pane.
5. Under Additional Properties, select **Custom properties**. The custom properties of the connection factory are displayed in the content pane.
6. Click **New**.
7. Set the **Name** to `was_nondeferredreaper` and set the **Value** to `true`. Leave the other properties with their default values.
8. Click **OK**.
9. Save your changes to the master configuration.
10. To have a changed configuration take effect, stop then restart the application server.

Example

For example, consider an application server that is configured with listener ports `lp1`, and `lp2`.

The following rules apply:

No properties set

If none of the properties are set, server session pool monitoring is disabled and JMS sessions used by server sessions are not returned to the JMS session pool until the listener port (lp1 or lp2), or its associated message-driven bean, is shut down.

SERVER.SESSION.POOL.REAP.TIME and SERVER.SESSION.POOL.UNUSED.TIMEOUT set

Consider, for example, the following settings:

```
SERVER.SESSION.POOL.REAP.TIME=60
SERVER.SESSION.POOL.UNUSED.TIMEOUT=120
```

The server session pool of both listener ports (lp1 and lp2) is checked for inactive server sessions every 60 seconds. If a server session is detected as being inactive for more than 120 seconds, it is removed from the server session pool and its JMS session is returned to the JMS session pool. Taking into account the SERVER.SESSION.POOL.REAP.TIME value, the server session pool could be removed from the session pool between two and three minutes after the server session was last used.

SERVER.SESSION.POOL.REAP.TIME and SERVER.SESSION.POOL.UNUSED.TIMEOUT set, and overrides set for SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*

Consider, for example, the following settings:

```
SERVER.SESSION.POOL.REAP.TIME=60
SERVER.SESSION.POOL.UNUSED.TIMEOUT=120
SERVER.SESSION.POOL.UNUSED.TIMEOUT.lp2=-1
SERVER.SESSION.POOL.UNUSED.TIMEOUT.lp1=60
```

The server session pool for listener port lp2 is not checked because it has a negative timeout value. In the server session pool for listener port lp1, any server sessions that are inactive for more than 60 seconds are removed from the server session pool.

Chapter 16. Administering Naming and directory

This page provides a starting point for finding information about naming support. Naming includes both server-side and client-side components. The server-side component is a Common Object Request Broker Architecture (CORBA) naming service (CosNaming). The client-side component is a Java™ Naming and Directory Interface (JNDI) service provider. JNDI is a core component in the Java Platform, Enterprise Edition (Java EE) programming model.

The WebSphere® JNDI service provider can be used to interoperate with any CosNaming name server implementation. Yet WebSphere name servers implement an extension to CosNaming, and the JNDI service provider uses those WebSphere extensions to provide greater capability than CosNaming alone. Some added capabilities are binding and looking up of non-CORBA objects.

Java EE applications use the JNDI service provider supported by WebSphere Application Server to obtain references to objects related to server applications, such as enterprise bean (EJB) homes, which have been bound into a CosNaming name space.

Configuring namespace bindings

Instead of creating namespace bindings from a program, you can configure namespace bindings using the administrative console. Name servers add these configured bindings to the namespace view by reading the configuration data for the bindings. Configured bindings are created each time a server starts, even when the binding is created in a transient partition of the namespace. One major use of configured bindings is to provide fixed qualified names for server application objects.

Before you begin

Assemble and deploy your application onto an application server. If the application is a client to an application running in another server process, specify qualified `jndiName` values for the server objects of the other application during assembly or deployment. For more information on qualified names, refer to the topic on lookup names support in deployment descriptors and thin clients.

About this task

A deployed application requires qualified fixed names if the application is accessed by thin client applications or by Java Platform, Enterprise Edition (Java EE) client applications or server applications running in another server process.

When you configure a namespace binding, you create a qualified fixed name for a server object. A fixed name does not change if the object is moved to another server. A qualified fixed name with a cell scope has the following form:

```
cell/persistent/fixedName
```

The *fixedName* is an arbitrary fixed name.

You can configure namespace bindings, and thus qualified fixed names, for the following objects:

- A string constant value
- An enterprise bean (EJB) home installed on a server in the cell
- A CORBA object available from a CosNaming name server
- An object bound in a WebSphere Application Server namespace that is accessible using a Java Naming and Directory Interface (JNDI) indirect lookup

To view or configure a namespace binding for an object of a deployed application, complete the following:

Procedure

1. Go to the Name space bindings page.

In the administrative console, click **Environment > Naming > Name space bindings**.

2. Select the desired scope.

The scope determines where in the namespace binding is created. It also affects which name servers contain the binding in the namespace that they manage. Regardless of the scope, a namespace binding is accessible from all name servers in the cell. However, the scope can affect whether the lookup can be resolved locally by a name server or whether the name server must make a remote call to another name server to resolve the binding.

Only namespace bindings created with the selected scope are visible in the collection table on the page. By changing the scope, you can see and create bindings in other scopes.

- a. Select a scope.

If you are creating a new namespace binding, refer to the table below as a guide in selecting a scope:

Table 63. Namespace binding scope descriptions. The scope can be a cell, node, server, or cluster.

Scope	Description
Cell	<p>Cell-scoped bindings are created under the cell persistent root context. Select Cell if the namespace binding is not specific to any particular node or server, or if you do not want the binding to be associated with any specific node, cluster or server. For example, you can use cell-scoped bindings to create fixed qualified names for enterprise beans. Fixed qualified names do not have any node, cluster or server names embedded within them.</p> <p>Cell-scoped bindings are created in all processes in the cell that contain a name server, specifically in administrative agent, deployment manager, node agent, and application server processes. Therefore all name servers in the cell can resolve those bindings locally. No remote invocations to other name servers are necessary to resolve the bindings.</p>
Node	<p>Node-scoped bindings are created under the node persistent root context for the selected node. Select Node if the namespace binding is specific to a particular node, or if you want the binding to be associated with a specific node.</p> <p>Node-scoped bindings are created in the node agent and all application server processes in the selected node. Therefore, all name servers in the node can resolve those bindings locally. No remote invocations to other name servers are necessary to resolve the bindings. However, name servers in other nodes must make remote calls to the node agent in the selected node in order to resolve the bindings. For example, in order for a name server running in node <i>node1</i> to resolve the name <code>cell/nodes/node2/persistent/nodeScopedConfiguredBinding</code>, the name server must make a remote call to the node agent running in <i>node2</i>. Any name server running in <i>node2</i> can resolve that name without invoking any other name servers.</p>
Server	<p>Server-scoped bindings are created under the server root context for the selected server. Select Server if a binding is to be used only by clients of an application running on a particular server, or if you want to configure a binding with the same name on different servers which resolve to different objects. Note that two servers can have configured bindings with the same name but resolve to different objects.</p> <p>Server-scoped bindings are created in the process of the selected application server. Therefore, the name server running in the selected application server can resolve those bindings locally. No remote invocations to other name servers are necessary to resolve the bindings. However, all other name servers in the cell must make remote calls to the selected server in order to resolve the bindings. For example, in order for the name server running in <i>server1</i> in node <i>node1</i> to resolve the name <code>cell/nodes/node1/servers/server2/serverScopedConfiguredBinding</code>, it must make a remote call to <i>server2</i> in <i>node1</i>. Only the name server in <i>server2</i> in <i>node1</i> can resolve that name without invoking any other name servers.</p>

Table 63. Namespace binding scope descriptions (continued). The scope can be a cell, node, server, or cluster.

Scope	Description
Cluster	<p>Cluster-scoped bindings are created under the server root context for all members in the selected cluster. Select Cluster if the namespace binding is specific to a particular cluster, or if you want the binding to be associated with a specific cluster.</p> <p>Cluster-scoped bindings are created in all member processes of the selected cluster. Therefore, the name server running in each member of the selected cluster can resolve those bindings locally. No remote invocations to other name servers are necessary to resolve the bindings. However, all other name servers in the cell must make remote calls to the node agent in the selected node in order to resolve the bindings. For example, in order for a name server running in any member of <i>cluster1</i> to resolve the name <code>cell/clusters/cluster2/clusterScopedConfiguredBinding</code>, it must make a remote call to some member in <i>cluster2</i>. Only the name servers in <i>cluster2</i> members can resolve that name without invoking any other name servers.</p> <p>Server-scoped bindings in cluster members override cluster-scoped bindings with the same binding name. However, cluster members generally should all be configured identically, and server-scoped bindings should not be required for individual cluster members.</p>

- b. Click **Apply**.
3. Create a new namespace binding.
 - a. Open the New Name Space Binding wizard.
On the Name space bindings page, click **New**.
 - b. On the **Specify binding type** page, select the binding type.
The namespace binding can be for a constant string value, an EJB home, a CORBA CosNaming NamingContext or CORBA leaf node object, or an object that you can look up indirectly using JNDI.
 - c. On the **Specify basic properties** page, specify the binding identifier and other properties for the binding.
For property descriptions, refer to the following:
 - “String binding settings” on page 1110
 - “EJB binding settings” on page 1111
 - “CORBA object binding settings” on page 1112
 - “Indirect lookup binding settings” on page 1113
 - d. Optional: On the **Other context properties** page, specify new properties to be passed to the `javax.naming.InitialContext` constructor.
This step applies to indirect lookup bindings only.
 - e. On the **Summary** page, verify the settings and click **Finish**.
The name of the new binding is displayed in the collection table on the Name space bindings page.
4. Optional: Edit a previously created binding.
 - a. From the collection table on the Name space bindings page, click the name of the binding that you want to edit.
 - b. Edit the binding properties as desired. Step 3(c) provides links to property descriptions.
 - c. Click **OK**.

Results

Cell-scoped bindings are created under the cell persistent root context. Node-scoped bindings are created under the node persistent root context for the specified node. Server-scoped bindings are created under the server root context for the selected server. Cluster-scoped bindings are created under the server root context for each member of the selected cluster.

Name space binding collection

Use this page to configure a name binding of an EJB, a CORBA CosNaming NamingContext, a CORBA leaf node object, an object that you can look up using Java Naming and Directory Interface (JNDI), or a constant string value.

Binding information for configured bindings is stored in the configuration and applied upon startup of the name server for each server within the scope of the binding.

To view the Name space bindings page, click **Environment > Naming > Name space bindings**.

Click the check boxes to select one or more of the bindings in your collection. Use the buttons to control the selected bindings.

When creating a new binding, select a scope before clicking **New**. The **Scope** setting filters what bindings are listed in the collection as well as sets the scope of the new binding.

Name

Shows the names given to uniquely identify these configured bindings.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the namebindings.xml file. This field is for information purposes only and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

On multiple-server installations, the configured binding can also be cluster-scoped. For cluster-scoped bindings, the starting context is the server's server root context.

Binding type

Shows the type of binding configured. Valid values are String, EJB, CORBA, and Indirect. This field is for information purposes only and cannot be updated.

Specify binding type settings

Use this page to select the type of namespace binding that you want.

To view this administrative console page, click **Environment > Naming > Name space bindings > New**.

You can configure a namespace binding for any of the following objects:

- A string constant value
- An enterprise bean (EJB) home installed on a server in the cell
- A CORBA object available from a CosNaming name server
- An object bound in a WebSphere Application Server namespace that is accessible using a Java Naming and Directory Interface (JNDI) indirect lookup

On this page, select a binding type and then click **Next**.

Binding type

Specifies the type of binding configured.

Table 64. Namespace binding types. Available types include *String*, *EJB*, *CORBA*, or *Indirect*.

String	<p>Select String to configure a namespace binding for a string constant value.</p> <p>To configure a String binding, you need the following information:</p> <ul style="list-style-type: none">• The string constant value• The target root context for the configured binding (scope)• The name of the configured binding, relative to the target root context <p>You can create a file that maps multiple variable names to values and specify the file name for the String value. By default, a name server performs variable substitution on the string value of a String namespace binding. Thus, by default, the <code>com.ibm.websphere.naming.expandStringBindings</code> property is set to <code>true</code> and a name server expands the value of String bindings.</p> <p>Tip: Variable substitution can result in errors or unexpected changes to a string. For example, with variable substitution, a <code>\$\$</code> string is expanded as <code>\$</code>. You can disable variable substitution and cause the name server to treat the String value as a literal or constant. Create a custom property with Name set to <code>com.ibm.websphere.naming.expandStringBindings</code> and Value set to <code>false</code>. You can define a custom property at the cell, node, server, or name server scope. Create the custom property on a console page for the appropriate scope:</p> <p>Cell scope Click System administration > Cell > Custom properties > New.</p> <p>Node scope Click System administration > Nodes > <i>node_name</i> > Custom properties > New.</p> <p>Server scope Click Application servers > <i>server_name</i> > Administration > Custom properties > New.</p> <p>Name server scope Click Application servers > <i>server_name</i> > Administration > Server components > Name server > Custom properties > New.</p> <p>All name servers within the specified custom property scope apply the setting. Settings at a narrower scope override settings at a wider scope. For example, on multiple-server products, settings at the node scope override settings at the cell scope. Select a custom property scope that is at least as wide as the namespace binding scope. Thus, to prevent variable expansion in a cell-scoped String namespace binding, define the custom property at the cell scope. If the custom property has a scope narrower than the namespace binding, only name servers within the scope prevent variable expansion in the String namespace binding. Name servers outside of the scope expand the variable reference and handle the reference differently.</p>
EJB	<p>Select EJB to configure a namespace binding for an EJB home installed on a server in the cell. Use a cell-scoped EJB binding to create a fixed qualified lookup name for an enterprise bean. A fixed qualified lookup name is not dependent on the cell topology.</p> <p>To configure an EJB home binding, you need the following information:</p> <ul style="list-style-type: none">• The JNDI name of the EJB server or server cluster where the enterprise bean is deployed• The target root context for the configured binding (scope)• The name of the configured binding, relative to the target root context <p>On stand-alone servers, do not configure an EJB binding that resolves to another server. The name server cannot read configuration data for other servers. That data is required to construct the binding.</p>

Table 64. Namespace binding types (continued). Available types include String, EJB, CORBA, or Indirect.

CORBA	<p>Select CORBA to configure a namespace binding for a Common Object Request Broker: Architecture and Specification (CORBA) object available from a Object Management Group (OMG) Interoperable Naming (CosNaming) name server. Identify a CORBA object bound into an INS compliant CosNaming server with a corbaname URL. The referenced object does not have to be available until the binding is actually referenced by an application.</p> <p>To configure a CORBA binding, you need the following information:</p> <ul style="list-style-type: none"> • The corbaname URL of the CORBA object • An indicator if the bound object is a context or leaf node object (to set the correct CORBA binding type of context or object) • The target root context for the configured binding • The name of the configured binding, relative to the target root context
Indirect	<p>Select Indirect to configure a namespace binding for an object bound in a WebSphere Application Server namespace that is accessible using a JNDI indirect lookup. You can select Indirect for CORBA objects as well as for javax.naming.Referenceable, javax.naming.Reference, and java.io.Serializable objects.</p> <p>The target object itself is not bound to the namespace. Only the information required to look up the object is bound. Therefore, the referenced name server does not have to be running until the binding is actually referenced by some application.</p> <p>To configure an indirect JNDI lookup binding, you need the following information:</p> <ul style="list-style-type: none"> • The JNDI provider URL of the name server where the object resides • The JNDI lookup name of the object • The target root context for the configured binding (scope) • The name of the configured binding, relative to the target root context <p>The following information is optional:</p> <ul style="list-style-type: none"> • The JNDI initial context factory class name. The default is the WebSphere Application Server initial context factory, com.ibm.websphere.naming.WsnInitialContextFactory. • Additional properties to pass to the javax.naming.InitialContext constructor. <p>A cell-scoped indirect binding is useful when creating a fixed qualified lookup name for a bound object so that the qualified lookup name is not dependent on the cell topology.</p>

String binding settings

Use this page to view or configure a string binding.

To view this administrative console page, click **Environment > Naming > Name space bindings > *string_namespace_binding***. The settings on this page are similar to those on the **Specify basic properties** panel of the New name space binding wizard.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the namebindings.xml file.

The **Scope** setting is shown only when you edit an existing binding on the console page, and is not shown when you create a new binding on the wizard panel. This setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

On multiple-server installations, the configured binding can also be cluster-scoped. For cluster-scoped bindings, the starting context is the server's server root context.

Binding type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes only and cannot be updated.

Binding identifier

Specifies the name that uniquely identifies this configured binding.

Name in name space

Specifies the name used for this binding in the namespace. This name can be a simple or compound name depending on the portion of the namespace where this binding is configured.

String value

Specifies the string to be bound into the namespace.

You can create a file that maps multiple variable names to values and specify the file name for the **String** value. By default, a name server performs variable substitution on the string value of a String namespace binding. Thus, by default, the `com.ibm.websphere.naming.expandStringBindings` property is set to `true` and a name server expands the value of String bindings.

Tip: Variable substitution can result in errors or unexpected changes to a string. For example, with variable substitution, a `$$` string is expanded as `$`. You can disable variable substitution and cause the name server to treat the **String** value as a literal or constant. Create a custom property with **Name** set to `com.ibm.websphere.naming.expandStringBindings` and **Value** set to `false`. You can define a custom property at the cell, node, server, or name server scope. Create the custom property on a console page for the appropriate scope:

Cell scope

Click **System administration > Cell > Custom properties > New**.

Node scope

Click **System administration > Nodes > *node_name* > Custom properties > New**.

Server scope

Click **Application servers > *server_name* > Administration > Custom properties > New**.

Name server scope

Click **Application servers > *server_name* > Administration > Server components > Name server > Custom properties > New**.

All name servers within the specified custom property scope apply the setting. Settings at a narrower scope override settings at a wider scope. For example, on multiple-server products, settings at the node scope override settings at the cell scope. Select a custom property scope that is at least as wide as the namespace binding scope. Thus, to prevent variable expansion in a cell-scoped String namespace binding, define the custom property at the cell scope. If the custom property has a scope narrower than the namespace binding, only name servers within the scope prevent variable expansion in the String namespace binding. Name servers outside of the scope expand the variable reference and handle the reference differently.

EJB binding settings

Use this page to configure a new enterprise bean (EJB) binding, or to view or edit an existing EJB binding.

To view this console page, click **Environment > Naming > Name space bindings > *EJB_namespace_binding***. The settings on this page are similar to those on the **Specify basic properties** panel of the New name space binding wizard.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the `namebindings.xml` file.

The **Scope** setting is shown only when you edit an existing binding on the console page, and is not shown when you create a new binding on the wizard panel. This setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

On multiple-server installations, the configured binding can also be cluster-scoped. For cluster-scoped bindings, the starting context is the server's server root context.

Binding type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes only and cannot be updated.

Binding identifier

Specifies the name that uniquely identifies this configured binding.

Name in name space

Specifies the name used for this binding in the namespace. This name can be a simple or compound name depending on the portion of the namespace where this binding is configured.

Enterprise bean location

Specifies whether the enterprise bean is running in a single server. If *Single server* is specified, type the node name.

On multiple-server installations, the enterprise bean can run in a single server or a server cluster.

Server

Specifies the name of the server in which the enterprise bean is configured.

On multiple-server installations, the server can be a cluster or non-clustered server in which the enterprise bean is configured.

JNDI name

Specifies the Java Naming and Directory Interface (JNDI) name of the deployed enterprise bean. It is the bean's JNDI name that is in the enterprise bean bindings, not the java:comp name.

CORBA object binding settings

Use this page to configure a new name binding of a CORBA object binding, or to view or edit an existing CORBA object binding.

To view this console page, click **Environment > Naming > Name space bindings > *CORBA_namespace_binding***. The settings on this page are similar to those on the **Specify basic properties** panel of the New name space binding wizard.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the namebindings.xml file.

The **Scope** setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

On multiple-server installations, the configured binding can also be cluster-scoped. If the configured binding is cluster-scoped, the starting context is the server's server root context.

Binding type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes and cannot be updated.

Binding identifier

Specifies the name that uniquely identifies this configured binding.

Name in name space

Specifies the name used for this binding in the namespace. This name can be a simple or compound name depending on the portion of the namespace where this binding is configured.

Corbaname URL

Specifies the CORBA name URL string identifying where the object is bound in a CosNaming server.

Federated context

Specifies whether the target is a CosNaming context (true) or a leaf node object (false).

true

The target object is bound with a context CORBA binding type. If the corbaname URL does not resolve to a NamingContext, an error occurs when the binding is first used (which is when the URL is first resolved).

false

The target object is bound with an object CORBA binding type.

Indirect lookup binding settings

Use this page to configure a new indirect lookup name binding, or to view or edit an existing indirect lookup binding.

To view this console page, click **Environment > Naming > Name space bindings > indirect_lookup_namespace_binding**. The settings on this page are similar to those on the **Specify basic properties** panel of the New name space binding wizard.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the namebindings.xml file.

The **Scope** setting is shown only when you edit an existing binding on the console page, and is not shown when you create a new binding on the wizard panel. This setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

On multiple-server installations, the configured binding can also be cluster-scoped. For cluster-scoped bindings, the starting context is the server's server root context.

Binding type

Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes only and cannot be updated.

Binding identifier

Specifies the name that uniquely identifies this configured binding.

Name in name space

Specifies the name used for this binding in the namespace. This name can be a simple or compound name depending on the portion of the namespace where this binding is configured.

Provider URL

Specifies the provider URL string needed to obtain a Java Naming and Directory Interface (JNDI) initial context.

JNDI name

Specifies the name used to look up the target object from the initial context.

Initial context factory name

Specifies the class name of the initial context factory used to obtain a JNDI initial context.

This field is optional. If no factory is specified, the WebSphere Application Server initial context factory is used.

If the scope of the indirect lookup binding includes servers or nodes previous to Version 6.1, the initial context factory name and other context factory properties are not shown on the console page.

Other context properties settings

Use this page to specify properties to be passed to the `javax.naming.InitialContext` constructor for an indirect Java Naming and Directory Interface (JNDI) lookup name binding. Completion of this page is optional. The properties are in addition to the basic properties specified for an indirect namespace binding.

To specify new context properties and view this page, click **Environment > Naming > Name space bindings > New > Indirect > *indirect_binding_basic_properties* > Specify additional context properties**.

Only Version 6.1 and later nodes use these properties.

To add a property to be passed to the `javax.naming.InitialContext` constructor when obtaining the initial JNDI context, specify a name and value pair to be passed to the constructor and click **Apply**. You can add multiple name-value properties. The specified properties are displayed in the collection table.

To view existing context properties, click **Environment > Naming > Name space bindings > *indirect_binding_name* > Other context properties**.

If the scope of the indirect lookup binding includes servers or nodes previous to Version 6.1, the initial context factory name and other context factory properties are not shown on the console page.

Name

Specifies the name (or key) for the property.

Each property name must be unique. If the same name is specified for multiple properties, the value used is undefined.

Do not start your property names with `was.` because this prefix is reserved for properties that are predefined in the product.

Value

Specifies the value paired with the specified name.

Description

Specifies information about the name-value pair.

Configuring name servers

Name servers add configured name space bindings to the name space view by reading the configuration data for the bindings. If you use configured bindings, you do not need to create name space bindings from a program.

About this task

You can configure a name server to provide a display name and initial state for an application server, as well as specify custom properties for the name server. Configure a name server using the administrative console.

Procedure

1. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server_name* > Administration > Server components > Name server**.
2. Edit the fields as needed.
All of the fields are mandatory.
3. To make other changes, click **Custom properties** and configure a custom property.
4. Click **OK** to register your changes.

What to do next

Examine and start the name server.

Name server settings

Use this page to configure Naming Service Provider settings for the application server. On multiple-server products, you also can configure Naming Service Provider settings for a deployment manager or node agent.

To view this administrative console page, click one of the following paths:

- **Servers > Server Types > WebSphere application servers > *server_name* > Administration > Server components > Name server**
- **Servers > Server Types > Version 5 JMS servers > *server_name* > Administration > Server components > Name server**
- **System administration > Deployment manager > Administration > Server components > Name server**
- **System administration > Node agents > *node_agent_name* > Administration > Server components > Name server**

Name

Specifies the display name for the server component.

Data type String

Initial state

Specifies the execution state. The options are: *Started* and *Stopped*.

Data type String
Default Started

Configuring foreign cell bindings

Configure foreign cell name bindings to enable your applications to access other applications in other cells. A *foreign cell* is a cell other than the one in which an application resides. A foreign cell name binding is a context binding that resolves to the Cell Root context of a foreign cell. All applications in the local cell can look up objects in the foreign cell through the foreign cell binding.

Before you begin

Configure server clusters for failover support as needed.

Migrate any Version 5.x or 6.0.x bootstrap addresses to use Version 6.1 or later foreign cell bindings. Version 6.1 or later foreign cell bindings enable you to specify more than one bootstrap address and enhance failover support.

About this task

If applications in the local cell access applications in one or more foreign cells, configure a foreign cell binding for each foreign cell.

Administrators typically configure a foreign cell binding before they configure any applications with Java Naming and Directory Interface (JNDI) names that resolve through the binding. However, you can create a foreign cell binding any time before you start an application that uses the binding.

The foreign cell and the local cell must have different names.

To view or configure a foreign cell binding, use the administrative console.

Procedure

1. Go to the Foreign cell bindings page.
In the administrative console, click **Environment > Naming > Foreign cell bindings**.
2. Create a new foreign cell binding.
 - a. Open the New Foreign Cell Binding wizard.
On the Foreign cell bindings page, click **New**.
 - b. On the **Specify foreign cell name** panel, specify the name of the cell that applications in the local cell will access.
 - c. On the **Specify bootstrap addresses** panel, specify a host name and port for a new bootstrap address, and then click **Apply**.
Repeat this step for each bootstrap address that you need. The name of each new bootstrap address is displayed in the collection table on the Bootstrap addresses page.
 - d. On the **Summary** panel, verify the settings and click **Finish**.
The name of the new binding is displayed in the collection table on the Foreign Cell Bindings page.
3. Optional: Edit a previously created foreign cell binding.
 - a. From the collection table on the Foreign cell bindings page, click the name of the binding that you want to edit.
 - b. On the foreign cell binding settings page, edit the foreign cell name as desired.
 - c. Edit the list of bootstrap addresses used for the foreign cell binding.
 - 1) From the collection table on the Foreign cell bindings page, click **foreign_cell_binding_name > Bootstrap addresses**.
 - 2) On the foreign cell binding settings page, click **Bootstrap addresses**. The Bootstrap addresses page opens.

To add a new bootstrap address, click **New** and specify the host and port.

To delete a bootstrap address, click the check box next to the cell name and click **Delete**.

To edit an existing bootstrap address, click the address you want to edit. On the bootstrap address settings page, edit the host and port as desired and click **OK** to register the change.

Results

Configurations for foreign cell bindings are created or changed as specified.

What to do next

Save changes to your administrative configuration. Configure namespace bindings for your applications as needed.

Foreign cell binding collection

Use this page to manage foreign cell bindings.

If you have applications in a cell that access other applications in another cell, you can configure a foreign cell name binding for the other cell. A *foreign cell name binding* is a context binding that resolves to the Cell Root context of the other cell. All applications in the local cell can look up objects in the foreign cell through the foreign cell binding.

Foreign cell bindings limit bootstrap address information for a foreign cell to a single location, instead of placing in the local cell's application deployment data the bootstrap address information contained in every foreign cell reference. If the bootstrap address for the foreign cell changes, you only need to update the foreign cell binding. You do not need to update the deployment data for any application in the local cell that looks up application objects in the foreign cell through the foreign cell binding.

For example, assume the foreign cell CellB has a cell-scoped EJB namespace binding configured with a name in the namespace of `ejb/AccountHome`. Applications running in CellB would look up the home with a JNDI name of `cell/persistent/ejb/AccountHome`. (Java EE applications use a `java:comp/env` name that maps to that JNDI name through deployment descriptor data.) If you configure a foreign cell binding to CellB in the local cell, applications running in the local cell can look up `AccountHome` with a JNDI name of `cell/cells/CellB/persistent/ejb/AccountHome`. In both lookup names, the suffix `persistent/ejb/AccountHome` is relative to the Cell Root context in CellB.

To view the Foreign cell bindings page, click **Environment > Naming > Foreign cell bindings**.

Click the check boxes to select one or more of the bindings in your collection. Use the buttons to control the selected bindings.

Foreign cell name

Shows the names given to uniquely identify these foreign cell bindings.

The foreign cell and the local cell must have different names.

Foreign cell binding settings

Use this page to configure a foreign cell binding.

To view this administrative console page, click **Environment > Naming > Foreign cell bindings > *foreign_cell_binding***. The setting on this page is similar to that on the **Specify foreign cell name** panel of the New foreign cell binding wizard.

Foreign cell name

Specifies the name of the foreign cell. The foreign cell name must be different from the cell that contains the foreign cell binding. Otherwise, incorrect behavior might result.

Bootstrap address collection

Use this page to manage bootstrap addresses for a foreign cell binding. Multiple bootstrap addresses can enhance the failover support provided by clusters.

To view this administrative console panel, click **Environment > Naming > Foreign cell bindings > *foreign_cell_binding_name* > Bootstrap addresses**.

Click the check boxes to select one or more of the bootstrap addresses in your collection. Use the buttons to control the selected bootstrap addresses.

Host name

Specifies the host name of the administrative agent, deployment manager, node agent, server or cluster member in the foreign cell that is used for bootstrapping.

Port

Specifies the bootstrap port number for the administrative agent, deployment manager, node agent, server or cluster member running on the specified host.

Bootstrap address settings

Use this page to specify one or more bootstrap addresses for a foreign cell binding. Multiple bootstrap addresses can enhance the failover support provided by clusters.

Only one bootstrap address is required on the z/OS platform to enhance the failover support provided by clusters.

To view this administrative console page, click **Environment > Naming > Foreign cell bindings > *foreign_cell_binding_name* > Bootstrap addresses > *bootstrap_address_host_name***. This page is similar to the **Specify bootstrap addresses** panel on the new foreign cell binding wizard.

Host name

Specifies the host name of the administrative agent, deployment manager, node agent, server or cluster member in the foreign cell that is used for bootstrapping.

Specify the IP address, domain name server (DNS) host name with domain name suffix, or just the DNS host name, of the bootstrap host for the deployment manager of the backup cluster.

For example, if the host name is `myhost`, the fully qualified DNS name can be `myhost.myco.com` and the IP address can be `155.123.88.201`.

A single address is sufficient for high availability.

Port

Specifies the bootstrap port number for the administrative agent, deployment manager, node agent, server or cluster member running on the specified host. The port value is used in conjunction with the host name.

Chapter 17. Administering Object pools

This page provides a starting point for finding information about object pools.

Object pools provide an effective means of improving application performance at run time, by supporting the reuse of multiple instances of objects.

Using object pools

An object pool helps an application avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused.

About this task

Object pools are not meant to be used for pooling JDBC connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To use an object pool, the product administrator must define an *object pool manager* using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Note: The Object pool manager service is only supported from within the EJB container or Web container. Looking up and using a configured object pool manager from a Java 2 Platform Enterprise Edition (J2EE) application client container is not supported.

Procedure

1. Start the administrative console.
2. Click **Resources > Object pool managers**.
3. Specify a **Scope** value and click **New**.
4. Specify the required properties for work manager settings.
 - Scope** The scope of the configured resource. This value indicates the location for the configuration file.
 - Name** The name of the object pool manager. This name can be up to 30 ASCII characters long.
 - JNDI Name**
 - The Java Naming and Directory Interface (JNDI) name for the pool manager.
5. [Optional] Specify a **Description** and a **Category** for the object pool manager.

Results

After you have completed these steps, applications can find the object pool manager by doing a JNDI lookup using the specified JNDI name.

Example

The following code illustrates how an application can find an object pool manager object:

```
InitialContext ic = new InitialContext();
ObjectPoolManager opm = (ObjectPoolManager)ic.lookup("java:comp/env/pool");
```

When the application has an ObjectPoolManager, it can cache an object pool for classes of the types it wants to use. The following is an example:

```
ObjectPool arrayListPool = null;
ObjectPool vectorPool = null;
try
```

```

{
  arrayListPool = opm.getPool(ArrayList.class);
  vectorPool = opm.getPool(Vector.class);
}
catch(InstantiationException e)
{
  // problem creating pool
}
catch(IllegalAccessException e)
{
  // problem creating pool
}

```

When the application has the pools, the application can use them as in the following example:

```

ArrayList list = null;
try
{
  list = (ArrayList)arrayListPool.getObject();
  list.clear(); // just in case
  for(int i = 0; i < 10; ++i)
  {
    list.add("" + i);
  }
  // do what ever we need with the ArrayList
}
finally
{
  if(list != null) arrayListPool.returnObject(list);
}

```

This example presents the basic pattern for using object pooling. If the application does not return the object, then the only adverse effect is that the object cannot be reused.

Object pool managers

Object pool managers control the reuse of application objects and Developer Kit objects, such as Vectors and HashMaps.

Multiple object pool managers can be created in an Application Server cell. Each object pool manager has a unique cell-wide Java Naming and Directory Interface (JNDI) name. Applications can find a specific object pool manager by doing a JNDI lookup using the specific JNDI name.

The object pool manager and its associated objects implement the following interfaces:

```

public interface ObjectPoolManager
{
  ObjectPool getPool(Class aClass)
    throws InstantiationException, IllegalAccessException;
  ObjectPool createFastPool(Class aClass)
    throws InstantiationException, IllegalAccessException;
}

public interface ObjectPool
{
  Object getObject();
  void returnObject(Object o);
}

```

The getObject() method removes the object from the object pool. If a getObject() call is made and the pool is empty, then an object of the same type is created. A returnObject() call puts the object back into the object pool. If returnObject() is not called, then the object is no longer allocatable from the object pool. If the object is not returned to the object pool, then it can be garbage collected.

Each object pool manager can be used to pool any Java object with the following characteristics:

- The object must be a public class with a public default constructor.
- If the object implements the `java.util.Collection` interface, it must support the optional `clear()` method.

Each pooled object class must have its own object pool. In addition, an application gets an object pool for a specific object using either the `ObjectPoolManager.getPool()` method or the `ObjectPoolManager.createFastPool()` method. The difference between these methods is that the `getPool()` method returns a pool that can be shared across multiple threads. The `createFastPool()` method returns a pool that can only be used by a single thread.

If in a Java virtual machine (JVM), the `getPool()` method is called multiple times for a single class, the same pool is returned. A new pool is returned for each call when the `createFastPool()` method is called. Basically, the `getPool()` method returns a pool that is thread-synchronized.

The pool for use by multiple threads is slightly slower than a fast pool because of the need to handle thread synchronization. However, extreme care must be taken when using a fast pool.

Consider the following interface:

```
public interface PoolableObject
{
    void init();
    void returned();
}
```

If the objects placed in the pool implement this interface and the `ObjectPool.getObject()` method is called, the object that the pool distributes has the `init()` method called on it. When the `ObjectPool.returnObject()` method is called, the `PoolableObject.returned()` method is called on the object before it is returned to the object pool. Using this method objects can be pre-initialized or cleaned up.

It is not always possible for an object to implement `PoolableObject`. For example, an application might want to pool `ArrayList` objects. The `ArrayList` object needs clearing each time the application reuses it. The application might extend the `ArrayList` object and have the `ArrayList` object implement a poolable object. For example, consider the following:

```
public class PooledArrayList extends ArrayList implements PoolableObject
{
    public PooledArrayList()
    {
    }

    public void init() {
    }

    public void returned()
    {
        clear();
    }
}
```

If the application uses this object, in place of a true `ArrayList` object, the `ArrayList` object is cleared automatically when it is returned to the pool.

Clearing an `ArrayList` object simply marks it as empty and the array backing the `ArrayList` object is not freed. Therefore, as the application reuses the `ArrayList`, the backing array expands until it is big enough for all of the application requirements. When this point is reached, the application stops allocating and copying new backing arrays and achieves the best performance.

It might not be possible or desirable to use the previous procedure. An alternative is to implement a custom object pool and register this pool with the object pool manager as the pool to use for classes of

that type. The class is registered by the WebSphere administrator when the object pool manager is defined in the cell. Take care that these classes are packaged in Java Archive (JAR) files available on all of the nodes in the cell where they might be used.

Object pool managers collection

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers**.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Name

Specifies the name by which the object pool manager is known for administrative purposes.

Data type	String
Range	1 through 30 ASCII characters

JNDI name

Specifies the Java Naming and Directory Interface (JNDI) name for the object pool manager.

Data type	String
------------------	--------

Scope

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Description

Specifies the description of the object pool manager.

Data type	String
------------------	--------

Category

Specifies the category name used to classify or group this object pool manager.

Data type	String
------------------	--------

Object pool managers settings

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers > *objectpoolmanager_name***

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

The name by which the object pool manager is known for administrative purposes.

Data type	String
Range	1 through 30 ASCII characters

JNDI Name:

The Java Naming and Directory Interface (JNDI) name for the object pool manager.

Data type	String
------------------	--------

Description:

A description of the object pool manager.

Data type	String
------------------	--------

Category:

A category name used to classify or to group this object pool manager.

Data type	String
------------------	--------

Custom object pool collection:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers > *objectpoolmanager_name* > Custom object pools**.

Use custom object pools to insert additional logic around the following mechanisms:

- Constructing an object pool (A list of properties can be set)
- Flushing the object pool
- Getting objects from the pool
- Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool the product administrator must define an object pool manager using the administrative console. You can create multiple object pool managers in an Application Server cell.

Pool class name:

Specifies the fully qualified class name of the objects that are stored in the custom object pool.

Data type String

Pool implementation class name:

Specifies the fully qualified class name of the implementation class for the custom object pool.

Data type String

Custom object pool settings:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers > *objectpoolmanager_name* > Custom object pools > *objectpool_name***.

- Constructing an object pool (A list of properties can be set)
- Flushing the object pool
- Getting objects from the pool
- Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Pool Class Name:

The fully qualified class name of the objects that are stored in the object pool.

Data type String

Pool Impl Class Name:

The fully qualified class name of the CustomObjectPool implementation class for this object pool.

Data type String

Object pool service settings

Use this page to enable or disable the object pool service, which manages object pool resources used by the server.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > *server_name* > Container Services > Object pool service.**

Enable service at server startup

Specifies whether the server attempts to start the object pool service.

Default	Cleared
Range	Selected When the application server starts, it attempts to start the object pool service automatically.
	Cleared The server does not try to start the object pool service. If object pool resources are used on this server, then the system administrator must start the object pool service manually or select this property, and then restart the server.

Object pools: Resources for learning

This topic provides links to find relevant supplemental information about object pools.

Use the following links to find relevant supplemental information about object pools. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Furthermore, these links provide guidance on using object pools. Since object pooling is a general topic and the WebSphere Application Server product implementation is only one way to use it, you must understand when object pooling is necessary. These articles help you make that decision.

Programming model and decisions

- Build your own ObjectPool in Java to boost application speed
- Improve the robustness and performance of your ObjectPool
- Recycle broken objects in resource pools

MBeans for object pool managers and object pools

Legacy MBean names for object pool managers and object pools are deprecated. The legacy names are based on the object pool manager name (which is not required to be unique) rather than the object pool manager JNDI name.

About this task

For object pools, the legacy name is also lacking any identifier of the version of the pooled class. Additionally, object pool Performance Monitoring Instrumentation (PMI) statistics are aggregated for object pools with the same legacy object pool MBean name.

For example, if the object pool manager and pooled class are as follows:

```
object pool manager name:      My ObjectPool
object pool manager JNDI name: op/MyObjectPool
pooled class name:           java.util.ArrayList
hash code of java.util.ArrayList.class: 1111eb3f (hexadecimal)
```

the legacy object pool manager MBean name will be:

ObjectPoolManager_My ObjectPool

and the legacy object pool MBean name will be:

ObjectPool_My ObjectPool_java.util.ArrayList

Instead of using the deprecated legacy MBean names, use the MBean names that are based on the JNDI name of the object pool manager.

For the example above, the JNDI name-based object pool manager MBean name is:

ObjectPoolManager_op/MyObjectPool

and the JNDI name-based object pool MBean name is:

ObjectPool_op/MyObjectPool_java.util.ArrayList.class@1111eb3f

Formats for MBean names

Type	Name format
Deprecated legacy object pool manager MBean name:	ObjectPoolManager_[object pool manager name]
JNDI name-based object pool manager MBean name:	ObjectPoolManager_[object pool manager JNDI name]
Deprecated legacy object pool MBean name:	ObjectPool_[object pool manager name]_[pooled class name]
JNDI name-based object pool MBean name:	ObjectPool_[object pool manager JNDI name]_[pooled class name].class@[hexadecimal representation of the hash code of the pooled class' java.lang.Class reference]

In all of the above formats, characters that are not valid for MBean names are replaced with the '.' character.

Chapter 18. Administering Object Request Broker (ORB)

This page provides a starting point for finding information about the Object Request Broker (ORB). The product uses an ORB to manage communication between client applications and server applications as well as among product components. These Java Platform, Enterprise Edition (Java EE) standard services are relevant to the ORB: Remote Method Invocation/Internet Inter-ORB Protocol (RMI/IIOP) and Java Interface Definition Language (Java IDL).

The ORB provides a framework for clients to locate objects in the network and call operations on those objects as though the remote objects were located in the same running process as the client, providing location transparency.

Administering Object Request Brokers

Object Request Broker service settings

Use this page to configure the Java Object Request Broker (ORB) service.

To view this administrative console page:

- For an application server, click **Servers > Server Types > WebSphere application servers > *server_name* > Container services > ORB service.**
- For a deployment manager, click **System administration > Deployment manager > ORB service.**

Several settings are available for controlling internal Object Request Broker (ORB) processing. You can use these settings to improve application performance in the case of applications that contain enterprise beans. You can make changes to these settings for the default server or any application server that is configured in the administrative domain.

Request timeout

Specifies the number of seconds to wait before timing out on a request message.

If you use command-line scripting, the full name of this system property is `com.ibm.CORBA.RequestTimeout`.

Data type	int
Units	Seconds
Default	180
Range	0 - largest integer recognized by Java

ORB tracing

Enables the tracing of ORB General Inter-ORB Protocol (GIOP) messages.

This setting affects two system properties: `com.ibm.CORBA.Debug` and `com.ibm.CORBA.CommTrace`. If you set these properties through command-line scripting, you must set both properties to `true` to enable the tracing of GIOP messages.

Data type	Boolean
Default	Not enabled (false)

Pass by reference

Specifies how the ORB passes parameters. If enabled, the ORB passes parameters by reference instead of by value, to avoid making an object copy. If you do not enable the pass by reference option, a copy of the parameter passes rather than the parameter object itself. This can be expensive because the ORB must first make a copy of each parameter object.

You can use this option only when the Enterprise JavaBeans (EJB) client and the EJB are on the same classloader. This requirement means that the EJB client and the EJB must be deployed in the same EAR file.

If the Enterprise JavaBeans (EJB) client and server are installed in the same instance or the product, and the client and server use remote interfaces, enabling the pass by reference option can improve performance up to 50%. The pass by reference option helps performance only where non-primitive object types are passed as parameters. Therefore, int and floats are always copied, regardless of the call model.

gotcha: Enable this property with caution because unexpected behavior can occur. If an object reference is modified by the callee, the caller's object is modified as well, since they are the same object.

If you use command-line scripting, the full name of this system property is `com.ibm.CORBA.iiop.noLocalCopies`.

Data type	Boolean
Default	Not enabled (false)

The use of this option for enterprise beans with remote interfaces violates Enterprise JavaBeans (EJB) Specification, Version 2.0 (see section 5.4). Object references passed to Enterprise JavaBeans (EJB) methods or to EJB home methods are not copied and can be subject to corruption.

Consider the following example:

```
Iterator iterator = collection.iterator();
MyPrimaryKey pk = new MyPrimaryKey();
while (iterator.hasNext()) {
    pk.id = (String) iterator.next();
    MyEJB myEJB = myEJBHome.findByPrimaryKey(pk);
}
```

In this example, a reference to the same `MyPrimaryKey` object passes into the product with a different ID value each time. Running this code with pass by reference enabled causes a problem within the application server because multiple enterprise beans are referencing the same `MyPrimaryKey` object. To avoid this problem, set the `com.ibm.websphere.ejbcontainer.allowPrimaryKeyMutation` system property to `true` when the pass by reference option is enabled. Setting the pass by reference option to `true` causes the EJB container to make a local copy of the `PrimaryKey` object. As a result, however, a small portion of the performance advantage of setting the pass by reference option is lost.

As a general rule, any application code that passes an object reference as a parameter to an enterprise bean method or to an EJB home method must be scrutinized to determine if passing that object reference results in loss of data integrity or in other problems.

After examining your code, you can enable the pass by reference option by setting the `com.ibm.CORBA.iiop.noLocalCopies` system property to `true`. You can also enable the pass by reference option in the administrative console. Click **Servers > Server Types > Application servers > *server_name* > Container services > ORB Service** and select **Pass by reference**.

Object Request Broker custom properties

There are several ways to configure an Object Request Broker (ORB). For example, you can use ORB custom property settings, or system property settings to configure an ORB, or you can provide objects during ORB initialization. If you use the following ORB custom properties to configure an ORB, remember that two types of default values exist for some of these properties: the Java SE Development Kit (JDK) default values and the WebSphere Application Server default values.

The JDK default is the value that the ORB uses for a property if the property is not specified in any way. The WebSphere Application Server default is the value that the WebSphere Application Server sets for a property in one of the following files:

- The orb.properties file when an application server is installed.
- The server.xml file when an application server is configured.

Because WebSphere Application Server explicitly sets its default value, if both a WebSphere Application Server and a JDK default value are defined for a property, the WebSphere Application Server default takes precedence over the JDK default.

For more information about the different ways to specify ORB properties and the precedence order, read the JDK Diagnostic Guide for the version of the JDK that you are using.

The orb.properties file, that is located in the *was_home/properties* directory, contains ORB custom properties that are initially set to the WebSphere Application Server default values during the product installation process. These values are passed to the ORB in a properties object and take precedence over Java virtual machine (JVM) arguments and other orb.properties files in either the *java_home/lib* or *user_home* directories.

You can use the administrative console to specify new values for these ORB custom properties. Any value that you specify takes precedence over any JDK or WebSphere Application Server default values for these properties, including JVM arguments. The ORB custom properties settings that you specify in the administrative console are stored in the server.xml system file and are passed to an ORB in a properties object whenever an ORB is initialized.

To use the administrative console to set ORB custom properties, click **Servers > Server Types > Application servers > server_name > Container services > ORB service > Custom properties**. You can then change the setting of one of the listed custom properties or click **New** to add a new property to the list. Then, click **Apply** to save your change. When you finish the changes, click **OK** and then click **Save** to save your changes.

To use the java command on a command line, use the -D option; for example:

```
java -Dcom.ibm.CORBA.propname1=value1 -Dcom.ibm.CORBA.propname2=value2 ... application name
```

To use the launchclient command on a command line, prefix the property with -CC; for example:

```
launchclient yourapp.ear -CCDcom.ibm.CORBA.propname1=value1 -CCDcom.ibm.CORBA.propname2=value2  
... optional application arguments
```

The Custom properties page might already include Secure Sockets Layer (SSL) properties that were added during product installation. A list of the additional properties that are associated with the ORB service follows. Unless otherwise indicated, the default values that are provided in the descriptions of these properties are the JDK default values.

You can use the custom properties page to define the following properties for use by the ORB.

- “com.ibm.CORBA.BootstrapHost” on page 1130
- “com.ibm.CORBA.BootstrapPort” on page 1130
- “com.ibm.CORBA.ConnectTimeout” on page 1130

- “com.ibm.CORBA.ConnectionInterceptorName” on page 1131
- “com.ibm.CORBA.enableLocateRequest” on page 1131
- “com.ibm.CORBA.ListenerPort” on page 1131
- “com.ibm.CORBA.LocalHost” on page 1131
- “com.ibm.CORBA.RasManager” on page 1132
- “com.ibm.CORBA.ServerSocketQueueDepth” on page 1132
- “com.ibm.CORBA.ShortExceptionDetails” on page 1132
- “com.ibm.CORBA.WSSSLClientSocketFactoryName” on page 1132
- “com.ibm.CORBA.WSSSLServerSocketFactoryName” on page 1132
- “com.ibm.websphere.ObjectIDVersionCompatibility” on page 1132
- “com.ibm.websphere.orb.threadPoolTimeout” on page 1133
- “com.ibm.ws.orb.services.redirector.MaxOpenSocketsPerEndpoint” on page 1133
- “com.ibm.ws.orb.services.redirector.RequestTimeout” on page 1133
- “com.ibm.ws.orb.transport.SSLHandshakeTimeout” on page 1134
- “com.ibm.ws.orb.transport.useMultiHome” on page 1134
- “javax.rmi.CORBA.UtilClass” on page 1134

com.ibm.CORBA.BootstrapHost

Specifies the domain name service (DNS) host name or IP address of the machine on which initial server contact for this client resides.

deprecat: This setting is deprecated.

For a command-line or programmatic alternative, read the topic *Client-side programming tips for the Object Request Broker service*.

com.ibm.CORBA.BootstrapPort

Specifies the port that the ORB uses to bootstrap to the machine on which the initial server contact for this client listens.

deprecat: This setting is deprecated.

For a command line or programmatic alternative, read the topic *Client-side programming tips for the Object Request Broker service*.

Default

2809

com.ibm.CORBA.ConnectTimeout

The com.ibm.CORBA.ConnectTimeout property specifies the maximum time, in seconds, that the client ORB waits before timing out when attempting to establish an IOP connection with a remote server ORB. Typically, client applications use this property. You can specify the property for each individual application server through the administrative console.

Client applications can specify the com.ibm.CORBA.ConnectTimeout property in one of two ways:

- By including it in the orb.properties file
- By using the -CCD option to set the property with the launchclient script. The following example specifies a maximum timeout value of 10 seconds:

```
launchclient clientapp.ear -CCDcom.ibm.com.CORBA.ConnectTimeout=10...
```

Begin with the default timeout value, but consider factors such as network congestion and application server load and capacity. Lower values provide better failover performance in the case of extended problems with the remote server, such as downtime. Higher values are better for slow network or remote

server performance. However, exceptions can occur if the remote server does not have enough time to complete the subsequent request. A value of 0 means that the ORB relies on the timeout set by the operating system TCP/IP layer. For most operating systems, the timeout is set to 75 seconds.

Note: The default for the `com.ibm.CORBA.ConnectTimeout` property for Version 8 is 10. Before Version 8, the default is 0.

Valid Range	0-300
Default	10

com.ibm.CORBA.ConnectionInterceptorName

Specifies the connection interceptor class that is used to determine the type of outbound IOP connection to use for a request, and if secure, the quality of protection characteristics associated with the request.

WebSphere Application Server default	<code>com.ibm.ISecurityLocalObjectBaseL13InSecSecurityConnectionInterceptor</code>
JDK default	None

com.ibm.CORBA.enableLocateRequest

Specifies whether the ORB uses the locate request mechanism to find objects in a WebSphere Application Server cell. Use this property for performance tuning.

When this property is set to `true`, the ORB first sends a short message to the server to find the object that it needs to access. This first contact is called the *locate request*. If most of your initial method invocations are small, setting this property to `false` might improve performance because this setting change can reduce the GIOP traffic by as much as one-half. If most of your initial method invocations are large, you should set this property to `true`. When the property is set to `true`, the small locate request message is sent instead of the large locate request message. The large message is then sent to the target after the desired object is found.

WebSphere Application Server default	<code>true</code>
JDK default	<code>false</code>

com.ibm.CORBA.ListenerPort

Specifies the port on which this server listens for incoming requests. This setting only applies for client-side ORBs.

Default	Next available system-assigned port number
Range	0 - 2147483647

com.ibm.CORBA.LocalHost

Specifies the host name or IP address of the system on which the application server or client application ORB is running.

For application servers, this property is automatically set to the host name of the `ORB_LISTENER_ADDRESS` endpoint. Any value specified by the user will be overwritten by the `ORB_LISTENER_ADDRESS` host name.

- If the `ORB_LISTENER_ADDRESS` host name is `""`, then the property is set to the local host name by using the `InetAddress.getLocalHost().getCanonicalHostName()` method.
- For client applications, if no value is specified for this property, the ORB obtains a value at run time by calling the `InetAddress.getLocalHost().getHostAddress()` method.

Note: Do not set this property to the "localhost" string or "127.0.0.1" value as these values can result in unpredictable behavior for both clients and servers. Those values might impact callback behavior, the use of server IORs, and the creation of ORB connections.

com.ibm.CORBA.RasManager

Specifies an alternative to the default RAS manager of the ORB. This property must be set to `com.ibm.websphere.ras.WsOrbRasManager` before the ORB can be integrated with the rest of the RAS processing for the product.

WebSphere Application Server default	<code>com.ibm.websphere.ras.WsOrbRasManager</code>
JDK default	None

com.ibm.CORBA.ServerSocketQueueDepth

Specifies the maximum number of connection requests that can be waiting to be handled by the Server ORB before the product starts to reject new incoming connection requests. This property corresponds to the `backlog` argument to a `ServerSocket` constructor and is handled directly by TCP/IP.

If you see a "connection refused" message in a trace log, typically, either the port on the target machine is not open, or the server is overloaded with queued-up connection requests. Increasing the value specified for this property can help alleviate this problem if there does not appear to be any other problem in the system.

Default	50
Range	From 50 to the largest value of the Java int type

com.ibm.CORBA.ShortExceptionDetails

Specifies that the exception detail message that is returned whenever the server ORB encounters a CORBA system exception contains a short description of the exception as returned by the `toString` method of `java.lang.Throwable` class. Otherwise, the message contains the complete stack trace as returned by the `printStackTrace` method of `java.lang.Throwable` class.

com.ibm.CORBA.WSSSLClientSocketFactoryName

Specifies the class that the ORB uses to create SSL sockets for secure outbound IOP connections.

WebSphere Application Server default	<code>com.ibm.ws.security.orbssl.WSSSLClientSocketFactoryImpl</code>
JDK default	None

com.ibm.CORBA.WSSSLServerSocketFactoryName

Specifies the class that the ORB uses to create SSL sockets for inbound IOP connections.

WebSphere Application Server default	<code>com.ibm.ws.security.orbssl.WSSSLServerSocketFactoryImpl</code>
JDK default	None

com.ibm.websphere.ObjectIDVersionCompatibility

This property applies when you have a mixed release cluster for which you are performing an incremental cell upgrade, and at least one of the releases is earlier than Version 6.x.

In an environment that includes mixed release cells, the migration program automatically sets this property to 1.

After you upgrade all of the cluster members to the same release, you can remove this property from the list of ORB custom properties, or you can change the value that is specified for the property to 2. Either action improves performance.

When this property is set to 1, the ORB runs using version 1 object identities, which are required for mixed cells that contain application servers with releases before V6.x. If you do not specify a value for this property or if you set this property to 2, the ORB runs using version 2 object identities, which cannot be used with pre-V6.x application servers.

The *Migrating, coexisting, and interoperating* PDF includes instructions on how to perform an incremental cell upgrade.

com.ibm.websphere.orb.threadPoolTimeout

Use this custom property to specify the length of time in which the object request broker (ORB) waits for an available thread from the ORB thread pool before rejecting a request.

When the ORB receives an incoming request, the request is read by an ORB reader thread. The ORB reader thread attempts to hand off the request for processing by a worker thread in the ORB thread pool. When all the worker threads are handling other requests, the reader thread waits until a worker thread becomes available. While the reader thread is waiting, new requests are not processed by that particular reader thread. This situation can lead to deadlocks between the ORB thread pools on two different Java virtual machine (JVM) processes. The deadlocks are prominent when the ORB in one JVM process must call back to the ORB in the other JVM process to complete its request. Therefore, it is highly advisable to set this property to a positive non-zero value, which configures a finite wait period and can limit deadlock situations. However, configure the value for this custom property based on its effect on the average request processing time, the ORB request timeout value, and whether servers are making additional circular or backend calls.

Data type	Integer
Units	Milliseconds
Default	0
Range	0 - largest integer that is recognized by the Java run time

com.ibm.ws.orb.services.redirector.MaxOpenSocketsPerEndpoint

Specifies the maximum number of connections that the IIOP Tunnel Servlet maintains in its connection cache for each target host and port. If the number of concurrent client requests to a single host and port exceeds the setting for this property, the IIOP Tunnel Servlet opens a temporary connection to the target server for each extra client request, and then closes the connection after it receives the reply. Connections that are opened, but not used within 5 minutes, are removed from the cache for the IIOP Tunnel Servlet.

WebSphere Application Server default	3
JDK default	Not applicable
Range	0 - largest integer recognized by Java

com.ibm.ws.orb.services.redirector.RequestTimeout

Specifies the number of seconds that the IIOP Tunnel Servlet waits for a reply from the target server on behalf of a client before timing out. If a value is not specified for this property, or is incorrectly specified, the `com.ibm.CORBA.RequestTimeout` property setting for the application server, on which the IIOP Tunnel Servlet is installed, is used as the setting for the `com.ibm.ws.orb.services.redirector.RequestTimeout` property.

The value you specify for this property must be at least as high as the highest client setting for the `com.ibm.CORBA.RequestTimeout` property; otherwise the IIOP Tunnel Servlet might timeout more quickly than the client typically times out while waiting for a reply. If this property is set to zero, the IIOP Tunnel Servlet does not timeout.

WebSphere Application Server default

com.ibm.CORBA.RequestTimeout property setting for the application server on which the IOP Tunnel Servlet is installed.

The request_timeout request-level Reliability Availability and Serviceability (RAS) attribute overrides the com.ibm.CORBA.RequestTimeout property for IOP requests. You define the request-level RAS attributes in the workload classification file.

JDK default

Not applicable

Range

0 - largest integer recognized by Java

com.ibm.ws.orb.transport.SSLHandshakeTimeout

This custom property specifies a timeout value for reading Secure Sockets Layer (SSL) handshake-related messages.

When you set the com.ibm.ws.orb.transport.SSLHandshakeTimeout custom property to a positive integer value, the listener thread does not hang if a message is received after the specified timeout period. If you do not set this custom property or do not set it to a positive integer value, the timeout value defaults to zero (0), a timeout period is not added, and the listener thread can hang.

Data type

Integer

Default

Zero (0)

Units

Milliseconds

com.ibm.ws.orb.transport.useMultiHome

Specifies whether the server ORB binds to all network interfaces in the system. If you specify true, the ORB binds to all network interfaces that are available to it. If you specify false, the ORB only binds to the network interface that is specified for the com.ibm.CORBA.LocalHost system property.

WebSphere Application Server default

true

JDK default

true

javax.rmi.CORBA.UtilClass

Specifies the name of the Java class that the product uses to implement the javax.rmi.CORBA.UtilDelegate interface.

This property supports delegation for method implementations in the javax.rmi.CORBA.Util class. The javax.rmi.CORBA.Util class provides utility methods that can be used by stubs and ties to perform common operations. The delegate is a singleton instance of a class that implements this interface and provides a replacement implementation for all of the methods of javax.rmi.CORBA.Util. To enable a delegate, provide the class name of the delegate as the value of the javax.rmi.CORBA.UtilClass system property. The default value provides support for the com.ibm.CORBA.iop.noLocalCopies property.

WebSphere Application Server default

com.ibm.ws.orb.WSUtilDelegateImpl

JDK default

None

Character code set conversion support for the Java Object Request Broker service

The CORBA/IOP specification defines a framework for negotiation and conversion of character code sets used by the Java Object Request Broker (ORB) service.

This product supports the framework and provides the following system properties for modifying the default settings:

com.ibm.CORBA.ORBCharEncoding

Specifies the name of the native code set that the ORB uses for character data (referred to as *NCS-C* in the CORBA/IIOP specification). By default, the ORB uses UTF8. Valid code set values for this property are shown in the table that follows this list; values that are valid only for ORBWCharDefault are indicated.

com.ibm.CORBA.ORBWCharDefault

Specifies the default code set that the ORB uses for transmission of wide character data when no code set for wide character data is found in the tagged component in the Interoperable Object Reference (IOR) or in the GIOP service context. If no code set for wide character data is found and this property is not set, the ORB raises an exception, as specified in the CORBA specification. No default value is set for this property. The only valid code set values for this property are UCS2 or UTF16.

Note: If you are using a distributed application server with a z/OS application server, you must set this property on the distributed client to UCS2 or you might experience an exception.

The CORBA code set negotiation and conversion framework specifies the use of code set registry IDs as defined in the Open Software Foundation (OSF) code set registry. The ORB translates the Java file.encoding names shown in the following table to the corresponding OSF registry IDs. These IDs are then used by the ORB in the IOR Code set tagged component and GIOP code set service context as specified in the CORBA and IIOP specification.

Table 65. OSF code set registry IDs for Java file.encoding names. The following table lists the OSF code set registry IDs for the Java file.encoding names.

Java name	OSF registry ID	Comments
ASCII	0x00010020	
ISO8859_1	0x00010001	
ISO8859_2	0x00010002

ORB services advanced settings on the z/OS platform

Use this topic to support Object Request Broker (ORB) service advanced settings. This support includes ORB listener keep alive, ORB Secure Sockets Layer (SSL) listener keep alive, control threads, and workload profile.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > server_name > Container services > ORB service > z/OS additional settings**.

ORB listener keep alive

Defines the value in seconds provided to TCP/IP on the SOCK_TCP_KEEPALIVE option for the Internet Inter-ORB Protocol (IIOP) listener.

This option verifies that idle sessions are still valid by polling the client TCP/IP stack. If the client goes away without notifying the server, the session is still active on the server side. Use this property to clean up these unnecessary sessions. If the client does not respond, the session closes. The default is 0 (zero). If the property is not set, the TCP/IP option is not set. Setting the SOCK_TCP_KEEPALIVE option generates network traffic on idle sessions, which can cause problems.

Data type	Integer
Range	0 - 2147040

ORB SSL listener keep alive

This property defines the value in seconds provided to TCP/IP on the SOCK_TCP_KEEPALIVE option for the SSL IIOp listener.

This option verifies if idle sessions are still valid by polling the client TCP/IP stack. If the client goes away without notifying the server, the session is still active on the server side. Use this option to clean up these unnecessary sessions. If the client does not respond, the session closes. The default is 0 (zero). If the property is not set, the TCP/IP option is not set. Setting the SOCK_TCP_KEEPALIVE option generates network traffic on idle sessions, which can be undesirable.

Data type	Integer
Range	0 - 2147040

Workload manager timeout

Specifies the maximum time in seconds that IIOp requests are queued and dispatched to a servant process.

Data type	Integer
Range	0 - 2147040
Default	300
Disable workload manager queue timeout	0

Workload profile

Specifies the server workload profile, which can be ISOLATE, IOBOUND, CPUBOUND, LONGWAIT, or CUSTOM.

The workload profile controls workload-pertinent decisions that are made by the WebSphere Application Server for z/OS run time, such as the number of threads used in the servant. The default value is IOBOUND, which is the appropriate value for most applications. Use one of the other values when your application requires more threads.

Workload profile	Number of Threads	Description
ISOLATE	1	Specifies that the servants are restricted to a single application thread. Use ISOLATE to ensure that concurrently dispatched applications do not run in the same servant. Two requests processed in the same servant can cause one request to corrupt another.
IOBOUND	MIN(30, MAX(5,(Number of CPUs*3)))	Specifies more threads in applications that perform I/O-intensive processing on the z/OS operating system. The calculation of the thread number is based on the number of CPUs. IOBOUND is used by most applications that have a balance of CPU intensive and remote operation calls. A gateway or protocol converter are two examples of applications that use the IOBOUND profile.

CPUBOUND	MAX((Number of CPUs-1),3)	Specifies that the application performs processor-intensive operations on the z/OS operating system, and therefore would not benefit from more threads than the number of CPUs. The calculation of the thread number is based on the number of CPUs. Use the CPUBOUND profile setting in CPU intensive applications, like XML parsing and XML document construction, where the vast majority of the application response time is spent using the CPU.
LONGWAIT	40	Specifies more threads than IOBOUND for application processing. LONGWAIT spends most of its time waiting for network or remote operations to complete. Use this setting when the application makes frequent calls to another application system, like Customer Information Control System (CICS) screen scraper applications, but does not do much of its own processing.
CUSTOM	User defined	Specifies that the number of servant application threads is determined by the value that is specified for the servant_region_custom_thread_count server custom property. The minimum number of application threads that can be defined for this custom property is 1; the maximum number of application threads that can be specified is 500. bprac: Before you specify a value greater than 100 in a production environment, you should try the value in a test environment to ensure you do not negatively affect performance.

Note: **Number of CPUs** is the number of CPUs online when the controller comes up.

You can look at message BBOO0234I in the controller job log to check the number of worker threads.

Chapter 19. Administering OSGi applications

This page provides a starting point for finding out how to administer OSGi applications.

Note: The OSGi Applications support in WebSphere Application Server helps you to develop and deploy modular applications that use both Java EE and OSGi technologies. This enables the same, or different, applications to use different versions of the same third party libraries without interference. You can configure a business-level application to contain an OSGi application, you can maintain the bundle versions used by an OSGi application, and you can administer bundles and bundle repositories.

Chapter 20. Administering Portlet applications

This page provides a starting point for finding information about portlet applications, which are special reusable Java servlets that appear as defined regions on portal pages. Portlets provide access to many different applications, services, and web content.

Portlet container settings and custom properties

Portlet container settings

Use this page to configure and manage the portlet container of this application server.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers > *server_name* > Portlet Container Settings > Portlet container**.

Enable portlet fragment cache

Specifies whether to create a cached entry when a portlet is invoked, similar to servlet caching of the web container settings.

Portlet fragment caching requires that servlet caching is enabled. Therefore, enabling portlet fragment caching automatically enables servlet caching. Disabling servlet caching automatically disables portlet fragment caching.

Portlet container custom properties

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console. The following is a list of the available Portlet container custom properties.

To specify Portlet container custom properties:

1. In the administrative console click **Servers > Server Types > WebSphere application servers > *server_name* > Portlet Container Settings > Portlet container**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the name of the custom property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

You can use the custom properties page to define the following portlet container custom properties:

- “useShortMBeanNames”

useShortMBeanNames

Portlet MBeans are registered by both their short name and full name. To enable the use of short MBean names for Portlet and PortletApplication MBeans, create the following name-value pair:

Name	Value
useShortMBeanNames	true

The default is false.

MBeans registered by the full identifiable name, have the following format:

```
<ApplicationName>#<WARfilename.war>_portlet.<portlet_name> for the Portlet MBean  
<ApplicationName>#<WARfilename.war>_portlet for the PortletApplication MBean
```

where <.> is replaced by the corresponding application data. For example,
SampleApplication#SamplePortlet.war_portlet.SamplePortlet.

Portlet and PortletApplication MBeans

The MBeans of type portlet and portletapplication provide information about a given portlet application and its portlets. Through the MBean of type portletapplication, you can retrieve a list of names of all portlets that belong to a portlet application. By querying the MBean of type portlet with a given portlet name, you can retrieve portlet specific information from the MBean of type portlet.

Each MBean that corresponds to a portlet or portlet application is uniquely identifiable by its name. Portlet applications are not required to have a name set within the portlet.xml. The MBean name for MBeans of the portletapplication type is the enterprise archive (EAR) file name followed by "#" and the web module name concatenated with the string "_portlet". For example, portletapplication type MBeans have the following format:

```
<EarFileName>#<WarFileName>_portlet
```

The name chosen for the MBean of type portlet is the name of the MBean of type portletapplication that the portlet belongs to, concatenated with the portlet name:

```
<EarFileName>#<WarFileName>_portlet.<portletname>
```

The following is an example of the resulting PortletApplication MBean name and portlet names:

```
EarName           SampleEar  
WebModule         SampleWar.war
```

```
PortletApplication MBean name: SampleEar#SampleWar_portlet  
Portlet:           SampleEar#SampleWar_portlet.BookmarkPortlet
```

The MBean names have been changed compared to version 6.1, because the old naming patterns are not unique and can lead to problems under certain circumstances. If you rely on the old naming pattern, you can set the portlet container custom property, useShortMBeanNames, to true to activate the previous known MBean names. Because this is a performance impact, you might not want to activate the old naming pattern if it is not necessary.

A full stop separates the preceding web module name from the portlet name. Review the Portlet and PortletApplication MBean type API documentation for additional information. The generated API documentation is available in the information center table of contents from the path, **Reference > Administrator > API documentation > MBean interfaces**.

The following code is an example of how to invoke the MBean of type portletapplication for an application with the name, SampleWar.

```
String myPortletApplicationName = "SampleEar#SampleWar_portlet";  
This name is composed by the Ear file name followed by "#" and  
the web module name concatenated with the substring "_portlet"
```

```
com.ibm.websphere.management.AdminService adminService =  
    com.ibm.websphere.management.AdminServiceFactory.getAdminService();  
javax.management.ObjectName on =  
    new ObjectName("WebSphere:type=PortletApplication,name=" + myPortletApplicationName + ",*");
```

```
Iterator onIter = adminService.queryNames(on, null).iterator();
```

```

while(onIter.hasNext())
{
    on = (ObjectName)onIter.next();
}

String ctxRoot = (java.lang.String)adminService.getAttribute(on, "webApplicationContextRoot");

```

In the previous example, the MBeanServer is first queried for an MBean of type portletapplication. If this query is successful, the webApplicationContextRoot attribute is retrieved on that MBean or the first MBean that is found. The result is stored in the ctxRoot variable. This variable now contains the context root of the web application that contains the portlet application that was searched. The variable is similar to "/bookmark".

The next code example demonstrates how to invoke the MBean of type portlet for a portlet with the name, BookmarkPortlet.

```
String myPortletName = "SampleEar#SampleWar_portlet.BookmarkPortlet";
```

This name is composed by the name of the MBean of type portletapplication and the portlet name, separated by a full stop because the same portlet name may be used within different web modules, but must be unique within the system.

```

com.ibm.websphere.management.AdminService adminService =
    com.ibm.websphere.management.AdminServiceFactory.getAdminService();
javax.management.ObjectName on =
    new ObjectName("WebSphere:type=Portlet,name=" + myPortletName + ",*");
Iterator iter = adminService.queryNames(on, null).iterator();

while(iter.hasNext())
{
    on = (ObjectName)iter.next();
}

java.util.Locale locale = (java.util.Locale) adminService.getAttribute(on, "defaultLocale");

```

The locale returned by the method getAttribute method for the MBean is the default locale defined for this portlet.

Full names for Portlet and PortletApplication MBeans

MBeans are also registered by the full identifiable name:

```

<ApplicationName>#<WARfilename.war>_portlet.<portlet_name> for the Portlet MBean
<ApplicationName>#<WARfilename.war>_portlet for the PortletApplication MBean

```

where <.> is replaced by the corresponding application data. For example, SampleApplication#SamplePortlet.war_portlet.SamplePortlet. You can enable the short MBean names by setting the useShortMBeanNames portlet container custom property to true.

Chapter 21. Administering Scheduler service

This page provides a starting point for finding information about the scheduler service, a WebSphere programming extension responsible for starting actions at specific times or intervals.

Schedulers are persistent and transactional timer services that run Enterprise JavaBeans methods or send Java Message Service messages using any Java Message Service messages using any Java Platform, Enterprise Edition (Java EE) server application.

The scheduler service helps minimize IT costs and increase application speed and responsiveness by maximizing utilization of existing computing resources.

The scheduler service provides the ability to reliably process workloads using parallel processing and schedule resource-intensive tasks to process during low traffic off-hours.

Installing default scheduler calendars

Scheduler calendars

The scheduler provides stateless session bean interfaces which allow creating common calendars which can be used by the scheduler and any Java Platform, Enterprise Edition (Java EE) application.

The SchedulerCalendars.ear application is available and provides a default UserCalendar Enterprise Java Beans (EJB) implementation which allows using the SIMPLE and CRON calendars. Although this application is not required when using the scheduler, it is available to use from any Java EE application.

For details on how the SIMPLE and CRON calendars behave, see the API documentation for the com.ibm.websphere.scheduler.UserCalendar interface.

Specifying a UserCalendar with the scheduler

A UserCalendar is specified using the setUserCalendar() method of the TaskInfo interface of the scheduler. This interface allows you to select the Java Naming and Directory Interface (JNDI) name of the home interface of a UserCalendar bean. Because some UserCalendar bean implementations might handle multiple types of calendars, the interface also allows you to optionally select which type of calendar to use. A list of valid calendar types can be retrieved by invoking the getCalendarNames() method of the UserCalendar interface.

If the setUserCalendar() method is not invoked, or if a value of null or empty-string is specified for the home JNDI name parameter, then the default UserCalendar is used internally by the scheduler. When the default UserCalendar is accessed internally, it is not necessary that the SchedulerCalendars.ear system application be installed. If you want to use the default UserCalendar with a CRON entry, you must switch to the CRON entry manually. The following code sample shows this switch:

```
BeanTaskInfo taskInfo = (BeanTaskInfo)scheduler.createTaskInfo(BeanTaskInfo.class);
String calendarVariant = "CRON";
taskInfo.setUserCalendar(null, calendarVariant);
// cron table entry
String cronTableEntry = "0 17,20,23 * ? * *";
taskInfo.setStartTimeInterval(cronTableEntry);
```

You might want to use the default UserCalendar directly in your other Java EE applications, apart from the scheduler. In this case, you may use the UserCalendarHome.DEFAULT_CALENDAR_JNDI_NAME value to look up the default UserCalendar from your applications. You may also supply this value to the setUserCalendar() method of the TaskInfo interface. You will need to ensure the SchedulerCalendars.ear system application was either automatically installed or that you have installed it manually.

Installing default scheduler calendars

The default scheduler SIMPLE and CRON calendars are available in the SchedulerCalendars.ear system application and are automatically installed on standalone server profiles. System applications cannot be installed and uninstalled like traditional Java Platform, Enterprise Edition (Java EE) applications.

About this task

The following steps are required to map the SchedulerCalendars.ear system application on a server or cluster in a network deployment environment.

Procedure

1. Start the wsadmin tool and connect to the deployment manager.
2. Install the system application.

- To install on a non-clustered server:

- Using Jacl:

```
$AdminApp install
"/${WAS_INSTALL_ROOT}/systemApps/SchedulerCalendars.
ear" {-systemApp -appname SchedulerCalendars -cell
mycell -node mynode -server myserver}
```

- Using Jython list:

```
AdminApp.install('${WAS_INSTALL_ROOT}/systemApps/
SchedulerCalendars.ear', ['-systemApp', '-appname',
'SchedulerCalendars', '-cell', 'mycell', '-node',
'mynode', '-server', 'myserver'])
```

- Using Jython string:

```
AdminApp.install('${WAS_INSTALL_ROOT}/systemApps/
SchedulerCalendars.ear', '[-systemApp -appname
SchedulerCalendars -cell mycell -node mynode
-server myserver]')
```

Where:

Table 66. Variable options.. Variable values and options

Value	Option
mycell	the value of the cell option
mynode	the value of the node option
myserver	the value of the server option

- To install on a cluster:

- Using Jacl:

```
$AdminApp install
"\${WAS_INSTALL_ROOT}/systemApps/SchedulerCalendars.
ear" {-systemApp -appname SchedulerCalendars -cell
mycell -cluster mycluster}
```

- Using Jython list:

```
AdminApp.install('${WAS_INSTALL_ROOT}/systemApps/
SchedulerCalendars.ear', ['-systemApp', '-appname',
'SchedulerCalendars', '-cell', 'mycell', '-cluster',
'mycluster'])
```

- Using Jython string:

```
AdminApp.install('${WAS_INSTALL_ROOT}/systemApps/
SchedulerCalendars.ear', '[-systemApp -appname
SchedulerCalendars -cell mycell -cluster mycluster]')
```

Where:

Table 67. Variable options.. Variable values and options

Value	Option
mycell	the value of the cell option
mycluster	the value of the cluster option

3. Save the configuration changes. Refer to the Saving configuration changes with the wsadmin tool topic for more information.
4. Synchronize the node. Refer to the Synchronizing nodes with the wsadmin tool topic for more information.

Uninstalling default scheduler calendars

The default scheduler SIMPLE and CRON calendars are available in the SchedulerCalendars.ear system application and are automatically installed on standalone server profiles. System applications cannot be installed and uninstalled like traditional Java Platform, Enterprise Edition (Java EE) applications.

About this task

Remove the SchedulerCalendars system application on federated node, as follows:

Procedure

1. Open a command window on the federated node.
2. Run the following command:

On Unix platforms:

```
$Install_Root/bin/wsadmin.sh -conntype none -profile $Profile_Name
```

On Windows platforms:

```
$Install_Root/bin/wsadmin -conntype none -profile $Profile_Name
```

where:

- *Install_Root* is the directory where WebSphere Application Server is installed.
- *Profile_Name* is the name of the profile where the target server is located.

3. At the **wsadmin>** prompt, enter the following command for each server that exists on the node where you want to have the SchedulerCalendars application available:

```
wsadmin> $AdminApp uninstall SchedulerCalendars "-cell $MyCell -node $MyNode -server $MyServer"
```

where:

- *Install_Root* is the directory where WebSphere Application Server is installed.
- *MyCell*, *MyNode*, and *MyServer* are the values with the name of the cell, node, and server.

Important: Each of these values are case-sensitive.

4. Repeat step three for each server in the current profile for which you will uninstall the SchedulerCalendars application.
5. When uninstallation is complete for the system application on all appropriate servers, enter the following commands:

```
wsadmin> $AdminConfig save
wsadmin> exit
```
6. Repeat steps 1-5 for each federated node or profile where the SchedulerCalendars application is to be removed.
7. Using the Administrative Console or scripting, start or restart the servers to unload the SchedulerCalendars application.

Results

The SchedulerCalendars application should now be removed.

Example: Using default scheduler calendars

The SIMPLE and CRON calendars can be used from any J2EE application. This topic describes that process.

Using default scheduler calendars involves looking-up the default UserCalendarHome Enterprise JavaBeans (EJB) home object, creating the UserCalendar bean and calling the applyDelta() method. For details on the applyDelta method as well as the syntax for the SIMPLE and CRON calendars, see the UserCalendar interface topic.

Example:

```
import java.util.Date;
import javax.naming.InitialContext;
import javax.rmi.PortableRemoteObject;
import com.ibm.websphere.scheduler.UserCalendar;
import com.ibm.websphere.scheduler.UserCalendarHome;

// Create an initial context
InitialContext ctx = new InitialContext();

// Lookup and narrow the default UserCalendar home.
UserCalendarHome defaultCalHome=(UserCalendarHome)
    PortableRemoteObject.narrow(ctx.lookup(
        UserCalendarHome.DEFAULT_CALENDAR_JNDI_NAME),
        UserCalendarHome.class);

// Create the default UserCalendar instance.
UserCalendar defaultCal = defaultCalHome.create();

// Calculate a date using CRON based on the current
// date and time. Return the next date that is
// Saturday at 2AM
Date newDate =
    defaultCal.applyDelta(new Date(),
        "CRON", "0 0 2 ? * SAT");
```

Managing schedulers

Managing schedulers

Schedulers are configured using the administrative console, configuration service or scripting and are available to all servers on which a scheduler is visible.

About this task

You can create multiple schedulers within a single server, cluster, node or cell. Each configured scheduler is an independent task scheduling engine that has a unique Java Naming and Directory Interface (JNDI) name, persistent storage device and daemon.

Procedure

1. Configure schedulers.
2. Create the database for schedulers.

Scheduler daemon

A scheduler daemon is a background thread that searches for tasks to run in the database.

A scheduler daemon is started for each scheduler defined on each server. If Scheduler 1 is configured on server1, then only one scheduler daemon runs on server1 unless it is cloned. If Scheduler 1 is defined at the node scope level, then the scheduler will run on each server within that node.

The poll interval determines the frequency at which the persistent store is queried. By default, this value is set to 30 seconds. When a task is found that is scheduled to run within the current poll interval, an asynchronous beans alarm is set. The task then runs as close to this time as possible using an alarm thread from the scheduler's associated work manager. Thus, the number of alarm threads configured on the work manager determines how many concurrent tasks are executed. No tasks are lost. If we reach this limit, then new tasks are simply queued to be executed when an alarm thread becomes available. The actual firing time is dictated by server load and availability of free threads in the alarm thread pool of the associated work manager.

Scheduler daemons in a cluster

When multiple schedulers are configured to use the same tables (as is the case in a clustered environment), any of the daemons can find a task and set the alarm in its Java virtual machine (JVM). The task is executed in the virtual machine where the scheduler daemon first runs, until the daemon is stopped and another daemon starts. If an application on server1 schedules a task to run and server2 was started before server1, then the task runs on server2.

Example: Stopping and starting scheduler daemons using Java Management Extensions API

Use the wsadmin scripting tool to invoke a JACL script and stop and start a scheduler daemon.

This example JACL script can be invoked using the wsadmin scripting tool. It will attempt to stop and start a scheduler daemon.

```
# Example JACL Script to restart a Scheduler Daemon

set schedJNDIName sched/MyScheduler

# Find the WASScheduler MBean
regsub -all {/} $schedJNDIName "." schedJNDIName
set mbeanName Scheduler_$schedJNDIName
puts "Looking up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]

# Invoke the stopDaemon operation.
puts "Stopping the daemon..."
$AdminControl invoke $sched stopDaemon
puts "The daemon has stopped."

# Invoke the startDaemon operation.
puts "Starting the daemon..."
$AdminControl invoke $sched startDaemon 0
puts "The daemon has started."
```

Example: Dynamically changing scheduler daemon poll intervals using Java Management Extensions API

Use the wsadmin scripting tool to invoke a JACL script and dynamically change scheduler daemon poll intervals.

To dynamically change scheduler daemon poll intervals, use the wsadmin scripting tool to invoke this example JACL script. Invoking this example sets the poll interval of the scheduler daemon to 60 seconds.

```
# Example JACL Script to set the Scheduler daemon's poll interval

set schedJNDIName sched/MyScheduler
```

```

# Find the WASScheduler MBean
regsub -all {/} $schedJNDIName "." schedJNDIName
set mbeanName Scheduler_$schedJNDIName
puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]

# Set the poll interval to 60 seconds (60000 ms)
$AdminControl setAttribute $sched pollInterval 60000
puts "Poll interval set."

```

Configuring schedulers

Before your application can make use of the scheduler service, you must configure a scheduler using the administrative console, configuration service or scripting. Conceptually, a scheduler is similar to a data source in that you must specify various configuration attributes, including a JNDI name where the instance is bound. Once defined, an application using the Scheduler API or WASScheduler MBean can look up the scheduler object and call various methods to manage tasks.

About this task

The scheduler service is always enabled. In previous versions of the product, the scheduler service could be disabled using the administrative console or configuration service. Scheduler service configuration objects are present in the configuration service, but the enabled attribute is ignored.

To achieve high availability, you can configure a duplicate scheduler on each server in a cluster, or create a scheduler at the cluster scope. For example, each server that contains a scheduler with the JNDI name `sched/MyScheduler`, with the same database configuration parameters (data source and table prefix) behaves as a single clustered scheduler. Each server in the scheduler cluster has a running scheduler instance, which increases the number of poll daemons and allows automatic failover. For more information on creating clusters for high availability, see the article, "WebSphere Enterprise Scheduler planning and administration guide."

Typically, create schedulers at the server or cluster scope. Scheduler poll daemons run in each server within the configured scope, which means that if you create a scheduler at the node or cell scope, the scheduler poll daemon can attempt to run tasks on any of the servers in the node or cell. If applications are not mapped uniformly over each server in that scope, the scheduler might not run tasks correctly. Because applications are mapped to servers and clusters, there is less chance for error and less competition between daemons to run tasks.

Depending on your preferred method of configuration, select one of the following steps to configure schedulers.

Procedure

1. Configuring schedulers using the administrative console.
2. Configuring schedulers using Java Management Extensions API (JMX).

Results

A scheduler is configured and ready to use.

Configuring scheduler default transaction isolation

The scheduler uses read-committed transaction isolation, by default, when reading tasks using the `get` or `find` APIs on the `com.ibm.websphere.scheduler.Scheduler` interface and WASScheduler MBean. The default behavior for a scheduler can be changed to read-uncommitted, which allows the `get` and `find` methods to return the current or next state of the task in the database. This topic describes how to change the default behavior for the `get` and `find` methods.

About this task

See the scheduler API documentation to view the `com.ibm.websphere.scheduler.TaskInfo.setTaskExecutionOptions()` method, which details how to return the next state of the task or the current state of the task.

Attention: If the scheduler database does not support uncommitted reads, such as Oracle, this parameter has no effect.

To change the default behavior for the get and find methods, complete the following steps:

Procedure

1. From the administrative console, click **Resources** > **Schedulers** > *scheduler_name*.
2. Click **Custom Properties**.
3. Click **New**.
4. Add the following properties:

Name	defaultReadTransactionIso
Type	java.lang.Integer
Value	1 (for read-uncommitted transaction isolation) 2 (for read-committed transaction isolation)

5. Click **Apply** or
6. Click **OK**.
7. Save the changes and verify that you initiate a file synchronization before restarting the servers.
8. Restart the application server for the changes to take effect.

Configuring schedulers using the administrative console

Schedulers can be created or configured using the administrative console.

Procedure

1. Start the administrative console.
2. Select **Resources** > **Schedulers**.
3. Click **New**.
4. Specify configuration settings.

Fields marked with an asterisk (*) are required. The settings are described in detail in the topic "Scheduler settings".

bprac: If you do not require interoperability with PME Version 5.0 tasks, under Additional Properties, click **Custom Properties** > **New**. Then specify `disableV50TaskInteroperability` in the **Name** field, `true` in the **Value** field, and select `java.lang.boolean` from the list of available Type options. When this property is set to `true`, tablespace scans that are only required for PME Version 5.0 tasks no longer occur.

5. Click **OK** or **Apply** to save the changes.
6. Save the changes to the configuration repository.

Results

A scheduler is now configured and ready to use for newly installed applications. If the scheduler JNDI name is not yet visible to your application, restarting the application or restarting application server will allow the scheduler to be seen.

When schedulers are created for the first time, the poll daemon will not automatically start and must be started manually and will only start automatically the next time the server is started. To start the poll daemon manually, refer to the scheduler daemons topic.

Attention: Changes to existing scheduler configurations will not take effect until after the application server is restarted.

Schedulers collection:

Use this page to manage scheduler configurations. Schedulers are persistent and transactional timer services that can run business logic. Each scheduler runs tasks independently and has a programming interface accessible from Java Platform, Enterprise Edition (Java EE) applications using the Java Naming and Directory Interface (JNDI). You can also manage schedulers using a Java Management Extensions (JMX) MBean. See the scheduler documentation in the Information Center for details on how to configure and use schedulers.

To view this administrative console page, click **Resources > Schedulers**.

Name:

Specifies the name of the data source where persistent tasks are stored.

Data type String

JNDI name:

Specifies the JNDI name of the work manager, which is used to manage the number of tasks that can run concurrently with the scheduler. The work manager also can limit the amount of Java EE context applied to the task.

The JNDI name specifies where this scheduler instance is bound in the name space. Clients can look this name up directly, although the use of resource references is recommended.

Data type String

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Data source JNDI name:

Specifies the alias for the user name and password that are used to access the data source.

Any data source available in the name space can be used with a scheduler. Multiple schedulers can share a single data source while using different tables by specifying a table prefix.

Data type String

Table prefix:

Specifies the string prefix to affix to the scheduler tables.

Multiple independent schedulers can share the same database if each instance specifies a different prefix string.

Data type String

Poll interval:

Specifies the interval, in seconds, that a scheduler polls the database. The default value is appropriate for most applications.

Each poll operation can be consuming. If the interval is extremely small and there are many scheduled tasks, polling can consume a large portion of system resources.

Data type	Integer
Units	Seconds
Default	30
Range	Any positive long integer

Work manager JNDI name:

Specifies the JNDI name of the work manager, which is used to manage the number of tasks that can run concurrently with the scheduler. The work manager also can limit the amount of Java EE context applied to the task.

The work manager is a server object that serves as a logical thread pool for the scheduler. Each repeating task that is created using this scheduler uses the **Number of alarm threads** specified in the work manager, which affects the number of tasks that can run concurrently. Use the work manager **Service Names** property to limit the amount of context information that is propagated to the task when it runs.

When a task runs, the task is run in the work manager associated with the scheduler instance. You can control the number of actively running tasks at a given time by configuring schedulers with a specific work manager. The number of tasks that can run concurrently is governed by the **Number of alarm threads** parameter on the work manager.

Verify tables:

Specifies to validate that scheduler data sources, table prefixes, security authentication information and tables are configured correctly.

You can use this verification method in production and development environments without altering database properties.

Create tables:

Specifies to create the necessary tables and indices required for a scheduler to operate.

This method of creating scheduler tables is designed for simple topologies and development environments. Use the supplied scheduler data definition language files for advanced or production environments and for databases that do not support this feature.

Drop tables:

Specifies the removal of tables and indices required for schedulers to operate.

This method of removing scheduler tables and indices is recommended for development environments and does not delete previously scheduled tasks.

Schedulers settings:

Use this page to modify scheduler settings.

To view this administrative console page, click **Resources > Schedulers > scheduler_name**.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

Specifies the name by which this scheduler is known for administrative purposes.

Data type String

JNDI name:

Specifies the name of the data source where persistent tasks are stored.

The Java™ Naming and Directory Interface (JNDI) name specifies where this scheduler instance is bound in the namespace. Clients can look this name up directly, although the use of resource references is recommended.

Data type String

Description:

Specifies the description of this scheduler for administrative purposes.

Data type String

Category:

Specifies a string that can be used to classify or group this scheduler.

Data type String

Data source JNDI name:

Specifies the name of the data source where persistent tasks are stored.

Any data source available in the name space can be used with a scheduler. Multiple schedulers can share a single data source while using different tables by specifying a table prefix.

Data type String

Data source alias:

Specifies the alias for the user name and password that are used to access the data source.

Data type String

Table prefix:

Specifies the string prefix to affix to the scheduler tables. Multiple independent schedulers can share the same database if each scheduler specifies a different prefix string.

Multiple independent schedulers can share the same database if each instance specifies a different prefix string.

Important: Use a table prefix with all capital characters. If lowercase characters are used for the table prefix, they are automatically capitalized at run time.

Data type	String
------------------	--------

Poll interval:

Specifies the interval, in seconds, that a scheduler polls the database. The default value is appropriate for most applications.

Each poll operation can be consuming. If the interval is extremely small and there are many scheduled tasks, polling can consume a large portion of system resources.

Data type	Integer
Units	Seconds
Default	30
Range	2000000

Work manager JNDI name:

Specifies the JNDI name of the work manager, which is used to manage the number of tasks that can run concurrently with the scheduler. The work manager also can limit the amount of Java Platform, Enterprise Edition (Java EE) context applied to the task.

The work manager is a server object that serves as a logical thread pool for the scheduler. Each repeating task that is created using this scheduler uses the **Number of alarm threads** specified in the work manager, which affects the number of tasks that can run concurrently. Use the work manager **Service Names** property to limit the amount of context information that is propagated to the task when it runs.

When a task runs, the task is run in the work manager associated with the scheduler instance. You can control the number of actively running tasks at a given time by configuring schedulers with a specific work manager. The number of tasks that can run concurrently is governed by the **Number of alarm threads** parameter on the work manager.

Use administration roles:

Specifies that when this option and administrative security are both enabled, the user administration roles are enforced when the scheduler JMX commands or APIs are used to create and modify tasks. If this option is not enabled, all the users can create and modify tasks.

Schedulers require several user roles to plan for, develop, administer and operate the scheduler service: administrator, developer and operator.

Data type	check box
Default	unchecked

Range

- Operator, Administrator - Calls any of the scheduler MBean or API methods and runs any of the scheduler administrative console functions.
- Monitor, Configurator - Calls the scheduler MBean or API methods, but cannot create tasks or modify the state of any tasks. Only read-only methods and properties are accepted.

Configuring schedulers using Java Management Extensions

Schedulers can be created or configured using the Java Management Extensions (JMX) API using one of several scripting languages or Java.

About this task

To run with Java, the following JAR file needs to be present in the program class path:
`com.ibm.ws.admin.client_6.1.0.jar..`

Complete these steps when using Java programs that utilize JMX.

Procedure

1. Look up the host and get an administration client handle.
2. Get a configuration service handle.
3. Update the `resource-pme.xml` file using the configuration service, as needed.
 - a. Find the SchedulerProvider for a given scope.
 - b. Create a SchedulerConfiguration and specify all required parameters identifying the SchedulerProvider as the parent object.
4. Reload the `resource-pme.xml` file to bind the newly created scheduler into the JNDI namespace. Perform this step if you want to use the newly created scheduler immediately, without restarting the application server.
 - a. Locate the DataSourceConfigHelper MBean using the name.
 - b. Invoke the reload() operation.

Results

A scheduler is now configured and ready to use for newly installed applications. If the scheduler JNDI name is not yet visible to your application, reinstalling the application or restarting the application server will allow the scheduler to be seen.

When schedulers are created for the first time, the poll daemon does not automatically start, and you must start it manually. When you restart the server, the poll daemon starts automatically. To start the poll daemon manually, refer to the scheduler daemons topic.

Note: Changes to existing scheduler configurations will not take affect until after the application server is restarted.

Example: Using scripting to create and configure schedulers:

Use the wsadmin scripting tool to invoke a Jac1 script and create a SchedulerConfiguration resource.

The following Jac1 example script can be invoked using the wsadmin scripting tool, which creates a SchedulerConfiguration resource using the DefaultWorkManager at the server scope.

```

# Example JACL Script to create a SchedulerConfiguration
# at the server scope

# Change the cell, node and server to match your environment
set cellName MyCell
set nodeName MyNode
set serverName server1

# We can just grab the first provider, since there is only one at the
# server scope level.

set schedProv [$AdminConfig getid /Cell:$cellName/Node:$nodeName/Server:$serverName/
SchedulerProvider:SchedulerProvider]
if {$schedProv == ""} {
    puts "Unable to find SchedulerProvider for server: $serverName. Aborting."
    exit
}
puts "Found a SchedulerProvider"

# Create a WorkManager for our scheduler at the server scope.
# We could use any of the other scopes as long as it is at the same
# or higher than the Scheduler's scope.

set wrkMgrProv [$AdminConfig getid /Cell:$cellName/Node:$nodeName/Server:$serverName/
WorkManagerProvider:WorkManagerProvider/]
if {$wrkMgrProv == ""} {
    puts "Unable to find the WorkManagerProvider for server: $serverName. Aborting."
    exit
}
puts "Found a WorkManagerProvider"

set wmName "MyScheduler WorkManager"
set wmJNDIName "wm/MySchedWorkManager"
set wmIsGrowable false
set wmMaxThreads 1
set wmMinThreads 0
set wmNumAlarmThreads 10
set wmServiceNames "com.ibm.ws.i18n;security;UserWorkArea;zos.wlm"
set wmThreadPriority 5

# Setup our DefaultWorkManager attributes
set createAttrs [subst { \
    {isGrowable $wmIsGrowable} \
    {jndiName $wmJNDIName} \
    {maxThreads $wmMaxThreads} \
    {minThreads $wmMinThreads} \
    {name "$wmName"} \
    {numAlarmThreads $wmNumAlarmThreads} \
    {serviceNames "$wmServiceNames"} \
    {threadPriority $wmThreadPriority} }}]

puts "Creating a WorkManager"
$AdminConfig create WorkManagerInfo $wrkMgrProv $createAttrs
puts "WorkManager Created"

# Setup our SchedulerConfiguration attributes
set schedulerName MyScheduler
set schedulerJNDIName sched/MyScheduler
set datasourceJNDIName jdbc/MySchedulerDatasource
set datasourceAlias MySchedulerAlias
set pollInterval 30
set tablePrefix MSCD
set useAdminRoles true

set createAttrs [subst { \
    {name $schedulerName} \
    {datasourceJNDIName $datasourceJNDIName} \

```

```

{datasourceAlias $datasourceAlias} \
{jndiName $schedulerJNDIName} \
{pollInterval $pollInterval} \
{tablePrefix $tablePrefix} \
{useAdminRoles true} \
{workManagerInfoJNDIName $wmJNDIName}}]

puts "Creating a Scheduler"
$AdminConfig create SchedulerConfiguration $schedProv $createAttrs
puts "Scheduler created"

# Save the configuration
$AdminConfig save

```

Creating a scheduler resource reference

When you define schedulers in the server configuration, the object instance is bound into the global name space under the configured Java Naming Directory Interface (JNDI) name. You can use a resource reference to avoid manually coding this JNDI name into your application. Using a resource reference allows administrators to map applications to the appropriate schedulers.

About this task

You can alternatively create a scheduler resource reference by editing the XML directly. A Scheduler resource reference is a Java Platform, Enterprise Edition (Java EE) compliant resource that uses the class `com.ibm.websphere.scheduler.Scheduler` as the object type. For information regarding the XML file format, see the Java EE Specification.

Procedure

1. Start an assembly tool, such as Rational Application Developer.
2. Open the Java EE perspective.
3. Open your Enterprise JavaBeans (EJB) or Web module with the Deployment Descriptor Editor.
4. Click the **Reference** tab at the bottom of the window.
5. Click **Add**.
6. Select the **Resource reference** option.
7. Click **Next**.
8. Complete the Reference fields as shown in the following properties:
 - Name** The reference name, for example, *sched/MyScheduler*. According to this example, the name you choose has a local reference name of **java:comp/env/sched/MyScheduler**.
 - Type** Select **com.ibm.websphere.scheduler.Scheduler**, and click **OK**.
 - Authentication**
Select container.
 - Description**
Any relevant description.
9. Click finish.
10. **(Optional)** Enter a global JNDI name of a configured scheduler in the JNDI name field in the **Bindings** section of the **Reference** window. You can specify or override this value when you install the application.
11. Save your changes to the deployment descriptor.

Results

A scheduler resource reference is now available to use within your application

Creating the database for schedulers

Each scheduler requires a database in which to store its persistent information. Schedulers use this database for storing tasks and then running them. The choice of database and location should be determined by the application developer and server administrator.

Before you begin

Scheduler performance is ultimately limited by database performance. If you need more tasks per second, you can run the scheduler daemons on larger systems, use clusters for the session beans used by the tasks or partition the tasks by using multiple schedulers. Eventually, however, the scheduler database becomes saturated, and a larger or better-tuned database system is needed. For detailed information on scheduler topologies refer to the "WebSphere Enterprise Scheduler planning and administration guide" technical paper.

Multiple schedulers can share a database when you specify unique table prefix values in each scheduler configuration. This sharing can lower the cost of administering scheduler databases. However, do not configure schedulers with non-unique table prefixes such that two separate servers share the same database table. A lease occurs between a specific database table and a scheduler running on a server. This lease allows one server at a time to own the lease to a specific database table. This process exists to ensure that one server runs schedule events, such as Enterprise JavaBeans (EJB) timers, in a cluster environment. If the server with this lease is unavailable, another server in the cluster obtains the lease.

About this task

Complete the following steps to create scheduler databases.

Procedure

1. Create a database. To create the database for a scheduler or to determine if an existing database is adequate for a scheduler, review the Create scheduler databases topic.
2. Create the scheduler tables. There are three methods for creating the tables for a scheduler:
 - a. Create tables for schedulers using the administrative console. Use the administrative console to add, delete and verify database tables through your Web browser. This method is ideal for developers and simple scheduler topologies.
 - b. Create tables for schedulers using JMX or scripting.
Use JMX to add, delete and verify database tables programmatically with Java or scripting. This method is ideal for automating scheduler configurations for simple scheduler topologies.
 - c. Create tables for schedulers using DDL files. Manually edit the DDL files using your favorite text editor, and verify that mapping between the table names and the scheduler resources and data sources is correct.

Creating scheduler databases

The scheduler uses the scheduler database for storing and running tasks. To create a scheduler database, your database system must be installed and available.

Before you begin

The performance of schedulers is ultimately limited by the performance of the database. If you need more tasks per second, you can run the scheduler daemons on larger systems or you can use clusters for the session beans used by the tasks. Eventually, however, the task database becomes saturated and you then need a larger or better-tuned database system.

Multiple applications can share a scheduler database. This sharing can lower the cost of administering scheduler databases.

About this task

The scheduler requires a database, a JDBC provider, and a data source.

Procedure

1. Create the database according to the description for your database system:
 - Creating Apache Derby databases for schedulers.
 - Creating a DB2 database for schedulers.
 - Creating a DB2 database for z/OS for schedulers.
 - Creating an Informix database for schedulers.
 - Creating a Microsoft SQL Server database for schedulers.
 - Creating an Oracle database for schedulers.
 - Creating a Sybase database for schedulers.
2. If the database is not on the same machine as your IBM WebSphere Application Server, verify that you can access the database from your application server machine.
3. Configure your JDBC provider and data source. For details, refer to the Creating and configuring a JDBC provider and data source topic. The JDBC driver can be either one-phase or two-phase commit depending on whether other transactions take place using other data sources, for example, while using the scheduler. The data source can represent multiple versions of the product.

Results

The database is created and ready for you to create scheduler tables.

Creating Apache Derby databases for schedulers:

This topic describes how to create Apache Derby databases for schedulers using data definition language (DDL) or structured query language (SQL) files.

About this task

To create Apache Derby databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Verify that you have administrator rights for the database system.
3. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in Java code, which results in code page conversion problems when a client uses an incompatible code page.
4. Use the ij utility supplied with the Apache Derby system to create the database. To use ij to create a database called scheddb which is located in /opt, for example, you would do the following:

```
ij.sh
ij>connect '/opt/scheddb;create=true';
ij>quit;
```

The embedded version of Apache Derby supports only one local connection. If the Application Server product is running and accessing a Apache Derby database, then any attempts to open a second connection to the database from the command line are rejected.

Note: Add a semi-colon (;) at the end of each command. Otherwise, ij does not execute the command.

5. Exit the ij utility by issuing the quit command: `quit`;

Results

The Apache Derby database for the scheduler service exists.

Creating DB2 databases for schedulers:

This topic describes how to create DB2 databases for scheduler, using data definition language (DDL) or structured query language (SQL) files.

About this task

To create DB2 databases for scheduler, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a DB2 command-line window.
2. Make sure that you have administrator rights for the database system.
3. Verify that the database supports Unicode (UTF-8). Otherwise, it cannot store all the characters that can be handled in Java code, which might result in code page conversion problems, when a client uses an incompatible code page.

To avoid deadlocks, be sure that the DB2 isolation level is set to "read stability". If necessary, enter the command

```
db2set DB2_RR_TO_RS=YES
```

then restart the DB2 instance to activate the change.

4. In the DB2 command line processor, enter this command to create the database with an example name, `scheddb`:

```
db2 CREATE DATABASE scheddb USING CODESET UTF-8 TERRITORY en-us
```

A DB2 database named `scheddb` has been created.

Results

The DB2 database for the scheduler exists.

Creating DB2 for z/OS databases for schedulers:

This topic describes how to create DB2 for z/OS databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

About this task

To create DB2 for z/OS databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. You must have a DB2 subsystem installed in the z/OS platform on a UNIX or Windows machine.
2. On the z/OS machine that hosts the database:
 - a. Log on to the native z/OS environment.
 - b. If multiple DB2 systems are installed, then decide which subsystem you want to use.
 - c. Create a storage group and note the name.

- d. Decide which user ID is used to connect to the database from the remote machine running the product. Normally, for security reasons, this user ID is not the one you used to create the database.
 - e. Grant the user ID the rights to access the database and storage group. The user ID must also have permission to create new tables for the database.
3. On the server machine:
- a. Change to the *Scheduler* subdirectory in the application server installation root directory.
 - b. Edit the createTablespaceDB2ZOS.dd1 script. Replace @STG@ with the storage group name. Replace @DBNAME@ with the database name (not the subsystem name), and replace @SCHED_TABLESPACE@ with the name of a valid tablespace.
 - c. Run your customized version of createTablespaceDB2ZOS.dd1, as described in the header of the script.

Results

The DB2 for z/OS database for the scheduler service is created.

Creating DB2 for iSeries databases for schedulers:

This topic describes how to create DB2 for iSeries databases for scheduler, using data definition language (DDL) or structured query language (SQL) files.

About this task

To create DB2 for iSeries databases for scheduler, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Run the following command to start an interactive SQL session:
STRSQL
2. In interactive SQL, enter this command to create the collection with an example name, scheddb:
CREATE COLLECTION scheddb
3. Exit the interactive SQL session.
4. Change the owner for the new collection to QEJBSVR by executing the following command:
CHGOBJOWN OBJ(scheddb) OBJTYPE(*LIB) NEWOWN(QEJBSVR)

where scheddb is the name of the collection you created in the previous step.

Results

The DB2 for iSeries database for the scheduler exists.

Creating Informix databases for schedulers:

This topic describes how to create Informix databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

About this task

To create Informix databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Verify that you have administrator rights for the database system.
3. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible code page.
4. If you want to create a new database named scheddb, for example, enter the command:

```
dbaccess CREATE DATABASE scheddb with log
```

Results

The Informix database for scheduler exists.

Creating Microsoft SQL Server databases for schedulers:

This topic describes how to create Microsoft SQL Server databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

About this task

To create Microsoft SQL Server databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Make sure that you are using a user ID that has administrator rights for the database system.
2. In the **Enterprise Manager**, expand a server group, then expand a server. A Microsoft SQL Server database named scheddb is created.
3. Right-click **Databases**, then click **New Database**.
4. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible codepage.
5. Type the name scheddb.
6. Modify any default values, and save your changes. The Microsoft SQL Server database, scheddb, is created.

Results

The Microsoft SQL Server database for scheduler exists.

Creating Oracle databases for schedulers:

This topic describes how to create Oracle databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

About this task

To create Oracle databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.

3. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible code page.
4. Use the Database Configuration Assistant to create the database, scheddb, for example. Verify that you select the **JServer** option for the database. Use a Unicode code page when creating the database. The text data you pass to the APIs must be compatible with the selected code page.

Results

The Oracle database for scheduler exists.

Creating Sybase databases for schedulers:

This topic describes how to create Sybase databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

About this task

This topic describes how to create Sybase databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Make sure that you have the DTM option for Sybase ASE installed.
4. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible code page.
5. Use the Sybase isql utility to create the database, scheddb, for example. See your Sybase product documentation for details.

Results

The Sybase database for the scheduler exists.

Scheduler table management functions

The administration console and the WASSchedulerConfiguration MBeans provide simplified methods for creating scheduler tables and schema, verifying that the scheduler tables and schema are setup properly and are accessible and removing scheduler tables and schema.

When connecting to a deployment manager or node agent, the operation attempts to verify, create, or drop the tables based on the most granular scope where the scheduler and associated data source is located. If a scheduler is configured at the server scope, the data source at the node scope, and the verify tables operation is being run from a deployment manager for example, the deployment manager attempts to connect to server1 and run the operation there. If the server is unavailable, then it attempts to verify at the node agent level and then at the deployment manager level.

Note: There are limitations when running the table management functions relating to data source access. See the Verifying a connection topic for details on these limitations. If a connection cannot be verified successfully, the scheduler table management functions will fail.

Verify tables

Validates that scheduler data sources, table prefixes, security authentication information and tables are configured correctly. You can use this verification method in production and development environments without altering database properties.

Create tables

Creates the necessary tables and indices required for schedulers to operate. This method of creating scheduler tables is designed for simple topologies and development environments. Use the supplied scheduler data definition language files for advanced or production environments and for databases that do not support this feature. For details, see the topic [Creating scheduler tables using the administrative console](#).

Drop tables

Specifies the removal of tables and indices required for schedulers to operate. This method of removing scheduler tables and indices is recommended for development environments. When you drop tables, the action removes all previously scheduled tasks, and the scheduler no longer operates successfully, until the tables are recreated.

Scheduler table definition

Schedulers require database tables and indices with a table prefix. This page provides reference information about the tables.

Each scheduler requires several database tables and indices to operate. Each table name and index described in this topic requires a table prefix. For example, if the scheduler is configured with a table prefix value, **SCHED_**, the table with the name, **TASK**, would be named **SCHED_TASK**. See [Scheduler settings](#) for details on the table prefix.

To create the tables, see [Creating the database for schedulers](#). To see the exact schema definition such as field sizes and types, see [Creating scheduler tables using DDL files](#). This section references the location where the DDL or SQL statements are stored. These statements create the table schema.

Note: The information in this topic is provided for problem determination. Do not alter the scheduler table names, field names or index names. The data content format might change without notice. Be aware of this factor when accessing the tables directly. Modifying data in the tables without using the Scheduler API might cause failures.

TASK

The TASK table contains the tasks that have been scheduled, but not yet purged. The primary key for this table is the TASKID which equates to the `getTaskID()` method on the `com.ibm.websphere.scheduler.TaskStatus` interface.

Since there is one row in this table for each task, it is important that the database and table support row-locking. Using page, or table locks, inhibits the scheduler from running tasks concurrently.

Table 68. TASK table.. Displays scheduled tasks

Field name	Purpose and notes
------------	-------------------

Table 68. TASK table. (continued). Displays scheduled tasks

TASKID	Contains all of the tasks that have been scheduled, but not yet purged. The primary key for this table is TASKID which equates to the <code>getTaskID()</code> method on the <code>com.ibm.websphere.scheduler.TaskStatus</code> interface. Since there is one row in this table for each task, it is important that the database and table support row-locking. Using page, or table locks, will inhibit the scheduler from running tasks concurrently.
VERSION	Internal version ID of this row format.
ROW_VERSION	The version of this row. Used for optimistic locking.
TASKTYPE	The type of task: 1 =BeanTaskInfo, 2 =MessageTaskInfo
TASKSUSPENDED	This value indicates if the task is suspended or if it is running. The task is suspended if the value BITWISE AND 1 equals 1. The task is running if the value BITWISE AND 2 equals 2.
CANCELLED	The value, 1 , if the task is cancelled.
NEXTFIRETIME	The date in milliseconds using <code>java.util.Date.getTime()</code> when the task is scheduled to run next.
STARTBYINTERVAL	The start-by-interval of the task.
STARTBYTIME	Reserved.
VALIDFROMTIME	The task start time.
VALIDTOTIME	Reserved.
REPEATINTERVAL	The task repeat interval.
MAXREPEATS	The number of times to run the task.
REPEATSLEFT	The number of times the task has yet to run.
TASKINFO	Internal binary data.
NAME	The task name.
AUTOPURGE	The value, 1 , if the task is to automatically purge upon completion.
FAILUREACTION	Reserved.
MAXATTEMPTS	Reserved.
QOS	Reserved.
PARTITIONID	Reserved.
OWNERTOKEN	The task owner.
CREATETIME	The time in milliseconds using <code>java.util.Date.getTime()</code> when the task was created.

The TASK table also has the following indices that are required to allow the scheduler to run and access tasks concurrently:

- TASK_IDX1 – Used to access individual tasks using the Scheduler API.
- TASK_IDX2 – Used by the poll daemon to load expiring tasks.

TREG

The TREG table is used to store scheduler information that is shared between redundant schedulers. This table is not highly used.

Table 69. TREG table.. Displays scheduler information between redundant schedulers

Field name	Purpose and notes
REGKEY	The registry key. This is the primary key of the table.
REGVALUE	The registry value.

LMGR

The LMGR table is used to track the leases that redundant schedulers use. This table is not highly used.

Table 70. LMGR table.. Displays redundant scheduler leases

Field name	Purpose and notes
LEASENAME	The name of the lease. This is the scheduler JNDI name and is the primary key.
LEASEOWNER	The owner of the lease. The format is Ce11/Node/Server.
LEASE_EXPIRE_TIME	The time in milliseconds using java.util.Date.getTime() when the lease for the scheduler expires.
DISABLED	Reserved.

LMPR

The LMPR table is used to store arbitrary properties for the lease. This table is not highly utilized.

Table 71. LMPR table.. Displays arbitrary lease properties

Field name	Purpose and notes
LEASENAME	The name of the lease. See the LMGR table.
NAME	The name of the property.
VALUE	The value of the property.

The LMPR table also has the following index:

- LMPR_IDX1 – Used to retrieve properties for a given lease.

Creating scheduler tables using the administrative console

To create scheduler tables using the administrative console, the scheduler requires a database, a Java DataBase Connectivity (JDBC) provider and a data source.

Before you begin

Note: Limitations for Oracle XA databases

Oracle XA prohibits required schema operations in a global transaction environment. Local transactions are not supported. If you have schedulers that use an Oracle XA data source, either temporarily change the scheduler configuration to use a non-XA Oracle data source, or create the tables manually using the supplied DDL files. If you use the administrative console to create or drop scheduler tables for a scheduler configured to use an Oracle XA data source, then you receive a SchedulerDataStoreException error message, and the operation fails.

Note: Limitations for DB2 z/OS databases

Creating and dropping tables using the administrative console is not supported for DB2 z/OS databases. A database administrator is typically involved with defining and managing databases on DB2 z/OS systems. The administration interface is targeted for the non-database administrator or developer who does not want to know the specifics of setting up the scheduler database. The scheduler has DDL files available for the database administrator to create the required tables.

Procedure

1. Verify that the database to be used for this scheduler is available and accessible by the application server. Review the Creating scheduler databases and tables topic for instructions on creating a database. The remaining steps describe how to create scheduler tables in an existing database.
2. Start the administrative console.
3. Create a JDBC data source that refers to the scheduler database.
4. Test the data source connection.
5. Create a scheduler. This configuration object contains the desired table prefix and the JNDI name of the JDBC data source. Verify that you save the new Scheduler to the configuration repository before you proceed to the next step.
6. Click **Resources > Schedulers** to view all defined schedulers.
7. Select one or more schedulers.
8. Click **Create Tables** to create the tables for the selected schedulers in their associated database. The tables and indices you created reflect the table prefixes and data sources specified in each scheduler configuration.
9. Restart the server or start the poll daemon to run scheduler tasks.

Results

Scheduler tables and schema are created.

Creating scheduler tables using scripting and Java Management Extensions

Creating scheduler tables using scripting and Java Management Extensions requires a database, a Java DataBase Connectivity (JDBC) provider, and a data source.

Before you begin

Attention: Limitations for Oracle XA databases

Oracle XA prohibits required schema operations in a global transaction environment. Local transactions are not supported. If you have schedulers that use an Oracle XA data source, either temporarily change the scheduler configuration to use a non-XA Oracle data source, or create the tables manually using the supplied DDL files. If you use the administrative console to create or drop scheduler tables for a scheduler configured to use an Oracle XA data source, then you receive a SchedulerDataStoreException error message, and the operation fails.

Attention: Limitations for DB2 z/OS databases

Creating and dropping tables using the administrative console is not supported for DB2 z/OS databases. A database administrator is typically involved with defining and managing databases on DB2 z/OS systems. The administration interface is targeted for the non-database administrator or developer who does not want to know the specifics of setting up the scheduler database. The scheduler has DDL files available for the database administrator to create the required tables.

Procedure

1. Verify that the database to be used for this Scheduler is available and accessible by the application server. Review the Creating scheduler databases and tables topic for instructions on creating a database. The remainder of these steps describe how to create scheduler tables in an existing database.
2. Launch the wsadmin tool and connect to a deployment manager or application server. This process requires an active server to be available and fails, if you are disconnected from the server.
3. Create a JDBC data source that refers to the scheduler database.
4. Test the data source connection.

5. Create a scheduler. This configuration object contains the desired table prefix and the JNDI name of the JDBC data source. Verify that you save the new Scheduler to the configuration before you proceed to the next step.
6. Run the **createTables** MBean operation.
 - a. Look up the SchedulerConfiguration object or use the object you created in a previous step.
 - b. Locate the **WASSchedulerConfiguration** MBean.
 - c. Run one of the **createTables** MBean operation on the **WASSchedulerConfiguration** object to create the tables for the specified **SchedulerConfiguration** object in its associated database. The tables and indices that you created reflect the table prefix and data source specified in the scheduler configuration.
7. Restart the server or start the poll daemon to run scheduler tasks.

Results

Scheduler tables and schema are created.

Example: Using scripting to verify scheduler tables:

Use the wsadmin scripting tool to invoke a Jac1 script and verify tables and indices for a scheduler.

The following Jac1 example script can be invoked using the wsadmin scripting tool, which verifies that the tables and indices are created correctly for a scheduler. See the “Configuring Schedulers” topic for details on how a scheduler is created.

```
# Example JACL Script to verify the scheduler tables

# The name of the scheduler to verify
set schedName "My Scheduler"

puts ""
puts "Looking-up Scheduler Configuration Helper MBean"
puts ""
set schedHelper [$AdminControl queryNames WebSphere:*,type=WASSchedulerCfgHelper]

#Access the configuration object.
set myScheduler [$AdminConfig getid /SchedulerConfiguration:$schedName/]

if {$myScheduler == ""} {
  puts ""
  puts "Error: Scheduler $schedName could not be found."
  puts ""
  exit
}

# Invoke the verifyTables method on the helper MBean.

puts ""
puts "Verifying tables for:"
puts "$myScheduler"
puts ""

if { [catch {$AdminControl invoke $schedHelper verifyTables $myScheduler} errorInfo] } {
  puts ""
  puts "Error verifying tables: $errorInfo"
  puts ""
} else {
  puts ""
  puts "Tables verified successfully."
  puts ""
}
```

Example: Using scripting to create scheduler tables:

Use the wsadmin scripting tool to invoke a Jac1 script and create scheduler tables.

The following Jac1 example script can be invoked using the wsadmin scripting tool, which creates the scheduler tables for a configured scheduler. See the Configuring Schedulers topic for details on how to create a scheduler.

```
# Example JACL Script to create the scheduler tables

# The name of the scheduler to create tables for
set schedName "My Scheduler"

puts ""
puts "Looking-up Scheduler Configuration Helper MBean"
puts ""
set schedHelper [AdminControl queryNames WebSphere:*,type=WASSchedulerCfgHelper]

#Access the configuration object.
set myScheduler [AdminConfig getid /SchedulerConfiguration:$schedName/]

if {$myScheduler == ""} {
    puts ""
    puts "Error: Scheduler with name: $schedName could not be found."
    puts ""
    exit
}

# Invoke the createTables method on the helper MBean.

puts ""
puts "Creating tables for:"
puts "$myScheduler"
puts ""

if {[catch {
    set result [AdminControl invoke $schedHelper createTables $myScheduler]
    if {$result} {
        puts ""
        puts "Successfully created the tables."
        puts ""
    } else {
        puts ""
        puts "The tables were already created."
        puts ""
    }
} errorInfo ]} {
    puts ""
    puts $errorInfo
    puts ""
}
```

Example: Using scripting to drop scheduler tables:

Use the wsadmin scripting tool to invoke a Jac1 script and remove scheduler tables.

The following Jac1 example script can be invoked using the wsadmin scripting tool, which removes the scheduler tables for a configured scheduler. See the “Configuring Schedulers” topic for details on how a scheduler is created

```
# Example JACL Script to drop the scheduler tables

# The name of the scheduler to drop the tables for
set schedName "My Scheduler"

puts ""
puts "Looking-up Scheduler Configuration Helper MBean"
puts ""
```

```

set schedHelper [AdminControl queryNames WebSphere:*,type=WASSchedulerCfgHelper]

#Access the configuration object.
set myScheduler [AdminConfig getid /SchedulerConfiguration:$schedName/]

if {$myScheduler == ""} {
    puts ""
    puts "Error: Scheduler with name: $schedName could not be found."
    puts ""
    exit
}

# Invoke the dropTables method on the helper MBean.

puts ""
puts "Dropping tables for:"
puts "$myScheduler"
puts ""

if {[catch {
    set result [AdminControl invoke $schedHelper dropTables $myScheduler]
    if {$result} {
        puts ""
        puts "Successfully dropped the tables."
        puts ""
    } else {
        puts ""
        puts "The tables were already dropped."
        puts ""
    }
} errorInfo ]} {
    puts ""
    puts $errorInfo
    puts ""
}

```

Creating scheduler tables using DDL files

This topic provides the steps for creating scheduler tables using DDL files.

Before you begin

Your database system must be installed and available.

The scheduler requires a database, a Java™ Database Connectivity (JDBC) provider, and a data source.

About this task

Complete the following steps to create scheduler tables using DDL files.

Procedure

1. Verify that your database is created. Refer to the Creating scheduler databases topic.
2. Create the database tables according to the instructions for your database system:
 - Creating Apache Derby tables for schedulers
 - Creating DB2 tables for schedulers.
 - Creating DB2 tables for z/OS for schedulers.
 - Creating Informix tables for schedulers.
 - Creating Microsoft SQL Server tables for schedulers.
 - Creating Oracle tables for schedulers.
 - Creating Sybase tables for schedulers.

The following scripts are deprecated, but will still work:

Table 72. *Deprecated scripts.. Deprecated DDL scripts*

Deprecated script	New script
createSchemaDB2.ddl	createSchemaMod1DB2.ddl
createSchemaDB2iSeries.ddl	createSchemaMod1DB2iSeries.ddl
createSchemaDerby.ddl	createSchemaMod1Derby.ddl
createSchemaMSSQL.sql	createSchemaMod1MSSQL.sql
createSchemaInformix.sql	createSchemaMod1Informix.sql
createSchemaOracle.ddl	createSchemaMod1Oracle.ddl
createSchemaSybase12.ddl	createSchemaMod1Sybase12.ddl
dropSchemaMSSQL.sql	dropSchemaMod1MSSQL.sql
dropSchemaDB2.ddl	dropSchemaMod1DB2.ddl
dropSchemaDB2iSeries.ddl	dropSchemaMod1DB2iSeries.ddl
dropSchemaDerby.ddl	dropSchemaMod1Derby.ddl
dropSchemaInformix.sql	dropSchemaMod1Informix.sql
dropSchemaOracle.ddl	dropSchemaMod1Oracle.ddl
dropSchemaSybase12.ddl	dropSchemaMod1Sybase12.ddl

Creating Apache Derby tables for schedulers:

This topic describes how to create tables for schedulers on Apache Derby databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires you to configure a database and make it available. Refer to the *Creating Cloudscape databases for schedulers* topic, for more information.

About this task

To create tables for schedulers on Apache Derby databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Create the schema.
 - a. Using a text editor, edit the script, `%app_server_root%\Scheduler\createSchemaMod1Derby.ddl`, according to the instructions at the top of the file.

Attention: When setting the table prefix, capitalize all characters.

- b. Enter one of the following commands.

Attention: Apache Derby provides both an embedded and network server version. This example is for the embedded version of Apache Derby. See the Apache Derby product documentation for more details on running DDL scripts.

On Windows systems (using the example name, scheddb):

```
%app_server_root%\derby\bin\embedded\ij.bat %app_server_root%\Scheduler\createSchemaMod1Derby.ddl
```

On UNIX systems (using the example name, scheddb):

```
%app_server_root%/derby/bin/embedded/ij.sh %app_server_root%/Scheduler/createSchemaMod1Derby.ddl
```

Results

The Apache Derby tables and schema for the scheduler exist.

Creating DB2 tables for schedulers:

This topic describes how to create tables for scheduler on DB2 databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires you to configure a database and make it available. Refer to the Creating DB2 databases for schedulers topic for more information.

About this task

To create tables for scheduler on DB2 databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a DB2 command-line window.
2. Verify that you have administrator rights for the database system.
3. Create the table space and schema.
 - a. Analyze the results of your experiences during development and system testing. The size of your database depends on many factors. If possible, distribute table space containers across different logical disks, and implement an appropriate security policy. Consider the performance implications of your choices for buffer pools and log file settings.
 - b. Using a text editor, edit the following scripts according to the instruction at the top of each file.

Note: When setting the table prefix, capitalize all characters.

`%WAS_HOME%\Scheduler\createTablespaceDB2.dd1`, `%WAS_HOME%\Scheduler\createSchemaMod1DB2.dd1`, `%WAS_HOME%\Scheduler\dropSchemaMod1DB2.dd1`, and `%WAS_HOME%\Scheduler\dropTablespaceDB2.dd1`.

- c. Verify that you are attached to the correct instance. Check the environment variable `DB2INSTANCE`.
- d. To connect to the database, `scheddb`, for example, and enter the command:
`db2 connect to scheddb`
- e. Create the table space. Enter the following command:
`db2 -tf createTablespaceDB2.dd1`

Verify that the script output contains no errors. If there were any errors, you can drop the table space using the following script:

`dropTablespaceDB2.dd1`

- f. To create the schema (tables and indices), in the DB2 command line processor, enter the command `db2 -tf createSchemaMod1DB2.dd1`. Verify that the script output contains no errors. If there were any errors, you can use the following file to drop the schema:
`dropSchemaMod1DB2.dd1`
- g. Verify that the `DB2_RR_TO_RS` DB2 flag is set to **YES** to avoid deadlocks. Restart the DB2 instance to activate the change, if needed.

Results

The DB2 tables and schema for the scheduler exist.

Creating DB2 for z/OS tables for schedulers:

This topic describes how to create tables for a scheduler on a DB2 for z/OS database using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires that you configure a database and make it available. See the "Creating DB2 for z/OS databases for schedulers" topic for more information.

In addition, you must have the following two machines:

1. The z/OS machine that is hosting the database
2. The WebSphere Application Server machine that is running the scheduler

About this task

To create tables for a scheduler on a DB2 for z/OS database, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Work with the z/OS machine that hosts the database to:
 - a. Log on to the native z/OS environment.
 - b. Decide which subsystem you want to use, if multiple DB2 systems are installed.
 - c. Note of the Internet Protocol (IP) port to which the DB2 subsystem is listening.
 - d. Use the DB2 administration menu to create a new database named, for example, SCHEDDB. Note the database name.
 - e. Create a storage group and note the name.
 - f. Decide which user ID is used to connect to the database from the remote machine running the product. Normally, for security reasons, this user ID is not the one you used to create the database.
 - g. Grant the user ID the rights to access the database and storage group. The user ID must also have permission to create new tables for the database.
2. Work with the Application Server machine to:
 - a. Verify that you have DB2 Connect™ Gateway (Version 8.1 fix pack 3 or higher) installed. This component is part of the DB2 UDB ESE package; however, you can also install it separately.
 - b. Catalog the remote database using the following commands, either in a script or in a DB2 command line window:

```
catalog tcpip node zosnode remote hostname server IP_port ostype mvs;  
catalog database subsystem as subsystem at node zosnode authentication dcs;  
catalog dcs database subsystem as subsystem parms ',,INTERRUPT_ENABLED'
```

An important difference exists between DB2 UDB and DB2 for z/OS. DB2 UDB does not have the concept of a subsystem, but DB2 for z/OS does have subsystems. To avoid confusion between Database name and Subsystem name, remember that because DB2 for z/OS runs in a subsystem, the `catalog node` and `catalog database` commands must identify the appropriate subsystem. On DB2 UDB, the subsystem name is not a known concept, and the database name to which it connects is actually the name of the DB2 for z/OS subsystem.

- c. Verify that you can establish a connection to the remote subsystem by entering the following command:

```
db2 connect to subsystem user userid using password
```

- d. Change to the scheduler subdirectory in the application server installation root directory.
- e. Edit the createTablespaceDB2ZOS.dd1 script. Replace @STG@ with the storage group name. Replace @DBNAME@ with the database name (not the subsystem name), and replace @SCHED_TABLESPACE@ with the name of a valid table space. After you replace the database name, place it into an existing JCL and run the job.
- f. Run your customized version of createTablespaceDB2ZOS.dd1, as described in the header of the script. If this script does not work, or if you want to remove the table space, edit and run the dropTablespaceDB2ZOS.dd1 script.
- g. Edit the createSchemaDB2ZOS.dd1 script. Replace @STG@ with the storage group name. Replace @DBNAME@ with the database name (not the subsystem name). Replace @TABLE_PREFIX@ with the Table Prefix in the configured scheduler resource, and replace @SCHED_TABLESPACE@ with a valid table space that was created by the createTablespaceDB2ZOS.dd1 script.

Note: When setting the table prefix, capitalize all characters.

- h. Run your customized version of the createSchemaDB2ZOS.dd1 script, as described in the header of the script. If this script does not work, or if you want to remove the tables and views, use dropSchemaDB2ZOS.dd1 to drop the schema.

Results

The DB2 for z/OS tables and schema for the scheduler exist.

Creating Informix tables for schedulers:

This topic describes how to create tables for schedulers on Informix databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires that you configure a database and make it available. Refer to the Creating Informix databases for schedulers topic for more information.

About this task

To create tables for schedulers on Informix databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Verify that you have administrator rights for the database system.
3. Create the schema.
 - a. Using a text editor, edit the script %WAS_HOME%\Scheduler\createSchemaMod1Informix.sql according to the instruction at the top of the file.

Note: When setting the table prefix, capitalize all characters.

- b. Enter the following command, using the database, scheddb, for example:

```
dbaccess scheddb createSchemaMod1Informix.sql
```

Results

The Informix tables and schema for the scheduler exist.

Creating Microsoft SQL Server tables for schedulers:

This topic describes how to create tables for schedulers on Microsoft SQL Server databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires you to configure a database and make it available. Refer to the Creating Microsoft SQL Server databases for schedulers topic for more information.

About this task

To create tables for schedulers on Microsoft SQL Server databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Change to the directory where the configuration scripts for scheduler are located. This is the Scheduler subdirectory of the IBM WebSphere Application Server installation directory.
3. Use a text editor to edit the schema creation script, `createSchemaMod1MSSQL.sql`, according to the instructions at the beginning of the file.

Tip: When setting the table prefix, capitalize all characters.

4. Create the schema:
 - a. Verify that you have administrator rights for the database system. The user ID you use to create the schema must be the one that you configure WebSphere Application Server to use when accessing the database.
 - b. Run the following script to create the schema (tables and views) :

```
sqlcmd -S <servername> -U<userid> -P<password> -d<databaseName> -i<script name>
```

Results

The Microsoft SQL Server tables and schema for scheduler exist.

Creating Oracle tables for schedulers:

This topic describes how to create tables for schedulers on Oracle databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires you to configure a database and make it available. Refer to the Creating Oracle databases for schedulers topic for more information.

About this task

To create tables for schedulers on Oracle databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Create the table space and schema.
 - a. Using a text editor, edit the following scripts according to the instructions at the top of the files.

Tip: When setting the table prefix, capitalize all characters.

`%app_server_root%\Scheduler\createTablespaceOracle.ddl` and `%app_server_root%\createSchemaMod1Oracle.ddl`

- b. Set the environment variable ORACLE_SID, if you do not want the schema to be created in the default instance.
- c. Run the script, `createTablespaceOracle.ddl`, to create the table space.
For test purposes, use the same location for all table spaces and pass the path as a command line argument to the script.
- d. Run the script, `createSchemaMod1Oracle.ddl`, to create the schema.

Results

The Oracle tables and schema for scheduler exist.

Creating Sybase tables for schedulers:

This topic describes how to create tables for schedulers on Sybase databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires you to configure a database and make it available. Refer to the [Creating Sybase databases for schedulers](#) topic for more information.

About this task

To create tables for schedulers on Sybase databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Make sure that you have the Distributed Transaction Management (DTM) option for Sybase ASE installed.
 - a. Set enable DTM to **1** in the Sybase server configuration.
 - b. Set enable xact coordination to **1** in the Sybase server configuration.
 - c. Add the **dtm_tm_role** role to the Sybase administration user ID. For example, enter the user ID `sa`.
 - d. Restart the Sybase server.
4. Use the Sybase `isql` utility to create a database. For example, enter the database name `scheddb`. See your Sybase product documentation for details.
5. Create the schema:
 - a. Using a text editor, edit the following script according to the instructions located at the top of the file.

Tip: When setting the table prefix, capitalize all characters.

`app_server_root\Scheduler\createSchemaMod1Sybase12.ddl`

- b. Enter the following command:
`isql -S <servername> -U <userid> -P <password> -D scheddb -i createSchemaMod1Sybase12.ddl`

Results

The Sybase tables and schema for scheduler exist.

Chapter 22. Administering application security

Setting up, enabling and migrating security

You must address several issues prior to authenticating users, authorizing access to resources, securing applications, and securing communications. These security issues include migration, interoperability, and installation.

About this task

After installing WebSphere Application Server, you can determine the proper level of security that is needed for your environment. By default, administrative security is enabled and provides the authentication of users using the WebSphere administration functions, the use of Secure Sockets Layer (SSL), and the choice of user account repository.

The following information is covered in this section:

Procedure

- Determine if any migration and interoperability issues might affect your installation. For more information, see “Migrating, coexisting, and interoperating – Security considerations.”
- Prepare your environment before and after installing WebSphere Application Server. For more information, see “Preparing for security at installation time” on page 1195.
- Enable security for all your application servers or for specific application servers in your realm. For more information, see either “Enabling security” on page 1230 or “Configuring multiple security domains” on page 1306.

What to do next

After installing WebSphere Application Server and securing your environment, you must authenticate users. For more information, see “Authenticating users” on page 1344.

Migrating, coexisting, and interoperating – Security considerations

Use this topic to migrate the security configuration of previous WebSphere Application Server releases and its applications to the new installation of WebSphere Application Server.

Before you begin

This information addresses the need to migrate your security configurations from a previous release of IBM WebSphere Application Server to WebSphere Application Server 8.0. Complete the following steps to migrate your security configurations:

- If security is enabled in the previous release, obtain the administrative server ID and password of the previous release. This information is needed in order to run certain migration jobs.
- You can optionally disable security in the previous release before migrating the installation. No logon is required during the installation.
- If `scriptCompatibility` is `false` when migrating to WebSphere Application Server 8.0 on z/OS, any SSLConfig repertoire of type System SSL (SSSL) is converted to type JSSE. The exception is when the SSLConfig repertoire belongs to the daemon; the repertoire is not converted from type SSSL to type JSSE in this case.

Note: In WebSphere Application Server Version 8.0, be aware of the following additional migration requirements for security:

- When migrating from WebSphere Application Server Version 7.x to Version 8.0, if you have a business need to preserve security audit logs from the older release you must first archive the

security audit log files in Version 7.x. WebSphere Application Server does not support the migration of security audit log files from the older release to Version 8.0.

- When migrating from WebSphere Application Server Version 7.x to Version 8.0 on a z/OS system, if you used a writeable System Authorization Facility (SAF) keyring setting on version 7.x make sure that writeable SAF is also enabled on the Version 8 system. Writeable SAF is a RACF setting.
- If your WebSphere Application Server Version 7.x environment is enabled for Kerberos, and you are migrating to version 8.0 on a different machine, the keytab and configuration files for Kerberos must be at the same location on the Version 8.0 machine as on the Version 7.x machine or the configuration will not work.

Procedure

Migrate the appropriate product configuration. You can migrate the base application server node, a deployment manager, and a federated node.

Results

The security configuration of previous WebSphere Application Server releases and its applications are migrated to the new installation of WebSphere Application Server Version 8.0.

What to do next

You must migrate any custom class files that are not migrated.

If you are migrating a Version 6.1 environment or earlier with System Authorization Facility (SAF) authorization enabled, be aware that the term describing the string that is prepended to the EJBROLE profile names, which was previously referred to as the z/OS security domain, has been updated to "SAF profile prefix". Additionally, the corresponding property name in the `security.xml` file has been updated to `com.ibm.security.SAF.profilePrefix`. The old property names are `security.zOS.domainName` and `security.zOS.domainType`. The term has changed to more accurately describe the purpose of this property and to avoid confusion with the WebSphere security domains feature that was introduced in Version 7.0. If a SAF profile prefix is specified and `scriptCompatibility` is a false value, further action is not necessary during migration; the old properties are converted to the new properties.

Note: The SAF distributed identity mapping feature is not supported in a mixed-version cell (nodes prior to WebSphere Application Server Version 8.0).

If you are migrating a Version 6.0.x environment with Sync to OS Thread enabled to a Version 8.0 environment, you should be aware of the following migration considerations:

- In addition to the application and configuration specifying the desire to use Sync to OS Thread that was required in earlier versions of WebSphere Application Server, the RACF administrator must also define a resource role in order for Sync to OS Thread to operate in Version 6.1 and later. A FACILITY class profile must be defined to allow or disallow the use of Sync to OS Thread. Also, an optional SURROGAT class profile can be used to further refine the use of Sync to OS Thread to particular authenticated users.

See "System Authorization Facility classes and profiles" on page 1207.

- In Version 6.1 and later, a FACILITY class profile must be defined to enable trusted applications. WebSphere Applications Server checks this FACILITY class profile during initialization to ensure that only authorized trusted applications are enabled. This FACILITY class profile expands the RACF administrator's role in ensuring that only authorized trusted applications are enabled.

See "System Authorization Facility classes and profiles" on page 1207.

Interoperating with previous product versions

IBM WebSphere Application Server inter-operates with the previous product versions. Use this topic to configure this behavior.

Before you begin

Interoperability is achieved using the z/OS Secure Authentication Service (z/SAS) security mechanism for local OS and System Authorization Facility (SAF)-based authorization.

Important: z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Procedure

1. Configure WebSphere Application Server Version 8.0 with the same distributed user registry (that is, LDAP or Custom) that is configured with the previous version. Make sure that the same LDAP user registry is shared by all of the product versions.
 - a. In the administrative console, select **Security > Global security**.
 - b. Choose an available Realm definition and click **Configure**.
 - c. If SAF authorization is disabled, enter a **Primary administrative user name**. This identity is the user with administrative privileges that is defined in your local operating system. If you are not using the local OS as the user registry, select the **Server identity that is stored in the user repository**, enter the Server user ID, and the associated password. The user name is used to log on to the administrative console when administrative security is enabled. WebSphere Application Server Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

Attention: In WebSphere Application Server, Versions 5.x and 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 8.0, this identity is used as the server user identity. You need to specify another user for the administrative user identity.
 - d. When interoperating with Version 6.0.x or previous versions, you must select the Server identity that is stored in the user repository. Enter the **Server user id** and the associated **Password**.
2. Configure the LTPA authentication mechanism. Automatic generation of the LTPA keys should be disabled. If not, keys used by a previous release are lost. Export the current LTPA keys from WebSphere Application Server Version 8.0 and import them into the previous release.
 - a. In the administrative console select **Security > Global security**.
 - b. From Authentication mechanisms and expiration, click **LTPA**.
 - c. Click the **Key set groups** link , then click the key set group that displays in the Key set groups panel.
 - d. Clear the **Automatically generate keys** check box.
 - e. Click **OK**, then click **Authentication mechanisms and expiration** in the path at the top of the Key set groups panel.
 - f. Scroll down to the Cross-cell single sign-on section, and enter a password to use for encrypting the LTPA keys when adding them to the file.
 - g. Enter the password again to confirm the password.
 - h. Enter the **Fully qualified key file name** that contains the exported keys.
 - i. Click **Export keys**.
 - j. Follow the instructions provided in the previous release to import the exported LTPA keys into that configuration.
3. If you are using the default SSL configuration, extract all of the signer certificates from the WebSphere Application Server Version 8.0 common trust store. Otherwise, extract signers where necessary to import them into the previous release.

- a. In the administrative console, click **Security > SSL certificate and key management**.
- b. Click **Key stores and certificates**.
- c. Click **CellDefaultTrustStore**.
- d. Click **Signer certificates**.
- e. Select one signer and click **Extract**.
- f. Enter a unique path and filename for the signer. For example, /tmp/signer1.arm.
- g. Click **OK**. Repeat for all of the signers in the trust store.
- h. Check other trust stores for other signers that might need to be shared with the other server. Repeat steps e through h to extract the other signers.

You can also import a signer certificate, which is also called a certificate authority (CA) certificate, from a truststore on a non-z/OS platform server to a z/OS keyring. The z/OS keyring contains the signer certificates that originated on the non-z/OS platform server. For more information, see Importing a signer certificate from a truststore to a z/OS keyring.

4. Add the exported signers to DummyServerTrustFile.jks and DummyClientTrustFile.jks in the /etc directory of the back-level product version. If the previous release is not using the dummy certificate, the signer certificate(s) from the previous release must be extracted and added into the WebSphere Application Server Version 8.0 release to enable SSL connectivity in both directions.
 - a. Open the key management utility, iKeyman, for that product version.
 - b. Start ikeyman.bat or ikeyman.sh from the \${USER_INSTALL_ROOT}/bin directory.
 - c. Select **Key Database File > Open**.
 - d. Open \${USER_INSTALL_ROOT}/etc/DummyServerTrustFile.jks.
 - e. Enter WebAS for the password.
 - f. Select **Add** and enter one of the files extracted in step 2. Continue until you have added all of the signers.
 - g. Repeat steps c through f for the DummyClientTrustFile.jks file.
5. Verify that the application uses the correct Java Naming and Directory Interface (JNDI) name and naming bootstrap port for performing a naming lookup.
6. Stop and restart all of the servers.

Interoperating with a C++ common object request broker architecture client

WebSphere Application Server supports security in the CORBA C++ client to access-protected enterprise beans. If configured, C++ CORBA clients can access protected enterprise bean methods using a client certificate to achieve mutual authentication on WebSphere Application Server applications.

About this task

Interoperability can be achieved between C++ CORBA clients and WebSphere Application Server using the Common Secure Interoperability Version 2 (CSIv2) or by using the z/OS Secure Authentication Service (z/SAS) protocols. CSIv2 should be used unless interoperability is required with a WebSphere Application Server Version 4.

Important: z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Security authentication from non-Java based C++ client to enterprise beans. WebSphere Application Server supports security in the CORBA C++ client to access-protected enterprise beans. If configured, C++ CORBA clients can access protected enterprise bean methods using a client certificate to achieve mutual authentication on WebSphere Application Server applications.

To support the C++ CORBA client in accessing protected enterprise beans, complete the following steps:

- Create an environment file for the client, such as `current.env`. Set the variables presented in the following list in the file:

Table 73. Environment Variables.

This table lists the environment variables needed to support the C++ CORBA client in accessing protected enterprise beans.

C++ security setting	Description
<code>client_protocol_password</code>	Specifies the password for the user ID.
<code>client_protocol_user</code>	Specifies the user ID to authenticate at the target server.
<code>security_sslKeyring</code>	Specifies the name of the RACF keyring for the client to use. The keyring must be defined under the user ID that is issuing the command to run the client.

- Point to the environment file using the fully qualified path name through the `WAS_CONFIG_FILE` environment variable. For example, in the `test.sh` test shell script, export:

```
/WebSphere/V6R0M0/DeploymentManager/profiles/default/config/cells
/PLEX1Network/nodes/PLEX1Manager/servers/dmgr
```

Some of the environment file terms are explained below:

default

profile name

PLEX1Network

cell name

PLEX1Manager

node name

dmgr server name

Migrating trust association interceptors

Use this topic to manually migrate trust associations.

Before you begin

Note: Data sources are not supported for use within a Trust Association Interceptor (TAI). Data sources are intended for use within J2EE applications and designed to operate within the EJB and web containers. Trust Association Interceptors do not run within a container, and while data sources may function in the TAI environment, they are untested and not guaranteed to function properly.

The following topics are addressed in this document:

- Changes to the product-provided trust association interceptors
- Migrating product-provided trust association interceptors
- Changes to the custom trust association interceptors
- Migrating custom trust association interceptors

Changes to the product-provided trust association interceptors

For the product-provided implementation for the WebSEAL server, a new optional `com.ibm.websphere.security.webseal.ignoreProxy` property is added. If this property is set to `true` or `yes`, the implementation does not check for the proxy host names and the proxy ports to match any of the host names and ports that are listed in the `com.ibm.websphere.security.webseal.hostnames` and the `com.ibm.websphere.security.webseal.ports` property respectively. For example, if the VIA header contains the following information:

```
HTTP/1.1 Fred (Proxy), 1.1 Sam (Apache/1.1),
HTTP/1.1 webseal1:7002, 1.1 webseal2:7001
```

and the `com.ibm.websphere.security.webseal.ignoreProxy` property is set to `true` or `yes`, the host name Fred, is not used when matching the host names. By default, this property is not set, which implies that any proxy host names and ports that are expected in the VIA header are listed in the host names and the ports properties to satisfy the `isTargetInterceptor` method.

The previous VIA header information was split onto two lines for illustrative purposes only.

For more information about the `com.ibm.websphere.security.webseal.ignoreProxy` property, see the article in the information center on configuring single signon using trust association interceptor ++.

Migrating product-provided trust association interceptors

The properties that are located in the `webseal.properties` and `trustedserver.properties` files are not migrated from previous versions of WebSphere Application Server. You must migrate the appropriate properties to WebSphere Application Server Version 6.0.x using the trust association panels in the administrative console. For more information, see [Configuring trust association interceptors](#).

Changes to the custom trust association interceptors

If the custom interceptor extends the `com.ibm.websphere.security.WebSphereBaseTrustAssociationInterceptor` property, implement the following new method to initialize the interceptor:

```
public int init (java.util.Properties props);
```

WebSphere Application Server checks the return status before using the trust association implementation. Zero (0) is the default value for indicating that the interceptor is successfully initialized.

However, if a previous implementation of the trust association interceptor returns a different error status, you can either change your implementation to match the expectations or make one of the following changes:

Method 1:

Add the `com.ibm.websphere.security.trustassociation.initStatus` property in the trust association interceptor custom properties. Set the property to the value that indicates the interceptor is successfully initialized. All of the other possible values imply failure. In case of failure, the corresponding trust association interceptor is not used.

Method 2:

Add the `com.ibm.websphere.security.trustassociation.ignoreInitStatus` property in the trust association interceptor custom properties. Set the value of this property to `true`, which tells WebSphere Application Server to ignore the status of this method. If you add this property to the custom properties, WebSphere Application Server does not check the return status, which is similar to previous versions of WebSphere Application Server.

The `public int init (java.util.Properties props)` method replaces the `public int init (String propsFile)` method.

The `init(Properties)` method accepts a `java.util.Properties` object, which contains the set of properties that is required to initialize the interceptor. All of the properties set for an interceptor are sent to this method. The interceptor can then use these properties to initialize itself. For example, in the product-provided implementation for the WebSEAL server, this method reads the hosts and ports so that a request coming in can be verified to come from trusted hosts and ports. A return value of Zero (0) implies that the interceptor initialization is successful. Any other value implies that the initialization is not successful and the interceptor is not used.

The `init(String)` method still works if you want to use it instead of implementing the `init(Properties)` method. The only requirement is that you enter the file name containing the custom trust association properties using the **Custom Properties** link of the interceptor in the administrative console or by using scripts. You

can enter the property using either of the following methods. The first method is used for backward compatibility with previous versions of WebSphere Application Server.

Method 1:

The same property names used in the previous release are used to obtain the file name. The file name is obtained by concatenating `.config` to the `com.ibm.websphere.security.trustassociation.types` property value. If the `myTAI.properties` file is located in the `app_server_root/properties` directory, set the following properties:

- `com.ibm.websphere.security.trustassociation.types = myTAItype`
- `com.ibm.websphere.security.trustassociation.myTAItype.config = app_server_root/properties/myTAI.properties`

Method 2:

You can set the `com.ibm.websphere.security.trustassociation.initPropsFile` property in the trust association custom properties to the location of the file. For example, set the following property:

```
com.ibm.websphere.security.trustassociation.initPropsFile=  
app_server_root/properties/myTAI.properties
```

The previous line of code is split into two lines for illustrative purposes only. Type as one continuous line.

In a WebSphere Application Server, Network Deployment installation, where the location of the file name can vary for different nodes, use the variable `install_root` to refer to the WebSphere Application Server installation directory.

However, it is highly recommended that your implementation be changed to implement the `init(Properties)` method instead of relying on the `init (String propsfile)` method.

Migrating custom trust association interceptors

The trust associations from previous versions of WebSphere Application Server are not automatically migrated to WebSphere Application Server Version 8.0. You can manually migrate these trust associations using the following steps:

Procedure

1. Recompile the implementation file, if necessary.

For more information, refer to the "Changes to the custom trust association interceptors" section previously discussed in this document.

To recompile the implementation file, type the following code:

```
%WAS_HOME%/java/bin/javac -classpath %WAS_HOME%/plugins/com.ibm.ws.runtime.jar;  
%WAS_HOME%/dev/JavaEE/j2ee.jar your_implementation_file.java
```

The previous line of code is broken into two lines for illustrative purposes only. Type the code as one continuous line.

2. Copy the custom trust association interceptor class files to a location in your product class path. Copy these class files into the `%WAS_HOME%/lib/ext` directory.
3. Start WebSphere Application Server.
4. Enable security to use the trust association interceptor. The properties that are located in your custom trust association properties file and in the `trustedserver.properties` file are not migrated from previous versions of WebSphere Application Server. You must migrate the appropriate properties to WebSphere Application Server Version 8.0 using the trust association panels in the administrative console.

For more information, see [Configuring trust association interceptors](#).

Migrating Common Object Request Broker Architecture programmatic login to Java Authentication and Authorization Service (CORBA and JAAS)

Use this topic as an example of how to perform programmatic login using the CORBA-based programmatic login APIs.

Before you begin

Common Object Request Broker Architecture (CORBA) application programming interfaces (API) are not supported in the WebSphere Application Server for z/OS environment. If you have an application that you are porting from another WebSphere Application Server product to WebSphere Application Server for z/OS you must be aware that the security APIs that are deprecated in Version 6.0.x. If you want to use these applications on WebSphere Application Server for z/OS Version 8.0, you must migrate to Java Authentication and Authorization Service (JAAS).

The following list includes the deprecated CORBA programmatic login APIs.

- `{user.install.root}/installedApps/sampleApp.ear/default_app.war/WEB-INF/classes/LoginHelper.java`.
- `{user.install.root}/installedApps/sampleApp.ear/default_app.war/WEB-INF/classes/ServerSideAuthenticator.java`.

The APIs that are provided in WebSphere Application Server are a combination of standard JAAS APIs and a product implementation of standard JAAS interfaces.

The supported APIs that are provided in WebSphere Application Server for z/OS are a combination of standard JAAS APIs and a product implementation of standard JAAS interfaces with some minor extension.

The following information is only a summary; refer to the JAAS documentation for your platform located at: <http://www.ibm.com/developerworks/java/jdk/security/>.

- Programmatic login APIs:
 - `javax.security.auth.login.LoginContext`
 - `javax.security.auth.callback.CallbackHandler` interface: The WebSphere Application Server product provides the following implementation of the `javax.security.auth.callback.CallbackHandler` interface:
 - **`com.ibm.websphere.security.auth.callback.WSCallbackHandlerImpl`**
Provides a non-prompt `CallbackHandler` handler when the application pushes basic authentication data (user ID, password, and security realm) or token data to product login modules. This API is recommended for server-side login.
 - **`com.ibm.websphere.security.auth.callback.WSStdinCallbackHandlerImpl`**
Provides a `stdin` login prompt `CallbackHandler` handler to gather basic authentication data (user ID, password, and security realm). This API is recommended for client-side login.
 - **Note:** If this API is used on the server side, the server is blocked for input.
 - `javax.security.auth.callback.Callback` interface:
 - **`javax.security.auth.callback.NameCallback`**
Provided by JAAS to pass the user name to the `LoginModules` interface.
 - **`javax.security.auth.callback.PasswordCallback`**
Provided by JAAS to pass the password to the `LoginModules` interface.
 - **`com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl`**
Provided by the product to perform a token-based login. With this API, an application can pass a token-byte array to the `LoginModules` interface.
 - **`javax.security.auth.spi.LoginModule` interface**
WebSphere Application Server provides a `LoginModules` implementation for client and server-side login. Refer to the *Securing applications and their environment* PDF for details.
- `javax.security.Subject`:

com.ibm.websphere.security.auth.WSSubject

An extension provided by the product to invoke remote J2EE resources using the credentials in the `javax.security.Subject`

An application must invoke the `WSSubject.doAs` method for J2EE resources access using the subject that is generated by an explicit invocation of a WebSphere Application Server login module.

com.ibm.websphere.security.cred.WSCredential

After a successful JAAS login with the WebSphere Application Server LoginModules interfaces, a `com.ibm.websphere.security.cred.WSCredential` credential is created and stored in the Subject.

com.ibm.websphere.security.auth.WSPincipal

An authenticated principal that is created and stored in a Subject that is authenticated by the WebSphere Application Server LoginModules interface.

Procedure

Use the following example to migrate the CORBA-based programmatic login APIs to the JAAS programmatic login APIs.

The following example assumes that the application code is granted for the required Java 2 security permissions. For more information, see the *Securing applications and their environment* PDF and the JAAS documentation located at <http://www.ibm.com/developerworks/java/jdk/security/>.

```
public class TestClient {
    ...
    private void performLogin() {
        // Create a new JAAS LoginContext.
        javax.security.auth.login.LoginContext lc = null;

        try {
            // Use GUI prompt to gather the BasicAuth data.
            lc = new javax.security.auth.login.LoginContext("WSLogin",
                new com.ibm.websphere.security.auth.callback.WSGUICallbackHandlerImpl());

            // create a LoginContext and specify a CallbackHandler implementation
            // CallbackHandler implementation determine how authentication data is collected
            // in this case, the authentication date is collected by login prompt
            // and pass to the authentication mechanism implemented by the LoginModule.
        } catch (javax.security.auth.login.LoginException e) {
            System.err.println("ERROR: failed to instantiate a LoginContext and the exception: "
                + e.getMessage());
            e.printStackTrace();

            // may be javax.security.auth.AuthPermission "createLoginContext" is not granted
            // to the application, or the JAAS Login Configuration is not defined.
        }

        if (lc != null)
            try {
                lc.login(); // perform login
                javax.security.auth.Subject s = lc.getSubject();
                // get the authenticated subject

                // Invoke a J2EE resources using the authenticated subject
                com.ibm.websphere.security.auth.WSSubject.doAs(s,
                    new java.security.PrivilegedAction() {
                        public Object run() {
                            try {
                                bankAccount.deposit(100.00); // where bankAccount is an protected EJB
                            } catch (Exception e) {
                                System.out.println("ERROR: error while accessing EJB resource, exception: "
                                    + e.getMessage());
                                e.printStackTrace();
                            }
                        }
                    });
                return null;
            }
        }
    }
}
```

```

);

// Retrieve the name of the principal from the Subject
// so we can tell the user that login succeeded,
// should only be one WSPrincipal.
java.util.Set ps =
s.getPrincipals(com.ibm.websphere.security.auth.WSPrincipal.class);
java.util.Iterator it = ps.iterator();
while (it.hasNext()) {
com.ibm.websphere.security.auth.WSPrincipal p =
(com.ibm.websphere.security.auth.WSPrincipal) it.next();
System.out.println("Principal: " + p.getName());
}
} catch (javax.security.auth.login.LoginException e) {
System.err.println("ERROR: login failed with exception: " + e.getMessage());
e.printStackTrace();

// login failed, might want to provide relogin logic
}
}
...
}

```

Migrating from the CustomLoginServlet class to servlet filters

Use this topic to allow migration in an application that uses form-based login and servlet filters without the use of the CustomLoginServlet class.

Before you begin

The CustomLoginServlet class is deprecated in WebSphere Application Server Version 5. Those applications using the CustomLoginServlet class to perform authentication now need to use form-based login. Using the form-based login mechanism, you can control the look and feel of the login screen. In form-based login, a login page is specified and displays when retrieving the user ID and password information. You also can specify an error page that displays when authentication fails.

If login and error pages are not enough to implement the CustomLoginServlet class, use servlet filters. Servlet filters can dynamically intercept requests and responses to transform or use the information that is contained in the requests or responses. One or more servlet filters attach to a servlet or a group of servlets. Servlet filters also can attach to JavaServer Pages (JSP) files and HTML pages. All the attached servlet filters are called before invoking the servlet.

Both form-based login and servlet filters are supported by any Servlet 2.3 specification-compliant web container. A form login servlet performs the authentication and servlet filters can perform additional authentication, auditing, or logging tasks.

To perform pre-login and post-login actions using servlet filters, configure these servlet filters for either form login page or for /j_security_check URL. The j_security_check is posted by the form login page with the j_username parameter that contains the user name and the j_password parameter that contains the password. A servlet filter can use user name and password information to perform more authentication or meet other special needs.

Procedure

1. Develop a form login page and error page for the application.
Refer to the *Securing applications and their environment* PDF for details.
2. Configure the form login page and the error page for the application.
Refer to the *Securing applications and their environment* PDF for details.
3. Develop servlet filters if additional processing is required before and after form login authentication.
Refer to the *Securing applications and their environment* PDF for details.

4. Configure the servlet filters that are developed in the previous step for either the form login page URL or for the `/j_security_check` URL. Use an assembly tool or development tools like Rational Application Developer to configure filters. After configuring the servlet filters, the `web.xml` file contains two stanzas. The first stanza contains the servlet filter configuration, the servlet filter, and its implementation class. The second stanza contains the filter mapping section and a mapping of the servlet filter to the URL. For more information, see the *Securing applications and their environment* PDF.

Results

This migration results in an application that uses form-based login and servlet filters without the use of the `CustomLoginServlet` class.

What to do next

The new application uses form-based login and servlet filters to replace the `CustomLoginServlet` class. Servlet filters also are used to perform additional authentication, auditing, and logging.

Migrating Java 2 security policy

Use this topic for guidance pertaining to migrating Java 2 security policy.

About this task

Previous WebSphere Application Server releases

WebSphere Application Server uses the Java 2 security manager in the server runtime to prevent enterprise applications from calling the `System.exit` and the `System.setSecurityManager` methods. These two Java application programming interfaces (API) have undesirable consequences if called by enterprise applications. The `System.exit` API, for example, causes the Java virtual machine (application server process) to exit prematurely, which is not a beneficial operation for an application server.

To support Java 2 security properly, all the server runtime must be marked as privileged (with `doPrivileged` API calls inserted in the correct places), and identify the default permission sets or policy. Application code is not privileged and subject to the permissions that are defined in the policy files. The `doPrivileged` instrumentation is important and necessary to support Java 2 security. Without it, the application code must be granted the permissions that are required by the server runtime. This situation is due to the design and algorithm that is used by Java 2 security to enforce permission checks. Refer to the Java 2 security check permission algorithm.

The following two permissions are enforced by the Java 2 security manager (hard coded) for WebSphere Application Server:

- `java.lang.RuntimePermission(exitVM)`
- `java.lang.RuntimePermission(setSecurityManager)`

Application code is denied access to these permissions regardless of what is in the Java 2 security policy. However, the server runtime is granted these permissions. All the other permission checks are not enforced.

Only two permissions are supported:

- `java.net.SocketPermission`
- `java.net.NetPermission`

However, not all the product server runtime is properly marked as privileged. You must grant the application code all the other permissions besides the two listed previously or the enterprise application can potentially fail to run. This Java 2 security policy for enterprise applications is liberal.

What changed

Java 2 Security is fully supported in WebSphere Application Server, which means that all permissions are enforced. The default Java 2 security policy for an enterprise application is the recommended permission set defined by the Java Platform, Enterprise Edition (Java EE) Version 1.4 specification. Refer to the *profile_root/config/cells/cell_name/nodes/node_name/app.policy* file for the default Java 2 security policy that is granted to enterprise applications. This policy is a much more stringent compared to previous releases.

All policy is declarative. The product security manager honors all policy that is declared in the policy files. There is an exception to this rule: enterprise applications are denied access to permissions that are declared in the *profile_root/config/cells/cell_name/filter.policy* file.

Note: The default Java 2 security policy for enterprise applications is much more stringent and all the permissions are enforced in WebSphere Application Server Version 8.0. The security policy might fail because the application code does not have the necessary permissions granted where system resources, such as file I/O, can be programmatically accessed and are now subject to the permission checking.

In application code, do not use the `setSecurityManager` permission to set a security manager. When an application uses the `setSecurityManager` permission, there is a conflict with the internal security manager within WebSphere Application Server. If you must set a security manager in an application for RMI purposes, you also must enable the **Use Java 2 security to restrict application access to local resources** option on the Global security page within the WebSphere Application Server administrative console. WebSphere Application Server then registers a security manager. The application code can verify that this security manager is registered by using `System.getSecurityManager()` application programming interface (API).

Migrating system properties

The following system properties are used in previous releases in relation to Java 2 security:

- **java.security.policy.** The absolute path of the policy file (action required). This system property contains both system permissions (permissions granted to the Java virtual machine (JVM) and the product server runtime) and enterprise application permissions. Migrate the Java 2 security policy of the enterprise application to Version 8.0. For Java 2 security policy migration, see the steps for migrating Java 2 security policy.
- **enableJava2Security.** Used to enable Java 2 security enforcement (no action required). This system property is deprecated; a flag in the WebSphere configuration application programming interface (API) is used to control whether to enable Java 2 security. Enable this option through the administrative console.
- **was.home.** Expanded to the installation directory of WebSphere Application Server (action might be required). This system property is deprecated; superseded by the `${user.install.root}` and `${was.install.root}` properties. If the directory contains instance-specific data then `${user.install.root}` is used; otherwise `${was.install.root}` is used. Use these properties interchangeably for the WebSphere Application Server or the WebSphere Application Server, Network Deployment environments. See the steps for migrating Java 2 security policy.

Migrating the Java 2 Security Policy

No easy way exists to migrate the Java policy file to Version 8.0 automatically because of a mixture of system permissions and application permissions in the same policy file. Manually copy the Java 2 security policy for enterprise applications to a `was.policy` or `app.policy` file. However, migrating the Java 2 security policy to a `was.policy` file is preferable because symbols or relative code base is used instead of an absolute code base. This process has many advantages. Grant the permissions that are defined in the `was.policy` to the specific enterprise application only, while permissions in the `app.policy` file apply to all the enterprise applications that run on the node where the `app.policy` file belongs.

Refer to the *Securing applications and their environment* PDF for more details on policy management.

The following example illustrates the migration of a Java 2 security policy from a previous release. The contents include the Java 2 security policy file for the app1.ear enterprise application and the system permissions, which are permissions that are granted to the Java virtual machine (JVM) and the product server runtime.

The default location for the Java 2 security policy file is *profile_root/properties/java.policy*. Default permissions are omitted for clarity:

```
// For product Samples
grant codeBase "file:${app_server_root}/installedApps/app1.ear/-" {
    permission java.security.SecurityPermission "printIdentity";
    permission java.io.FilePermission "${app_server_root}${/}temp${/}somefile.txt",
        "read";
};
```

For clarity of illustration, all the permissions are migrated as the application level permissions in this example. However, you can grant permissions at a more granular level at the component level (Web, enterprise beans, connector or utility Java archive (JAR) component level) or you can grant permissions to a particular component.

Procedure

1. Ensure that Java 2 security is disabled on the application server.
2. Create a new was.policy file, if the file is not present, or update the was.policy file for migrated applications in the configuration repository with the following contents:

```
grant codeBase "file:${application}" {
    permission java.security.SecurityPermission "printIdentity";
    permission java.io.FilePermission "
        ${user.install.root}${/}temp${/}somefile.txt", "read";
};
```

The third and fourth lines in the previous code sample are presented on two lines for illustrative purposes only.

The was.policy file is located in the *profile_root/config/cells/cell_name/applications/app.ear/deployments/app/META-INF/* directory.

3. Use an assembly tool to attach the was.policy file to the enterprise archive (EAR) file. You also can use an assembly tool to validate the contents of the was.policy file. For more information, see the *Securing applications and their environment* PDF.
4. Validate that the enterprise application does not require additional permissions to the migrated Java 2 security permissions and the default permissions set declared in the *\${user.install.root}/config/cells/cell_name/nodes/node_name/app.policy* file. This validation requires code review, code inspection, application documentation review, and sandbox testing of migrated enterprise applications with Java 2 security enabled in a preproduction environment. Refer to developer kit APIs protected by Java 2 security for information about which APIs are protected by Java 2 security. If you use third-party libraries, consult the vendor documentation for APIs that are protected by Java 2 security. Verify that the application is granted all the required permissions, or it might fail to run when Java 2 security is enabled.
5. Perform preproduction testing of the migrated enterprise application with Java 2 security enabled. Enable trace for the WebSphere Application Server Java 2 security manager in a preproduction testing environment with the following trace string: `com.ibm.ws.security.core.SecurityManager=all=enabled`. This trace function can be helpful in debugging the `AccessControlException` exception that is created when an application is not granted the required permission or some system code is not properly marked as privileged. The trace dumps the stack trace and permissions that are granted to the classes on the call stack when the exception is created.

For more information, see the *Securing applications and their environment* PDF.

Note: Because the Java 2 security policy is much more stringent compared with previous releases, the administrator or deployer must review their enterprise applications to see if extra

permissions are required before enabling Java 2 security. If the enterprise applications are not granted the required permissions, they fail to run.

Migrating with Tivoli Access Manager for authentication enabled on a single node

When Tivoli Access Manager security is configured for your existing environment and security is enabled for a single node, you can migrate to WebSphere Application Server, Version 8.0.

Before you begin

Your profiles must be migrated using the migration tools to migrate product configurations.

Important: Do not restart the WebSphere Application Server Version 8.0 server until after performing the following procedure. The migration tools omit some files that enable the server to start correctly.

About this task

After migrating your profiles, additional steps are required when Tivoli Access Manager security is configured.

Note: WebSphere Application Server Version 8.0 hosts Tivoli Access Manager specific files under the %WAS_HOME%/tivoli/tam directory. In previous versions, these files were hosted under the %WAS_HOME%/java/jre/ hierarchy.

Note: In the following steps, %WASX% refers to the installation root of the source WebSphere Application Server product, and %WAS8% refers to the installation root of the target WebSphere Application Server product (the Version 8.0 installation root).

Procedure

1. Copy the following files from the source location to target location.

Table 74. Files to copy from the source location to the target location. Files to copy from the source location to the target location

Source Location	Target Location
%WASX%\java\jre\PDPerm.properties	%WAS8%\tivoli\tam\PDPerm.properties
%WASX%\java\jre\lib\security\PdPerm.ks (if found)	%WAS8%\tivoli\tam\lib\security\PdPerm.ks
%WASX%\java\jre\lib\PdPerm.ks (if found)	%WAS8%\tivoli\tam\PdPerm.ks
%WASX%\java\jre\PolicyDirector\PDCA.ks	%WAS8%\tivoli\tam\PolicyDirector\PDCA.ks
%WASX%\java\jre\PolicyDirector\PD.properties	%WAS8%\tivoli\tam\PolicyDirector\PD.properties
%WASX%\java\jre\PolicyDirector\etc\pdjrte_paths	%WAS8%\tivoli\tam\PolicyDirector\etc\pdjrte_paths
%WASX%\java\jre\PolicyDirector\etc\pdjrte_mapping	%WAS8%\tivoli\tam\PolicyDirector\etc\pdjrte_mapping

2. Edit the PD.properties file, and change the following configuration settings:

```
appsvr-plcysvrs=null\0:0:1
config_type=standalone
```

Make the appropriate changes to point to your Tivoli Access Manager Policy Server, for example:

```
appsvr-plcysvrs=pdmgrd.test.gc.au.ibm.com:7135:1
config_type=full
```

3. Edit the following four files on the target system and make sure that all of the path references are corrected:

- %WAS8%/tivoli/tam/PdPerm.properties
- %WAS8%/tivoli/tam/PolicyDirector/PD.properties
- %WAS8%/tivoli/tam/PolicyDirector/etc/pdjrte_paths
- %WAS8%/tivoli/tam/PolicyDirector/etc/pdjrte_mapping

When you correct the paths, complete the following steps in order:

- a. Ensure that all references from %WASX%/java/jre/PolicyDirector are changed to %WAS8%/tivoli/tam/PolicyDirector.
- b. Ensure that all references (in the PdPerm.properties file) from the %WASX%/java/jre/[security]/PdPerm.ks file are changed to %WAS8%/tivoli/tam/pdPerm.ks.
- c. Ensure that all remaining references from %WASX%/java/jre are changed to %WAS8%/java/jre.
- d. Edit the %WAS8%/tivoli/tam/PolicyDirector/etc/pdjrte_mapping file. It contains the JRE->JRE mapping: %WAS8%/java/jre=%WAS8%/java/jre.

Change this mapping to JRE->tivoli/tam: %WAS8%/java/jre=%WAS8%/tivoli/tam.

What to do next

Also see Migrating with Tivoli Access Manager for authentication enabled on multiple nodes for more information.

Migrating with Tivoli Access Manager for authentication enabled on multiple nodes

When Tivoli Access Manager security is configured for your existing environment and security is enabled for multiple nodes, you can migrate to WebSphere Application Server, Version 8.0.

Before you begin

Your profiles must be migrated using the migration tools to migrate product configurations.

Important: Do not restart the WebSphere Application Server Version 8.0 server until after performing the following procedure. The migration tools omit some files that enable the server to start correctly.

About this task

After migrating your profiles, additional steps are required when Tivoli Access Manager security is configured.

Note: WebSphere Application Server Version 8.0 hosts Tivoli Access Manager specific files under the %WAS_HOME%/tivoli/tam directory. In previous versions, these files were hosted under the %WAS_HOME%/java/jre/ hierarchy.

Note: In the following steps, %WASX% refers to the installation root of the source WebSphere Application Server product, and %WAS8% refers to the installation root of the target WebSphere Application Server product (the Version 8.0 installation root).

Migration in a multi-node environment involves migrating individual nodes, starting with the deployment manager. The following procedure discuss both the overall migration steps and the host-specific migration steps.

Procedure

1. For the overall migration steps, do the following:
 - a. On the deployment manager (host1) perform the host specific migration steps as described in step 2 below.
 - b. Start the deployment manager.
 - c. For each of the application server node/hosts (such as host2, host3 and so on), do the following:
 - Perform the host specific migration steps as described in step 2 below.
 - Start the node-agent and associated application server on the respective host.
2. For the host specific migration steps, do the following:

- a. Copy the following files from the source location to the target location:

Table 75. Files to copy from the source location to the target location. Files to copy from the source location to the target location

Source Location	Target Location
%WASX%\java\jre\PDPerm.properties	%WAS8%\tivoli\tam\PDPerm.properties
%WASX%\java\jre\lib\security\PdPerm.ks (if found)	%WAS8%\tivoli\tam\lib\security\PdPerm.ks
%WASX%\java\jre\lib\PdPerm.ks (if found)	%WAS8%\tivoli\tam\PdPerm.ks
%WASX%\java\jre\PolicyDirector\PDCA.ks	%WAS8%\tivoli\tam\PolicyDirector\PDCA.ks
%WASX%\java\jre\PolicyDirector\PD.properties	%WAS8%\tivoli\tam\PolicyDirector\PD.properties
%WASX%\java\jre\PolicyDirector\etc\pdjrte_paths	%WAS8%\tivoli\tam\PolicyDirector\etc\pdjrte_paths
%WASX%\java\jre\PolicyDirector\etc\pdjrte_mapping	%WAS8%\tivoli\tam\PolicyDirector\etc\pdjrte_mapping

- b. Edit the PD.properties file, and change the following configuration settings:

```
appsvr-plcysvrs=null\:\:0:\:1
config_type=standalone
```

Make the appropriate changes to point to your Tivoli Access Manager Policy Server, for example:

```
appsvr-plcysvrs=pdmgrd.test.gc.au.ibm.com\:\:7135\:\:1
config_type=full
```

- c. Edit the following four files on the target system and make sure that all of the path references are corrected:

- %WAS8%/tivoli/tam/PdPerm.properties
- %WAS8%/tivoli/tam/PolicyDirector/PD.properties
- %WAS8%/tivoli/tam/PolicyDirector/etc/pdjrte_paths
- %WAS8%/tivoli/tam/PolicyDirector/etc/pdjrte_mapping

When you correct the paths, complete the following steps in order:

- 1) Ensure that all references from %WASX%/java/jre/PolicyDirector are changed to %WAS8%/tivoli/tam/PolicyDirector.
- 2) Ensure that all references (in the PdPerm.properties file) from the %WASX%/java/jre/[security]/PdPerm.ks file are changed to %WAS8%/tivoli/tam/pdPerm.ks.
- 3) Ensure that all remaining references from %WASX%/java/jre are changed to %WAS8%/java/jre.
- 4) Edit the %WAS8%/tivoli/tam/PolicyDirector/etc/pdjrte_mapping file. It contains the JRE->JRE mapping: %WAS8%/java/jre=%WAS8%/java/jre.

Change this mapping to JRE->tivoli/tam: %WAS8%/java/jre=%WAS8%/tivoli/tam.

What to do next

Also see Migrating with Tivoli Access Manager for authentication enabled on a single node for more information.

Migrating unrestricted jurisdiction policy files, local_policy.jar and US_export_policy.jar

You can migrate the unrestricted jurisdiction policy files, local_policy.jar and US_export_policy.jar.

About this task

If you want to use encryption keys that are greater than 128-bits, you must use the unrestricted jurisdiction policy files, local_policy.jar and US_export_policy.jar.

The files are located in the [WAS_HOME/java/lib/security directory.

If your back-level version of WebSphere Application Server is using the unrestricted jurisdiction policy files, you must perform special steps to migrate these files to your new version of WebSphere Application Server. If you are not using the unrestricted jurisdiction policy files, you do not need to take any action.

Procedure

1. Before migrating, copy the modified `local_policy.jar` file to a temporary location.
2. Migrate the WebSphere Application Server installation.
3. Mount the new product HFS as read/write.
4. Copy the modified `local_policy.jar` file from step 1 to the following directory on the new WebSphere Application Server installation: `WAS_HOME/java/lib/security`.
5. Mount the new product HFS as read-only.
6. Start the new WebSphere Application Server installation as normal.

Preparing for security at installation time

Complete the following tasks to implement security before, during, and after installing WebSphere Application Server.

Procedure

1. Install WebSphere Application Server. This step describes how to install WebSphere Application Server on the z/OS platform. For more information, see "Installing the product and additional software" in the InfoCenter.
2. Migrate security configurations from previous releases during installation, when you are prompted to do so. This step describes how to migrate security configurations from a previous release of WebSphere Application Server to WebSphere Application Server Version 8.0.
For more information, see "Migrating product configurations" in the InfoCenter.
3. If you go into the advanced profile creation, a panel is available for changing the default settings for your certificate, a *root certificate* (used to sign your personal certificate) and a *personal certificate* (used to sign/encrypt data over the network). Ensure that the root certificate has a long lifetime and the personal certificate a shorter one. Import your own personal certificate and or root certificate. If your personal certificate is signed by the certificate authority (CA), it is not important to change your root certificate. You should also change the default keystore password to something more secure.
4. Optional: During customization of a stand-alone application server or WebSphere Application Server, Network Deployment cell, you can enable administrative security "out of the box" by using either a z/OS security product or WebSphere Application Server to manage users, groups, and the security policy.
5. Secure your environment after installation. This step provides information on how to protect password information after you install WebSphere Application Server. For more information, see "Securing your environment after installation."
6. For information about enabling security after customization is complete, see "Enabling security" on page 1230.

Securing your environment after installation

WebSphere Application Server depends on several configuration files that are created during installation. These files contain password information and need protection. Although the files are protected to a limited degree during installation, this basic level of protection is probably not sufficient for your site. You should verify that these files are protected in compliance with the policies of your site.

Before you begin

Note: A Kerberos keytab configuration file contains a list of keys that are analogous to user passwords. The default keytab file is `krb5.keytab`. It is important for hosts to protect their Kerberos keytab files by storing them on the local disk, which makes them readable only by authorized users.

The files in the *WAS_HOME/config* and the *WAS_HOME/properties* directories need protection. For example, give permission to the user who logs onto the system for WebSphere Application Server primary administrative tasks. Other users or groups, such as WebSphere Application Server console users and console groups need permissions as well.

The files in the *WAS_HOME/properties* directory that must be readable by everybody are:

- TraceSettings.properties
- client.policy
- client_types.xml
- ipc.client.props
- sas.client.props
- sas.stdclient.properties
- sas.tools.properties
- soap.client.props
- wsadmin.properties
- wsjaas_client.conf

The value for *WAS_HOME* directory is specified in the WebSphere z/OS Profile Management Tool or the **zpm**t command when WebSphere Application Server for z/OS is installed, for both the base product and WebSphere Application Server, Network Deployment.

Procedure

Secure files on WebSphere Application Server for z/OS systems.

1. Use the WebSphere z/OS Profile Management Tool or the **zpm**t command and follow the generated instructions to customize your system.

The customization jobs that are generated perform the following functions:

- Create System Authorization Facility (SAF) WebSphere Application Server user IDs that are needed for administrator and server processes.
- Create a SAF WebSphere Application Server configuration group and add the SAF WebSphere Application Server user IDs.
- Provide a mapping from a Java 2, Enterprise Edition (J2EE) principal to SAF user ID. You can generate a sample mapping module or you can specify one that you created yourself.
- Associate WebSphere Application Server-started tasks with the SAF user IDs and groups that are defined previously.
- Populate the file system with the system and property files that are needed to run WebSphere Application Server.
- Change the ownership of these files to the WebSphere Application Server administrator.
- Create the appropriate file permissions.

All files in the *WAS_HOME/config* directory must have write and read access by all the members of the WebSphere Application Server configuration group, but must not be accessible by everyone (mode 770). All files in the *WAS_HOME/properties* directory must have write and read access by all the members of the WebSphere Application Server configuration group. Set the access permissions for the following files as it pertains to your security guidelines:

- TraceSettings.properties
- client.policy
- client_types.xml
- ipc.client.props
- sas.client.props
- sas.stdclient.properties
- sas.tools.properties

- soap.client.props
- wsadmin.properties
- wsjaas_client.conf

For example, you might issue the following command: `chmod 775 file_name`. *file_name* is the name of the file listed previously. These files contain sensitive information such as passwords.

Note: If you enabled Kerberos authentication or SPNEGO web authentication, set the access permissions for the following files as it pertains to your security guidelines: the Kerberos configuration file (**krb5.conf** or **krb5.ini**) and the Kerberos keytab file.

2. Add administrators who perform full or partial WebSphere Application Server administration tasks to the configuration group.
3. Restrict access to the `/var/mqm` directories and the log files that are needed for WebSphere Application Server embedded messaging or WebSphere MQ as the JMS provider. Give write access only to the mqm user ID or members of the mqm user group.

Results

After securing your environment, only the users with permission can access the files. Failure to adequately secure these files can lead to a breach of security in your WebSphere Application Server applications.

What to do next

If failures occur that are caused by file accessing permissions, check the permission settings.

WebSphere Application Server security for z/OS

WebSphere Application Server for z/OS supports access to resources by clients and servers in a distributed environment. Determine how to control access to these resources and prevent inadvertent or malicious destruction of the system or data.

These are the pieces in the distributed network that you must consider:

- You must authorize servers to the base operating system services in z/OS. These services include System Authorization Facility (SAF) security, database management, and transaction management.
 - For the server clusters, you must distinguish between controllers and servants. Controllers run authorized system code, so they are trusted. Servants run application code and are given access to resources, so carefully consider the authorization you give servants.
 - You must also distinguish between the level of authority for run-time servers and for your own application servers have. For example, the node needs the authority to start other clusters, while your own application clusters do not need this authority.
- You must authorize clients (users) to servers and objects within servers. The characteristics of each client requires special consideration:
 - Is the client on the local system or is it remote? The security of the network becomes a consideration for remote clients.
 - Will you allow unidentified (unauthenticated) clients to access the system? Some resources on your system might be intended for public access, while others you might need to protect. To access protected resources, clients must establish their identities and have authorization to use those resources.
- *Authentication* is the process of establishing the identity of a client in a particular context. A client can be an end user, a machine, or an application. The term authentication mechanism in WebSphere Application Server on z/OS refers more specifically to the facility in which WebSphere identifies an authenticated identity, using HTTP and Java Management Extensions (JMX) facilities. When configuring a cell, you must select an authentication mechanism. The choices for authentication mechanism include:
 - Simple WebSphere Authorization Mechanism (SWAM) - only on Base Application Server, not available on the Network Deployment configuration

Note: SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

- Lightweight Third Party Authentication (LTPA)
- Kerberos
- Information about users and groups reside in a user registry. In WebSphere Application Server, a user registry authenticates a user and retrieves information about users and groups to perform security-related functions, including authentication and authorization. Implementation is provided to support multiple operating system or operating environment-based user registries. When configuring a cell, you must select a single user registry. The user registry can be local or remote. The choices for user registry include:
 - SAF-based local registry (default when a z/OS security product is chosen for administrative security during customization)
 - Standalone Lightweight Directory Access Protocol (LDAP) registry - LDAP can be either a local or remote registry
 - Stand-alone custom user registry - A custom user registry is set up to meet unique registry needs. WebSphere Application Server provides a simple user registry sample called the FileBasedRegistrySample.
 - Federated repositories (default when the WebSphere Application Server is chosen for administrative security during customization)

If you need to protect resources, it is critical that you identify who accesses those resources. Thus, any security system requires client (user) identification, also known as authentication. In a distributed network supported by WebSphere Application Server for z/OS, clients can access resources from:

- Within the same system as a server
- Within the same sysplex as the server
- Remote z/OS systems
- Heterogeneous systems, such as WebSphere Application Server on distributed platforms, Customer Information Control System (CICS), or other Java Platform, Enterprise Edition-compliant systems.

Additionally, clients can request a service that requires a server to forward the request to another cluster. In such cases, the system must handle delegation, the availability of the client identity for use by intermediate clusters and target clusters.

Finally, in a distributed network, how do you verify that messages being passed are confidential and have not been tampered? How do you verify that clients are who they claim to be? How do you map network identities to z/OS identities? These issues are addressed by the following support in WebSphere Application Server for z/OS:

- The use of Secure Sockets Layer (SSL) and digital certificates
- Kerberos
- Common Secure Interoperability, Version 2 (CSIv2)
- Simple and Protected GSS-API Negotiation Mechanism (SPNEGO)
- Distributed identity mapping feature in SAF

z/OS Profile Management Tool security settings:

The z/OS Profile Management Tool allows you to specify System Authorization Facility (SAF) profile prefixes (previously referred to as z/OS security domains) for your WebSphere Application Server for z/OS configuration.

Note:

- You must set up a base Application Server using the WebSphere z/OS Profile Management Tool or the **zpm**t command before using the Application Server to set up a WebSphere Application Server, Network Deployment node, which is managed by the deployment manager process (dmgr). It is critical that you **LOAD** saved environment variables from the base Application Server into the deployment manager node that federates the base node. Do this before performing security customization on the deployment manager node.

- If the APPL class is active and you have defined a profile for WebSphere Application Server, make sure that all z/OS identities using WebSphere Application Server services have READ permission to the WebSphere Application Server APPL profile. This includes all WebSphere Application Server identities, WebSphere Application Server unauthenticated identities, WebSphere Application Server administrative identities, user IDs based on role-to-user mappings, and all user identities for system users. If you have not specified a SAF profile prefix, the APPL profile used is CBS390 or the name used as the SAF profile prefix. If you have specified a SAF profile prefix, the APPL profile used. When adding an administrator to the administrative console using local operating system security, if the APPL class is activated, the administrator's user ID must be authorized to the CBS390 (or the name specified as the SAF profile prefix) APPL class for RACF as well. If the administrator's user ID is not authorized to CBS390 APPL, message BBOS0108E is issued, indicating that the credential-handling function (RunAsGetSpecCred) failed in routine because the user is not authorized.
- Once a profile is created, it is possible to control checking the APPL class profile from the administrative console by navigating to the SAF authorization options panel and by configuring the check box labeled "Use APPL profile to restrict access to the server".

SAF profile prefixes and the customization jobs:

You can configure a System Authorization Facility (SAF) profile prefix (previously referred to as a z/OS security domain) by using the z/OS Profile Management Tool.

An SAF profile prefix allows an installation to add a prefix to the SAF profiles that represent their roles. For example, an installation can define SAF class EJBRole and a SAF profile of myPrefix.administrator. A SAF profile prefix can be defined for the entire cell or it can be defined at the WebSphere security domain-level granularity of security permissions. SAF profile prefixes:

- Provide WebSphere security domain-level granularity of roles
- Allow different administrators to be assigned for test and production
- Are used as the APPL profile for servers in the WebSphere security domain

You can configure a SAF profile prefix by using the z/OS Profile Management Tool to customize your settings or on the SAF authorization options panel in the administrative console. This provides a new sample set of Resource Access Control Facility (RACF) customization jobs that must only be run once when the domain is created.

The RACF profiles that are created and checked differently because of this are:

- CBIND
- EJBROLE
- APPL

Use CBIND profiles to restrict access to servers if no other specific profile is set. If there is no SAF profile prefix, enter the following RACF commands:

```
/* CBIND profiles in case no server definition is set      */
"RDEFINE CBIND CB.BIND.* UACC(NONE)"
"RDEFINE CBIND CB.* UACC(NONE)"
```

If there is a SAF profile prefix defined as TESTSYS, enter:

```
/* CBIND CB.BIND.domain_name.                            */
"RDEFINE CBIND CB.BIND.TESTSYS.* UACC(NONE)"
"RDEFINE CBIND CB.TESTSYS.* UACC(NONE)"
```

Use an APPL profile to protect WebSphere Application Server for z/OS. Sample profiles can grant a certain level of APPL access to everyone if you use the universal access authority, UACC, and grant access to the configuration group, unauthenticated user IDs, and all valid WebSphere Application Server for z/OS user IDs. A UACC(NONE) will give a default access of NONE to everyone. You can control

whether the APPL class profile is used for authorization by setting the checkbox labeled "Use APPL profile to restrict access to the server" on the SAF authorization options panel in the administrative console.

For example, if there is no SAF profile prefix, enter the following RACF commands:

```
RDEFINE APPL CB390 UACC(NONE)
PERMIT CB390 CLASS(APPL) ID(TSCLGP) ACCESS(READ)
```

And if there is a SAF profile prefix defined as TESTSYS, for example, enter:

```
RDEFINE APPL TESTSYS UACC(NONE)
PERMIT TESTSYS CLASS(APPL) ID(TSCLGP) ACCESS(READ)
```

The following EJBROLE profiles are defined for role-based authorization checks if there is no SAF profile prefix and the configuration group is defined as TSTCFG. Note that these are the minimum set of users requiring access to naming and administrative roles when System Authorization Facility (SAF) authorization is selected.

The following roles must be defined for both operating system and application security. Enter the following RACF commands:

```
RDEFINE EJBROLE administrator UACC(NONE)
RDEFINE EJBROLE monitor UACC(NONE)
RDEFINE EJBROLE configurator UACC(NONE)
RDEFINE EJBROLE operator UACC(NONE)
RDEFINE EJBROLE deployer UACC(NONE)
RDEFINE EJBROLE adminsecuritymanager UACC(NONE)
RDEFINE EJBROLE auditor UACC(NONE)

PERMIT administrator CLASS(EJBROLE) ID(TSTCFG) ACCESS(READ)
PERMIT auditor CLASS(EJBROLE) ID(TSTCFG) ACCESS(READ)
PERMIT adminsecuritymanager CLASS(EJBROLE) ID(TSTCFG) ACCESS(READ)

/* Setting up EJBRoles Profiles for Naming roles */
RDEFINE EJBROLE CosNamingRead UACC(NONE)
PERMIT CosNamingRead CLASS(EJBROLE) ID(TSGUEST) ACCESS(READ)
RDEFINE EJBROLE CosNamingWrite UACC(NONE)
PERMIT CosNamingWrite CLASS(EJBROLE) ID(TSGUEST) ACCESS(READ)
RDEFINE EJBROLE CosNamingCreate UACC(NONE)
PERMIT CosNamingCreate CLASS(EJBROLE) ID(TSGUEST) ACCESS(READ)
RDEFINE EJBROLE CosNamingDelete UACC(NONE)
PERMIT CosNamingDelete CLASS(EJBROLE) ID(TSGUEST) ACCESS(READ)
```

If there is a SAF profile prefix defined as TESTSYS and the configuration group is defined as TSTCFG, enter the following RACF commands:

```
RDEFINE EJBROLE TESTSYS.administrator UACC(NONE)
RDEFINE EJBROLE TESTSYS.monitor UACC(NONE)
RDEFINE EJBROLE TESTSYS.configurator UACC(NONE)
RDEFINE EJBROLE TESTSYS.operator UACC(NONE)
RDEFINE EJBROLE TESTSYS.deployer UACC(NONE)
RDEFINE EJBROLE TESTSYS.adminsecuritymanager UACC(NONE)
RDEFINE EJBROLE TESTSYS.auditor UACC(NONE)

PERMIT TESTSYS.administrator CLASS(EJBROLE) ID(TSTCFG) ACCESS(READ)
PERMIT TESTSYS.auditor CLASS(EJBROLE) ID(TSTCFG) ACCESS(READ)
PERMIT TESTSYS.adminsecuritymanager CLASS(EJBROLE) ID(TSTCFG) ACCESS(READ)

/* Setting up EJBRoles Profiles for Naming roles */
RDEFINE EJBROLE TESTSYS.CosNamingRead UACC(NONE)
PERMIT TESTSYS.CosNamingRead CLASS(EJBROLE) ID(TSGUEST) ACCESS(READ)
RDEFINE EJBROLE TESTSYS.CosNamingWrite UACC(NONE)
PERMIT TESTSYS.CosNamingWrite CLASS(EJBROLE) ID(TSGUEST) ACCESS(READ)
RDEFINE EJBROLE TESTSYS.CosNamingCreate UACC(NONE)
PERMIT TESTSYS.CosNamingCreate CLASS(EJBROLE) ID(TSGUEST) ACCESS(READ)
RDEFINE EJBROLE TESTSYS.CosNamingDelete UACC(NONE)
PERMIT TESTSYS.CosNamingDelete CLASS(EJBROLE) ID(TSGUEST) ACCESS(READ)
```

CBIND profile definitions for servers

If there is no SAF profile prefix, enter the following RACF commands:

```
RDEFINE CBIND CB.BIND.BBO* UACC(NONE)
RDEFINE CBIND CB.BIND.TSTC001 UACC(NONE)
PERMIT CB.BIND.BBO* CLASS(CBIND) ID(TSTCFG) ACCESS(CONTROL)
PERMIT CB.BIND.TSTC001 CLASS(CBIND) ID(TSTCFG) ACCESS(CONTROL)
RDEFINE CBIND CB.BBO* UACC(NONE)
RDEFINE CBIND CB.TSTC001 UACC(NONE)
```

If there is a SAF profile prefix defined as TESTSYS, enter:

```
RDEFINE CBIND CB.BIND.TESTSYS.BBO* UACC(NONE)
RDEFINE CBIND CB.BIND.TESTSYS.TSTC001 UACC(NONE)
PERMIT CB.BIND.TESTSYS.BBO* CLASS(CBIND) ID(TSTCFG) ACCESS(CONTROL)
PERMIT CB.BIND.TESTSYS.TSTC001 CLASS(CBIND) ID(TSTCFG) ACCESS(CONTROL)
RDEFINE CBIND CB.TESTSYS.BBO* UACC(NONE)
RDEFINE CBIND CB.TESTSYS.TSTC001 UACC(NONE)
```

Note:

- If you wish to create a new specific server that has a jobname starting with a prefix other than BBO*, define a specific CBIND profile by entering the following RACF commands:

```
RDEFINE CBIND CB.BIND.TSTC002 UACC(NONE)
PERMIT CB.BIND.TSTC002 CLASS(CBIND) ID(TSTCFG) ACCESS(CONTROL)
RDEFINE CBIND CB.TSTC002 UACC(NONE)
```

- The samples create server definitions with specific server names (but a generic profile with a server prefix of BBO). If you have created an alternative server prefix and wish to avoid additional CBIND definitions, add generic CBIND profiles that reflect the new name by entering the following RACF commands, where TST is your server jobname prefix:

```
RDEFINE CBIND CB.BIND.TESTSYS.TST* UACC(NONE)
PERMIT CB.BIND.TESTSYS.TST* CLASS(CBIND) ID(TSTCFG) ACCESS(CONTROL)
RDEFINE CBIND CB.TESTSYS.TST* UACC(NONE)
```

Note:

- While the SAF profile prefix separates the RACF classes (CBIND, EJBROLE, APPL), it does not separate the file permissions for configuration files in the Hierarchical File System (HFS). For example, if:
 - The administrator is WSADMIN in group WSCFG
 - The Servant region identity is WASSRV (which must also belong to the WSCFG group)
 - The user TOM has READ access to the TEST.administrator EJBROLE but not to the PROD.administrator EJBROLE,TOM cannot use the administration application to make changes to the PROD cell.
- A rogue application running in the TEST application server can modify HFS files in the PROD cell. This is because the TEST server runs with the WASSRV user ID that belongs to the WSCFG group. Both the TEST and PROD HFS files can be modified by the WSCFG group. For maximum protection, PROD should be created and associated with a different RACF group from TEST. Also, consider enabling application server and z/OS thread identity synchronization. This process enables that z/OS system services, such as writing to the HFS, are performed using the Java Platform, Enterprise Edition (Java EE) identity, instead of the servant region identity. For more information, read about z/OS security options.

System Authorization Facility considerations for the operating system and application levels:

There are a few things to consider when enabling System Authorization Facility (SAF) authorization for the operating system and application levels.

With WebSphere Application Server for z/OS, authorization can happen at two different levels:

- Resources can be protected at the operating system level. If a program accesses a protected resource, the resource manager uses a call to SAF to let the security manager, typically RACF, perform an authorization check.
- Resources can be protected at the application level. If a Java Platform, Enterprise Edition (Java EE) application has a security constraint, the container will use a SAF call to let the security manager (RACF) perform an authorization check.

When SAF authorization is enabled, authorization on any level is always performed by the operating system's security manager (RACF or an equivalent product). Therefore, it is essential that users are authenticated with a security manager (RACF) user ID. Refer to "Summary of controls" on page 1204 for more information.

When SAF Authorization is selected during systems customization, administrative EJBROLE profiles for all administrative roles are defined by the RACF jobs generated using the z/OS Profile Management Tool or the **zpm**t command. SAF authorization (the use of SAF EJBROLE profiles to assign SAF users and groups to roles) can be used as an authorization mechanism for all user registries. If SAF authorization is selected on the administrative console it overrides any other authorization choice (such as Tivoli Access Manager authorization).

If you do not select local operating system, you must map the distributed identity to a SAF user id using one of two options. You can configure and install a Java Authentication and Authorization Service (JAAS) login module to perform the mapping, or in WebSphere Application Server Version 8.0 you can use the SAF distributed identity mapping feature.

Note that SAF authorization is also supported for non-local operating system registries. If you turn on SAF, it becomes the default provider (will handle naming and administration functions). Enable SAF and it becomes the native authorization provider.

For more information, refer to “Selecting a registry or repository” on page 1345.

When SAF Authorization is enabled, use SAF EJBROLE profiles to enforce Java EE roles (the profile name is the role name for the application). Additionally, you can define a SAF profile prefix, which is an eight or less character string that is prepended to every SAF EJBROLE profile name. Refer to the following articles for more information:

- “System Authorization Facility for role-based authorization” on page 1729
- “Special considerations for controlling access to naming roles using SAF authorization” on page 1737
- “Role-based authorization” on page 1707

Note that when SAF Authorization is enabled, the Everyone and All Authenticated settings are ignored. These attributes are managed in RACF. Everyone and All Authenticated are intended for WebSphere Authorization when they are enabled.

Everyone

Because no authentication is required (any user can sign on to the Web application and subjects or principals are not authenticated) for *Everyone*, RACF will return false if you do not take the following into consideration. WebSphere Application Server for z/OS uses the default (unauthenticated) user ID and uses an ACEE that checks for ACCESS(READ) access defined with the RESTRICTED attribute (the universal access authority (UACC) does not apply). If you want *Everyone* to be able to access a particular role, you must grant the default user ID READ access.

All Authenticated

You can permit any name in the user registry to sign on to the web application (All user names are authenticated when signing on). You must define UACC(READ) on the profile being accessed and do not issue the RACF PERMIT command for the default user ID.

Note: The universal access authority does not apply to users defined with the RESTRICTED attribute. For example, if you want the WebSphere unauthenticated identity to have READ access to an EJBROLE, then you must explicitly grant the id READ permission, regardless of the UACC setting.

When using a Local OS Registry, you can control access to console users .

If you decide at a future date to turn on SAF authorization, you must issue these RACF commands to enable proper WebSphere Application Server operation. (Change the value of the configured default user ID if you have chosen a different unauthenticated user ID.)

Authentication mechanisms:

After you have your system up and running, the next step in setting up security is to select an authentication mechanism. An authentication mechanism defines rules about security information (for example, whether a credential is forwardable to another Java process) and the format of how security information is stored in both credentials and tokens. Authentication is the process of establishing whether a client is valid in a particular context. A client can be either an end user, a machine, or an application.

An authentication mechanism in WebSphere Application Server typically collaborates closely with a user registry. The user registry is the user and groups accounts repository that the authentication mechanism consults with when performing authentication. The authentication mechanism is responsible for creating a credential which is an internal product representation of successfully authenticated client user. Not all credentials are created equal. The abilities of the credential are determined by the configured authentication mechanism.

Although this product provides several authentication mechanisms, only a single active authentication mechanism can be configured at once. The active authentication mechanism is selected when configuring WebSphere Application Server administrative security. WebSphere Application Server supports the following authentication mechanisms:

- Lightweight Third Party Authentication (LTPA)
- Kerberos
- Simple WebSphere Authentication Mechanism (SWAM)

Note: SWAM was deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

Specifics about identification and authentication:

For identification, each controller and servant start procedure must have its own user ID and you must define it in the STARTED class. Because you should give differing resource authorizations to each, you should give differing user IDs to controllers and servants.

Note: For identification, each controller and servant start procedure must have its own user ID and you must define it in the STARTED class. Because you should give differing resource authorizations to each, you should give differing user IDs to controllers and servants

Additional user IDs are required for installation. We provide the definitions for these user IDs in our RACF sample. See the customized instructions produced when you run the z/OS Profile Management Tool.

- User IDs for controllers and servants.
- A user ID for the Installation Verification Test (IVT) and its application cluster. Our RACF sample uses WSIVT.
- A user ID called WSADMIN used by the Administration application.
- A default local and remote user ID associated with each cluster through the administrative console. We use WSGUEST.

Regarding authentication, an operator starts a cluster by using the START command and the controller start procedure. Authentication of the start procedure's user ID is made by virtue of the fact that an operator started the start procedure—that is, no password is required. If you want to restrict an operator's ability to start clusters, do so through the OPERCMDS class in RACF.

The WAS installer automatically generates the STARTED class profile to assign the User ID to WebSphere Application Server. If you are not using AUTO UID and AUTO GID in the OMVS segment for the WebSphere Application Server STC User ID, make sure that you have UNIQUE UID and GID assigned to the WebSphere Application Server STC. If they are not unique, you might either have problems starting WebSphere Application Server or in logging in to the administrative console if admin security is enabled.

All WebSphere user ids and groups must have an OMVS segment with a valid and unique UID or GID.

Authorization checking:

Each controller, servant, and client must be associated with an MVS user ID. When a request flows from a client to the server or from a server to another server, WebSphere Application Server for z/OS passes the user identity (client or server) with the request. This way, each request is performed on behalf of the user identity and the system checks to see if the user identity has the authority to make such a request.

When security is enabled, WebSphere Application Server administrative and Java EE authorizations can be performed using the identity authenticated with the configured user registry or repository.

When the user registry or repository is configured to be the local operating system, the operating system and WebSphere Application Server identities are the same. You can configure authorization to use either WebSphere Authorization, System Authorization Facility (SAF) authorization, or a Java Authorization Contract for Containers (JACC) external provider.

Summary of controls:

Each controller, servant, and client must have its own MVS user ID. When a request flows from a client to the cluster or from a cluster to a cluster, WebSphere Application Server for z/OS passes the user identity (client or cluster) with the request. Thus, each request is performed on behalf of the user identity and the system checks to see if the user identity has the authority to make such a request. The tables in this article outline System Authorization Facility (SAF) and non-SAF authorizations.

Summary of z/OS security controls independent of administrative security setting

In a WebSphere Application Server for z/OS configuration, there are many different types of processes:

- Deployment managers
- Node agents
- Location service daemons
- WebSphere Application Servers

Each of these can be viewed as either a WebSphere Application Server for z/OS controller process or pair of processes (a controller and servant).

Each controller and servant must run under a valid MVS user ID assigned as part of the definition of a started task. This MVS user ID must have a valid UNIX Systems Services user identity (UID) and be connected to WebSphere configuration group that is common to all servers in the cell with a valid MVS and UNIX System Services group identity (GID) identity.

The following table summarizes the controls used to grant authorizations needed by these controllers and servants to access operating system resources. By understanding and using these controls, you can control all resource accesses in WebSphere Application Server for z/OS.

Table 76. Summary of controls and SAF authorizations.

This table contains a summary of controls and their SAF authorizations.

Control	Authorization
DATASET class	Access to data sets
DSNR class	Access to Database 2 (DB2)
FACILITY class (BPX.WLMSEVER)	Access to the BPX.WLMSEVER profile to perform Workload Manager (WLM) enclave management in the servant. Without this access, classification is not performed.

Table 76. Summary of controls and SAF authorizations (continued).

This table contains a summary of controls and their SAF authorizations.

Control	Authorization
FACILITY class (IMSXCF.OTMACI)	Access to Open Transaction Manager Access (OTMA) for Information Management System (IMS), and access to the BPX.WLMSEVER profile
HFS file permissions	Access to Hierarchical File System (HFS) files
LOGSTRM class	Access to log streams
OPERCMD5 class	Access to startServer.sh shell script and Integral JMSPProvider
SERVER class	Access to controller by a servant
STARTED class	Associate user ID (and optionally group ID) to start procedure
SURROGAT class (*.DFHEXCI)	Access to EXCI for Customer Information Control System (CICS) access

The WebSphere z/OS Profile Management Tool or the **zpm** command and Resource Access Control Facility (RACF) customization jobs set these up for the initial server settings for the *'ed profiles.

Note: Examples of authorizations for the other profiles can be found in the generated exec file in HLQ.DATA(BBOWBRAC). The selection of an identity to be used for authorization to native connector resources (CICS, DB2,, IMS) is dependent on the:

- Type of connector
- Resource authentication (resAuth) setting of the deployed application
- Availability of an alias
- Security setting

Resource managers such as DB2, IMS, and CICS have implemented their own resource controls, which control the ability of clients to access resources. When resource controls are used by DB2, use the DSNR RACF class (if you have RACF support) or issue the relevant DB2 GRANT statements. You can:

- Access OTMA for IMS through the FACILITY Class (IMSXCF.OTMACI)
- Access EXCI for CICS through the SURROGAT class (*.DFHEXCI)
- Control access to data sets through the DATASET class and HFS files through file permission

Note that MVS SAF Authorization to all other MVS subsystem resources accessed by J2EE applications is typically performed using the identity of the servant MVS user ID. Refer to “Java Platform, Enterprise Edition identity and an operating system thread identity” on page 1241 for more information.

The BPX.WLMSEVER profile in the FACILITY class is used to authorize an address space to use the Language Environment® (LE) run-time services that interface with workload management (WLM) to perform workload management within a server region. These LE run-time services are by used by WebSphere Application Server to extract classification information from enclaves and to manage the association of work with an Enclave. Because unauthorized interfaces are used to manipulate WLM enclaves for server region work that has not been passed from a controller to a servant, WebSphere Application Server servants should be permitted READ access to this profile. Without this permission, attempts to create, delete, join, or leave a WLM enclave fails with a `java.lang.SecurityException`.

Summary of z/OS security controls in effect when administrative and application security are enabled

When administrative and application security are enabled, SSL must be available for encryption and message protection. In addition, authentication and authorization of J2EE and administrative clients is enabled.

The FACILITY class authorization needed for SSL services and the definition of SAF keyrings are required when administrative security is enabled.

When a request flows from a client to WebSphere Application Server or from a cluster to a cluster, WebSphere Application Server for z/OS passes the user identity (client or cluster) with the request. Thus each request is performed on behalf of the user identity and the system checks to see if the user identity has the authority to make such a request. The tables in this article outline z/OS specific authorizations using SAF.

The following table summarizes the controls used to grant authorizations to resources. By understanding and using these controls, you can control access to all resources in WebSphere Application Server for z/OS.

Table 77. Summary of controls and SAF authorizations.

This table contains a summary of controls and their SAF authorizations.

Control	Authorization
CBIND class	Access to a cluster
EJBROLE or GEJBROLE class	Access to methods in enterprise beans
FACILITY class (IRR.DIGTCERT.LIST and IRR.DIGTCERT.LISTRING)	SSL key rings, certificates, and mappings
FACILITY Class (IRR.RUSERMAP)	Kerberos credentials
FACILITY Class (BBO.SYNC)	Enables Synch to OS Thread Allowed
FACILITY Class (BBO.TRUSTEDAPPS)	Enables trusted applications
SURROGAT Class (BBO.SYNC)	Enables Synch to OS Thread Allowed
PTKTDATA class	PassTicket enabling in the sysplex
Set OS Thread Identity to RunAs Identity	J2EE cluster property used to enable the start identity for non-J2EE resources

Enabling trusted applications:

From a z/OS perspective, trusted applications imply that the WebSphere Application Server started task control (STC) is to be considered a "trusted application" and is allowed to change System Authorization Facility (SAF) identity on the thread of execution. When a z/OS applications (such as WebSphere Application Server) are trusted, the security infrastructure allows the creation of MVS credentials without using a password, passticket, or certificate as an authenticator, while still preserving the integrity of the MVS system.

Through the use of the FACILITY class and BBO.TRUSTEDAPPS class profile, trusted applications (as a general rule) are needed when using SAF as the local operating system user registry or when you plan to use SAF authorization. When WebSphere Application Server is configured to use: SAF security for a local operating system user registry, SAF authorization, or Sync to Thread Allowed, trusted applications must be enabled so that MVS system integrity remains preserved. Trusted applications meet the MVS integrity rules so that unauthorized callers are NOT allowed to call sensitive WebSphere Application Server code to perform authorized functions. When using SAF, you must define the trusted application within the

Resource Access Control Facility (RACF) or an equivalent product. The SAF authorization resource rules need to define WebSphere Application Server as the trusted application with the authority to change the identity on thread execution. In this way, WebSphere Application Server and MVS can work together without jeopardizing each other's integrity.

Using FACILITY class profiles

You enable the trusted applications by ensuring that the WebSphere Application Server has SAF access of **READ** to the RACF class of FACILITY and profile of BBO.TRUSTEDAPPS.<cell short name>.<cluster short name>.

Once defined, the trusted applications need to be enabled. You use the FACILITY class profile to give the RACF administrator control over the enabling of trusted applications. The following examples illustrates how you use the FACILITY class and the BBO.TRUSTEDAPPS class profile to provide this control.

- Generic Example:

```
RDEF FACILITY BBO.TRUSTEDAPPS.**UACC(NONE)
PERMIT BBO.TRUSTEDAPPS.** CLASS(FACILITY) ID(MYCBGROUP) ACC(READ)
SETOPTS RACLIST(FACILITY) REFRESH
```

- Specific Example with a specific server identified by a cell short name of SY1, a cluster short name of BBOC001, and a controller region userid of MYSTCCR.

```
RDEF FACILITY BBO.TRUSTEDAPPS.SY1.BBOC001 UACC NONE
PERMIT BBO.TRUSTEDAPPS.SY1.BBOC001 CLASS(FACILITY) ID(MYSTCCR) ACC(READ)
SETOPTS RACLIST(FACILITY) REFRESH
```

System Authorization Facility classes and profiles:

When you are using Resource Access Control Facility (RACF) or System Authorization Facility (SAF) you must consider:

1. Using roles for enterprise beans and web applications, and servlets
2. Using RACF class profiles
 - a. Using CBIND to access servers and objects in the servers
 - b. Using SERVER to access controllers using servant regions
 - c. Using STARTED to associate user IDs and groups with started procedures
 - d. Using APPL to restrict access of authenticated users to applications in the server
 - e. Using FACILITY to establish permission to enable Synch to OS Thread Allowed and allow mapping of distributed identities to SAF identities using the JAAS mapping login modules.
 - f. Using SURROGAT to optionally establish permission to enable Synch to OS Thread Allowed
3. Creating multiple security configurations within a sysplex
4. Generating new user IDs and Profiles for a new server
5. Using minimalist profiles

Roles for Enterprise JavaBeans and web applications, and servlets

Roles are associated with Java Platform, Enterprise Edition (Java EE) applications. Modules within the applications refer to roles using the role reference that points to the application role. Access to web applications, servlets, or EJB methods is based upon the user or caller. Roles are associated with web applications, and servlets or enterprise beans at assembly time. The role needed to use a servlet or EJB method is named in the application's deployment descriptors.

Which users and groups have which roles is determined using RACF profiles in the EJBROLE class (if SAF authorization is selected). If a user is in the access list of an EJBROLE profile, the user has that role. If a group is in the access list of an EJBROLE profile, users in that group have that role. If the EJBROLE profile has ACCESS(READ), all users have that role.

The SAF profile prefix (previously referred to as z/OS security domain), if specified, becomes a prefix used by WebSphere Application Server for z/OS and RACF when checking EJBROLE profiles. This provides WebSphere SAF profile prefix-level granularity of roles.

For example:

```
Test  
Cell has Security Domain=TEST Production Cell has Security Domain=PROD
```

For example, an application using role Clerk is deployed on both cells. On the test cell, users need READ access to the EJBROLE profile TEST.Clerk. On the production cell, users need READ access to the EJBROLE profile PROD.Clerk.

The following profiles are defined in the RACF EJBROLE class for administrative authorization: administrator, configurator, monitor, operator, deployer, adminsecuritymanager, and auditor.

Refer to “System Authorization Facility for role-based authorization” on page 1729 for more information on how SAF can be used for Java EE-based role authorization.

Using the RACF profiles

It is important to understand the security mechanisms used to protect the server resources using the CBIND, SERVER, and STARTED classes in RACF (or your equivalent security product). You must also understand the techniques for managing the security environment.

The RACF profiles that protect the WebSphere Application Server for z/OS resources use the following classes:

1. **CBIND:** Use this class to access to servers, and access to objects in the servers
2. **SERVER:** Use this class to access to controllers by servant regions
3. **STARTED:** Use this class to associate user IDs and groups to started procedures
4. **APPL:** Use this class to restrict access of authenticated users to applications running on the server
5. **FACILITY:** Use this class to:
 - associate user IDs and groups to the Synch to OS Thread Allowed option
 - control which security configurations are allowed to map distributed identities to SAF identities using the JAAS mapping login modules
6. **SURROGAT:** Use this optional class to associate user IDs and groups to the Synch to OS Thread Allowed option

Refer to “System Authorization Facility considerations for the operating system and application levels” on page 1201 for more information.

Basic information about the RACF profiles used by WebSphere Application Server for z/OS can be found in the SAF-based authorization. This section adds some additional details about the CBIND, SERVER, FACILITY, SURROGAT, and STARTED class profiles.

User IDs and Group IDs

When creating a profile for an application server, the BBOCBRAK job generates the RACF commands. When creating a profile for a cell, deployment manager, job manager, or admin agent, the job name is BBODBRAJ. When creating a profile for a custom node, the job name is BBOMBRAJ. Enter the following information:

```
CR = Controller Region SR = Servant  
Region CFG = Configuration (group) server = server short name cluster = generic  
server (short) name (also called cluster transition name)
```

Six users and six groups, defined as follows, are shown symbolically to help you understand how they are used in the various permissions later on:

```
<CR_userid> <CR_groupid>, <CFG_groupid> <SR_userid> <SR_groupid>, <CFG_groupid> <demn_userid> <demn_groupid>,
<CFG_groupid> <admin_userid> <CFG_groupid> <client_userid> <client_groupid> <ctracewtr_userid> <ctracewtr_groupid>
```

Below are the various profiles used to protect the WebSphere Application Server for z/OS resources, along with the permissions and access levels.

Using CBIND class profiles

There are two formats and levels of CBIND class profiles for protecting access to application servers and objects in those servers:

```
CBIND Class profiles - access to generic servers CB.BIND.<cluster> UACC(READ); PERMIT <CR_group> ACC(CONTROL)
CBIND Class profiles - access to objects in servers
CB.<cluster> UACC(READ) PERMIT <CR_group> ACC(CONTROL)
```

If you are using “SAF profile prefix”, the CBIND profiles are qualified by the “profilePrefix” as follows:

```
CBIND Class profiles - access to generic servers CB.BIND.<profilePrefix>.<cluster> UACC(READ)
CBIND Class profiles - access to objects in servers
CB.<profilePrefix>.<cluster> UACC(READ)
```

CBIND profiles control access to WebSphere Application Server for z/OS servers, including web servers running the WebSphere Application Server plug-in, and to objects in the servers, from Java application clients and other WebSphere Application Server servers. For access to servers, enter:

```
CB.CBIND.<cluster>
CB.CBIND.<SAF profile prefix>.<cluster>
```

For access to objects within servers, enter:

```
CB.<cluster> CB.<SAF profile prefix>.<cluster>
```

Using SERVER class profiles

There are currently two formats of the SERVER class profiles for protecting access to the server controllers.

```
SERVER
class profiles - access to controllers using static Application Environments
  CB.<server>.<cluster> UACC(NONE) PERMIT <SR_userid> ACC(READ)
  SERVER class profiles - access to controllers using dynamic Application
  Environments CB.<server>.<cluster>.<cell> UACC(NONE) PERMIT <SR_userid>
  ACC(READ)
```

In using the WebSphere z/OS Profile Management Tool or the **zpm**t, both formats are predefined, and one of these is actually required at runtime. The required format is determined dynamically by the WebSphere Application Server for z/OS Runtime based on the availability of Dynamic Application Environment (DAE) support. The following command provides access to controllers using static Application Environments:

```
RDEFINE
CB.&<server><cluster> UACC(NONE); PERMIT &<SR_userid> ACCESS(READ)
```

For this example, server = server name, cluster = cluster name or cluster transition name if a cluster has not yet been created, and SR is the MVS user ID for the server region.

The following command provides access to controllers using dynamic Application:

```
CB.& <server>.&<cluster>.<cell>
UACC(NONE); PERMIT &<SR_userid> ACC(READ)
```

For this example, server = server name, cluster = cluster name or cluster transition name if a cluster has not yet been created, cell = cell short name, and SR is the MVS user ID for the server region.

SERVER class profiles control whether a servant can call authorized routines in the associated controller.

For access to Controller using Static Application Environment, enter:

```
CB.<server>.<cluster>
CB.<SAF profile prefix>.<server>.<cluster>
```

For access to Controller using Dynamic Application Environment, enter:

```
CB.<server>.<cluster>.<cell>  
22
```

Using STARTED class profiles

There are three formats of STARTED class profiles used to assign user IDs and group IDs to controllers:

```
STARTED Class profiles - (MGCRE) - for control regions, daemons, and Node agents  
<<CR_proc>.<CR_jobname> STDATA(USER(CR_userid) GROUP(CFG_groupid))  
<denn_proc>.* STDATA(USER(denn_userid) GROUP(CFG_groupid))
```

```
STARTED Class profiles - (ASCRE) - for servant regions and adjuncts  
<SR_jobname>.<SR_jobname> STDATA(USER(SR_userid) GROUP(CFG_groupid))
```

```
STARTED Class profiles for IJP - (MGCRE)  
<MQ_ssname>.* STDATA(USER(IJP_userid) GROUP(CFG_groupid)) - These IJPs don't exist in WAS 6.1
```

STARTED class profiles are generated to assign user IDs to the various WebSphere Application Server for z/OS regions. Regions include:

- Daemon
- Deployment Manager (controller and servant)
- Node Agent
- Application Servers (controller, servant and adjunct)
- Admin agents (controller and servant)
- Job managers (controller and servant)

Using APPL class profiles

An APPL class profile controls whether an authenticated user can use any applications in the cell. If a SAF profile prefix is specified, the APPL class profile name will be the SAF profile prefix name. If SAF profile prefix is not specified, the APPL class profile name will be CBS390. Refer to “System Authorization Facility considerations for the operating system and application levels” on page 1201.

The APPL class profile only takes effect when both the APPL class is active in RACF and when the option to use the APPL profile is enabled in WebSphere. The WebSphere option can be enabled or disabled from the administrative console by navigating to the SAF authorization options panel and setting the checkbox “Use APPL profile to restrict access to the server”. For more information on this setting, read about “z/OS System Authorization Facility authorization” on page 1734.

Creating multiple security configurations within a cell

You might require distinct sets of profiles within a given cell to separate logical WebSphere security domains in your enterprise, (for example, test, and production users).

You can define a SAF profile prefix during customization using the z/OS Profile Management Tool, the **zpm**t command, or the SAF Authorization options panel in the administration console.

Use the WebSphere Application Server for z/OS administrative console to set a SAF profile prefix under **Security > Global security > External authorization provider > System Authorization Facility (SAF) authorization > Configure > SAF profile prefix**, which creates the following property in the security.xml file.

```
xmi:id="Property_47" name="com.ibm.security.SAF.profilePrefix"  
value="<profile_prefix>" required="false"/>
```

When a SAF profile prefix identifier is set, the following profile definitions and checks are affected:

Table 78. Profile definitions and checks affected when SAF profile prefix identifier is set..

This table lists the profile definitions and checks affected when SAF profile prefix identifier is set.

Class	No SAF profile prefix	With a SAF profile prefix
CBIND	CB.clustername CB.BIND.clustername	CB.<profilePrefix>.clustername CB.BIND.<profilePrefix>.clustername
EJBRROLE	ApplicationRoleName	<profilePrefix>.ApplicationRoleName
APPL	CBS390	<profilePrefix>

Generating new user IDs and Profiles for a new Server

If you want to use unique user IDs for each new application server, you must define these users, groups, and profiles in the RACF database.

Through using the WebSphere z/OS Profile Management Tool or the **zpm**t command, you need to edit a copy of the BBOWBRAK member (or BBODBRAK depending on the type of profile) job's target .DATA partitioned data set, and change the following entries to the new users, groups, and unique New_server name, and New_cluster name profiles:

- If unique user IDs for the new servers are desired, define three new users and connect them to the following groups:
 - <New_CR_userid> <CR_groupid>, <CFG_groupid>
 - <New_SR_userid> <<SR_groupid>, <CFG_groupid>
 - <New_ADJUNCT_userid> <<ADJUNCT_groupid>, <CFG_groupid>
 - <New_client_userid> <client_groupid>
- CBIND class profiles for the new cluster (generic server short name):
 - CB.BIND.<New_cluster>
 - CB.<New_cluster>
- SERVER class profiles for the new server and cluster:
 - CB.<New_server>.<New_cluster>
 - CB.<New_server>.<New_cluster>.<cell>
- STARTED class profiles for the new server's controller and servant's regions:
 - <CR_proc>.<New_CR_jobname> STDATA(USER(New_CR_userid) GROUP(CFG_groupid))
 - <New_SR_jobname>.* STDATA(USER(New_SR_userid) GROUP(CFG_groupid))
 - <New_ADJUNCT_jobname>.* STDATA(USER(New_ADJUNCT_userid) GROUP(CFG_groupid))

Using FACILITY and SURROGAT class profiles (Synch to OS Thread Allowed Option)

The FACILITY and SURROGAT class profiles give the RACF administrator control over the use of Synch to OS Thread Allowed.

Attention: If these profiles are not defined in RACF, Sync to thread will not be allowed.

- FACILITY class profile BBO.SYNC.<cell short name>.<cluster short name>
 - If the WebSphere controller does not have access to the profile, Synch to OS Thread Allowed will be disabled.
 - If the WebSphere controller has READ access to profile. Sync to OS Thread Allowed can be used, but it is limited to security environments that represent certain users. The SURROGATE class profile (below) needs to be defined.
 - The WebSphere controller has CONTROL access to the profile. Sync to OS Thread Allowed can be used to build security environments to represent any user. The SURROGATE class profile will not be checked.

- SURROGAT class profile BBO.SYNC.<user ID>
 - If the WebSphere controller only has READ access to the FACILITY class profile of BBO.SYNC.<cell short name>.<cluster short name> that enables Synch to OS Thread Allowed, the SURROGAT class profile check is used to verify that the WebSphere servant is authorized to establish a security environment for the target user.
 - Class profile checks are consistent with other products that perform similar functions.

The formats and use of the FACILITY and SURROGAT class profiles is as follows:

```
RDEF FACILITY BBO.SYNC.<cell short name>.<cluster short name> UACC NONE
PE BBO.SYNC.<cell short name>.<cluster short name> CLASS(FACILITY)ID(<CR userid>) ACC(READ or CONTROL)
RDEF SURROGAT BBO.SYNC.<SR userid> UACC NONE
PE BBO.SYNC.<application> CLASS(SURROGAT) ID(<SR userid>)ACC(READ)
```

Note: The cluster short name is the server generic short name if no clustering is defined. Also, the SURROGAT class profile needs to be placed in a (RACLISTed) memory table to improve the performance of the access checks.

If the <CR userid> is given CONTROL access, then any individual user ids that request Synch to OS Thread Allowed are allowed to synch. If the <CR userid> is given READ access then any individual user ids that request Synch to OS Thread Allowed must also have READ access to a SURROGAT class profile that gives the application user id explicit permission to Synch to OS Thread Allowed in the servant region (SR). For example, assume a system with cell short name of SY1, a cluster short name (the server generic short name) of BBOC001, CR userid of CBSYMCR, SR userid of CBSYMSR, and an application running under the userid of JavaEEID. The following commands would be used to establish Synch to OS Thread Allowed control.

```
RDEF FACILITY BBO.SYNC.SY1.BBOC001 UACC NONE
PE BBO.SYNC.SY1.BBOC001 CLASS(FACILITY) ID(CBSYMCR) ACC(READ)
RDEF SURROGAT BBO.SYNC.J2EEID UACCNONE
PE BBO.SYNC.J2EEID CLASS(SURROGAT) ID(CBSYMSR) ACC(READ)
```

Using FACILITY class profiles (Enabling Trusted Applications)

The FACILITY class profile gives the RACF administrator control over the enabling of trusted applications. To enable trusted applications, you must define the following FACILITY class profile and give the controller region user id READ access to it.

```
RDEF FACILITY BBO.TRUSTEDAPPS.<cell
short name>.<cluster short name> UACC NONE PE
BBO.TRUSTEDAPPS.<cell short name>.<cluster
short name> CLASS(FACILITY) ID(CR userid) ACC(READ)
```

The following generic example can be user for all servers:

```
RDEFINE FACILITY BBO.TRUSTEDAPPS.myce1101.**UACC(NONE)
PERMIT BBO.TRUSTEDAPPS.myce1101.** CLASS(FACILITY) ID(MYCBGROUP) ACCESS(READ)
SETROPTS RACLIST(FACILITY) REFRESH
```

The following example is for a specific server, that is, a system with a cell short name of SY1, a cluster short name (the server generic short name) or BBOC001, and a controller region userid of CBSYMCR:

```
RDEF FACILITY BBO.TRUSTEDAPPS.SY1.BBOC001 UACC
NONE PE BBO.TRUSTEDAPPS.SY1.BBOC001 CLASS(FACILITY) ID(CBSYMCR) ACC(READ)
```

Using minimalist profiles

To minimize the number of users, groups, and profiles in the RACF data set, you can use one user ID, one group ID, and very generic profiles so they cover multiple servers in the same cell. This technique can also be used with Integral Java Message Service provider and WebSphere Application Server, Network Deployment configurations.

The advantages of using minimalist profiles include having fewer:

- Profile definitions to define
- Digital certificates to consider for interprocess Secure Sockets Layer communication

A disadvantage is that you must more closely monitor applications because if multiple servers run with the same user IDs or groups, an application can cause problems in one server and potentially corrupt the configuration of its own server (for example, by turning security off) and other servers as well.

Cluster authorizations:

This section discusses the kinds of authorization checking WebSphere Application Server for z/OS does for a clusters. Servants must have access to profiles in the RACF SERVER class. This controls whether a servant can call authorized routines in the controller.

The following explains the kinds of authorization checking WebSphere Application Server for z/OS does for clusters.

1. Servants must have access to profiles in the RACF SERVER class. This controls whether a servant can call authorized routines in the controller.

Controllers do not require such access control. Only authorized programs, loaded from Authorized Program Facility (APF) libraries, run in controllers.

2. Resource managers such as DB2, IBM Information Management System (IMS), and Customer Information Control System (CICS) have implemented their own resource controls, which control the ability of applications to access resources.

When resource controls are used by DB2, all controllers and servants need to be granted access to the relevant resources. You can grant access by using the DSNR RACF class (if you have RACF support) or by issuing the relevant DB2 GRANT statements.

Access to Open Transaction Manager Access (OTMA) for IMS access is accomplished through the FACILITY Class (IMSXCF.OTMACI). Access to EXCI for CICS is accomplished through the SURROGAT class (*.DFHEXCI).

You can control access to data sets through the DATASET class and hierarchical file system (HFS) files through file permissions.

Server process authorization checking:

You can specify specific access restrictions to z/OS resources.

To control access to WebSphere Application Server for z/OS resources:

- As a general rule, give greater authority to controllers and less authority to servants.

Table 79. Level of trust and authority for regions.

This table indicates the level of trust and authority for regions.

Region	Level of trust and access authority
Controller	<p>Note:</p> <ul style="list-style-type: none"> • Contains WebSphere Application Server for z/OS system code. • Trusted, runs APF-authorized • Contains communication ports and manipulation of System Authorization Facility (SAF) client identities
Servant	<p>Note:</p> <ul style="list-style-type: none"> • Contains WebSphere Application Server for z/OS system code, application code, and pluggable service providers (such as jdbc drivers) • Supports Java 2 Security to protect sensitive data and system services • Untrusted

- Regarding the WebSphere Application Server for z/OS run-time clusters, the general rule is to give less authority to the location service daemon, and greater authority to the node, as explained in the table below:

Table 80. Assigning authorities to WebSphere Application Server for z/OS run-time cluster control and servants.

This table lists the required authorities for z/OS run-time cluster control and servants.

Run-time Cluster	Region	Required Authorities
Location service daemon	Control	<ul style="list-style-type: none"> • STARTED class • Access to Workload Manager (WLM) services • Access to DNS • OPERCMDS access to START, STOP, CANCEL, FORCE, and MODIFY other clusters • IRR.DIGTCERT.LIST and IRR.DIGTCERT.LISTRING in FACILITY (SSL)
Node	Control	STARTED class
Controller	Control	<ul style="list-style-type: none"> • SSL • Kerberos • READ authority to the SERVER class, • OPERCMDS access to START, STOP, CANCEL, FORCE and MODIFY other servers
Servant	Control	The following classes: <ul style="list-style-type: none"> • OTMA • SERVER • DSNR, • DATASET • SURROGATE • STARTED • LOGSTREAM

- Remember to protect the Resource Recovery Services (RRS) log streams. By default, UACC is READ.
- Protect the WebSphere Application Server for z/OS properties XML files, especially if they contain passwords. For more information, see the WebSphere Application Server variables in the administrative console or the documentation.
- Deployment Manager also needs permission to start and stop servers.

Secure Sockets Layer security for WebSphere Application Server for z/OS:

This topic assumes you understand the Secure Sockets Layer (SSL) protocol and how cryptographic services system SSL works on z/OS. SSL is used by multiple components within WebSphere Application Server to provide trust and privacy. Such components include the built-in HTTP transport, the Object Request Broker (ORB) (client and server), and the secure Lightweight Directory Access Protocol (LDAP) client. Configuring SSL is different between client and server with WebSphere Application Server. If you want the added security of protected communications and user authentication in a network, you can use SSL security.

SSL is an integral part of the security provided by WebSphere Application Server for z/OS. It is activated when administrative security is enabled. When administrative security is enabled, SSL is always used by the administrative subsystem to secure administrative commands, the administration console, and communications between WebSphere Application Server processes.

The WebSphere Application Server for z/OS runtime can optionally use SSL when server security is enabled in these cases:

- SSL is used to protect web application when confidentiality is specified as a Web Application Security Constraint. A transport guarantee of CONFIDENTIAL or INTEGRAL guarantees that the communication between the web client and the web server is secured and is transported over HTTPS (HTTP SSL). In addition, you can use SSL to perform client authentication when the security constraint (CLIENT_CERT) is specified during application deployment .

- SSL can be used to protect Inter-ORB Protocol (IIOP) requests when SSL/TLS is supported (or required) in the Common Secure Interoperability version 2 (CSlv2) transport settings. These are set by clicking **Security > Global security**. Under RMI/IIOP security, click **CSlv2 inbound transport** or **CSlv2 outbound transport**.
- SSL can be used to protect communications between an LDAP client and server when the active user registry is LDAP.

When configuring SSL, there are two types of SSL repertoires on WebSphere Application Server for z/OS. The type of repertoire relates to the underlying services used to process SSL.

- Java Secure Socket Extension (JSSE) must be selected as the SSL repertoire type for administrative requests using the HTTP/SOAP Connector. JSSE repertoires can (with APAR PQ77586 applied) specify either a SAF keyring for the keystore or truststore, or an hierarchical file system (HFS) file.

Note: All SSL configuration repertoires of the System Secure Sockets Layer (SSSL) type, except those that belong to the daemon, are converted to the Java Secure Socket Extension (JSSE) type. System SSL is now only used by the Daemon Address Space because the daemon runs without a JVM and JSSE is only supported in Java.

This topic gives a brief explanation of the SSL protocol and how SSL works on z/OS. For information about the SSL protocol, go to the following website: <http://home.netscape.com/eng/ssl3/ssl-toc.html>

Secure Sockets Layer (SSL) is used by multiple components within WebSphere Application Server to provide trust and privacy. These components are the built-in HTTP Transport, the ORB (client and server), and the secure LDAP client. Configuring SSL is different between client and server with WebSphere Application Server. If you want the added security of protected communications and user authentication in a network, you can use Secure Sockets Layer (SSL) security. The SSL support in WebSphere Application Server for z/OS has several objectives:

- To provide ways accepted by the industry to protect the security of messages as they flow across the network. This is often called *transport layer security*. Transport Layer Security (TLS) is a function that provides privacy and data integrity between two communicating applications. The protection occurs in a layer of software on top of the base transport protocol (for example, on top of TCP/IP).

SSL provides security over the communications link through encryption technology, ensuring the integrity of messages in a network. Because communications are encrypted between two parties, a third party cannot tamper with messages. SSL also provides confidentiality (ensuring the message content cannot be read), replay detection, and out-of-sequence detection.

- To provide a secure communications medium through which various authentication protocols can operate. A single SSL session can carry multiple authentication protocols, that is, methods to prove the identities of the parties communicating.

SSL support always provides a mechanism by which the server proves its identity. The SSL support on WebSphere Application Server for z/OS allows these ways for the client to prove its identity:

- Basic authentication (also known as SSL Type 1 authentication), in which a client proves its identity to the server by passing a user identity and password (or password phrase) known by the target server.

With SSL basic authentication:

- A z/OS client can communicate securely with WebSphere Application Server for z/OS with a user ID and password as defined by the CSlv2 user name and password mechanism Generic Security Services Username Password (GSSUP).
- A WebSphere Application Server client can communicate securely with a WebSphere Application Server for z/OS server by using a MVS user ID and password (or password phrase).
- Because a password is always required on a request, only simple client-to-server connections can be made. That is, the server cannot send a client's user ID to another server for a response to a request.
- Client certificate support, in which both the server and client supply digital certificates to prove their identities to each other.

When digital certificates are provided for authentication to WebSphere Application Server for z/OS the decrypted certificate is mapped to a valid user identity in the enabled user repository. Web applications can have thousands of clients, which makes managing client authentication an administrative burden. When the local operating system is the enabled user repository on WebSphere Application Server for z/OS, SAF certificate name filtering allows you to map client certificates, without storing them, to MVS user IDs. Through *certificate name filtering*, you can authorize sets of users to access servers without the administrative overhead of creating MVS user IDs and managing client certificates for every user.

- SSL support always provides a mechanism by which the server proves its identity. A variety of mechanisms can be used to prove the clients identity. The SSL v3 (and TLS) protocol provides for the ability for client digital certificates to optionally be exchanged. These certificates can be used for authentication.
- CSiv2 identity assertion, which provides support for z/OS principals, X501 distinguished names, and X509 digital certificates.
- Identity assertion, or trusted association, in which an intermediate server can send the identities of its clients to a target server in a secure yet efficient manner. This support uses client certificates to establish the intermediate server as the owner of an SSL session. Through the Resource Access Control Facility (RACF), the system can check that the intermediate server can be trusted (to confer this level of trust, CBIND authorization is granted by administrators to RACF IDs that run secure system code exclusively). After trust in this intermediate server is established, client identities (MVS user IDs) need not be separately verified by the target server; those client identities are simply asserted without requiring authentication.
- To be securely interoperable with other products, such as:
 - Customer Information Control System (CICS) Transaction Server for z/OS
 - Other WebSphere Application Server versions
 - Common Object Request Broker Architecture (CORBA)-compliant object request brokers

SSL is disabled by default and SSL support is optional. If you are running WebSphere Application Server for z/OS with security turned on, SSL is required by the administrative console. Java Secure Socket Extension (JSSE) is the SSL repertoire type used.

Table 81. SSL connection sequence.

This table describes how an SSL connection works.

Stage	Description
Negotiation	After the client locates the server, the client and server negotiate the type of security for communications. If SSL is to be used, the client is told to connect to a special SSL port.
Handshake	The client connects to the SSL port and the SSL handshake occurs. If successful, encrypted communication starts. The client authenticates the server by inspecting the server's digital certificate. If client certificates are used during the handshake, the server authenticates the client by inspecting the client's digital certificate.
Ongoing communication	During the SSL handshake, the client and server negotiate a cipher spec to be used to encrypt communications.
First client request	The determination of client identity depends upon the client authentication mechanism chosen, which is one of the following: <ul style="list-style-type: none"> • CSiv2 user ID and password (GSSUP) • CSiv2 asserted identity

Rules

- Either a Java or C++ client on z/OS is interoperable with a WebSphere Application Server for z/OS or workstation Application Server, and can use SSL. CSiv2 security only supports Java clients on z/OS.

- Part of the handshake is to negotiate the cryptographic specs used by SSL for message protection. There are two factors that determine the cipher specs and key sizes used:
 - The security level of the cryptographic services installed on the system, which determines the cipher specs and key sizes available to WebSphere Application Server for z/OS.
 - The configuration of the server through the administrative console allows you to specify SSL cipher suites.

For more information, see *z/OS System Secure Sockets Layer Programming*.

- For z/OS system SSL sockets you must use RACF or an equivalent to store digital certificates and keys. Placing digital certificates and keys into a key database in the HFS is not an option.

Tip: To define SSL basic authentication security, you must first request a signed certificate for your server and a certificate authority (CA) certificate from the certificate authority that signed your server certificate. After you have received a signed certificate for your server and a CA certificate from the certificate authority, you must use RACF to authorize the use of digital certificates, store server certificates, and server key rings in RACF, create an SSL repertoire alias, and define SSL security properties for your server through the administrative console.

For clients, you must create a key ring and attach to it the CA certificate from the certificate authority that issued the server's certificate. For a z/OS client, you must use RACF to create a client key ring and to attach the CA certificate to that key ring. For the client to authenticate the server, the server (actually, the controller user ID) must possess a signed certificate created by a certificate authority. The server passes the signed certificate to prove its identity to the client. The client must possess the CA certificate from the same certificate authority that issued the server's certificate. The client uses the CA certificate to verify that the server's certificate is authentic. After the certificate is verified, the client can be sure that messages are truly coming from that server, not someone else. For the server to authenticate the client, note that there is no client certificate that the client passes to prove its identity to the server. In the SSL basic authentication scheme, the server authenticates the client by challenging the client for a user ID and password (or password phrase).

See “Setting up a keyring for use by Daemon Secure Sockets Layer” on page 1221 for information on creating a keyring for the daemon's MVS user ID.

SSL repertoires:

With Secure Sockets Layer (SSL) configuration repertoire, administrators can define any number of SSL settings that can be used to make HyperText Transport Protocol SSL (HTTPS), Internet Inter-ORB Protocol SSL (IIOPS) or Lightweight Directory Access Protocol SSL (LDAPS) connections.

Using the SSL configuration repertoire, you can pick one of the SSL settings defined here from any location within the administrative console which allows SSL connections. This simplifies the SSL configuration process since you can reuse many of these SSL configurations by simply specifying the alias in multiple places. The appropriate repertoire is referenced during the configuration of a service that sends and receives requests encrypted using SSL, such as the web and enterprise beans containers. Before deleting SSL configurations from the repertoire, remember that if an SSL configuration alias is referenced somewhere, and it is deleted here, an SSL connection will fail if the deleted alias is accessed.

Note: You can also create an alias, but first you must create an SSL configuration repertoire alias or entry. You can then select the alias later when a component is configured for SSL support.

If you choose to use SSL, Java Secure Socket Extension (JSSE) is the SSL repertoire type used. An exception to this is that System SSL (SSSL) is the SSL repertoire type used by the Daemon Address Space as the daemon runs without a JVM, but JSSE is only supported in Java.

Daemon Secure Sockets Layer:

Use the administrative console panel to modify the port and Secure Sockets Layer (SSL) port settings and to specify the SSL settings (the SSL repertoire). The default repertoire is the same one used for the server, which is a SystemSSL IIOF repertoire. During daemon initialization the SSL usage initialization is attempted if security is enabled and a valid repertoire is found. In order to turn off the daemon SSL port a cell-level WebSphere variable (DAEMON_security_disable_daemon_ssl) must be created and set to true. The default for this variable is false.

SSL can be used to protect locations in the SSL daemon using the Location Service Daemon if:

- Administrative security is enabled
- A daemon SSL repertoire is configured in the administrative console (the daemon SSL repertoire refers to a valid RACF keyring that is owned by the MVS user ID associated with the daemon process)
- A certificate and keyring have been defined

On the administrative console, click **System administration > Node groups > sysplex_node_group_name**. Under Additional properties, click **z/OS location service**.

Location service daemon

This panel specifies the configuration settings for the location service daemon for this cell. Changes made to these settings to the entire cell and to the location service daemon instance on each node in the cell.

Job Name	BBODMNC	Specifies z/OS jobname of location service daemon.
Host Name	BOSSXXX.PLEX1.L2.IBM.COM	Specifies host name to be used when contacting location service daemon.
Port	5755	Specifies port location service daemon listens on for unencrypted communication.
SSL Port	5756	Specifies port location service daemon listens on for encrypted communication.
SSL Setting	PLEX1Manager/DefaultIIOFSSL	Specifies a list of predefined SSL settings to choose from for connections. These are configured at the SSL repertoire panel.

You can use the WebSphere z/OS Profile Management Tool or the **zpm** command to specify authentication information, including the daemon's user ID, UID, and SSL port. RACF commands are generated to create a keyring for server use (the default is WASKeyring). The z/OS Profile Management Tool or the **zpm** command generates the daemon keyring and the certificate. To generate the daemon keyring and certificate using the z/OS Profile Management Tool, select **Security Domain > SSL Customization > Enable SSL on the Location Service Daemon**. If you type Y next to this option, the RACF commands are generated to do the following tasks:

- Create a daemon keyring and certificate
- Connect the certificate and certificate authority (CA) certificates to the keyring.

Important: This option does not control the use of the daemon SSL.

This is appropriate if the user IDs are the same, but if the daemon has a separate user ID, see Setting up a Keyring for use by WebSphere Application Server for z/OS. The values selected are picked up by the administrative console.

If the daemon process is assigned the same MVS user ID assigned to a secure WebSphere Application Server, the keyring you use to secure WebSphere Application Server can also be used to secure daemon requests. If the daemon process is not assigned the same MVS user ID assigned to a secure WebSphere Application Server, it is recommended that you perform the daemon SSL setup similarly to the setup for your WebSphere Application Server. Modify the customization job commands generated in BBOCBRAK (or HLQ.DATA(BBODBRAK) on WebSphere Application Server, Network Deployment) to perform the steps in Setting up a Keyring for use by WebSphere Application Server for z/OS.

Setting permission for files created by applications:

Files created by applications running in the servant will have permission bits set according to the default umask. To change the default umask for the servant, specify the `_BPX_BATCH_UMASK` environment variable for the servant. Deployment manager and application servers require group read/write access to the data in their config root.

Before you begin

About this task

Deployment manager and application servers require group read/write access to the data in their config root. The server must run with a `007` umask in order to support system management functions. Do not change this umask setting and your server will function correctly.

Use the `_BPX_BATCH_UMASK` environment variable for the servant to set the umask to `007`. You define `_BPX_BATCH_UMASK` as a new environment variable using the administrative console.

To view the administrative console page, click **Environment > WebSphere variables**.

To define this new variable using the administrative console, select the appropriate scope from the list of available options and then click **New** to create the name `_BPX_BATCH_UMASK` and the desired value. You will need to restart the server to pick up the `_BPX_BATCH_UMASK` setting.

Recommendation: A umask value of `007` will cause applications to create directories with permission bits set to `770` and files with permission bits set to `660`. This is the value recommended by IBM.

Note: See the documents listed in the steps below for more information.

Procedure

- *z/OS Language Environment Programming Reference*, for more information on ENVAR
- *z/OS C/C++ Programming Guide*, for more information on how to change the UMASK defaults
- *z/OS UNIX System Services Command Reference*

RACF protection for DB2:

You can use the Resource Access Control Facility (RACF) DSNR resource class to protect DB2 resources. This helps you centralize security management. This section gives you pointers to general information about setting up RACF protection for DB2 and specific information about the resources, groups, user IDs, and permissions used by WebSphere Application Server for z/OS.

There are three functional areas in RACF to consider regarding protection for DB2:

- RACF DSNR class

The RACF DSNR class controls access to the DB2 subsystems. If the DSNR class is active, then WebSphere Application Server for z/OS controllers and servants need access to the `db2_ssn`. RRSF profiles, where `db2_ssn` is your DB2 subsystem name. If a controller or servant does not have access, then that region will not initialize.

- Secondary authorization IDs

DB2 identification and signon exits (DSN3@ATH and DSN3@SGN) are used to assign authorization IDs. If you want to use secondary authorization IDs (RACF group names), then you must replace the default exits with these two sample routines. For details on how to install these sample routines, see *DB2 Administration Guide*.

- Grant statements

WebSphere Application Server for z/OS does not support the protection of DB2 objects through the DSNX@XAC exit. To protect DB2 objects, you must use GRANT statements.

For more information on using RACF with DB2, see the documentation in the DB2 Information Centers.

System Authorization Facility (SAF) profile names:

The Profile Management Tool and the `zpm` command generate jobs that help you create the necessary System Authorization Facility (SAF) profiles—such as `STARTED`, `CBIND`, or `SERVER`—that enable your server to run.

At runtime, normal SAF specific and generic profile matching uses a combination of the cell short name, cluster short name (or cluster transition name for a non-clustered server), server short name, and the SAF profile prefix (if one is specified) to select the appropriate matching profile.

WebSphere Application Server for z/OS uses two schemes, specific and generic, in the creation of SAF profiles:

- With the specific profile scheme, a set of fully-qualified specific profiles is created to exactly match the short names that apply to the server you customize.
- With the generic profile scheme, a set of generic profiles is also created (the `STARTED` class `BBO*.*` profiles for example) The purpose of these generic profiles is to provide a default profile for any server that is created administratively and that has a default name so that the servers can operate successfully by default.

Examples:

- An application server created through the administrative console has a default server short name of `BBOSnnn` and a cluster short name (or cluster transition name for a non-clustered server) of `BBOCnnn`, where `nnn` is a unique number. By default, this server can start using the `BBO*` generic profiles.
- Node federation creates a node agent server. If the base application server that you federate is configured with a Java Message Service (JMS) integral provider, then a standalone JMS server is also created. The node agent has a default name of `BBONnnn` and the JMS server is `BBOJnnn`, where `nnn` is a unique number. By default, these servers can start using the `BBO*` generic profiles.

The generic profiles that are created are not required and exist only for your convenience in case you use the default server short names and cluster short names (or cluster transition names for non-clustered servers) generated by WebSphere Application Server for z/OS. You can choose to delete the generic profiles if, for example, your organization has particular naming conventions and you will not use the default names generated by WebSphere Application Server for z/OS. In that case, ensure that you have your own strategy for creating the required SAF profiles, either generic or specific, with your own naming convention—WebSphere Application Server for z/OS does not create them for you.

Defining Secure Sockets Layer security for servers

Complete these steps for RACF to authorize the server to use digital certificates. SSL uses digital certificates and public and private keys.

Before you begin

You need to request a certificate authority (CA) certificate and a signed certificate for your server. If you plan to implement Secure Sockets Layer (SSL) client certificate support, you must also have certificate authority certificates from each certificate authority that verifies your client certificates. You must have a user ID with the authority to use the `RACDCERT` command in the Resource Access Control Facility (RACF) (for example, `SPECIAL` authority).

About this task

If your application server uses SSL, you must use RACF to store digital certificates, and you must use public and private keys for the user identities under which the server controllers run.

Procedure

1. For each server that uses SSL, create a key ring for the controller user ID of that server. **Example:** Your controller is associated with the user ID called ASCR1. Issue the following command:

```
RACDCERT ADDRING(ACRRING) ID(ASCR1)
```

2. Receive the certificate for your application server from the certificate authority. **Example:** You requested a certificate and the certificate authority returned the signed certificate to you, which you stored in a file called ASCR1.CA. Issue the following command:

```
RACDCERT ID (ASCR1) ADD('ASCR1.CA') WITHLABEL('ACRCERT') PASSWORD('password')
```

3. Connect the signed certificate to the controller user ID's key ring and make the certificate the default certificate. **Example:** Connect the certificate labeled ACRCERT to the key ring ACRRING owned by ASCR1. Issue the following command:

```
RACDCERT ID(ASCR1) CONNECT (ID(ASCR1) LABEL('ACRCERT') RING(ACRRING) DEFAULT)
```

4. If you plan to have the server authenticate clients (SSL client certificate support), complete the following steps:

- a. Receive each certificate authority (CA) certificate that verifies your client certificates. **Example:** Receive the CA certificate that will verify a client with user ID CLIENT1. That certificate is in a file called USER.CLIENT1.CA. Issue the following command:

```
RACDCERT ADD('USER.CLIENT1.CA') WITHLABEL('CLIENT1 CA') CERTAUTH
```

- b. Give each CA certificate the CERTAUTH attribute.

Connect each client's certificate authority (CA) certificate to the controller user ID's key ring.

Example: Connect the CLIENT1 CA certificate to the ring ACRRING owned by ASCR1.

```
RACDCERT ID(ASCR1) CONNECT(CERTAUTH LABEL('CLIENT1 CA') RING(ACRRING))
```

5. Give read access for IRR.DIGTCERT.LIST and IRR.DIGTCERT.LISTRING in the RACF FACILITY class to the controller user ID. **Example:** Your controller user ID is ASCR1. Issue:

```
PERMIT IRR.DIGTCERT.LIST CLASS(FACILITY) ID(ASCR1) ACC(READ)  
PERMIT IRR.DIGTCERT.LISTRING CLASS(FACILITY) ID(ASCR1) ACC(READ)
```

What to do next

You are done with the RACF phase when the RACF commands succeed.

Setting up a keyring for use by Daemon Secure Sockets Layer:

Follow these steps to configure a keyring for use by Daemon Secure Sockets Layer.

About this task

Modify the customization job commands generated in BBOCBRAK (or HLQ.DATA(BBODBRAK) on WebSphere Application Server, Network Deployment) to perform these steps:

Procedure

1. Create a keyring for the daemon's MVS user ID to own. Generally, this is the same keyring name that was created for your application servers. Issue the following TSO command: RACDCERT ADDRING(keyringname) ID(daemonUserid)

2. Generate a digital certificate for the daemon's MVS user ID to own by issuing the following TSO command:

```
RACDCERT ID (daemonUserid) GENCERT SUBJECTSDN(CN('create a unique CN') O('IBM'))  
WITHLABEL('labelName') SIGNWITH(CERTAUTH LABEL('WebSphereCA'))
```

3. Connect the generated certificate to the daemon's keyring by issuing the following TSO command:

```
RACDCERT ID(daemonUserid) CONNECT (LABEL('labelName') RING(keyringname) DEFAULT)
```

4. Connect the certificate authority (CA) certificate to the server's keyring by issuing the following TSO command:

```
RACDCERT CONNECT (CERTAUTH LABEL(WebSphereCA) RING(keyringname))
```

Results

Tip: The CA certificate that is generated during configuration (WAS Test CertAuth) is an example. Use the CA you normally use to create user certificates, and connect the CA certificate to the daemon and server keyrings.

Defining SSL security for clients and servers:

Use the steps in this topic to allow the client to use digital certificates.

Before you begin

Note that this assumes you use z/OS Security Server (RACF) as your security server. You must obtain a copy of the certificate authority (CA) certificate used to sign the server certificates. The server certificates connect your client to the server. You must also have a user ID with the appropriate authority (such as SPECIAL) to use the z/OS Security Server Resource Access Control Facility (RACF) RACDCERT command. For more information on the RACDCERT command, refer to z/OS Security Server RACF Command Language Reference (SA22-7687-05), available at <http://www.ibm.com/servers/eserver/zseries/zos/bkserv/r5pdf/secserv.html>. For more information on the RACF in general, refer to z/OS Security Server RACF Security Administrator's Guide (SA22-7683-05), available at <http://www.ibm.com/servers/eserver/zseries/zos/bkserv/r5pdf/secserv.html>.

About this task

Complete the following RACF steps to allow the client to use digital certificates. SOAP, Secure Socket Layer (SSL), and Java Secure Socket Extensions (JSSE) use digital certificates that have public and private keys. If your client uses SOAP, SSL or JSSE, you must use RACF to store digital certificates that have public and private keys for the user identities under which the client runs.

Procedure

1. For each administrative client program that uses SOAP, create a keyring for the client user ID. For example, if your client is running with a user ID called CLIENTID, issue the following command:

```
RACDCERT ADDRING(ACRRING) ID(CLIENTID)
```

2. The keyring created in the step above must include the public certificate of any certificate authority (CA) certificates that are required to establish trust in the servers to which your administrative client connects to. For each CA certificate complete the following steps:

- a. Determine whether this CA certificate is currently stored in RACF. If so, record the existing certificate label. If not you must:

- 1) Receive each CA certificate used to sign a server certificate. For example, to receive the CA certificate that is stored in the USER.SERVER1.CA file and that verifies a server with the user ID SERVER1, issue the following command:

```
RACDCERT ADD('USER.SERVER1.CA') WITHLABEL('SERVER1 CA') CERTAUTH
```

- 2) Connect each server's CA certificate to the client user ID's keyring. For example, to connect the SERVER1 CA certificate to the ring ACRRING owned by CLIENTID:

```
RACDCERT ID(CLIENTID) CONNECT(CERTAUTH LABEL('SERVER1 CA') RING(ACRRING))
```

3. If the servers your administrative client connect to implements SSL client certificate support, you must create certificates for your client and add them to the server keyrings. Refer to Defining SSL security for servers for instructions on setting up keyrings for the servers.
4. Give READ access for the IRR.DIGTCERT.LIST and IRR.DIGTCERT.LISTRING profiles in the RACF FACILITY class to the client user ID. For example, if your client user ID is CLIENTID, issue the following command:

```
PERMIT IRR.DIGTCERT.LIST CLASS(FACILITY) ID(CLIENTID) ACC(READ)  
PERMIT IRR.DIGTCERT.LISTRING CLASS(FACILITY) ID(CLIENTID) ACC(READ)
```

What to do next

You are done with the RACF phase when the RACF commands have run successfully.

Secure Sockets Layer (SSL) considerations for WebSphere Application Server administrators:

The Resource Access Control Facility (RACF) customization jobs create an SSL keyring owned by the WebSphere Application Server for z/OS administrator. This SSL keyring contains the digital certificate needed to communicate with WebSphere Application Server. Other MVS user IDs, which require WebSphere Application Server for z/OS administration require additional customization.

Before you begin

The Resource Access Control Facility (RACF) customization jobs create an SSL keyring owned by the WebSphere Application Server for z/OS administrator containing the digital certificate needed to communicate with WebSphere Application Server. However, additional customization is required for administration by other MVS user IDs.

Note that the MVS user ID in the description below is the MVS user ID under which the **wsadmin** process is running, not the user ID specified in the wsadmin request.

About this task

In the example below:

- `yyyyy` is the user ID of the new WebSphere Application Server for z/OS administrator
- `xxxxx` is the name of the keyring that is specified in `soap.client.props` in the `profile_root/properties` directory.
- `zzzzz` is the label name used in the BBOCBRAK jobs to specify which certificate authority certificate was used to generate server keys

Procedure

1. If the new administrator is not a member of the WebSphere Application Server for z/OS administrative group, make sure that the new user ID has access to the appropriate RACF keyrings and digital certificates. For example:

```
PERMIT IRR.DIGTCERT.LIST CLASS(FACILITY) ID(yyyyy) ACC(READ)
PERMIT IRR.DIGTCERT.LISTRING CLASS(FACILITY) ID(yyyyy) ACC(READ)
```

2. Use the setup completed by the customization jobs as a model for the additional steps. This information is in the BBOCBRAK member of the <HLQ>.DATA data set generated during the customization process. The BBOCBRAK job contains the set of RACF commands that were used:

```
/* Generating SSL keyrings for WebSphere administrator */
RACDCERT ADDRING(xxxxx) ID( yyyyy )

/* Connect WebSphere Application Server CA Certificates to Servers keyring */
"RACDCERT ID(yyyyy) CONNECT (RING(xxxxx) LABEL('zzzzz') CERTAUTH"

SETROPTS RACLIST(FACILITY) REFRESH"
```

Creating Secure Sockets Layer digital certificates and System Authorization Facility keyrings that applications can use to initiate HTTPS requests

You can create Secure Sockets Layer (SSL) digital certificates and System Authorization Facility (SAF) keyrings that applications can use to initiate HTTPS requests.

About this task

The owner of the SAF keyring (and personal keys) must be the MVS user ID established by the servant region's STARTED class profile. This user ID must be the owner because these applications run in the WebSphere Application Server for z/OS servant region address. This user ID is different than the WebSphere Application Server for z/OS controller user ID.

If you use keystores and trust stores in a Hierarchical File System (HFS), a file name uniquely identifies the file within the file system.

Procedure

1. If you are using Resource Access Control Facility (RACF) as your security server, you can generate a personal keyring to be used by your HTTPS application by specifying:

```
RACDCERT ID(ASSR1) GENCERT SUBJECTSDN(CN('JZEE SERVER') O('Z/OS WEBSHERE'))  
L('POUGHKEEPSIE') SP('NEW YORK') C('US')) SIZE(512)  
WITHLABEL('ASSR1 SERVER CERTIFICATE') SIGNWITH(CERTAUTH LABEL('PVT CA'))
```

In this example, the certificate authority used to generate the unique servant region certificate is the same one used to generate the certificates for the WebSphere Application Server for z/OS servers by the customization job.

2. Create a keyring with the same name used for the control region user ID:

```
RACDCERT ADDRING(S1GRING) ID( ASSR1 )
```

The new keyring is owned by the servant user ID for the certificate authority certificate and the servant server certificate.

3. You must have a certificate authority certificate (a certificate from a certificate authority). You might choose to use the same certificate authority to generate a certificate used by HTTPS applications, which is similar to the certificate used for WebSphere Application Server runtime processing. The certificate authority certificate that is used to create the digital certificates is used by the WebSphere Application Server Runtime, and is created during system customization (and can be created by the WebSphere z/OS Profile Management Tool or the **zpm** command). You can connect this certificate authority certificate to the keyring you just created by specifying:

```
RACDCERT ID(ASSR1) CONNECT (RING(S1GRING) LABEL('PVT CA') CERTAUTH)
```

For this example:

- S1GRING represents the RACF keyring
- ASSR1 represents the servant user ID
- PVT CA represents the certificate authority

Note that if the target of the request is another WebSphere Application Server for z/OS server, you must also import the certificate authority certificate used by the WebSphere Application Server for z/OS HTTPS repertoire (which is generally set up during customization) into your keyring if it is different than the certificate signer. If authentication using client certificates is requested, you must also import the certificate authority of your application into the HTTPS repertoire.

4. Connect the personal certificate to your keyring:

```
RACDCERT ID(ASSR1) CONNECT(ID(ASSR1) LABEL('ASSR1 SERVER CERTIFICATE') RING(S1GRING) DEFAULT)
```

For this example:

- S1GRING represents the RACF keyring
- ASSR1 represents the servant user ID
- ASSR1 SERVER CERTIFICATE represents the server certificate for servant user ID

5. Enter the customizable information that needs to be unique across a sysplex. This can include the:

- Subject's public key
- Subject's Distinguished Name (which uniquely identifies an entity in an X.509 certificate)
 - Common Name
 - Title
 - Organization name
 - Organizational Unit name
 - Locality name
 - State or Province name

- Country
 - Distinguished Name of the certificate authority that is issuing the certificate
 - Date from which the certificate is valid
 - Expiration date of the certificate
 - Version number
 - Serial number
6. Verify the output of your customization jobs to see what is set up. Look at HLQ.DATA.(BBOWBRAK, BBOSBRAK if they were saved), and record the settings of the certificate authority certificate label, the servant region's started task identity. If you wish to use an existing repertoire definition for web services, the keyring name created.

Results

Note:

- Consider that:
 - The repertoire type that is pointed to by the SSLConfig definition must be a Java Secure Socket Extension (JSSE) repertoire. This repertoire can be configured to refer to:
 - Java Key Store (JKS) key store and trust store files in an HFS file
 - SAF keyrings such as RACFJSSESettings
 - The scope of the repertoire definition depends upon the type of repertoire. For example:
 - When the repertoire refers to a SAF keyring, the keyring must be owned by the MVS user ID of process that uses it. The customization jobs create keyrings that are owned by the WebSphere Application Server for z/OS controller started task user ID. WebSphere Application Server web services clients run using the user ID of the WebSphere Application Server for z/OS servant region's started task user ID. This means that you must create a new keyring to be owned by the servant region's user ID. This user ID is used by WebSphere Application Server web services clients even if you specify an existing SSL repertoire.
 - When the repertoire refers to an HFS file, all processes can share the key stores. If you use key stores and trust stores in an HFS, a file name uniquely identifies the file within the file system.

Some digital certificate and keyring management is required to edit and use the `sslConfig` property, which is one of the user-definable `ibm-webservicesclient-bnd.xmi` assembly properties. .

Creating a new System SSL repertoire alias

With Secure Sockets Layer (SSL) configuration repertoire, administrators can define any number of SSL settings that can be used to make HyperText Transport Protocol SSL (HTTPS), Internet Inter-ORB Protocol SSL (IIOPS) or Lightweight Directory Access Protocol SSL (LDAPS) connections. You can reuse many of these SSL configurations by simply specifying an alias in multiple places.

Before you begin

You must start the administrative console.

About this task

Using the SSL configuration repertoire, you can pick one of the SSL settings defined here from any location within the administrative console that allows SSL connections. This simplifies the SSL configuration process because you can reuse many of these SSL configurations by simply specifying the alias in multiple places.

Procedure

1. Click **Security > SSL certificate and key management > SSL configuration** to open the SSL configuration panel.
2. To create a new SSL alias, click **New SSSL Configuration**.
3. Type the alias name in the **Alias** field.
4. Specify the SSL Resource Access Control Facility (RACF) key ring in the **Key file name** field. All repertoires used by the same server (such as HTTPS, CSIV2, z/SAS) must have the same keyring name. If the keyring names are not the same, the HTTPS keyring name is used to initialize the server. If you specify the wrong RACF key ring, the server gets an error message at runtime.

Important: z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

5. Optional: Select the **Client authentication** option for your authentication protocol. Client authentication occurs if this repertoire is selected for HTTPS. However, the value is ignored if you use using Common Secure Interoperability Version 2 (CSiv2) or z/OS Secure Authentication Services (z/SAS).

To enable client authentication for CSiv2, click **Security > Global security**. Under Authentication, expand RMI/IOP, then click **CSiv2 inbound authentication**. Select the appropriate option for **Client certificate authentication**.

To enable client authentication for z/SAS, click **Security > Global security**. Under Authentication, expand RMI/IOP, then click **z/SAS authentication**. Select the **Client certificate** option.

6. Select **Strong**, **Medium**, or **Weak** from the **Security level** menu to specify the high, medium, or low set of cipher suites. If you add specific cipher suites on this panel, those cipher suites take precedence over the strong, medium, or weak specification. If a cipher list is specified, WebSphere Application Server uses the list. If the cipher list is empty, WebSphere Application Server uses the strong, medium, weak specification. The following list explains these specifications:

Strong

128-bit cipher suites with digital signature

Medium

40-bit cipher suites with digital signature

Weak No encryption is used, but digital signature is used

7. Specify the SSL V3 timeout value in the **V3 timeout** field. This value is the length of time, in seconds, that the system holds session keys. The range is 0-86400 (1 day). The default is 600 seconds.
8. Select the cipher suites that you want to add from the **Cipher suites** menu. By default, this is not set, and the cipher suites available are determined by the value of the Security Level (**Strong**, **Medium**, or **Weak**). A cipher suite is a combination of cryptographic algorithms used for an SSL connection.
9. Click **OK** when you have made all your selections.

Creating a new Java Secure Socket Extension repertoire alias

The following steps describe how to generate a new Java Secure Socket Extension (JSSE) repertoire alias. Using the JSSE repertoire, you can pick one of the JSSE repertoire settings defined here from any location within the administrative console.

About this task

This simplifies the JSSE repertoire configuration process because you can reuse many of these JSSE configurations by specifying the alias in multiple places.

Procedure

1. Click **Security > SSL** to open the SSL Configuration Repertoires panel.
2. To create a new JSSE repertoire, click **New JSSE repertoire** near the top of the panel. The JSSE Repertoire panel appears.

3. Enter the alias name in the **Alias** field.
4. Optional: Select the **Client authentication** option for your authentication protocol. This option enables client authentication to occur if this repertoire is selected for HTTPS. However, the value is ignored if you use using Common Secure Interoperability Version 2 (CSlv2) or z/OS Secure Authentication Services (z/SAS).

To enable client authentication for CSlv2, click **Security > Global security**. Under Authentication, expand RMI/IIOp, then click **Cslv2 inbound authentication**. Select the appropriate option for **Client certificate authentication**.

To enable client authentication for z/SAS, click **Security > Global security**. Under Authentication, expand RMI/IIOp, then click **z/SAS authentication**. Select the **Client certificate** option.

Important: z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

5. Select **Strong**, **Medium**, or **Weak** from the **Security level** menu to specify the strong, medium, or weak set of cipher suites. If you add specific cipher suites on this panel, those cipher suites take precedence over the strong, medium, or weak specification. If a cipher list is specified, WebSphere Application Server uses the list. If the cipher list is empty, WebSphere Application Server uses the strong, medium, or weak specification. The following list is an explanation of the high, medium, and low specifications:

Strong

128-bit cipher suites with digital signature

Medium

40-bit cipher suites with digital signature

Weak No encryption is used, but digital signature is used

6. Select the cipher suites that you want to add from the **Cipher suites** menu. By default, this is not set. The set of cipher suites available is determined by the value of the Security Level (**Strong**, **Medium**, or **Weak**). A cipher suite is a combination of cryptographic algorithms used for an SSL connection.
7. Select the **Cryptographic token** option if hardware or software cryptographic support is available.
8. Indicate which JSSE provider that you are using by selecting either **Predefined JSSE provider** or **Custom JSSE provider** in the **Provider** field. WebSphere Application Server comes with the IBMJSSE2 provider predefined.

If you are not using the IBMJSSE2 provider, configure a custom provider by selecting **Custom JSSE provider**. Under Additional properties, click **Custom Properties > New**. After specifying the custom provider, return to the JSSE repertoire panel.

9. Select a Secure Sockets Layer (SSL) or Transport Layer Security (TLS) protocol version.

Note: The protocol chosen for the server must match the protocol chosen for the client. Also, for two servers to interoperate, they must use the same protocol.

10. Specify the name of the key file in the **Key file name** field. Specify the fully qualified path to the Secure Sockets Layer (SSL) key file that contains public keys and private keys. Type safkeyring:/// if you are using a RACF key ring for the key file.
11. Specify the password needed to access the key file in the **Key file password** field. Type password if you are using a RACF key ring for the key store.
12. Select the format of the key file from the **Key file format** menu.
13. Click **OK** when you have made all your selections.

Setting up SSL connections for Java clients

Follow these steps to configure SSL for use between Java clients running on a workstation and the WebSphere Application Server for z/OS Java Platform, Enterprise Edition (Java EE) server.

Procedure

1. Determine what SSL repertoire the server is using. For example: WASKeyring.
2. Determine the user ID the server is running. For example: CBSYMSR1.
3. Export the certificate authority from RACF. For example:
RACDCERT CERTAUTH EXPORT(LABEL('WebSphereCA')) DSN('IBMUSER.WAS.CA') FORMAT(CERTDER)
4. Move the file to the workstation. (Note that the FTP transfer must use binary.) For example: \tmp directory
5. Add the digital certificate to the TrustStore used by the client. For example, for the DummyClientTrustFile.jks file, type:

```
keytool -import -file \tmp\IBMUSER.WAS.CA -keystore DummyClientTrustFile.jks]
```

Enabling administrative security and the default application security policy

Use this panel to configure administration and the default application security policy. This security configuration applies to the security policy for all administrative functions and is used as a default security policy for user applications. Security domains can be defined to override and customize the security policies for user applications.

About this task

Start the administrative console by specifying the following website:

```
http://server_hostname:port_number/ibm/console
```

Perform the following steps to enable administrative security. The options on the Global security panel provide greater flexibility than previous releases of WebSphere Application Server in enforcing security in your environment.

Procedure

1. Click **Security > Global security**.
2. Select the **Enable administrative security** option.
3. Optional: Clear the **Enable application security** option if you do not want to require WebSphere Application Server to authenticate application users.
4. Optional: Clear the **Use Java 2 security to restrict application access to local resources** option if you do not want to enable Java 2 Security permission checking.

When Java 2 Security is enabled and if an application requires more Java 2 security permissions than are granted in the default policy, then the application might fail to run properly until the required permissions are granted in either the `app.policy` file or the `was.policy` file of the application. AccessControl exceptions are generated by applications that do not have all the required permissions. Review the Java 2 Security and Dynamic Policy documentation if you are unfamiliar with Java 2 security.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the `app.policy` file belongs.

- a. Optional: Select the **Warn if applications are granted custom permissions** option. The `filter.policy` file contains a list of permissions that an application should not have according to the J2EE 1.3 Specification. If an application is installed with a permission specified in this policy file and this option is enabled, a warning is issued. The default is enabled.
- b. Optional: Select the **Restrict access to resource authentication data** option if you need to restrict application access to sensitive Java EE Connector Architecture (JCA) mapping authentication data.

For detailed information, see “Global security settings” on page 1257.

5. Select which authentication mechanism is active when security is enabled from the **Authentication mechanisms and expiration** menu. In this release of WebSphere Application Server, the authentication mechanism choices include LTPA and Kerberos.

Note: SWAM was deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

6. Use the User account repository menu to specify the repository that is active when security is enabled. You can configure settings for one of the following user repositories:

Federated repositories

The federated repositories functionality enables you to use multiple registries with WebSphere Application Server. These registries, which can be file-based registries, LDAP registries, or a sub-tree of an LDAP registry, are defined and theoretically combined under a single repository.

Local operating system

The implementation is a System Authorization Facility (SAF) compliant registry such as the Resource Access Control Facility (RACF), which is shared in an MVS sysplex.

Standalone LDAP registry

The stand-alone LDAP registry settings are used when users and groups reside in an external LDAP directory. When security is enabled and any of these properties are changed, go to the Global security panel and click **OK** or **Apply** to validate the changes.

Stand-alone custom registry

The stand-alone custom registry feature supports any user registry that is not implemented by WebSphere Application Server. You can use any user registry that is used in the product environment by implementing the UserRegistry interface.

7. Optional: Select the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option from the **Security > SSL certificate and key management** panel if you are using a FIPS-certified JSSE. WebSphere Application Server supports a channel framework that uses IBMJSSE2. IBMJSSE2 uses IBMJCEFIPS for cryptographic support when you enable the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option.
8. Click **OK**.

This panel performs a final validation of the security configuration. When you click **OK** or **Apply** from this panel, the security validation routine is performed and any problems are reported at the top of the page. When you complete all of the fields, click **OK** or **Apply** to accept the selected settings. Click **Save** (at the top of the panel) to persist these settings out to a file. If you see any informational messages in red text color, then there is a problem with the security validation. Typically, the message indicates the problem. So, review your configuration to verify that the user registry settings are accurate and the correct registry is selected. In some cases, the LTPA configuration might not be fully specified.

For detailed information, see “Global security settings” on page 1257.

9. Optional: Configure for SAF Authorization. For more information on these settings, see “z/OS System Authorization Facility authorization” on page 1734.

Results

Configuration is successful when error messages do not display at the top of the panel.

Disabling administrative security

You can disable administrative security through the administrative console. If administrative security is not working properly, it can cause the server to not start, or to start without providing you with the ability to log into the administrative console.

About this task

If you cannot log into the administrative console and you must disable administrative security, locate your *profile_root/bin* directory and first run the **wsadmin -conntype NONE** command. At the wsadmin prompt, type `securityoff` and then type `exit` to return to a command prompt. Restart the server with security disabled to check any incorrect settings through the administrative console.

If you can log into the administrative console, you can disable administrative security by completing the following steps:

Procedure

1. Click **Security > Global security**.
2. Deselect the **Enable administrative security** check box.
3. Restart the server.

Results

Administrative security is disabled.

Enabling security

The following provides information on how to configure security when security was not enabled during the WebSphere Application Server profile creation.

Before you begin

When you are installing WebSphere Application Server, it is recommended that you install with security enabled. By design, this option ensures that everything has been properly configured. By enabling security, you protect your server from unauthorized users and are then able to provide application isolation and requirements for authenticating application users.

It is helpful to understand security from an infrastructure perspective so that you know the advantages of different authentication mechanisms, user registries, authentication protocols, and so on. Picking the right security components to meet your needs is a part of configuring security. The following sections help you make these decisions.

Read the following articles before continuing with the security configuration:

- Security
- Security

After you understand the security components, you can proceed to configure security in WebSphere Application Server.

Attention: There are some security customization tasks that are required to enable security. These tasks require updates to the security server such as Resource Access Control Facility (RACF). You might need to include your security administrator in this process.

Procedure

1. Start the WebSphere Application Server administrative console.

Start the deployment manager and, in your browser, type in the address of your WebSphere Application Server, Network Deployment server. By default, the console is located at `http://your_host.your_domain:9060/ibm/console`.

If security is currently disabled, you are prompted for a user ID. Log in with any user ID. However, if security is currently enabled, you are prompted for both a user ID and a password. Log in with a predefined administrative user ID and password.

2. Click **Security > Global security**.

Use the Security Configuration Wizard, or configure security manually. The configuration order is not important.

gotcha: You must separately enable administrative security, and application security. Because of this split, WebSphere Application Server clients must know whether application security is disabled at the target server. Administrative security is enabled, by default. Application security is disabled, by default. Before you attempt to enable application security on the target server, verify that administrative security is enabled on that server. Application security can be in effect only when administrative security is enabled.

For more information on manual configuration, see “Authenticating users” on page 1344.

3. Configure the user account repository. For more information, see “Selecting a registry or repository” on page 1345. On the Global security panel, you can configure user account repositories such as federated repositories, local operating system, stand-alone Lightweight Directory Access Protocol (LDAP) registry, and stand-alone custom registry.

Note: You can choose to specify either a server ID and password for interoperability or enable a WebSphere Application Server installation to automatically generate an internal server ID. For more information about automatically generating server IDs, see “Local operating system settings” on page 1351.

One of the details common to all user registries or repositories is the *Primary administrative user name*. This ID is a member of the chosen repository, but also has special privileges in WebSphere Application Server. The privileges for this ID and the privileges that are associated with the administrative role ID are the same. The Primary administrative user name can access all of the protected administrative methods.

In stand-alone LDAP registries, verify that the Primary administrative user name is a member of the repository and not just the LDAP administrative role ID. The entry must be searchable.

When you use the stand-alone local operating system registry on WebSphere Application Server for z/OS, the user ID for the server is not set using the administrative console, but is set through the STARTED class in the z/OS operating system.

4. Select the **Set as current** option after you configure the user account repository. When you click **Apply** and the Enable administrative security option is set, a verification occurs to see if an administrative user ID has been configured and is present in the active user registry. The administrative user ID can be specified at the active user registry panel or from the console users link. If you do not configure an administrative ID for the active user registry, the validation fails.

Note: When you switch user registries, the `admin-authz.xml` file should be cleared of existing administrative ids and application names. Exceptions will occur in the logs for ids that exist in the `admin-authz.xml` file but do not exist in the current user registry.

5. **Optional:** You can configure and change your External Authorization provider to either WebSphere Authorization, System Authorization Facility (SAF) authorization, or an external JACC provider. For more information, see “z/OS System Authorization Facility authorization” on page 1734 and “Enabling an external JACC provider” on page 1752. To change the Authorization provider, click **Security > Global security**.

6. Configure the authentication mechanism.

Configure Lightweight Third-Party Authentication (LTPA) or Kerberos, which is new to this release of WebSphere Application Server, under Authentication mechanisms and expiration. LTPA credentials can be forwarded to other machines. For security reasons, credential expire; however, you can configure the expiration dates on the console. LTPA credentials enable browsers to visit different product servers, which means you do not have to authenticate multiple times. For more information, see Configuring the Lightweight Third Party Authentication mechanism

Note: You can configure Simple WebSphere Authentication Mechanism (SWAM) as your authentication mechanism. However, SWAM was deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release. SWAM credentials are not forwardable to other machines and for that reason do not expire.

If you want single sign-on (SSO) support, which provides the ability for browsers to visit different product servers without having to authenticate multiple times, see “Implementing single sign-on to minimize web user authentications” on page 1536. For form-based login, you must configure SSO when using LTPA.

7. Optional: Import and export the LTPA keys for cross-cell single Sign-on (SSO) between cells. For more information, see the following articles:
 - Exporting Lightweight Third Party Authentication keys.
 - Importing Lightweight Third Party Authentication keys

gotcha: If one of the cells you are connecting to resides on a Version 6.0.x system, see the topic Configuring Lightweight Third Party Authentication keys in the Version 6.0.x Information Center for more information.

8. Configure the authentication protocol for special security requirements from Java clients, if needed. You can configure Common Secure Interoperability Version 2 (CSlv2) through links on the Global security panel. The z/OS Security Authentication Service (z/SAS) protocol is provided for backwards compatibility with previous product releases, but is deprecated. Links to the z/SAS protocol panels display on the Global security panel if your environment contains servers that use previous versions of WebSphere Application Server and support the SAS protocol. For details on configuring CSlv2 or z/SAS, see the article, “Configuring Common Secure Interoperability Version 2 (CSIV2) inbound and outbound communication settings” on page 1647.

Important: z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Attention: IBM no longer ships or supports the z/OS Secure Authentication Service (z/SAS) IIOp security protocol. It is recommended that you use the Common Secure Interoperability version 2 (CSlv2) protocol. CSlv2 will interoperate with previous versions of WebSphere Application Server except for the Version 4 client.

9. Set the authorization. If you chose to use a z/OS security product during customization, then the authorization is by default set to use System Authorization Facility (SAF) authorization (EJBROLE profiles). Otherwise, the default is WebSphere Application Server authorization. Optionally, you can set a Java Authorization Contract for Containers (JACC) external authorization. See “Special considerations for controlling access to naming roles using SAF authorization” on page 1737 or “Authorization providers” on page 1713.
10. Verify the Secure Sockets Layer (SSL) repertoires for WebSphere Application Server to use. The sample customization jobs that are generated by the WebSphere z/OS Profile Management Tool or the **zpm**t command generate sample jobs to create SSL key rings that are usable if RACF is your security server. These jobs create a unique RACF certificate authority certificate for your installation with a set of server certificates signed by this certificate authority. The Application Server controller-started task ID has a SAF key ring that includes these certificates. Similarly in a WebSphere Application Server, Network Deployment environment, RACF key rings that are owned by the deployment manager user ID and the node agent user IDs are created.

A RACF key ring is uniquely identified by both the key ring name in the repertoire and the MVS user ID of the server controller process. If different WebSphere Application Server controller processes have unique MVS user IDs, you must be sure that a RACF key ring and a private key are generated, even if they share the same repertoire.

Two kinds of configurable SSL repertoires exist:

- The System SSL repertoire is used for HTTPS and Internet InterORB Protocol (IIOP) communication, and are used by the native transports. If you want to use the administrative

console after security is enabled you must define and select a System SSL type repertoire for HTTP. You must define a System SSL repertoire and select if IIOp security requires or supports SSL transport, or if a secure Remote Method Invocation (RMI) connector is selected for administrative requests.

- The Java Secure Socket Extension (JSSE) repertoire is for Java-based SSL communications.

Users must configure a System SSL repertoire to use HTTP or IIOp protocols and a Java Management Extensions (JMX) connector must be configured to use SSL. If the SOAP HTTP connector is chosen, a JSSE repertoire must be selected for the administrative subsystem. In a WebSphere Application Server, Network Deployment environment, click **System Administration > Deployment Manager > Administration Services > JMX Connectors > SOAP Connector > Custom Properties > sslConfig**.

A set of SSL repertoires are set up by the z/OS installation dialogs. These dialogs are configured to refer to SAF key rings and to files that are populated by the customization process, when generating RACF commands.

Table 82. SSL repertoires set up the z/OS installation dialogs.

This table lists the SSL repertoires that are set up by the z/OS installation dialogs.

Repertoire name	Type	Default use
NodeDefaultSSLSettings	JSSE	(Base only) configuration for SOAP JMX connector, SOAP client, web container HTTP transport
CellDefaultSSLSettings	JSSE	(Network deployment only) configuration for SOAP JMX connector, SOAP client, web container HTTP transport
DefaultIIOpSSL	SSSL	Used only if DAEMON SSL is enabled

No additional action is required if these settings are sufficient for your needs. If you want to create or modify these settings, you must ensure that the keystore files to which they refer are created.

11. Click **Security > Global security** to configure the rest of the security settings and enable security. For information about these settings, see “Global security settings” on page 1257. For additional information, see “Server and administrative security” on page 1235.
12. Validate the completed security configuration by clicking **OK** or **Apply**. If problems occur, they display at the top of the console page in red type.
13. If there are no validation problems, click **Save** to save the settings to a file that the server uses when it restarts. Saving writes the settings to the configuration repository.

Important: If you do not click **Apply** or **OK** in the Global security panel before you click **Save**, your changes are not written to the repository. The server must be restarted for any changes to take effect when you start the administrative console.

The save action enables the deployment manager to use the changed settings after WebSphere Application Server is restarted. For more information, see “Enabling security for the realm” on page 1254. A Deployment manager configuration differs from a stand-alone base application server. The configuration is stored temporarily in the deployment manager until it is synchronized with all of the node agents.

Also, verify that all of the node agents are up and running in the domain. Stop all application servers during this process. If any of the node agents are down, run a manual file synchronization utility from the node agent machine to synchronize the security configuration from the deployment manager. Otherwise, the malfunctioning node agent does not communicate with the deployment manager after security is enabled on the deployment manager.

14. Start the WebSphere Application Server administrative console.
Start the deployment manager and, in your browser, type in the address of your WebSphere Application Server, Network Deployment server. By default, the console is located at `http://your_host.your_domain:9060/ibm/console`.

If security is currently disabled, log in with any user ID. If security is currently enabled, log in with a predefined administrative ID and password. This ID is typically the server user ID that is specified when you configured the user registry.

Administrative security

Administrative security determines whether security is used at all, the type of registry against which authentication takes place, and other values, many of which act as defaults. Proper planning is required because incorrectly enabling administrative security can lock you out of the administrative console or cause the server to end abnormally.

Note: It is strongly recommended that you allow the default installation to install administrative security as on by default.

Administrative security can be thought of as a "big switch" that activates a wide variety of security settings for WebSphere Application Server. Values for these settings can be specified, but they will not take effect until administrative security is activated. The settings include the authentication of users, the use of Secure Sockets Layer (SSL), and the choice of user account repository. In particular, application security, including authentication and role-based authorization, is not enforced unless administrative security is active. Administrative security is enabled by default.

Note: Administrative security need not be activated in order for WebSphere applications to make use of JSSE methods to encrypt communication to remote sites.

Administrative security represents the security configuration that is effective for the entire security domain. A *security domain* consists of all of the servers that are configured with the same user registry *realm* name. In some cases, the realm can be the machine name of a local operating system registry. In this case, all of the application servers must reside on the same physical machine. In other cases, the realm can be the machine name of a stand-alone Lightweight Directory Access Protocol (LDAP) registry.

A multiple node configuration is supported because you can access remotely user registries that support the LDAP protocol. Therefore, you can enable authentication from anywhere.

The basic requirement for a security domain is that the access ID that is returned by the registry or repository from one server within the security domain is the same access ID as that returned from the registry or repository on any other server within the same security domain. The *access ID* is the unique identification of a user and is used during authorization to determine if access is permitted to the resource.

The administrative security configuration applies to every server within the security domain.

Why turn on administrative security?

Turning on administrative security activates the settings that protect your server from unauthorized users. Administrative security is enabled by default during the profile creation time. There might be some environments where no security is needed such as a development system. On these systems you can elect to disable administrative security. However, in most environments you should keep unauthorized users from accessing the administrative console and your business applications. Administrative security must be enabled to restrict access.

What does administrative security protect?

The configuration of administrative security for a security domain involves configuring the following technologies:

- Authentication of HTTP clients
- Authentication of IIOP clients
- Administrative console security

- Naming security
- Use of SSL transports
- Role-based authorization checks of servlets, enterprise beans, and mbeans
- Propagation of identities (RunAs)
- CBIND checks
- The common user registry
- The authentication mechanism
- Other security information that defines the behavior of a security domain includes:
 - The authentication protocol (Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) security)
 - Other miscellaneous attributes

Note: It is recommended that before registering a node with an administrative agent process, that you first have administrative security enabled in the administrative agent and base profile. Once you register a profile with the administrative agent, the state of administrative security enablement cannot be changed.

Server and administrative security:

The term *administrative security* refers to providing the authentication of users using the WebSphere administration functions, the use of Secure Sockets Layer (SSL), and the choice of user account repository.

When you configure a Local OS user registry, it uses the Resource Access Control Facility (RACF), or System Authorization Facility (SAF)-compliant, user database. Selecting the Local OS user registry as the active registry enables you to take advantage of z/OS System Authorization Facility functions directly using the WebSphere Application Server principals:

- Share identities with many other z/OS connector services
- Use SAF delegation, which minimizes the need to store user IDs and passwords in many locations in the configuration
- Utilize additional audit capabilities

These functions are available using other registries, but require identity mapping through modifications to the WebSphere Application Server system login configuration and Java Authentication and Authorization Service (JAAS) login modules. Refer to “Updating system login configurations to perform a System Authorization Facility identity user mapping” on page 1628 for more information.

Configuration of administrative security for a security domain consists of configuring the common user registry, the authentication mechanism, and other security information that defines the behavior of a security domain. The other security information that is configured includes the following components:

- Java 2 Security Manager
- Java Authentication and Authorization Service (JAAS)
- Java 2 Connector authentication data entries
- Common Secure Interoperability Version 2 (CSIv2) and z/OS Secure Authentication Service (z/SAS) authentication protocol (Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) security)
- Other miscellaneous attributes.

Where multiple nodes and multiple servers within a node are possible, you can configure certain attributes at a server level. The attributes that are configurable at a server level include security enablement for the server, Java 2 security manager enablement, and CSIv2 and z/SAS authentication protocol (RMI/IIOP

security). You can disable security on individual application servers while administrative security is enabled, however, you cannot enable security on an individual application server while administrative security is disabled.

While application server security is disabled for user requests, administrative and naming security is still enabled for that application server so that the administrative and naming infrastructure remains secure. If cell security is enabled, but security for individual servers is disabled, J2EE applications are not authenticated or authorized. However, naming and administrative security is still enforced. Consequently, because naming services can be called from user applications, grant Everyone access to the naming functions that are required so that these functions accept unauthenticated requests. User code does not directly access administrative security except through the supported scripting tools.

If you are using System Authorization Facility (SAF) authorization, then you should ensure that the UACC field for the EJBROLE profile of CosNamingRead is set to READ, and that the unauthenticated id has READ access to this profile.

Java thread identity and an operating system thread identity:

You can specify options to synchronize a Java thread identity and an operating system thread identity.

Enterprise JavaBeans (EJB) support a method-level RunAs role specification that associates a Java Platform, Enterprise Edition (Java EE) role with an EJB method invocation. The EJB method runs by using the authority associated with the designated security role. The authority is mapped to the designated role using a user identity. Normally, this identity is recognized by Web-based and Java EE runtime and is associated with the current dispatch thread. This identity governs access to only those resources and those facilities subject to Java EE security. The actual OS thread identity is unaffected by the EJB RunAs role selection and is typically the identity of the server.

Setting the OS identity thread synchronizes the Java EE role identity and OS thread (SyncToOSThread). This means that the OS thread identity is associated with the Java EE role identity for the duration of the EJB method invocation (application assemblers and deployers associate the RunAs identity with the operating system thread by setting the thread identity to the RunAs identity for specific bean methods). This association means that the caller or security role identity (rather than the server region identity) is used for z/OS system service requests such as access to files and database management systems. Note that the WebSphere Application Server for z/OS Java EE server can be configured to enable or disable this association (or synchronization). The default setting disables the ability to modify the identity on the operating system thread, regardless of the OS thread identity to RunAs identity setting in the deployment descriptor for the installed application. If the application installer does not enable synchronization, any method that sets the RunAs identity to the operating system thread fails with a no_permission error.

You complete the specification of options to synchronize a Java thread identity and an operating system thread identity by using the resource access control facility (RACF) to define FACILITY and optionally SURROGAT class profiles for Synch to OS Thread Allowed. This gives the RACF administrator in the WebSphere Application Server configuration the ability to control the permissions that allow the synchronization of the Java EE role identity and the OS thread (SyncToOSThread).

Using the administrative console, you can specify the following options for thread identity synchronization on the z/OS security options panel:

Enable WebSphere Application Server and z/OS thread identity synchronization

Specifies whether an application SyncToOSThread is permitted. When this security option is selected (meaning *true* is specified) the application-specified SyncToOSThread is honored and subsequently carried out by the EJB and web containers as indicated by EJB and web application SyncToOSThread specifications. The default is *false* or disabled.

Enable the connection manager RunAs thread identity

Specifies whether the connection manager synchronizes the current Java EE principal to the OS

thread when a connection is obtained from a resource reference that specifies `res-auth=container`. The default is *false* or disabled.

You can also select the `SyncToOSThread` support using a method-level extended deployment descriptor (XDD) for Enterprise JavaBeans (EJB). Enable this support using a distinguished environment entry defined through the EJB or web application standard deployment descriptor. During assembly or deployment, bind a value to this variable by specifying:

- *True*, which specifies that the Java EE principal or identity should be synchronized to the OS thread for all requests invoked on the EJB or web application.
- *False*, specifies the Java EE principal application or identity should not be synchronized to the OS thread for all requests invoked on the EJB or web application. This value is the default.

When processing a request, the web container understands what roles, if any, are required to access the component represented by the input URL. The container validates requestor authentication and that the authenticated user has been granted permission to the required roles. The web container makes use of the same System Authorization Facility (SAF)-based user registry and EJB role profiles as the EJB container to perform this validation. Therefore, you can use the same user registry and role profiles for administering web applications as you use for Enterprise Beans and Java EE Services. For setting thread identity, possible active user registries include:

- Local OS
- LDAP
- Custom

Application events that modify the thread identity value include:

Initial value when the first method is set

By default, invocations of servlet service methods and EJB business methods implicitly run as caller (`RunAsCaller`) unless the `Run as` field of a policy's attribute specifies otherwise. EJB client applications always run as server (`RunAsServer`).

Note: For web applications, if security constraints are not specified, the application might run with an unauthenticated user ID.

Method delegation changes to the Java EE identity (RunAs Specified)

The connection manager synchronizes the current Java EE identity with the OS thread when obtaining applications from resources references that have container-managed resource authorization (`res-auth=container`). EJB methods marked with `SyncToOSThread` cause the Java EE role identity to be synchronized to the OS thread.

WSSubject.doAs()

This setting offers flexibility when associating the Subject with remote calls on a thread without having to do a `WSSubject.doAs()` to associate the subject with the remote action.

Thread identity is temporarily reset on the server in the following situations:

JavaServer Pages (JSP) Compilation

Web container JSP compilation modifies the identity of the server if `SyncToOSThread` is enabled for the server (`security_EnableSyncToOSThread=1`).

Access of Stateful Backing Store

EJB container stateful session activation changes the identity of the server if `SyncToOSThread` is enabled. Always access the EJB stateful session backing store using the identity of the server.

Web application Reloading

When the web container reloads the web application, it changes the server identity if `SyncToOSThread` is enabled for web applications.

Connection Manager Requests

When the resource reference specifies `res-auth=application`, the thread identity is temporarily set to the identity of the server.

Note: When running with administrative security enabled, it is recommended that you have Java 2 security enabled. Exercise caution when enabling this support because it can cause general z/OS system resources (such as files and sockets) to fall outside the control of the WebSphere Application Server runtime and these system resources management to be accessible to identities established through Java EE applications.

Considerations for setting the Synch to OS Thread Allowed option:

There are a number of options to consider when setting the Synch to OS Thread Allowed option.

With the Synch to OS Thread Allowed support:

1. The application developer or assembler requests behavior by setting the special application environment entry `env-entry` in the deployment descriptor:
`com.ibm.websphere.security.SyncToOSThread=true|false`.
2. The system administrator grants the request made by the application developer or assembler using an application server configuration setting.
3. The resource access control facility (RACF) administrator controls if Synch to OS Thread Allowed can be used by defining a FACILITY class profile with an optional SURROGAT class profile to refine the control.

You can select the **Synch to OS Thread Allowed** option at development time or at assembly time:

- At development time, use Rational Application Developer to add an environment entry (environment variable) to the Enterprise JavaBean (EJB) component or web application module.

Important: Environment entries (environment variables) can be defined on individual EJB components but cannot be set on individual web components.

A Java Platform, Enterprise Edition (Java EE) standard deployment descriptor can be defined for each EJB component and for each web application module. Note that a web component is either a servlet or JavaServer Pages (JSP) files. For web components, environment entries (environment variables) can only be set on a web application module. A web application module contains servlets and JSP files.

- At assembly time, you can add or change environment entries (environment variables) using an assembly tool.

Application Synch to OS Thread Allowed:

Use application Sync to OS Thread Allowed to synchronize a Java thread identity (or JAAS subject) with the OS thread identity for the duration of the current Java Platform, Enterprise Edition (Java EE) application request.

If you do not choose this option, the OS thread identity value is the same as the servant identity value. Refer to “Java thread identity and an operating system thread identity” on page 1236 for more information.

Application Sync to OS Thread Allowed requires configuration in both the application and the application server as well as resource access control facility (RACF) permissions:

1. The WebSphere Application Server developer must configure the application to declare that it wants to run with application Sync to OS Thread
2. The WebSphere Application Server administrator must configure the application server to enable application Sync to OS Thread Allowed
3. The RACF administrator must define a FACILITY class profile and optional SURROGAT class profile to ensure that Synch to OS Thread Allowed is utilized.

The Java EE application developer configures the application for individual Enterprise JavaBeans (EJB) or web applications by setting a special env-entry in the deployment descriptor `com.ibm.websphere.security.SyncToOSThread={true|false}`. The default case in which this deployment descriptor is not specified is equivalent to defining it with a value of `false`.

When an EJB or web application that requests Sync to OS Thread Allowed is dispatched, the application server (at the request of the EJB container or the web container) synchronizes the OS thread identity associated with the current Java thread identity so the Java thread identity is current on the native thread. This synchronization is effective as long as the EJB or web application is running the current request. When the EJB or web completes processing, the native thread is restored to its former state.

If the application requests Sync to OS Thread Allowed but Sync to OS Thread Allowed is not enabled in the application server, when the application attempts to run a *no permission* exception is issued. If the application does not request Sync to OS Thread Allowed but Sync to OS Thread Allowed is enabled in the application server, no synchronization occurs and the current OS thread identity remains the same as the server identity.

Refer to “Java Platform, Enterprise Edition identity and an operating system thread identity” on page 1241 for more information about the identities discussed above.

Connection Manager RunAs Identity Enabled and system security:

WebSphere Application Server includes connector configurations that use operating system thread security. By enabling Connection Manager Sync to OS Thread support, the Java EE identity (the RunAs identity, for example) can be used to obtain the EIS connection for connector configurations that use operating system thread security.

Operating system thread security: Under certain configurations of Java EE Connector Architecture (JCA), Java Message Service (JMS), or Java database connectivity (JDBC) connectors on WebSphere Application Server for z/OS, the OS thread identity is the identity used to create the enterprise information systems (EIS) connection. Refer to Connection thread for more information on which configurations support OS thread security.

The Connection Manager Sync to OS Thread support is enabled by selecting the **Enable the connection manager RunAs thread identity** option, which is available by clicking **Security > Global security > z/OS security options**. If the **Enable WebSphere Application Server and z/OS thread identity synchronization** option is not enabled on the same administrative console panel, the connection to a resource manager under a connector configuration that uses operating system thread security is obtained using the server identity (which serves as a default in this case). Refer to the topic, z/OS security options, for more information.

The WebSphere Connection Manager performs the operating system thread security-related functions. The Connection Manager synchronizes the OS thread identity with the Java thread identity (this Java thread identity corresponds to the Java EE identity) before obtaining the EIS connection. Refer to the topic, Java thread identity and an operating system thread identity, for more information. After the Connection Manager performs the synchronization, the OS thread identity is temporarily replaced with the Java thread identity, and the Java thread identity is the identity used to obtain the EIS connection. This means that Connection Manager Sync to OS Thread support provides a way to obtain an EIS connection using the Java thread identity (the RunAs identity, for example). After obtaining the connection the Connection Manager restores the previous OS thread identity.

Note:

- The application Sync to OS Thread Allowed setting is not pertinent to determining which identity is used to create a connection under a connector configuration that supports operating system thread security. The topic, Using thread identity support, explains which identity is used to create a connection in which the configuration is unchanged by the application Sync to OS Thread

Allowed support. In particular, for connector configurations that use operating system thread security (but in which Connection Manager Sync to OS Thread is disabled), the server identity is used to create the connection regardless of the application Sync to OS Thread Allowed setting or the current RunAs identity.

- Connection Manager Sync to OS Thread support is only pertinent to obtaining EIS Connections managed by WebSphere Connection Management. For example Connection Manager Sync to OS Thread support might be pertinent to Java database connectivity (JDBC) Connections obtained from application requests on DataSource objects configured via WebSphere Application Server administrative console, and then looked up in Java Naming and Directory Interface (JNDI). (This would depend on whether or not a specific DataSource instance under a specific JDBC provider used OS thread security or not). However, Connection Manager Sync to OS Thread support would not be pertinent for JDBC Connections obtained using the unmanaged DriverManager.getConnection(...) API. Access to such unmanaged resources for which the authorization is performed against the OS thread identity might be affected by the application Sync to OS Thread Allowed support, however.
- Connection Manager Sync to OS Thread support is used (or not used) for connection requests made by user-written code (such as JMS or JDBC calls from a stateless session bean), connection requests made by certain components of WebSphere Application Server (such as the Message Driven Beans (MDB) Listener), or connection requests made by tooling-generated code (such as container-managed persistence (CMP) beans).
- Some (but not all) connector configurations that use the Java EE identity also use OS Thread Security. Connector configurations such as the Customer Information Control System (CICS) CTG Connector in local mode allow use of the Java EE identity using a different Connection Manager mechanism to create the EIS connection. This configuration does not use operating system thread security.

Refer to the topic, Connection thread identity, for details concerning connector configurations that use operating system thread security. You can also refer to the topic, Using thread identity support.

Refer to the topic, Java Platform, Enterprise Edition identity and an operating system thread identity, for more information about the identities discussed above.

When to use application Synch to OS Thread Allowed:

Specify application Synch to OS Thread Allowed to use the Java thread identity to access the non-WebSphere-managed resources accessed by your application.

As a result of exploiting the application Synch to OS Thread Allowed support, access control privileges associated with the current Java thread identity (not the access control privileges for the server identity) are applied when accessing these resources. (An example of a non-WebSphere-managed resource is the file system.)

Use application Synch to OS Thread Allowed to control file system access based on the Java thread identity. The default Java thread identity is the client identity, which is the user who invoked the application. The Java Platform, Enterprise Edition (Java EE) RunAS role deployment descriptor settings can override this default to choose from other choices. These choices include the server identity or the specified role, such as a user ID (chosen by the application server) configured to be in the specified role. By running with the Java thread identity and specifying Synch to OS Thread Allowed, all file system access control decisions are based on the access privileges of the Java thread identity.

Application Synch to OS Thread Allowed is not relevant to container managed persistence (CMP) entity beans but Connection Management RunAs Identity Enabled might be relevant, depending on the JDBC Provider.

Refer to the following:

- Deploying secured applications and Developing applications that use programmatic security for details on WebSphere role-based security.
- “Connection Manager RunAs Identity Enabled and system security” on page 1239 for more information for CMP entity beans.
- “Java Platform, Enterprise Edition identity and an operating system thread identity” for more information about identities.

Java Platform, Enterprise Edition identity and an operating system thread identity:

A user is identified using an identity that must be authenticated by WebSphere Application Server in order to access a WebSphere Application Server application in a secure environment.

Understanding the different types of identities: The WebSphere Application Server authenticates the user identity and represents the user with a Java Authentication and Authorization Service (JAAS) subject. A subject contains one or more principals (which are technology-dependent representations of the authenticated user identity). More detail follows:

User identities

Java EE identity

The user identity authenticated by WebSphere and used for access control decisions made by the WebSphere Application Server at Java Platform, Enterprise Edition (Java EE) runtime (such as the user identity associated with a Java EE application request and used in EJB method permission access control decisions).

Operating system (OS) identity

The user identity authenticated by the underlying operating system and used for access control decisions made by the OS and its subsystems (such as the user identity associated with a WebSphere Application Server for z/OS servant by the SAF STARTED class facility and used by the file system for access control decisions when the server attempts to access files).

Thread identity

Java thread identity

The Java EE identity currently associated with a Java thread managed by the WebSphere Java EE runtime (a Java thread is the Java Virtual Machine (JVM) representation of a thread). The Java thread identity is associated with an operating system (OS) thread, but the JVM manages the user identity on the Java representation of the thread - separate from the user identity that the operating system manages on the operating system thread. The Java EE identity is current on the Java thread for the life of the a given application request

OS thread identity

The operating system identity currently associated with the operating system thread. The OS thread identity is typically the user identity assigned to servant and is normally not the same as the Java thread identity. Note that Java EE maintains a Java EE identity that corresponds to the OS thread identity assigned to the servant. This Java EE identity can be used as a RunAs identity.

RunAs identity

The Java EE identity chosen as the Java thread identity for a given Java EE application request (based on the RunAs deployment descriptor policy on an Enterprise JavaBeans (EJB) invoked within the Java EE application request). The Java EE identity is normally the identity of the authenticated user who has made the Java EE application request. WebSphere Application Server RunAs policy allows three choices in assigning the Java thread identity for the current request:

1. Assign the client (for example, user) Java EE identity - also referred to as selecting RunAs of "Caller"
2. Assign the server's Java EE identity

3. Assign the Java EE identity that is in the specified role

When security is enabled, each WebSphere Application Server for z/OS request that invokes a Java EE component is authenticated to ensure that an authorized user is requesting access. A user is represented by a Java EE identity (also called a JAAS subject). This Java EE identity contains one or more principals, and each principal corresponds to a specific user identity. This association is managed by the WebSphere Application Server. The Java EE identity and operating system OS thread identity are associated with each other because they have the same name and represent the same user.

WebSphere Application Server for z/OS dispatches component requests in one of its available servant processes. Within the servant process the component request is dispatched on a Java thread. A Java thread is then mapped internally by the JVM to a z/OS thread control block (TCB). A TCB is an operating system thread and is considered part of the native process infrastructure. A servant process has a OS identity assigned to it when it starts. The z/OS security policy uses the SAF STARTED class facility to assign the identity.

Java EE authorization decisions including role authorization and permission checking are determined using the Java EE identity. Through a configuration setting, role authorization checking can be delegated to the underlying operating system security manager (such as System Authorization Facility (SAF)), in which case the associated operating system OS identity is used in the role authorization decision.

Some resource managers on z/OS use the OS thread identity to make authorization decisions. For example, file system access control is determined entirely based on which OS thread identity is currently on the TCB when the file is accessed. Similarly, local Java database connectivity (JDBC) connections to DB2 for z/OS use the TCB OS thread identity as the authorization identity under certain configurations. For resource managers that use the OS thread identity such as DB2 for z/OS (and unlike the file system) that applications access through Java Message Service (JMS), JDBC, or Java EE Connector Architecture (JCA) connectors managed by the WebSphere Application Server for z/OS connection management, we say that the connectors to these z/OS resource managers "use operating system thread security".

For more information, refer to:

- "Java thread identity and an operating system thread identity" on page 1236
- "Connection Manager RunAs Identity Enabled and system security" on page 1239
- "Application Synch to OS Thread Allowed" on page 1238
- Connection thread identity
- Using thread identity support

Security considerations when in a multi-node WebSphere Application Server WebSphere Application Server, Network Deployment environment

WebSphere Application Server, Network Deployment supports centralized management of distributed nodes and application servers. This support inherently brings complexity, especially when security is included. Because everything is distributed, security plays an even larger role in ensuring that communications are appropriately secure between application servers and node agents, and between node agents (a node-specific configuration manager) and the deployment manager (a domain-wide, centralized configuration manager).

Before you begin

Because the processes are distributed, an authentication mechanism must be selected that supports an authentication token such as Lightweight Third Party Authentication (LTPA). The tokens are encrypted, signed and forwardable to remote processes. However, the tokens have expiration times which are set on the WebSphere Application Server administrative console. The SOAP connector which is the default connector, is used for administrative security and does not have retry logic for expired tokens. However, the protocol is stateless so a new token is created for each request if there is not sufficient time to run the request with the given time left in the token. An alternative connector is the Remote Method Invocation

(RMI) connector, which is stateful, and has some retry logic to correct expired tokens by resubmitting the requests after the error is detected. Also, because tokens have time-specific expiration, the synchronization of the system clocks is crucial to the proper operation of token-based validation. If the clocks are off by too much (approximately 10-15 minutes), you can encounter unrecoverable validation failures that can be avoided by having them in sync. Verify that the clock time, date, and time zones are all the same between systems. It is acceptable for nodes to be across time zones, provided that the times are correct within the time zones (for example, 5 PM CST = 6 PM EST, and so on).

You have additional considerations with Secure Sockets Layer (SSL). WebSphere Application Server for z/OS can use Resource Access Control Facility (RACF) keyrings to store the keys and the truststores that are used for SSL, but different SSL protocols are used internally. You must be sure to set up both:

- A system SSL repertoire for use by the web container
- A Java Secure Sockets Extension (JSSE) SSL repertoire for use by the SOAP HTTP connector if the SOAP connector is used for administrative requests

Verify that the keystores and truststores that you configure are set up to trust only the servers to which they communicate. Make sure they do include the necessary signer certificates from those servers in the trust files of all servers in the domain. When using a certificate authority (CA) to create personal certificates, it is easier to ensure that all servers trust one another by having the CA root certificate in all the signers.

The WebSphere z/OS Profile Management Tool or the **zpm** command uses the same certificate authority to generate certificates for all servers within a given cell, including those of the node agents and the deployment manager.

About this task

Consider the following issues when using or planning for a WebSphere Application Server, Network Deployment environment.

Procedure

- When attempting to run system management commands such as the **stopNode** command, explicitly specify administrative credentials to perform the operation. Most commands accept **-user** and **-password** parameters to specify the user ID and password, respectively. Specify the user ID and password of an administrative user; for example, a user who is a member of the console users with Operator or Administrator privileges or the administrative user ID that is configured in the user registry. An example of the **stopNode** command follows:

```
stopNode.sh -username user -password pass
```
- Verify that the configuration at the node agents is always synchronized with the deployment manager prior to starting or restarting a node. To manually get the configuration synchronized, issue the **syncNode** command from each node that is not synchronized. To synchronize the configuration for node agents that are started, click **System Administration > Nodes**. Select all the started nodes, and then click **Synchronize**.
- Verify that the LTPA token expiration period is long enough to complete your longest downstream request. Some credentials are cached and therefore the timeout does not always include the length of the request.
- The administrative connector that is used by default for system management is SOAP. SOAP is a stateless HTTP protocol. For most situations, this connector is sufficient. If you have a problem using the SOAP connector, you might want to change the default connector on all the servers from SOAP to RMI. The RMI connector uses Common Secure Interoperability Version 2 (CSlv2), a stateful, interoperable protocol, and can be configured to use identity assertion (downstream delegation), message-layer authentication (BasicAuth or Token), and client certificate authentication (for server trust isolation). To change the default connector on a given server, go to **Administration Services** under Additional properties for that server.

- An error message might occur within the administrative subsystem security. This error indicates that the sending process did not supply a credential to the receiving process. Typically the cause of this problem is the sending process has security disabled while the receiving process has security enabled. This setup typically indicates that one of the two processes are not synchronized with the cell. Having security disabled for a specific application server does not have any effect on administrative security.

Results

Proper understanding of the security interactions between distributed servers greatly reduces the problems that are encountered with secure communications. Security adds complexity because additional function must be managed. For security to work properly, it needs thorough consideration during the planning of your infrastructure.

What to do next

When you have security problems that are related to the WebSphere Application Server, Network Deployment environment, see Troubleshooting security configurations to find additional information about the problem. When trace is needed to solve a problem because servers are distributed, it is often required to gather trace on all servers simultaneously while recreating the problem. This trace can be enabled dynamically or statically, depending on the type of problem that is occurring.

Application security

Application security enables security for the applications in your environment. This type of security provides application isolation and requirements for authenticating application users

In previous releases of WebSphere Application Server, when a user enabled global security, both administrative and application security were enabled. In WebSphere Application Server Version 6.1, the previous notion of global security is split into administrative security and application security, each of which you can enable separately.

As a result of this split, WebSphere Application Server clients must know whether application security is disabled at the target server. Administrative security is enabled, by default. Application security is disabled, by default. Before you can enable application security, you must verify that administrative security is enabled. Application security is in effect only when administrative security is enabled.

An Application Server Enablement Tag, which is specific to WebSphere Application Server, is imported into the Interoperable Object Reference (IOR) to indicate if application security is disabled for the server where the object lives. This tag is server-specific and enables clients to know when application security is disabled at the target server of its request.

For web resources, when application security is enabled, security constraints on those resources in web.xml are enforced. When accessing a protected resource, a web client is prompted for authentication.

For enterprise bean resources, when application security is disabled, the client Common Secure Interoperability version 2 (CSIv2) code ignores the CSIv2 security tags for objects that are unknown system objects. When pure clients see that application security is disabled, these clients prompt for naming lookups, but do not prompt for enterprise bean operations.

Java 2 security

Java 2 security provides a policy-based, fine-grain access control mechanism that increases overall system integrity by checking for permissions before allowing access to certain protected system resources. Java 2 security guards access to system resources such as file I/O, sockets, and properties. Java 2 Platform, Enterprise Edition (J2EE) security guards access to web resources such as servlets, JavaServer Pages (JSP) files and Enterprise JavaBeans (EJB) methods.

Because Java 2 security is relatively new, many existing or even new applications might not be prepared for the very fine-grain access control programming model that Java 2 security is capable of enforcing. Administrators need to understand the possible consequences of enabling Java 2 security if applications are not prepared for Java 2 security. Java 2 security places some new requirements on application developers and administrators.

Note: The application server does not support a custom Java security manager implementation.

Java 2 security for deployers and administrators

Although Java 2 security is supported, it is disabled by default. You can configure Java 2 security and administrative security independently of one another. Disabling administrative security does not disable Java 2 security automatically. You need to explicitly disable it.

If your applications, or third-party libraries are not ready, having Java 2 security enabled causes problems. You can identify these problems as Java 2 security `AccessControlExceptions` in the system log or trace files. If you are unsure about the Java 2 security readiness of your applications, disable Java 2 security initially to get your application installed and verify that it is working properly.

The policy embodied by these policy files cannot be made more restrictive because the product might not have the necessary Java 2 security `doPrivileged` APIs in place. The restrictive policy is the default policy. You can grant additional permissions, but you cannot make the default more restrictive because `AccessControlExceptions` exceptions are generated from within WebSphere Application Server. The product does not support a more restrictive policy than the default that is defined in the policy files previously mentioned.

Several policy files are used to define the security policy for the Java process. These policy files are static (code base is defined in the policy file) and in the default policy format provided by the IBM Developer Kit, Java Technology Edition. For enterprise application resources and utility libraries, WebSphere Application Server provides dynamic policy support. The code base is dynamically calculated based on deployment information and permissions are granted based on template policy files during runtime. Refer to the “Java 2 security policy files” on page 1249 for more information.

Syntax errors in the policy files cause the application server process to fail, so edit these policy files carefully.

If an application is not prepared for Java 2 security, if the application provider does not provide a `was.policy` file as part of the application, or if the application provider does not communicate the expected permissions the application is likely to cause Java 2 security access control exceptions at runtime. It might not be obvious that an application is not prepared for Java 2 security. Several run-time debugging aids help troubleshoot applications that might have access control exceptions. See the Java 2 security debugging aids for more details. See “Handling applications that are not Java 2 security ready” on page 1247 for information and strategies for dealing with such applications.

It is important to note when Java Security is enabled in the administrative security settings, the installed security manager does not currently check `modifyThread` and `modifyThreadGroup` permissions for non-system threads. Allowing web and Enterprise JavaBeans (EJB) application code to create or modify a thread can have a negative impact on other components of the container and can affect the capability of the container to manage enterprise bean life cycles and transactions.

Java 2 security for application developers

Application developers must understand the permissions that are granted in the default WebSphere policy and the permission requirements of the SDK APIs that their application calls to know whether additional permissions are required. The Permissions in the Java 2 SDK reference in the resources section describes which APIs require which permission.

Application providers can assume that applications have the permissions granted in the default policy previously mentioned. Applications that access resources not covered by the default WebSphere policy are required to grant the additional Java 2 security permissions to the application.

While it is possible to grant the application additional permissions in one of the other dynamic WebSphere policy files or in one of the more traditional `java.policy` static policy files, the `was.policy` file, which is embedded in the EAR file ensures the additional permissions are scoped to the exact application that requires them. Scoping the permission beyond the application code that requires it can permit code that normally does not have permission to access particular resources.

If an application component is being developed, like a library that might actually be included in more than one `.ear` file, then the library developer needs to document the required Java 2 permissions that are required by the application assembler. There is no `was.policy` file for library-type components. The developer must communicate the required permissions through application programming interface (API) documentation or some other external documentation.

If the component library is shared by multiple enterprise applications, the permissions can be granted to all enterprise applications on the node in the `app.policy` file.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the `app.policy` file belongs.

If the permission is only used internally by the component library and the application is never granted access to resources that are protected by the permission, it might be necessary to mark the code as **privileged**. Refer to the, `AccessControlException`, topic for more details. However, improperly inserting a `doPrivileged` call might open up security holes. Understand the implication of `doPrivileged` call to make a correct judgement.

The section on Dynamic policy files in “Java 2 security policy files” on page 1249 describes how the permissions in the `was.policy` files are granted at runtime.

Developing an application to use with Java 2 security might be a new skill and impose a security awareness not previously required of application developers. Describing the Java 2 security model and the implications on application development is beyond the scope of this section. The following URL can help you get started: <http://java.sun.com/j2se/1.5.0/docs/guide/security/index.html>.

Debugging Aids

The WebSphere Application Server `SYSOUT` file and the `com.ibm.websphere.java2secman.norethrow` property are the two primary aids for debugging.

The WebSphere System Log or Trace Files

The `AccessControl` exception that is logged in the system log or trace files contains the permission violation that causes the exception, the exception call stack, and the permissions granted to each stack frame. This information is usually enough to determine the missing permission and the code requiring the permission.

The `com.ibm.websphere.java2secman.norethrow` property

When Java 2 security is enabled in WebSphere Application Server, the security manager component creates a `java.security.AccessControl` exception when a permission violation occurs. This exception, if not handled, often causes a run-time failure. This exception is also logged in the `SYSOUT` file.

However, when the Java virtual machine `com.ibm.websphere.java2secman.norethrow` property is set and has a value of `true`, the security manager does not create the `AccessControl` exception. This information is logged.

This property is intended for a sandbox or debug environment because it instructs the security manager not to create the `AccessControl` exception. Java 2 security is not enforced. Do not use this property in a production environment where a relaxed Java 2 security environment weakens the integrity that Java 2 security is intended to produce.

This property is valuable in a sandbox or test environment where the application can be thoroughly tested and where the system log or trace files can be inspected for `AccessControl` exceptions. Because this property does not create the `AccessControl` exception, it does not propagate the call stack and does not cause a failure. Without this property, you have to find and fix `AccessControl` exceptions one at a time.

Handling applications that are not Java 2 security ready

If the increased system integrity that Java 2 security provides is important, then contact the application provider to have the application support Java 2 security or at least communicate the required additional permissions beyond the default WebSphere Application Server policy that must be granted.

The easiest way to deal with such applications is to disable Java 2 security in WebSphere Application Server. The downside is that this solution applies to the entire system and the integrity of the system is not as strong as it might be. Disabling Java 2 security might not be acceptable depending on the organization security policies or risk tolerances.

Another approach is to leave Java 2 security enabled, but to grant either just enough additional permissions or grant all permissions to just the problematic application. Granting permissions however, might not be a trivial thing to do. If the application provider has not communicated the required permissions in some way, no easy way exists to determine what the required permissions are and granting all permissions might be the only choice. You minimize this risk by locating this application on a different node, which might help isolate it from certain resources. Grant the `java.security.AllPermission` permission in the `was.policy` file that is embedded in the application `.ear` file, for example:

```
grant codeBase "file:${application}" {
    permission java.security.AllPermission;
};
```

The server.policy file

The `server.policy` file is located in the `app_server_root/properties/` directory.

This policy defines the policy for the WebSphere Application Server classes. At present, all the server processes on the same installation share the same `server.policy` file. However, you can configure this file so that each server process can have a separate `server.policy` file. Define the policy file as the value of the `java.security.policy` Java system properties. For details of how to define Java system properties, refer to the Process definition section of the Manage application servers file.

The `server.policy` file is not a configuration file managed by the repository and the file replication service. Changes to this file are local and do not get replicated to other machines. Use the `server.policy` file to define Java 2 security policy for server resources. Use the `app.policy` file (per node) or the `was.policy` file (per enterprise application) to define Java 2 security policy for enterprise application resources.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the `app.policy` file belongs.

The java.policy file

The file represents the default permissions that are granted to all classes. The policy of this file applies to all the processes launched by the Java Virtual Machine in the WebSphere Application Server.

The java.policy file is located in the *app_server_root/java/lib/security* directory.

Troubleshooting

Error message CWSCJ0314E

Symptom:

Error message CWSCJ0314E: Current Java 2 security policy reported a potential violation of Java 2 security permission. Refer to Problem Determination Guide for further information. {0}Permission\ : {1}Code\ : {2} {3}Stack Trace\ : {4}Code Base Location\ : {5} Current Java 2 security policy reported a potential violation of Java 2 Security Permission. Refer to Problem Determination Guide for further information. {0}Permission\ : {1}Code\ : {2} {3}Stack Trace\ : {4}Code Base Location\ : {5}

Problem:

The Java security manager checkPermission method reported a security exception on the subject permission with debugging information. The reported information can be different with respect to the system configuration. This report is enabled by either configuring a Reliability Availability Service Ability (RAS) trace into debug mode or specifying a Java property.

See Enabling trace for information on how to configure RAS trace in debug mode.

Specify the following property in the JVM Settings panel from the administrative console:

java.security.debug. Valid values include:

access

Print all debug information including: required permission, code, stack, and code base location.

stack Print debug information including: required permission, code, and stack.

failure Print debug information including: required permission and code.

Recommended response:

The reported exception might be critical to the secure system. Turn on security trace to determine the potential code that might have violated the security policy. After the violating code is determined, verify if the attempted operation is permitted with respect to Java 2 security, by examining all applicable Java 2 security policy files and the application code.

If the application is running with Java Mail, this message might be benign. You can update the was.policy file to grant the following permissions to the application:

```
permission java.io.FilePermission "${user.home}${/}.mailcap", "read";
permission java.io.FilePermission "${user.home}${/}.mime.types", "read";
permission java.io.FilePermission "${java.home}${/}lib${/}mailcap", "read";
permission java.io.FilePermission "${java.home}${/}lib${/}mime.types", "read";
```

SecurityException - Access denied

Symptom:

If Java security is enabled, and permissions to read the jaxm.properties file is not granted, when a SOAPFactory instance is created through a call to javax.xml.soap.SOAPFactory.newInstance(), or a MessageFactory instance is created through a call to MessageFactory.newInstance(), a SecurityException exception occurs, and the following exception is written to the system log:

Permission:

```
/opt/IBM/WebSphere/AppServer/java/jre/lib/jaxm.properties : access denied
(java.io.FilePermission /opt/IBM/WebSphere/AppServer/java/jre/lib/jaxm.properties
read)
```

Code:

```
com.ibm.ws.wsfvt.test.binding.addr1.binder.AddressBinder
in {file:/opt/IBM/WebSphere/AppServer/profiles/AppSrv01/installedApps/
ahp6405Node01Cell1/DataBinding.ear/address1.war/WEB-INF/lib
/addressbinder1.jar}
```

Stack Trace:

```
java.security.AccessControlException: access denied (java.io.FilePermission
/opt/IBM/WebSphere/AppServer/java/jre/lib/jaxm.properties read)
.
```

Problem:

The Java 2 Security policy reports a potential violation of Java 2 Security permission.

Recommended response:

The SOAPFactory ignores the exception, and continues on to the next means of determining which implementation to load. Therefore, you can ignore the log entry for this security exception.

Because this product uses the SOAPFactory to support other web services technologies, such as WS-Addressing (WS-A), WS-Atomic Transaction (WS-AT), and WS-Notification, you can ignore this SecurityException in any web services application where Java security is enabled.

Messages

Message:	CWSCJ0313E: Java 2 security manager debug message flags are initialized: TrDebug: {0}, Access: {1}, Stack: {2}, Failure: {3}
Problem:	Configured values of the valid debug message flags for security manager.

Message:	CWSCJ0307E: Unexpected exception is caught when trying to determine the code base location. Exception: {0}
Problem:	An unexpected exception is caught when the code base location is determined.

Java 2 security policy files:

The Java 2 Platform, Enterprise Edition (J2EE) Version 1.3 and later specifications have a well-defined programming model of responsibilities between the container providers and the application code. Using Java 2 security manager to help enforce this programming model is recommended. Certain operations are not supported in the application code because such operations interfere with the behavior and operation of the containers. The Java 2 security manager is used in the product to enforce responsibilities of the container and the application code.

Note: The application server does not support a custom Java security manager implementation.

This product provides support for policy file management. A number of policy files in the product are either static or dynamic. *Dynamic policy* is a template of permissions for a particular type of resource. No relative code base is defined in the dynamic policy template. The code base is dynamically calculated from the deployment and run-time data.

Static policy files

Table 83. Static policy files.

This table lists the location of the static policy files.

Policy file	Location
java.policy	<i>app_server_root/java/jre/lib/security/java.policy</i> . Default permissions are granted to all classes. The policy of this file applies to all the processes launched by WebSphere Application Server.
server.policy	<i>profile_root/properties/server.policy</i> . Default permissions are granted to all the product servers.
client.policy	<i>profile_root/properties/client.policy</i> . Default permissions are granted for all of the product client containers and applets on a node.

The static policy files are not managed by configuration and file replication services. Changes made in these files are local and are not replicated to other nodes in the WebSphere Application Server, Network Deployment cell.

Dynamic policy files

Table 84. Dynamic policy files.

This table lists the location of the dynamic policy files.

Policy file	Location
spi.policy	<i>profile_root/config/cells/cell_name/nodes/node_name/spi.policy</i> This template is for the Service Provider Interface (SPI) or the third-party resources that are embedded in the product. Examples of SPI are the Java Message Service (JMS) in MQ Series and Java database connectivity (JDBC) drivers. The code base for the embedded resources are dynamically determined from the configuration (<i>resources.xml</i> file) and run-time data, and permissions that are defined in the <i>spi.policy</i> files are automatically applied to these resources and JAR files that are specified in the class path of a resource adapter. The default permission of the <i>spi.policy</i> file is <i>java.security.AllPermissions</i> .
library.policy	<i>profile_root/config/cells/cell_name/nodes/node_name/library.policy</i> This template is for the library (Java library classes). You can define a shared library to use in multiple product applications. The default permission of the <i>library.policy</i> file is empty.
app.policy	<i>profile_root/config/cells/cell_name/nodes/node_name/app.policy</i> The <i>app.policy</i> file defines the default permissions that are granted to all of the enterprise applications running on <i>node_name</i> in <i>cell_name</i> . Note: Updates to the <i>app.policy</i> file only apply to the enterprise applications on the node to which the <i>app.policy</i> file belongs.
was.policy	<i>profile_root/config/cells/cell_name/applications/ear_file_name/deployments/application_name/META-INF/was.policy</i> This template is for application-specific permissions. The <i>was.policy</i> file is embedded in the enterprise archive (EAR) file.
ra.xml	<i>rar_file_name/META-INF/was.policy.RAR</i> This file can have a permission specification that is defined in the <i>ra.xml</i> file. The <i>ra.xml</i> file is embedded in the RAR file.

Grant entries that are specified in the *app.policy* and *was.policy* files must have a code base defined. If grant entries are specified without a code base, the policy files are not loaded properly and the application can fail. If the intent is to grant the permissions to all applications, use *file:\${application}* as a code base in the grant entry.

Syntax of the policy file

A policy file contains several policy entries. The following example depicts each policy entry format:

```
grant [codebase <Codebase>] {  
  permission <Permission>;  
  permission <Permission>;  
}
```

```

permission <Permission>;
};

<CodeBase>: A URL.
  For example, "file:${java.home}/lib/tools.jar"
  When [codebase <Codebase>] is not specified, listed
  permissions are applied to everything.
  If URL ends with a JAR file name, only the classes in the
  JAR file belong to the codebase.
  If URL ends with "/", only the class files in the specified
  directory belong to the codebase.
  If URL ends with "*", all JAR and class files in the specified
  directory belong to the codebase.
  If URL ends with "-", all JAR and class files in the specified
  directory and its subdirectories belong to the codebase.
<Permissions>: Consists from
  Permission Type : class name of the permission
  Target Name    : name specifying the target
  Actions        : actions allowed on target
  For example,
  java.io.FilePermission "/tmp/xxx", "read,write"

```

Refer to developer kit specifications for the details of each permission.

Syntax of dynamic policy

You can define permissions for specific types of resources in dynamic policy files for an enterprise application. This action is achieved by using *product-reserved symbols*. The reserved symbol scope depends on where it is defined. If you define the permissions in the `app.policy` file, the symbol applies to all the resources on all of the enterprise applications that run on `node_name`. If you define the permissions in the `META-INF/was.policy` file, the symbol applies only to the specific enterprise application. Valid symbols for the code base are listed in the following table:

Table 85. Dynamic policy syntax.

This table describes valid symbols for the code base for dynamic policy files.

Symbol	Meaning
file:\${application}	Permissions apply to all the resources within the application
file:\${jars}	Permissions apply to all the utility Java archive (JAR) files within the application
file:\${ejbComponent}	Permissions apply to the Enterprise JavaBeans (EJB) resources within the application
file:\${webComponent}	Permissions apply to the web resources within the application
file:\${connectorComponent}	Permissions apply to the connector resources within the application

You can specify the module name for a granular setting, except for these entries that are specified by the code base symbols. For example:

```

grant codeBase "file:DefaultWebApplication.war" {
  permission java.security.SecurityPermission "printIdentity";
};

grant codeBase "file:IncCMP11.jar" {
  permission java.io.FilePermission
  "${user.install.root}${/}bin${/}DefaultDB${/}-",
  "read,write,delete";
};

```

The sixth and seventh lines in the previous code sample are one continuous line. You can use a relative code base only in the `META-INF/was.policy` file. Several product-reserved symbols are defined to associate the permission lists to a specific type of resources.

Table 86. Dynamic policy syntax.

This table describes several product-reserved symbols that are defined to associate the permission lists to a specific type of resource.

Symbol	Meaning
file:\${application}	Permissions apply to all the resources within the application

Table 86. Dynamic policy syntax (continued).

This table describes several product-reserved symbols that are defined to associate the permission lists to a specific type of resource.

Symbol	Meaning
file:\${jars}	Permissions apply to all the utility JAR files within the application
file:\${ejbComponent}	Permissions apply to the enterprise beans resources within the application
file:\${webComponent}	Permissions apply to the web resources within the application
file:\${connectorComponent}	Permissions apply to the connector resources both within the application and in the standalone connector resources.

Five embedded symbols are provided to specify the path and the name for the `java.io.FilePermission` permission. These symbols enable flexible permission specification. The absolute file path is fixed after the installation of the application.

Table 87. Dynamic policy syntax.

This table describes the embedded symbols that are provided to specify the path and name for the `java.io.FilePermission` permission.

Symbol	Meaning
\${app.installed.path}	Path where the application is installed
\${was.module.path}	Path where the module is installed
\${current.cell.name}	Current cell name
\${current.node.name}	Current node name
\${current.server.name}	Current server name

Attention: Do not use the `${was.module.path}` in the `${application}` entry.

Carefully determine where to add a new permission. An incorrectly specified permission causes an `AccessControlException` exception. Because dynamic policy resolves the code base at runtime, determining which policy file has a problem is difficult. Add a permission only to the necessary resources. For example, use `${ejbcomponent}`, and etc instead of `${application}`, and update the `was.policy` file instead of the `app.policy` file, if possible.

Static policy filtering

Limited static policy filtering support exists. If the `app.policy` file and the `was.policy` file have permissions that are defined in the `filter.policy` file with the `filterMask` keyword, the runtime removes the permissions from the applications and an audit message is logged. However, if the permissions that are defined in the `app.policy` and the `was.policy` files are compound permissions, for example, `java.security.AllPermission`, the permission is not removed, but a warning message is written to the log file. The policy filtering only supports Developer Kit permissions; the permissions package name begins with `java` or `javax`.

Run-time policy filtering support is provided to force stricter filtering. If the `app.policy` file and the `was.policy` file have permissions that are defined in the `filter.policy` file with the `runtimeFilterMask` keyword, the runtime removes the permissions from the applications no matter what permissions are granted to the application. For example, even if a `was.policy` file has the `java.security.AllPermission` permission granted to one of its modules, specified permissions such as the `runtimeFilterMask` permission are removed from the granted permission during runtime.

Policy file editing

Using the policy tool that is provided by the Developer Kit (`app_server_root/java/jre/bin/policytool`), to edit the previous policy files is recommended. For WebSphere Application Server, Network Deployment, extract the policy files from the repository before editing. After the policy file is extracted, use the policy tool to edit the file. Check the modified policy files into the repository and synchronize them with other nodes.

Troubleshooting

To debug the dynamic policy, choose one of three ways to generate the detail report of the `AccessControlException` exception.

- **Trace** (Configured by RAS trace). Enables traces with the trace specification:

Attention: The following command is one continuous line

```
com.ibm.ws.security.policy.*=all=enabled:  
com.ibm.ws.security.core.SecurityManager=all=enabled
```

- **Trace** (Configured by property). Specifies a Java `java.security.debug` property. Valid values for the `java.security.debug` property are as follows:
 - **Access**. Print all debug information including required permission, code, stack, and code base location.
 - **Stack**. Print debug information including, required permission, code, and stack.
 - **Failure**. Print debug information including required permission and code.
- **ffdc**. Enable `ffdc`, modify the `ffdcRun.properties` file by changing `Level=4` and `LAE=true`. Look for an `Access Violation` keyword in the log file.

Access control exception for Java 2 security:

The Java 2 security behavior is specified by its *security policy*. The security policy is an access-control matrix that specifies which system resources certain code bases can access and who must sign them. The Java 2 security policy is declarative and it is enforced by the `java.security.AccessController.checkPermission` method.

The following example depicts the algorithm for the `java.security.AccessController.checkPermission` method. For the complete algorithm, refer to the Java 2 security check permission algorithm in the Security: Resources for learning article.

```
i = m;  
while (i > 0) {  
    if (caller i's domain does not have the permission)  
        throw AccessControlException;  
    else if (caller i is marked as privileged)  
        return;  
    i = i - 1;  
};
```

The algorithm requires that all the classes or callers on the call stack have the permissions when a `java.security.AccessController.checkPermission` method is performed or the request is denied and a `java.security.AccessControlException` exception is created. However, if the caller is marked as *privileged* and the class (caller) is granted these permissions, the algorithm returns and does not traverse the entire call stack. Subsequent classes (callers) do not need the required permission granted.

A `java.security.AccessControlException` exception is created when certain classes on the call stack are missing the required permissions during a `java.security.AccessController.checkPermission` method. Two possible resolutions to the `java.security.AccessControlException` exception are as follows:

- If the application is calling a Java 2 security-protected application programming interface (API), grant the required permission to the application Java 2 security policy. If the application is not calling a Java 2 security-protected API directly, the required permission results from the side-effect of the third-party APIs accessing Java 2 security-protected resources.
- If the application is granted the required permission, it gains more access than it needs. In this case, it is likely that the third party code that accesses the Java 2 security-protected resource is not properly marked as privileged.

Example call stack

This example of a call stack indicates where application code is using a third-party API utility library to update the password. The following example is presented to illustrate the point. The decision of where to mark the code as privileged is application-specific and is unique in every situation. This decision requires great depth of domain knowledge and security expertise to make the correct judgement. A number of well written publications and books are available on this topic. Referencing these materials for more detailed information is recommended.

You can use the **PasswordUtil** utility to change the password of a user. The utility types in the old password and the new password twice to ensure that the correct password is entered. If the old password matches the one stored in the password file, the new password is stored and the password file updates. Assume that none of the stack frame is marked as privileged. According to the `java.security.AccessController.checkPermission` algorithm, the application fails unless all the classes on the call stack are granted write permission to the password file. The client application does not have permission to write to the password file directly and to update the password file at will.

However, if the `PasswordUtil.updatePasswordFile` method marks the code that accesses the password file as privileged, then the check permission algorithm does not check for the required permission from classes that call the `PasswordUtil.updatePasswordFile` method for the required permission as long as the **PasswordUtil** class is granted the permission. The client application can successfully update a password without granting the permission to write to the password file.

The ability to mark code privileged is very flexible and powerful. If this ability is used incorrectly, the overall security of the system can be compromised and security holes can be exposed. Use the ability to mark code privileged carefully.

Resolution to the `java.security.AccessControlException` exception

As described previously, you have two approaches to resolve a `java.security.AccessControlException` exception. Judge these exceptions individually to decide which of the following resolutions is best:

1. Grant the missing permission to the application.
2. Mark some code as privileged, after considering the issues and risks.

Enabling security for the realm

Use this topic to enable IBM WebSphere Application Server security. You must enable administrative security for all other security settings to function.

About this task

WebSphere Application Server uses cryptography to protect sensitive data and to ensure confidentiality and integrity of communications between WebSphere Application Server and other components in the network. Cryptography is also used by Web Services Security when certain security constraints are configured for the web services application.

WebSphere Application Server uses Java Secure Sockets Extension (JSSE) and Java Cryptography Extension (JCE) libraries in the Software Development Kit (SDK) to perform this cryptography. The SDK provides strong but limited jurisdiction policy files. Unrestricted policy files provide the ability to perform full strength cryptography and to improve performance.

Attention: Fix packs that include updates to the Software Development Kit (SDK) might overwrite unrestricted policy files. Back up unrestricted policy files before you apply a fix pack and reapply these files after the fix pack is applied.

WebSphere Application Server provides a SDK 6 that contains strong, but limited jurisdiction policy files. You can download the unrestricted policy files from the following website: IBM developer kit: Security information.

Note: Fix packs that include updates to the Software Development Kit (SDK) might overwrite unrestricted policy files. Back up unrestricted policy files before you apply a fix pack and reapply these files after the fix pack is applied.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

Complete the following steps to download and install the new policy files:

1. Click **Java SE 6**
2. Scroll down the page then click **IBM SDK Policy files**.
The Unrestricted JCE Policy files for SDK 6 website displays.
3. Click **Sign in** and provide your IBM.com ID and password.
4. Select **Unrestricted JCE Policy files for SDK 6** and click **Continue**.
5. View the license and click **I Agree** to continue.
6. Click **Download Now**.
7. Extract the unlimited jurisdiction policy files that are packaged in the compressed file. The compressed file contains a `US_export_policy.jar` file and a `local_policy.jar` file.
8. In your WebSphere Application Server installation, mount your product HFS read/write. Go to the `$JAVA_HOME/jre/lib/security` directory and back up your `US_export_policy.jar` and `local_policy.jar` files.
9. Replace your `US_export_policy.jar` and `local_policy.jar` files with the two files that you downloaded from the IBM.com website.
10. Re-mount your product HFS as read/only.

The embedded Software Development Kit (SDK) ships with the unrestricted jurisdiction policy Java archive (JAR) files. Therefore, instead of downloading these files from the website, you can symbolically link to the files as allowed by your local country regulations. These unrestricted policy files are located in the `install_root/java/demo/jce/policy-files/unrestricted/` directory. The following UNIX-based commands enable you to symbolically link to these files:

```
# Export the paths. You can find the values of the following
# variables in the joblog by searching for was.install.root,
# java.home, and so on:
export was.install.root=<was.install.root>
export java.home=<java.home>
# The previous paths apply to both 31- and 64-bit configurations
# of WebSphere Application Server for z/OS. For a 64-bit
# configuration, the java.home path points to the 64-bit embedded
# Java virtual machine (JVM).

# Delete the original policy .jar files. Because a backup is
# automatically present in the smpe.home HFS, an explicit
# backup is not needed:
cd $java.home/lib/security
rm US_export_policy.jar
rm local_policy.jar

# Issue the following commands on separate lines to create
# the symbolic links to the unrestricted policy files:
ln -s $java.home/demo/jce/policy-files/unrestricted/US_export_policy.jar US_export_policy.jar
ln -s $java.home/demo/jce/policy-files/unrestricted/local_policy.jar local_policy.jar
```

To remove the symbolic links to the unrestricted policy files in the demo directory and link to the original files, use the following UNIX-based commands:

```

# Export the paths. You can find the values of the following
# variables in the joblog by searching for was.install.root,
# java.home, and so on:
export was.install.root=<was.install.root>
export java.home=<java.home>
export smpe.install.root=<smpe.install.root>
# The previous paths apply to both 31- and 64-bit configurations
# of WebSphere Application Server for z/OS. For a 64-bit
# configuration, the java.home path points to the 64-bit embedded
# Java virtual machine (JVM).

# Delete the current policy .jar files. You might want
# to back up the following files:
cd $java.home/lib/security
rm US_export_policy.jar
rm local_policy.jar

# Issue the following commands on separate lines to create
# symbolic links to the smpe HFS where the original files
# are kept:
ln -s $smpe.install.root/java/lib/security/US_export_policy.jar US_export_policy.jar
ln -s $smpe.install.root/java/lib/security/local_policy.jar local_policy.jar

```

Complete the following steps to enable security for the realm:

Procedure

1. Enable administrative security in WebSphere Application Server.

For more information, see “Enabling security” on page 1230. It is important to click **Security > Global security**. Select an available realm definition from the list, and then click **Set as current**. Save the configuration to the repository. Verify that the validation that occurs after you click **OK** on the **Security > Global security** panel is successful before continuing. If the validation is not successful and you continue with these steps, you risk the server not starting. Re-configure the security settings until validation is successful.

2. Send a copy of the new configuration to all of the running node agents using the administrative console. If a node agent fails to get the security-enabled configuration, communication with the deployment manager fails, due to a lack of access. The node agent is not security-enabled. To force synchronize a specific node, complete the following steps from the administrative console:
 - a. Click **System administration > Nodes** and select the option next to all the nodes. You do not need to select the deployment manager node.
 - b. Click **Full resynchronize** to verify that the file synchronization has occurred. The message might indicate that the nodes already are synchronized. This message is OK. When synchronization is initiated, verify that the Synchronized status displays for all nodes.
3. Stop the deployment manager. Manually restart the deployment manager from the command line or service. To stop the deployment manager, click **System administration > Deployment manager** and click **Stop**. This action logs you out of the administrative console and stops the deployment manager process.
4. Restart the deployment manager process.

To restart the deployment manager process, enter the following command:

```

START dmgr_proc_name,JOBNAME=server_short_name,
ENV=cell_short_name.node_short_name.server_short_name

```

You must enter this command on a single line. It is split here for illustrative purposes (refer to the related links below for more information on using z/OS MVS system commands). After the deployment manager initialization is complete, go back into the administrative console to complete this task. Remember that security is enabled in the deployment manager only. If you enabled single sign-on (SSO), specify the fully qualified domain name of your web address, for example, `http://myhost.domain:port_number/ibm/console`. When you are prompted for a user ID and password, type the one that you entered as the administrator ID in the configured user registry.

5. If the deployment manager does not start after enabling security, disable security using a script and restart. Disable security by issuing the following command from the `DeploymentManager/bin` directory:

```
./wsadmin.sh -conntype NONE
```

At the prompt, enter `securityoff`.

6. Restart all node agents to make them security enabled. You must have restarted the deployment manager in a previous step before completing this step. If the node agent is security-enabled before the deployment manager is security-enabled, the deployment manager cannot query the node agent for status or give the node agent commands. To stop all node agents, complete the following steps:
 - a. Go to **System administration > Node agents** and select the option beside all node agents. Click **Restart**. A message similar to the following example is displayed at the top of the panel: The node agent on node NODE NAME was restarted successfully.
 - b. Alternatively, if you previously did not stop your application servers, restart all of the servers within any given node by clicking **System administration > Node agents** and by clicking the node agents where you want to restart all the servers. Click **Restart all Servers on Node**. This action restarts the node agent and any started application servers.
7. If any node agent fails to restart, perform a manual resynchronization of the configuration. This step consists of going to the physical node and running the client `syncNode` command. This client logs into the deployment manager and copies all of the configuration files to the node agent. This action ensures that the configuration is security-enabled. If the node agent is started, but is not communicating with the deployment manager, stop the node agent by issuing the `stopServer` command.

Global security settings:

Use this panel to configure administration and the default application security policy. This security configuration applies to the security policy for all administrative functions and is used as a default security policy for user applications. Security domains can be defined to override and customize the security policies for user applications.

To view this administrative console page, click **Security > Global security**.

When security is configured, validate any changes to the user registry or authentication mechanism panels. Click **Apply** to validate the user registry settings. An attempt is made to authenticate the server ID or to validate the admin ID (if `internalServerID` is used) to the configured user registry. Validating the user registry settings after enabling administrative security can avoid problems when you restart the server for the first time.

Security configuration wizard:

Launches a wizard that enables you to configure the basic administrative and application security settings. This process restricts administrative tasks and applications to authorized users.

Using this wizard, you can configure application security, resource or Java 2 Connector (J2C) security, and a user registry. You can configure an existing registry and enable administrative, application, and resource security.

When you apply changes made by using the security configuration wizard, administrative security is turned on by default.

Security configuration report:

Launches a report that gathers and displays the current security settings of the application server. Information is gathered about core security settings, administrative users and groups, CORBA naming roles, and cookie protection. When multiple security domains are configured the report displays the security configuration associated with each domain.

A current limitation to the report is that it does not display application level security information. The report also does not display information on Java Message Service (JMS) security, bus security, or Web Services Security.

Enable administrative security:

Specifies whether to enable administrative security for this application server domain. Administrative security requires users to authenticate before obtaining administrative control of the application server.

For more information, see the related links for administrative roles and administrative authentication.

When enabling security, set the authentication mechanism configuration and specify a valid user ID and password (or a valid admin ID when internalServerID feature is used) in the selected registry configuration.

Note: There is a difference between the user ID (which is normally called the admin ID), which identifies administrators who manage the environment, and a server ID, which is used for server-to-server communication. You do not need to enter a server ID and password when you are using the internal server ID feature. However, optionally, you can specify a server ID and password. To specify the server ID and password, complete the following steps:

1. Click **Security > Global security**.
2. Under User accounts repository, select the repository and click **Configure**.

You can only specify the **the z/OS started task** option when the user registry is **Local OS**.

If you have problems, such as the server not starting after enabling security within the security domain, resynchronize all of the files from the cell to this node. To resynchronize files, run the following command from the node: `syncNode -username your_userid -password your_password`. This command connects to the deployment manager and resynchronizes all of the files.

If your server does not restart after you enable administrative security, you can disable security. Go to your `app_server_root/bin` directory and run the `wsadmin -conntype NONE` command. At the `wsadmin>` prompt, enter `securityoff` and then type `exit` to return to a command prompt. Restart the server with security disabled to check any incorrect settings through the administrative console.

Local OS user registry users: When you select **Local OS** as the active user registry, you do not need to supply a password in the user registry configuration.

Default: Enabled

Enable application security:

Enables security for the applications in your environment. This type of security provides application isolation and requirements for authenticating application users

In previous releases of WebSphere Application Server, when a user enabled global security, both administrative and application security were enabled. In WebSphere Application Server Version 6.1, the previous notion of global security is split into administrative security and application security, each of which you can enable separately.

As a result of this split, WebSphere Application Server clients must know whether application security is disabled at the target server. Administrative security is enabled, by default. Application security is disabled, by default. To enable application security, you must enable administrative security. Application security is in effect only when administrative security is enabled.

Default: Disabled

Use Java 2 security to restrict application access to local resources:

Specifies whether to enable or disable Java 2 security permission checking. By default, access to local resources is not restricted. You can choose to disable Java 2 security, even when application security is enabled.

When the **Use Java 2 security to restrict application access to local resources** option is enabled and if an application requires more Java 2 security permissions than are granted in the default policy, the application might fail to run properly until the required permissions are granted in either the `app.policy` file or the `was.policy` file of the application. AccessControl exceptions are generated by applications that do not have all the required permissions. See the related links for more information about Java 2 security.

Default: Disabled

Warn if applications are granted custom permissions:

Specifies that during application deployment and application start, the security runtime issues a warning if applications are granted any custom permissions. Custom permissions are permissions that are defined by the user applications, not Java API permissions. Java API permissions are permissions in the `java.*` and `javax.*` packages.

The application server provides support for policy file management. A number of policy files are available in this product, some of them are static and some of them are dynamic. Dynamic policy is a template of permissions for a particular type of resource. No code base is defined and no relative code base is used in the dynamic policy template. The real code base is dynamically created from the configuration and run-time data. The `filter.policy` file contains a list of permissions that you do not want an application to have according to the J2EE 1.4 specification. For more information on permissions, see the related link about Java 2 security policy files.

Important: You cannot enable this option without enabling the **Use Java 2 security to restrict application access to local resources** option.

Default: Disabled

Restrict access to resource authentication data:

Enable this option to restrict application access to sensitive Java Connector Architecture (JCA) mapping authentication data.

Consider enabling this option when both of the following conditions are true:

- Java 2 security is enforced.
- The application code is granted the `accessRuntimeClasses WebSphereRuntimePermission` permission in the `was.policy` file found within the application enterprise archive (EAR) file. For example, the application code is granted the permission when the following line is found in your `was.policy` file:

```
permission com.ibm.websphere.security.WebSphereRuntimePermission "accessRuntimeClasses";
```

The **Restrict access to resource authentication data** option adds fine-grained Java 2 security permission checking to the default principal mapping of the `WSPrincipalMappingLoginModule` implementation. You must grant explicit permission to Java 2 Platform, Enterprise Edition (J2EE) applications that use the `WSPrincipalMappingLoginModule` implementation directly in the Java Authentication and Authorization Service (JAAS) login when **Use Java 2 security to restrict application access to local resources** and the **Restrict access to resource authentication data** options are enabled.

Default: Disabled

Current realm definition:

Specifies the current setting for the active user repository.

This field is read-only.

Available realm definitions:

Specifies the available user account repositories.

The selections appear in a drop-down list containing:

- Local operating system
- Standalone LDAP registry
- Stand-alone custom registry

Set as current:

Enables the user repository after it is configured.

You can configure settings for one of the following user repositories:

Federated repositories

Specify this setting to manage profiles in multiple repositories under a single realm. The realm can consist of identities in:

- The file-based repository that is built into the system
- One or more external repositories
- Both the built-in, file-based repository and in one or more external repositories

Note: Only a user with administrator privileges can view the federated repositories configuration.

Local operating system

Specify this setting if you want your configured Resource Access Control Facility (RACF) or System Authorization Facility (SAF)-compliant security server used as the application server user registry.

Standalone LDAP registry

Specify this setting to use stand-alone LDAP registry settings when users and groups reside in an external LDAP directory. When security is enabled and any of these properties change, go to the **Security > Global security** panel and click **Apply** or **OK** to validate the changes.

Note: Since multiple LDAP servers are supported, this setting does not imply one LDAP registry.

Stand-alone custom registry

Specify this setting to implement your own stand-alone custom registry that implements the `com.ibm.websphere.security.UserRegistry` interface. When security is enabled and any of these properties change, go to the Global security panel and click **Apply** or **OK** to validate the changes.

Default: Disabled

Configure...:

Select to configure the global security settings.

Web and SIP security:

Under Authentication, expand Web and SIP security to view links to:

- General settings
- Single sign-on (SSO)
- SPNEGO web authentication
- Trust association

General settings:

Select to specify the settings for web authentication.

Single sign-on (SSO):

Select to specify the configuration values for single sign-on (SSO).

With SSO support, web users can authenticate once when accessing both WebSphere Application Server resources, such as HTML, JavaServer Pages (JSP) files, servlets, enterprise beans, and Lotus Domino® resources.

SPNEGO web authentication:

Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) provides a way for web clients and the server to negotiate the web authentication protocol that is used to permit communications.

Trust association:

Select to specify the settings for the trust association. Trust association is used to connect reversed proxy servers to the application servers.

You can use the global security settings or customize the settings for a domain.

Note: The use of trust association interceptors (TAIs) for SPNEGO authentication is now deprecated. The SPNEGO web authentication panels now provide a much easier way to configure SPNEGO.

RMI/IIOP security:

Under Authentication, expand RMI/IIOP security to view links to:

- CSiv2 inbound communications
- CSiv2 outbound communications

CSiv2 inbound communications:

Select to specify authentication settings for requests that are received and transport settings for connections that are accepted by this server using the Object Management Group (OMG) Common Secure Interoperability (CSI) authentication protocol.

Authentication features include three layers of authentication that you can use simultaneously:

- **CSiv2 attribute layer.** The attribute layer might contain an identity token, which is an identity from an upstream server that already is authenticated. The identity layer has the highest priority, followed by the message layer, and then the transport layer. If a client sends all three, only the identity layer is used. The only way to use the SSL client certificate as the identity is if it is the only information that is presented during the request. The client picks up the interoperable object reference (IOR) from the namespace and reads the values from the tagged component to determine what the server needs for security.

- **CSlv2 transport layer.** The transport layer, which is the lowest layer, might contain a Secure Sockets Layer (SSL) client certificate as the identity.

CSlv2 outbound communications:

Select to specify authentication settings for requests that are sent and transport settings for connections that are initiated by the server using the Object Management Group (OMG) Common Secure Interoperability (CSI) authentication protocol.

Authentication features include three layers of authentication that you can use simultaneously:

- **CSlv2 attribute layer.** The attribute layer might contain an identity token, which is an identity from an upstream server that already is authenticated. The identity layer has the highest priority, followed by the message layer, and then the transport layer. If a client sends all three, only the identity layer is used. The only way to use the SSL client certificate as the identity is if it is the only information that is presented during the request. The client picks up the interoperable object reference (IOR) from the namespace and reads the values from the tagged component to determine what the server needs for security.
- **CSlv2 transport layer.** The transport layer, which is the lowest layer, might contain a Secure Sockets Layer (SSL) client certificate as the identity.

Java authentication and authorization service:

Under Authentication, expand Java authentication and authorization service to view links to:

- Application logins
- System logins
- J2C authentication data

Application logins:

Select to define login configurations that are used by JAAS.

Do not remove the ClientContainer, DefaultPrincipalMapping, and WSLogin login configurations because other applications might use them. If these configurations are removed, other applications might fail.

System logins:

Select to define the JAAS login configurations that are used by system resources, including the authentication mechanism, principal mapping, and credential mapping.

J2C authentication data:

Select to specify the settings for the Java Authentication and Authorization Service (JAAS) Java 2 Connector (J2C) authentication data.

You can use the global security settings or customize the settings for a domain.

LTPA:

Select to encrypt authentication information so that the application server can send the data from one server to another in a secure manner.

The encryption of authentication information that is exchanged between servers involves the Lightweight Third-Party Authentication (LTPA) mechanism.

Kerberos and LTPA:

Select to encrypt authentication information so that the application server can send the data from one server to another in a secure manner.

The encryption of authentication information that is exchanged between servers involves the Kerberos mechanism.

Note: Kerberos must be configured before this option can be selected.

Kerberos configuration:

Select to encrypt authentication information so that the application server can send data from one server to another in a secure manner.

The encryption of the authentication information that is exchanged between servers involves the KRB5 of LTPA mechanism.

Authentication cache settings:

Select to set your authentication cache settings.

Enable Java Authentication SPI (JASPI):

Select to enable the use of Java Authentication SPI (JASPI) authentication.

You can then click **Providers** to create or edit a JASPI authentication provider and associated authentication modules in the global security configuration.

Use realm-qualified user names:

Specifies that user names that are returned by methods, such as the `getUserPrincipal()` method, are qualified with the security realm in which they reside.

Security domains:

Use the Security Domain link to configure additional security configurations for user applications.

For example, if you want use a different user registry for a set of user applications than the one used at the global level, you can create a security configuration with that user registry and associate it with that set of applications. These additional security configurations can be associated with various scopes (cell, clusters/servers, SIBuses). Once the security configurations have been associated with a scope all of the user applications in that scope use this security configuration. Read about "Multiple security domains" on page 1310 for more detailed information.

For each security attribute, you can use the global security settings or customize settings for the domain.

External authorization providers:

Select to specify whether to use the default authorization configuration or an external authorization provider.

The external providers must be based on the Java Authorization Contract for Containers (JACC) specification to handle the Java(TM) 2 Platform, Enterprise Edition (J2EE) authorization. Do not modify any settings on the authorization provider panels unless you have configured an external security provider as a JACC authorization provider.

Custom properties:

Select to specify name-value pairs of data, where the name is a property key and the value is a string.

Specify extent of protection wizard settings:

Use this security wizard page to determine whether to enable application security and restrict access to local resources. When you use the wizard, admin security is enabled by default.

To view this security wizard page, click **Security > Global security > Security configuration wizard**.

Enable application security:

Enables security for the applications in your environment. This type of security provides application isolation and requirements for authenticating application users

In previous releases of WebSphere Application Server, when a user enabled global security, both administrative and application security were enabled. In WebSphere Application Server Version 6.1, the previous notion of global security is split into administrative security and application security, each of which you can enable separately.

As a result of this split, WebSphere Application Server clients must know whether application security is disabled at the target server. Administrative security is enabled, by default. Application security is disabled, by default. To enable application security, you must enable administrative security. Application security is in effect only when administrative security is enabled.

Default: Disabled

Use Java 2 security to restrict application access to local resources:

Specifies whether to enable or disable Java 2 security permission checking. By default, access to local resources is not restricted. You can choose to disable Java 2 security, even when application security is enabled.

When the **Use Java 2 security to restrict application access to local resources** option is enabled and if an application requires more Java 2 security permissions than are granted in the default policy, the application might fail to run properly until the required permissions are granted in either the `app.policy` file or the `was.policy` file of the application. AccessControl exceptions are generated by applications that do not have all the required permissions. See the related links for more information about Java 2 security.

Default: Disabled

z/OS security options:

Use this page to determine which Global security options to specify for the application server for z/OS.

To view this administrative console page, click **Security > Global security > z/OS security options**.

You also can view this administrative console page, by completing the following steps:

1. Click **Servers > Server types > WebSphere application servers > server_name**.
2. Under Security, click **Server domain**.
3. Click **z/OS security options**.

If you are configuring security for the first time, complete the steps in the Global security article prior to making changes. After security is configured, validate any changes to the user registry or authentication mechanism panels. Click **Apply** to validate the user registry settings. An attempt is made to authenticate

the server ID to the configured user registry. Validating the user registry settings after enabling Global security can reduce potential problems when you restart the server for the first time.

Remote identity:

Specifies the System Authorization Facility (SAF) user ID that is assumed for the Internet Inter-ORB Protocol (IIOP) unauthenticated clients that make requests of this server from another system.

Specifies whether an application remote identity is permitted.

Note: This information applies to Version 6.0.x and previous servers only that are federated in a Version 6.1 cell.

Local identity:

Specifies the SAF user ID that is assumed for the Internet Inter-ORB Protocol (IIOP) unauthenticated clients that make requests of this server from the same system.

Specifies whether an application local identity is permitted.

Note: This information applies to Version 6.0.x and previous servers only that are federated in a Version 6.1 cell.

Enable application server and z/OS thread identity synchronization:

Specifies that application servers can process the SyncToOSThread option for application components that specify it.

Selecting this option indicates whether an operating system thread identity is enabled for synchronization with the Java Platform, Enterprise Edition (Java EE) identity that is used in the application server runtime when an application is coded to request this function.

Synchronizing the operating system identity to the Java EE identity causes the operating system identity to synchronize with the authenticated caller, or delegated RunAs identity in a servlet or Enterprise JavaBeans (EJB) file. This synchronization or association means that the caller or security role identity, rather than the server region identity, is used for z/OS system service requests such as access to files.

For this function to be active, the following conditions must all be true:

- The Sync to OS thread allowed value is true.
- An application includes within its deployment descriptor an env-entry of com.ibm.websphere.security.SyncToOSThread set to true.
- The configured user account repository is the local operating system.

When these conditions are true, the OS thread identity is initially set to the authenticated caller identity of a web or EJB request. The OS thread is modified each time the Java EE identity is modified. The Java EE identity can be modified either by a RunAs specification on the deployment descriptor or a programmatic `WSSubject.doAs()` request.

If the Sync to OS thread allowed value is `false`, which is the default setting, the ability to modify the identity on the operating system thread of the deployment descriptor setting in the deployment descriptor of the installed application is disabled. If the server is not configured to accept enable synchronization and the application deployment descriptor, `com.ibm.websphere.security.SyncToOSThread`, is set to `true`, a BBOJ0080W warning message indicates that the EJB is requesting the SyncToOSThread option, but the server is not enabled for the SyncToOSThread option.

Important: This option significantly increases the number of SMF 80 records used for security auditing. When security auditing is turned on for SMF 80 records, the amount of DASD used increases significantly.

Enable the connection manager RunAs thread identity:

Sets the MVS identity associated with the Java Platform, Enterprise Edition (Java EE) identity on the execution thread. Local Java EE Connector architecture (J2CA) connectors may honor the MVS identity for authentication and authorization when an application requests a connection.

When you enable this setting, the method can process a request that modifies the operating system identity to reflect the Java Platform, Enterprise Edition (Java EE) identity. This function is required to take advantage of thread identity support. Java EE Connector architecture (J2CA) connectors that access local resources on a z/OS system can use the thread identity support. A set of J2CA connectors that accesses local z/OS resources defaults to the Java EE identity of the application if all of the following conditions are true:

- Resource authorization is set to container-managed (res-auth=container).
- An alias entry is not coded when deploying the application.
- The connection manager Sync to OS thread setting is set to enabled.

For example, if you have a pre-existing DB2 for z/OS security policy that controls which users have access to each table, you want to have that policy enforced when users access WebSphere applications that also access DB2 for z/OS. The Java EE identity (the client identity by default) rather than the operating system identity (server identity) is used to establish connections to DB2 for z/OS when Connection Manager RunAs Identity Enabled is selected. DB2 for z/OS table access for the application is determined using your preexisting DB2 for z/OS security policy.

Any J2CA connector that uses the thread identity support must support thread identity. Customer Information Control System (CICS), Information Management System (IMS), and DATABASE 2 (DB2) support thread identity. CICS and IMS support thread identity only if the target CICS or IMS is configured on the same system as the application server for z/OS. DB2 always supports thread identity. If a connector does not support thread identity, the user identity that is associated with the connection is based on the default user identity that is supported by the particular connector.

Data type	Boolean
Default	Disabled
Range	Enabled or Disabled

Security custom properties:

Use this page to understand the `psecurity.allowCustomHTTPMethodsredefined` custom properties that are related to security.

To view this administrative console page, click **Security > Global security > Custom properties**. Then click **New** to add a new custom property and its associated value.

The custom properties in this topic are set in the administrative console through the previously listed path unless otherwise stated in the description.

You can use the custom properties page to define the following security custom properties:

- “com.ibm.audit.field.length.limit” on page 1268
- “com.ibm.audit.report.granularity” on page 1268
- “com.ibm.CSI.disablePropagationCallerList” on page 1269
- “com.ibm.CSI.localCommDataForNonLocalOSEnabled” on page 1269
- “com.ibm.CSI.propagateFirstCallerOnly” on page 1269

- “com.ibm.CSI.rmiInboundLoginConfig” on page 1270
- “com.ibm.CSI.rmiInboundMappingConfig” on page 1270
- “com.ibm.CSI.rmiInboundMappingEnabled” on page 1270
- “com.ibm.CSI.rmiOutboundLoginConfig” on page 1270
- “com.ibm.CSI.rmiOutboundMappingEnabled” on page 1270
- “com.ibm.CSI.supportedTargetRealms” on page 1271
- “com.ibm.security.multiDomain.setNamingReadUnprotected” on page 1271
- “com.ibm.security.SAF.forceDelegation” on page 1271
- “com.ibm.security.SAF.overrideStartupAPPL” on page 1271
- “com.ibm.security.useFIPS” on page 1271
- “com.ibm.websphere.crypto.config.certexp.notify.fromAddress” on page 1271

com.ibm.audit.field.length.limit:

This property only applies to the SMF Emitter implementation that IBM provides for the Security Auditing feature. You can use this property to specify, in bytes, the length at which variable-length audit data is truncated. By default, if this custom property is not specified, and the threshold limit of 20480 is exceeded, variable-length audit data fields are truncated to 128 bytes.

gotcha: You must use the `modifyAuditEmitter` command for the `AdminTask` object to enable this custom property. For a description of how to use this command, see the documentation about `AuditEmitterCommands` for the `AdminTask` object.

The SMF relocation data has a threshold size limit of 20480 bytes. If the audit data exceeds this limit, the audit data is truncated to prevent the loss of audit records.

Default	20480
Type	An integer between 1 and 512

com.ibm.audit.report.granularity:

This property enables you to specify how much auditing data is recorded for each event type. If you only need to record basic information about an event, such as who did what action to what resource, and when, setting this property to high, might improve your application server performance.

You can specify values of high, medium, or low for this property. The default value is low.

Table 88. Type of data that is recorded for each event type based on the setting for com.ibm.audit.report.granularity. The following table indicates the type of data that is recorded for each event type based on the setting for this property.

Event type	high setting	medium setting	low setting
SessionContext	sessionId	sessionId, remoteHost	sessionId, remoteHost, remoteAddr, remotePort
PropagationContext (is only reported if SAP is enabled)	firstCaller (as part of the who)	firstCaller, and if verbose mode is enabled, the callerList	firstCaller, and if verbose mode is enabled, the callerList
RegistryContext	nothing is recorded	registry type	registry type
ProcessContext	nothing is recorded	realm	realm, and domain if verbose is enabled

Table 88. Type of data that is recorded for each event type based on the setting for `com.ibm.audit.report.granularity` (continued). The following table indicates the type of data that is recorded for each event type based on the setting for this property.

Event type	high setting	medium setting	low setting
EventContext	creationTime	creationTime, globalInstanceId	creationTime, globalInstanceId, eventTrailId, and lastTrailId if verbose mode is enabled
DelegationContext	identityName	delegationType, and identityName	delegationType, roleName, and identityName
AuthnContext	nothing is recorded	authn type	authn type
ProviderContext	nothing is recorded	provider	provider, and providerStatus
AuthnMappingContext	mappedUserName	mappedUserName, and mappedSecurityRealm	mappedUserName, mappedSecurityRealm, and mappedSecurityDomain
AuthnTermContext	terminateReason	terminateReason	terminateReason
AccessContext	progName, action, appUserName, and resourceName	progName, action, appUserName, resourceName, registryUserName, and accessDecision	progName, action, appUserName, resourceName, registryUserName, accessDecision, resourceType, permissionsChecked, permissionsGranted, rolesChecked, and rolesGranted
PolicyContext	nothing is recorded	policyName	policyName, and policyType
KeyContext	keyLabel	keyLabel, and keyLocation	keyLabel, keyLocation, and certificateLifetime
MgmtContext	nothing is recorded	mgmtType, and mgmtCommand	mgmtType, mgmtCommand, and targetInfoAttributes

com.ibm.CSI.disablePropagationCallerList:

This property completely disables the caller list and will not allow the caller list to change. This property prevents the creation of multiple sessions.

This property completely disables adding a caller or host list in the propagation token. Setting this property can be a benefit when the caller or host list in the propagation token is not needed in the environment.

Note: If this property is set to **true** as well as **com.ibm.CSI.propagateFirstCallerOnly**, then **com.ibm.CSI.disablePropagationCallerList** takes precedence.

Default false

com.ibm.CSI.localCommDataForNonLocalOSEnabled:

This property allows local communication data to be used as authentication material for the CSIv2 transport layer when the user registry is not a LocalOS user registry.

When this property is set to `true`, the data retrieved from the local communication transport corresponds to the ASID of the local client connecting to a WebSphere Application Server process. A user corresponding to the ASID must exist in the user registry. When a CSIv2 Establish Message is received by a WebSphere Application Server process and Identity Assertion is requested, the data retrieved from the local communication transport can be used to validate that the client has permission to assert the user specified in the Identity Token in the Attribute Layer. If the user represented by the received ASID is in the Trusted Identities list on the CSIv2 Inbound Authentication page in the administrative console, then that ID is able to assert the Identity Token.

Default false

com.ibm.CSI.propagateFirstCallerOnly:

This property will not allow the caller list to change and thus prevent the creation of multiple session entries. This property specifically limits the caller list to the first caller only.

This property logs the first caller in the propagation token that stays on the thread when security attribute propagation is enabled. Without setting this property, all caller switches get logged, which affects performance. Typically, only the first caller is of interest.

Note: If this property is set to **true** as well as **com.ibm.CSI.disablePropagationCallerList**, then **com.ibm.CSI.disablePropagationCallerList** takes precedence.

Default true

Note: New for this release, the default value of the `com.ibm.CSI.propagateFirstCallerOnly` security custom property is set to `true`. When this custom property is set to `true`, the first caller in the propagation token that stays on the thread is logged when security attribute propagation is enabled. When this property is set to `false`, all of the caller switches are logged, which can affect performance.

com.ibm.CSI.rmiInboundLoginConfig:

This property specifies the Java Authentication and Authorization Service (JAAS) login configuration that is used for Remote Method Invocation (RMI) requests that are received inbound.

By knowing the login configuration, you can plug in a custom login module that can handle specific cases for RMI logins.

Default system.RMI_INBOUND

com.ibm.CSI.rmiInboundMappingConfig:

This property defines the system JAAS login configuration that is used to perform application specific principal mapping.

Default None

com.ibm.CSI.rmiInboundMappingEnabled:

This property, when set to `true`, enables the application specific principal mapping capability.

Default false

com.ibm.CSI.rmiOutboundLoginConfig:

This property specifies the JAAS login configuration that is used for RMI requests that are sent outbound.

Primarily, this property prepares the propagated attributes in the Subject to be sent to the target server. However, you can plug in a custom login module to perform outbound mapping.

Default system.RMI_OUTBOUND

com.ibm.CSI.rmiOutboundMappingEnabled:

This property, when set to `true`, enables the original caller subject embedded in the `WSSubjectWrapper` object to be restored.

Default false

com.ibm.CSI.supportedTargetRealms:

This property enables credentials that are authenticated in the current realm to be sent to any realm that is specified in the Trusted target realms field. The Trusted target realms field is available on the CSiv2 outbound authentication panel. This property enables those realms to perform inbound mapping of the data from the current realm.

It is not recommended that you send authentication information to an unknown realm. Thus, this provides a way to specify that the alternate realms are trusted. To access the CSiv2 outbound authentication panel, complete the following steps:

1. Click **Security > Global security**.
2. Under RMI/IIOP security, click **CSiv2 outbound authentication**.

com.ibm.security.multiDomain.setNamingReadUnprotected:

This property can be set to true or false to determine if the CosNamingRead role protects all naming read operations. Setting this property to true is the equivalent of assigning the CosNamingRead role the Everyone special subject. If this property is set, then it will override any assignments made to the CosNamingRead role.

Default none

com.ibm.security.SAF.forceDelegation:

Determines whether System Authorization Facility (SAF) delegation can be used independently of SAF authorization. When this property is set to true, SAF delegation can be used whenever the user registry is a Federated Repository user registry, and is configured with a SAF user registry bridge.

There is no default value for this property.

com.ibm.security.SAF.overrideStartupAPPL:

This property can be used to override the value for the APPL profile, specifically for the two RACROUTE calls that are made during server startup. For these calls the APPL value is not used for the authorization checking process, but is made available to the installation exit routine. The APPL profile value used for authorization checking is not controlled by this property, it is instead set to either CBS390 or the SAF profile prefix value.

Default none

com.ibm.security.useFIPS:

Specifies that Federal Information Processing Standard (FIPS) algorithms are used. The application server uses the IBMJCEFIPS cryptographic provider instead of the IBMJCE cryptographic provider.

Default false

com.ibm.websphere.crypto.config.certexp.notify.fromAddress:

This security property is used to customize the "from address" of certificate expiration notification email.

The value you assigned to this property should be an internet address, for example "Notification@abc-company.com" If this property is not set, WebSphere uses its email fromAddress: "WebSphereNotification@ibm.com" .

Default None

com.ibm.websphere.crypto.config.certexp.notify.textEncoding:

This security property is used to customize the text encoding character set for certificate expiration notification email.

WebSphere Application Server sends notification email for certificate expiration in either US-English or the machine default character set (if non-English locale is specified). If you want a different text encoding character set for the certificate expiration notification email, you can use this property to customize the text encoding character set.

Default None

com.ibm.websphere.lookupRegistryOnProcess:

This property can be set when realm registry lookups are performed via an MBean on a remote server if the realm is local OS security.

By default, the user registry tasks listRegistryUsers and listRegistryGroups perform lookups from the current process. In the case of Network Deployment (ND), that is the dmgr.

When dealing with a local OS user registry, lookup should occur on the actual server where the registry resides. In an ND environment that could be a remote machine. To perform lookup on the server process where the registry resides, the com.ibm.websphere.lookupRegistryOnProcess custom property should be set to true.

If com.ibm.websphere.lookupRegistryOnProcess is not set, or set to false, then the lookup is performed on the current process. The custom property can be set using the setAdminActiveSecuritySettings task for global security or the setAppActiveSecuritySettings task for a security domain.

com.ibm.websphere.security.allowAnyLogoutExitPageHost:

When you are using application form login and logout you can provide a URL for a custom logout page. By default, the URL must point to the host to which the request is made or to its domain. If this is not done, then a generic logout page is displayed rather than a the custom logout page. If you want to be able to point to any host, then you need to set this property in the security.xml file to a value of true. There is a risk that setting this property to have a value of true may open your systems to potential URL redirect attacks.

Default false

com.ibm.websphere.security.alwaysRestoreOriginalURL:

Use this property to indicate whether a cookie with the value WASReqURL is honored when the custom form login processor is used.

When this property is set to true, the value of WASReqURL takes precedence over the current URL, and the WASReqURL cookie is removed from subsequent requests.

When this property is set to `false`, the value of the current URL takes precedence, and the `WASReqURL` cookie is not removed from subsequent requests.

Default false

com.ibm.websphere.security.console.noSSLTreePortEndpoints:

This property is used to improve the response time for large topology configurations.

When this property is set to `true` the status of the of the SSL port endpoints does not display on the Manage endpoint security configurations page in the administrative console. Displaying the status of the SSL port endpoints sometimes makes the administrative console seem like it is no longer functioning because of a longer than expected response time.

Default false

com.ibm.websphere.security.customLTPACookieName:

This property is used to customize the name of the cookies used for Lightweight Third Party Authentication (LTPA) tokens.

WebSphere Application Server Version 8.0 enables you to customize the name of the cookies used for LTPA and LTPA2 tokens. Custom cookie names allow you to logically separate authentication between Single Sign-On (SSO) domains and to enable customized authentication to a particular environment.

To take advantage of this functionality, a custom property must be set. For LTPA tokens, the custom property `com.ibm.websphere.security.customLTPACookieName` can be set to any valid string (special characters and spaces are not permitted) for the LTPA token cookie, and `com.ibm.websphere.security.customSSOCookieName` for the LTPA2 (SSO) token cookie. Each property is case-sensitive.

The value for this property is a valid string.

Note: Before you set this custom property, consider the following:

- This property, as with most custom properties, can be set at the security domain level. In this manner, a separate login can be forced between an administrative console login and an application login.
- The original default `LTPAToken` or `LTPAToken2` cookie names are accepted and trusted by WebSphere Application Server Version 8.0. This enables compatibility with products such as Lotus Domino and WebSphere Portal which both utilize the default cookie name.
- Setting a custom cookie name can cause an authentication failure. For example, a connection to a server that has a custom cookie property set sends this custom cookie to the browser. A subsequent connection to a server that uses either the default cookie name or a different cookie name is not able to authenticate the request via a validation of the inbound cookie.
- This property does not function properly in a mixed-cell environment. For example, a deployment manager in WebSphere Application Server Version 8.0 might be able to create custom cookies. However, a WebSphere Application Server Version 7.0 node or server existing in this same cell does not understand what to do with this cookie and subsequently rejects it.
- If you utilize a product interacting with WebSphere Application Server that generates LTPA tokens, such as Lotus Domino or WebSphere Portal, be aware that these products might not be able to handle custom LTPA cookie names. Please consult the documentation for your product regarding its handling of custom LTPA cookie names.

Note: To activate this property, a restart of WebSphere Application Server is necessary.

com.ibm.websphere.security.customSSOCookieName:

This property is used to customize the name of the cookies used for Lightweight Third Party Authentication Version 2 (LTPA2) tokens.

WebSphere Application Server Version 8.0 enables you to customize the name of the cookies used for LTPA and LTPA2 tokens. Custom cookie names allow you to logically separate authentication between Single Sign-On (SSO) domains and to enable customized authentication to a particular environment.

To take advantage of this functionality, a custom property must be set. For LTPA tokens, the custom property `com.ibm.websphere.security.customLTPACookieName` can be set to any valid string (special characters and spaces are not permitted) for the LTPA token cookie, and `com.ibm.websphere.security.customSSOCookieName` for the LTPA2 (SSO) token cookie. Each property is case-sensitive.

The value for this property is a valid string.

Note: Before you set this custom property, consider the following:

- This property, as with most custom properties, can be set at the security domain level. In this manner, a separate login can be forced between an administrative console login and an application login.
- The original default `LTPAToken` or `LTPAToken2` cookie names are accepted and trusted by WebSphere Application Server Version 8.0. This enables compatibility with products such as Lotus Domino and WebSphere Portal which both utilize the default cookie name.
- Setting a custom cookie name can cause an authentication failure. For example, a connection to a server that has a custom cookie property set sends this custom cookie to the browser. A subsequent connection to a server that uses either the default cookie name or a different cookie name is not able to authenticate the request via a validation of the inbound cookie.
- This property does not function properly in a mixed-cell environment. For example, a deployment manager in WebSphere Application Server Version 8.0 might be able to create custom cookies. However, a WebSphere Application Server Version 7.0 node or server existing in this same cell does not understand what to do with this cookie and subsequently rejects it.
- If you utilize a product interacting with WebSphere Application Server that generates LTPA tokens, such as Lotus Domino or WebSphere Portal, be aware that these products might not be able to handle custom LTPA cookie names. Please consult the documentation for your product regarding its handling of custom LTPA cookie names.

Note: To activate this property, a restart of WebSphere Application Server is necessary.

com.ibm.websphere.security.displayRealm:

This property specifies whether the HTTP basic authentication login window displays the realm name that is not defined in the application `web.xml` file.

Note: If the realm name is defined in the application `web.xml` file, this property is ignored.

If the realm name is not defined in the `web.xml` file, one of the following occurs:

- If the property is set to `false`, the WebSphere realm name display is Default Realm.
- If this property is set to `true`, the WebSphere realm name display is the user registry realm name for the LTPA authentication mechanism or the Kerberos realm name for the Kerberos authentication mechanism.

Important: If this property is set to `true`, and the user registry's realm name contains sensitive information, it is displayed to the user. For example, if standalone LDAP configuration is used, the LDAP server hostname and port are displayed. For LocalOS, the hostname is displayed.

Default	false
Type	string

com.ibm.websphere.security.disableGetTokenFromMBean:

Use this property to disables the outbound SOAP call to retrieve the subject from the originating server when Single Sign-On is enabled.

Typically, when Single Sign-On is enabled, and an inbound request needs to be authenticated, the receiving server attempts to retrieve the authentication from the originating server. The connection between the sending and receiving servers never times out during this callback process.

When this property is set to `true`, the receiving server does not attempt to authenticate the inbound request.

Default	false
----------------	-------

com.ibm.websphere.security.enableAuditForIsCallerInRole:

Use this property to enable audit for the `isCallerInRole` method call.

If you set this property to `false`, it disables auditing for the invocation of `isCallerInRole`. In z/OS, SMF records are not issued for the invocation.

Default	true
----------------	------

com.ibm.websphere.security.InvokeTAIbeforeSSO:

Default invocation order of Trust Association Interceptors (TAIs) in relation to Single Sign On (SSO) user authentication can be changed using this property. The default order is to invoke Trust Association Interceptors after SSO. This property is used to change the default order of TAI invocation with SSO. The property value is a comma (,) separated list of TAI class names to be invoked before SSO.

Default	com.ibm.ws.security.spnego.TrustAssociationInterceptorImpl
Type	string

com.ibm.websphere.security.JAASAuthData.addNodeNameSecDomain:

By default, when JAAS authentication data entries are created at the domain security level, the alias name for the entry will be in the format *aliasName*. You can enable the addition of the node name to the alias name in order to create the alias name in the format `nodeName/aliasName` for the entry, by setting the following property at the domain security level.

Note: You can set `com.ibm.websphere.security.JAASAuthData.addNodeNameSecDomain=true` at the global security level, to enable the addition of the node name to the alias name of JAAS authentication data entries for all security domains.

Default	false
----------------	-------

com.ibm.websphere.security.JAASAuthData.removeNodeNameGlobal:

By default, when JAAS authentication data entries are created at the global security level, the alias name for the entry will be in the format *nodeName/aliasName*. You can disable the addition of the node name to the alias name for the entry, by setting a value of *true* for this property at the global security level.

Default false

com.ibm.websphere.security.krb.canonical_host:

This custom property specifies whether the application server uses the canonical form of the URL/HTTP host name in authenticating a client. This property can be used for both SPNEGO TAI and SPNEGO Web.

If you set this custom property to *false*, a Kerberos ticket can contain a host name that differs from the HTTP host name header and the application server might issue the following message:

CWSPN0011E: An invalid SPNEGO token has been encountered while authenticating a `HttpServletRequest`

If you set this custom property to *true*, you can avoid this error message and allow the application server to authenticate using the canonical form of the URL/HTTP host name.

Default true

com.ibm.websphere.security.ldap.logicRealm:

This custom property enables you to change the name of the realm that is placed in the token.

This custom property enables you to configure each cell to have its own LDAP host for interoperability and backward compatibility. Also, it provides flexibility for adding or removing the LDAP host dynamically. If you are migrating a previous installation, this modified realm name does not take effect until administrative security is re-enabled. To be compatible with a previous release that does not support the logic realm, the name must be the same name that is used by the previous installation. You must use the LDAP host name, including a trailing colon and port number.

Type String

This property must be set as the custom property of a stand-alone LDAP registry. To set this custom property, in the administrative console:

1. Click **Security > Global security**.
2. Under User account repository, expand the Available realm definitions list, and select **Standalone LDAP registry**, and then click **Configure**.
3. Under Custom properties, click **New**, and then enter `com.ibm.websphere.security.ldap.logicRealm` in the **Name** field, and the new name of the realm that is placed in the token in the **Value** field.
4. Select this custom property and then click **Apply** or **OK**.

com.ibm.websphere.security.ldapSSLConnectionTimeout:

Use this property, when SSL is enabled on the LDAP server, to specify, in milliseconds, the maximum amount of time the JVM waits for a socket connection before issuing a timeout.

If one or more standalone LDAP servers are offline when a server process starts, and LDAP-SSL is enabled, there might be a delay of up to 3 minutes in the startup procedure even if you specify a value for the `com.sun.jndi.ldap.connect.timeout` custom property. When LDAP-SSL is enabled, any value specified for the `com.sun.jndi.ldap.connect.timeout` property is ignored.

When a value is specified for this property, the JVM tries to use this connection timeout value when attempting to complete a socket connection, instead of trying to establish a directory context. When no value is specified for this property, the JVM tries to establish a directory context.

There will be no default value for this property.

com.ibm.websphere.security.logoutExitPageDomainList:

When you are using application form login and logout you can provide a URL for a custom logout page. By default, the URL must point to the host to which the request is made or to its domain. If this is not done, then a generic logout page is displayed rather than the custom logout page. If you need to point to a different host, then you can populate this property in `security.xml` with a pipe (|) separated list of URLs that are allowed for the logout page.

Default none

com.ibm.websphere.security.rsaCertificateAliasCache:

This property is used to control the size of the alias cache.

The default value is 5000 and can be increased for larger deployments.

The value must be entered into the range of 1 - N, where N is a valid positive integer that is greater than or equal to the number of nodes registered with the Job Manager. You do not need to add this property unless your Job Manager topology exceeds 5000 registered nodes.

Default 5000

com.ibm.websphere.security.strictCredentialExpirationCheck:

Specifies whether credential expiration check occurs for a local EJB call. Typically, when an EJB invokes another EJB that is located in a local machine, a direct method invocation occurs even if the credentials of the original invoker expire before the local EJB call occurs.

If this property is set to `true`, a credential expiration check occurs on a local EJB call before the EJB is invoked on the local machine. If the credentials have expired, the EJB call is rejected.

If this property is set to `false`, a credential expiration check does not occur for a local EJB call.

Default false

com.ibm.websphere.security.tokenFromMBeanSoapTimeout:

Use this property to specify the amount of time the receiving server waits for an outbound SOAP call to retrieve the proper authentication from the originating server when Single Sign-On is enabled.

There is no default value for this property. If no value is specified, the global SOAP timeout value is used as the timeout value for the SOAP connection.

com.ibm.websphere.security.useLoggedSecurityName:

This is a custom property of user registries. This property alters the behavior of creating `WSCredential`.

A setting of `false` indicates that the security name returned by a user registry is always used to construct `WSCredential`.

A setting of true indicates that either a security name that is supplied by login module is used or a display name that was supplied by a user registry is used. This setting is compatible with WebSphere Application Server version 6.1 and older releases.

Default false

com.ibm.websphere.security.util.csiv2SessionCacheIdleTime:

This property specifies the time in milliseconds that a CSiv2 session can remain idle before being deleted. The session is deleted if the `com.ibm.websphere.security.util.csiv2SessionCacheLimitEnabled` custom property is set to a true value and the maximum size of the CSiv2 session cache is exceeded.

This custom property only applies if you enable stateful sessions, set the `com.ibm.websphere.security.util.csiv2SessionCacheLimitEnabled` custom property to true, and set a value for the `com.ibm.websphere.security.util.csiv2SessionCacheMaxSize` custom property. Consider decreasing the value for this custom property if your environment uses Kerberos authentication and has a short clock skew for the configured key distribution center (KDC). In this scenario, a short clock skew is defined as less than 20 minutes.

Important: Do not set a value for this function through the custom property panel because the value is not validated against the expected range of values. Instead, set the value on the CSiv2 outbound communications panel, which is available in the administrative console by completing the following steps:

1. Expand the **Security** section and click **Global security**.
2. Expand the **RMI/IIOP security** section and click **CSiv2 outbound communications**

You can set the value in the **Idle session timeout** field. However, when you specify this value on the CSiv2 outbound communications panel, the administrative console value is expected in seconds and not milliseconds.

The range of values for this custom property is 60,000 to 86,400,000 milliseconds. By default, the value is not set.

com.ibm.websphere.security.util.csiv2SessionCacheLimitEnabled:

This custom property specifies whether to limit the size of the CSiv2 session cache.

When you set this custom property value to true, you must set values for the `com.ibm.websphere.security.util.csiv2SessionCacheIdleTime` and `com.ibm.websphere.security.util.csiv2SessionCacheMaxSize` custom properties. When you set this custom property to false, the CSiv2 session cache is not limited. The default property value is false.

Consider setting this custom property to true if your environment uses Kerberos authentication and has a small clock skew for the configured key distribution center (KDC). In this scenario, a small clock skew is defined as less than 20 minutes. A small clock skew can result in a larger number of rejected CSiv2 sessions. However, with a smaller value for the `com.ibm.websphere.security.util.csiv2SessionCacheIdleTime` custom property, the application server can clean out these rejected sessions more frequently and potentially reduce the resource shortages.

Important: This custom property only applies if you enable the stateful sessions.

Important: Although you can enable the CSiv2 session cache limit option as a custom property, it is advisable that you enable the option on the CSiv2 outbound communications panel, which is available in the administrative console by completing the following steps:

1. Expand the **Security** section and click **Global security**.

2. Expand the **RMI/IIOP security** section and click **CSiv2 outbound communications**

You can enable the **Enable CSiv2 session cache limit** option. The default value is false.

com.ibm.websphere.security.util.csiv2SessionCacheMaxSize:

This property specifies the maximum size of the session cache after which expired sessions are deleted from the cache.

Expired sessions are defined as sessions that are idle longer than the time that is specified by the `com.ibm.websphere.security.util.csiv2SessionCacheIdleTime` custom property. When you use the `com.ibm.websphere.security.util.csiv2SessionCacheMaxSize` custom property, consider setting its value between 100 and 1000 entries.

Consider specifying a value for this custom property if your environment uses Kerberos authentication and has a small clock skew for the configured key distribution center (KDC). In this scenario, a small clock skew is defined as less than 20 minutes. Consider increasing the value of this custom property if the small cache size causes the garbage collection to run so frequently that it impacts the performance of the application server.

This custom property only applies if you enable stateful sessions, set the `com.ibm.websphere.security.util.csiv2SessionCacheLimitEnabled` custom property to true, and set a value for the `com.ibm.websphere.security.util.csiv2SessionCacheIdleTime` custom property.

Important: Do not set a value for this function through the custom property panel because the value is not validated against the expected range of values. Instead, set the value on the CSiv2 outbound communications panel, which is available in the administrative console by completing the following steps:

1. Expand the **Security** section and click **Global security**.
2. Expand the **RMI/IIOP security** section and click **CSiv2 outbound communications**

You can set the value in the **Maximum cache size** field.

The range of values for this custom property is 100 to 1000 entries. By default, the value is not set.

com.ibm.websphere.security.util.postParamMaxCookieSize:

This property sets a size limit for WASPostParam cookies being generated by the security code.

When the Use available authentication data when an unprotected URI is accessed option is enabled and Form-based authentication is being used this, a WASPOSTParam is generated during the authentication procedure of the HTTP POST request even if the target URL is unprotected. A WASPOSTParam cookie is a temporary cookie used to store HTTP POST parameters. This results in the Web client being sent the unnecessary cookie with an HTTP response. This might cause unexpected behavior when the size of the cookie is larger than the browser limit. To avoid this behavior, `com.ibm.websphere.security.util.postParamMaxCookieSize` can be set to cause the security code to stop generating the cookie if the maximum size specified by this property is reached. The value of this property must be a positive integer and represents the maximum size of the cookie in bytes.

Default none

com.ibm.websphere.security.webAlwaysLogin:

This property specifies whether the login() method will throw an exception if an identity had already been authenticated. You can overwrite this behavior by setting this property to true.

Default	false
Type	string

Note: The login() method always uses the user ID and password to authenticate to the WebSphere application server irrespective of the presence of the SSO information in the HttpServletRequest.

com.ibm.ws.security.addHttpOnlyAttributeToCookies:

This custom property enables you to set the HTTPOnly attribute for single sign-on (SSO) cookies.

You can use the com.ibm.ws.security.addHttpOnlyAttributeToCookies custom property to protect cookies that contain sensitive values. When you set this custom property value to true, the application server sets the HTTPOnly attribute for SSO cookies whose values are set by the server. The HTTPOnly attribute enables the protection of sensitive values in cookies.

Also, a true value enables the application server to properly recognize, accept, and process inbound cookies with HTTPOnly attributes and inhibit any *cross-site scripting* from accessing sensitive cookie information.

A common security problem, which impacts web servers, is cross-site scripting. Cross-site scripting is a server-side vulnerability that is often created when user input is rendered as HTML. Cross-site scripting attacks can expose sensitive information about the users of the website. Most modern web browsers honor the HTTPOnly attribute to prevent this attack. A cookie with this attribute is called an *HTTPOnly cookie*. Information that exists in an HTTPOnly cookie is less likely to be disclosed to a hacker or a malicious website. For more information about the HTTPOnly attribute, see the Open Web Application Security Project (OWASP) website.

Important: When you use this custom property, HTTPOnly attribute is not added to every cookie that passes through the application server. Also, the attribute is not added to other non-secure cookies that are created by the application server. A list of non-HTTPOnly cookies includes:

- JSESSIONID cookies
- SSO cookies that are created by authenticators or providers from another software vendor
- Client or browser cookies that do not already contain the HTTPOnly attribute

You can set or remove this custom property from the Single sign-on panel in the administrative console by doing the following:

1. Click **Security > Global security**.
2. Under Authentication, click **Web and SIP security > Single sign-on (SSO)**.

Default	true	Type	Boolean
----------------	------	-------------	---------

com.ibm.ws.security.allowNonAdminToSecurityXML:

This property specifies whether the non-admin security roles are allowed the ability to modify the security.xml file. Setting this property to true gives non-admin security roles the ability to modify the security.xml file. In Version 6.1 and above, by default, non-admin security roles have the ability to modify the security.xml file.

Default	false
Type	Boolean

com.ibm.ws.security.config.SupportORBConfig:

Specifies whether to check or not check the object request broker (ORB) for properties. This property needs to be set as a system property. You set this property to true or yes so that the ORB is checked for properties. For any other setting, the ORB is completely ignored.

The property is to be used when a pluggable application client connects to the WebSphere Application Server. Specifically, this property is used whenever a hashmap containing security properties is passed in a hashmap on a new InitialContext(env) call.

com.ibm.ws.security.createTokenSubjectForAsynchLogin:

In this release, the actual LTPA token data is not available from a WSCredential.getCredentialToken() call when called from an asynchronous bean. For an existing configuration, you can add the `com.ibm.ws.security.createTokenSubjectForAsynchLogin` custom property and a true value to allow the LTPAToken to be forwarded to asynchronous beans. This property allows portlets to successfully perform LTPA token forwarding. This custom property is case sensitive. You must restart the application server after you add this custom property.

Note: This custom property applies only to system conditions where Server A makes EJB calls from asynchronous beans to Server B. This property does not apply for JAAS login situations.

Default not applicable

com.ibm.ws.security.defaultLoginConfig:

This property is the JAAS login configuration that is used for logins that do not fall under the WEB_INBOUND, RMI_OUTBOUND, or RMI_INBOUND login configuration categories.

Internal authentication and protocols that do not have specific JAAS plug points call the system login configuration that is referenced by `com.ibm.ws.security.defaultLoginConfig` configuration.

Default system.DEFAULT

com.ibm.ws.security.failSSODuringCushion:

Use the `com.ibm.ws.security.failSSODuringCushion` custom property to update custom JAAS Subject data for the LTPA token.

When you do not set this custom property to true, new JAAS Subjects might not contain the custom JAAS Subject data.

The default value is true.

com.ibm.ws.security.ltpa.forceSoftwareJCEProviderForLTPA:

Use the `com.ibm.ws.security.ltpa.forceSoftwareJCEProviderForLTPA` custom property to correct an "invalid library name" error when you attempt to use a PKCS11 type keystore with a Java client.

Also, use this custom property if you are using the IBMJCECCA provider because distributed and z/OS operating systems use different provider types for hardware cryptography.

The `ssl.client.props` file points to a configuration file, which in turn, points to the library name for the cryptographic device. The code for the Java client looks for a keystore type for the correct provider name. Without this custom property, the keystore type constant for PKCS11 is not specified correctly as it references the `IBMPKCS11Impl` provider instead. Also, the Lightweight Third Party Authentication (LTPA) code uses the provider list to determine the Java Cryptography Extension (JCE) provider. This approach

causes a problem when Secure Sockets Layer (SSL) acceleration is attempted because the IBMPKCS11Impl provider needs to be listed before the IBMJCE provider within the `java.security` file.

This custom property corrects both issues so that SSL and other cryptographic mechanisms can use hardware acceleration.

Note: LTPA cannot use hardware acceleration because the software keys for LTPA do not implement the `java.security.interfaces.RSAPrivateCrtKey` interface, which is required by many accelerator cards.

Set this custom property to true when you want to use a PKCS11 type keystore with a Java client.

Default false

com.ibm.ws.security.ltpa.useCRT:

Use this property to improve the CPU utilization during the `sign()` operation that occurs when a new LTPA2 (SSO) token is created. When this property is set to true, the product implements the Chinese Remainder Theorem (CRT) algorithm when signing the new token. This property has no effect on the old style LTPA token.

Default false

com.ibm.ws.security.ssoInteropModeEnabled:

This property determines whether to send `LtpaToken2` and `LtpaToken` cookies in the response to a web request (interoperable).

When this property value is false, the application server just sends the new `LtpaToken2` cookie which is stronger, but not interoperable with some other products and Application Server releases prior to Version 5.1.1. In most cases, the old `LtpaToken` cookie is not needed and you can set this property to false.

Default true

com.ibm.ws.security.unprotectedUserRegistryMethods:

Specifies the method names on the `UserRegistry` interface, such as `getRealm`, `getUsers`, and `isValidUser`, that you do not want protected from remote access. If you specify multiple method names, separate the names with either a space, a comma, a semi-colon, and a separator bar. See your implementation of the `UserRegistry` interface file for a complete list of valid method names.

If you specify an `*` as the value for this property, all methods are unprotected from remote access.

If a value is not specified for this property, all methods are protected from remote access.

If an attempt is made to remotely access a protected `UserRegistry` interface method, the remote process receives a `CORBA NO_PERMISSION` exception with minor code 49421098.

There is no default value for this property.

com.ibm.ws.security.webChallengelfCustomSubjectNotFound:

This property determines the behavior of a single sign-on `LtpaToken2` login.

If the token contains a custom cache key and the custom Subject cannot be found, then the token is used to log in directly as the custom information needs to be regathered if this property value is set to true. A

challenge also occurs so that the user is required to login again. When this property value is set to false and the custom Subject is not found, the LtpaToken2 is used to login and gather all of the registry attributes. However, the token might not obtain any of the special attributes that downstream applications might expect.

Default true

com.ibm.ws.security.webInboundLoginConfig:

This property is the JAAS login configuration that is used for web requests that are received inbound.

By knowing the login configuration, you can plug in a custom login module that can handle specific cases for web logins.

Default system.WEB_INBOUND

com.ibm.ws.security.webInboundPropagationEnabled:

This property determines whether a received LtpaToken2 cookie should search for the propagated attributes locally before searching the original login server that is specified in the token. After the propagated attributes are received, the Subject is regenerated and the custom attributes are preserved.

You can configure the data replication service (DRS) to send the propagated attributes to front-end servers such that a local dynacache lookup can find the propagated attributes. Otherwise, an MBean request is sent to the original login server to retrieve these attributes.

Default true

com.ibm.ws.security.zOS.useSAFidForTransaction:

This property is used to enable a server to use the user identity for the z/OS started task as the server identity when calling transactional methods.

This property is used to enable a server to use the user identity for the z/OS started task as the server identity when calling transactional methods, such as commit(), and prepare(), that require the server identity. This behavior occurs regardless of the server identity setting for that server.

As an example, a server can be configured to use the automatically generated server identity, which is not the actual identity stored in a user repository. Furthermore, this server might need to communicate with CICS 3.2, and CICS 3.2 requires the use of System Authorization Facility (SAF) identities. If `com.ibm.ws.security.zOS.useSAFidForTransaction` is set to true, then the server uses a SAF identity to communicate with CICS instead of using the automatically generated identity.

Default false

com.ibm.wsspi.security.ltpa.tokenFactory:

This property specifies the Lightweight Third Party Authentication (LTPA) token factories that can be used to validate the LTPA tokens.

Validation occurs in the order in which the token factories are specified because LTPA tokens do not have object identifiers (OIDs) that specify the token type. The Application Server validates the tokens using each

token factory until validation is successful. The order that is specified for this property is the most likely order of the received tokens. Specify multiple token factories by separating them with a pipe (|) without spaces before or following the pipe.

Default `com.ibm.ws.security.ltpa.LTPATokenFactory |
com.ibm.ws.security.ltpa.LTPAToken2Factory |
com.ibm.ws.security.ltpa.AuthzPropTokenFactory`

com.ibm.wsspi.security.token.authenticationTokenFactory:

This property specifies the implementation that is used for an authentication token in the attribute propagation framework. The property provides an old LTPA token implementation for use as the authentication token.

Default `com.ibm.ws.security.ltpa.LTPATokenFactory`

com.ibm.wsspi.security.token.authorizationTokenFactory:

This property specifies the implementation that is used for an authorization token. This token factory encodes the authorization information.

Default `com.ibm.ws.security.ltpa.AuthzPropTokenFactory`

com.ibm.wsspi.security.token.propagationTokenFactory:

This property specifies the implementation that is used for a propagation token. This token factory encodes the propagation token information.

The propagation token is on the thread of execution and is not associated with any specific user Subjects. The token follows the invocation downstream wherever the process leads.

Default `com.ibm.ws.security.ltpa.AuthzPropTokenFactory`

com.ibm.wsspi.security.token.singleSignonTokenFactory:

This property specifies the implementation that is used for a Single Sign-on (SSO) token. This implementation is the cookie that is set when propagation is enabled regardless of the state of the `com.ibm.ws.security.ssoInteropModeEnabled` property.

By default, this implementation is the `LtpaToken2` cookie.

Default `com.ibm.ws.security.ltpa.LTPAToken2Factory`

com.ibm.wsspi.wssecurity.kerberos.failAuthForExpiredKerberosToken:

Use this property to specify how you want the system to handle authentication for a request after the Kerberos token for the request expires.

When this property is set to `true`, if a Kerberos token cannot be refreshed after it expires, authentication for the request fails.

When this property is set to `false`, authentication for the request does not fail even if the token has expired.

The default value for this property is false.

security.allowCustomHTTPMethods:

Use this custom property to permit custom HTTP methods. The custom HTTP methods are other than the standard HTTP methods, which are: DELETE, GET, HEAD, OPTIONS, POST, PUT or TRACE.

When this property is set to `false`, which is the default, if a combination of a URI pattern and a custom HTTP method are not listed in the security-constraint element, a search of the security constraint is performed using an URI pattern only. If there is a match, the value of the `<auth-constraints>` element is enforced. This behavior minimizes a potential security exposure.

When this property is set to `true`, the custom HTTP methods are treated as the standard HTTP methods. An authorization decision is made by both the URI pattern and the HTTP method. To properly protect a target URI, make sure that the proper HTTP methods are listed in the `<web-resource-collection>` element.

security.enablePluggableAuthentication:

This property is no longer used. Instead, use WEB_INBOUND login configuration.

Complete the following steps to modify the WEB_INBOUND login configuration:

1. Click **Security > Global security**.
2. Under Java Authentication and Authorization Service, click **System logins**.

Default true

security.useDefaultPolicyWhenJ2SDisabled:

The `NullDynamicPolicy.getPermissions` method provides an option to delegate a default policy class to construct a `Permissions` object when the `security.useDefaultPolicyWhenJ2SDisabled` custom property is set to `true`. When this property is set to `false`, an empty `Permissions` object is returned.

Default false

Security custom property collection:

Use this page to view and manage arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties.

The administrative console contains several custom properties pages that work similarly. To view one of these administrative pages, click a **Custom properties** link.

Name:

Specifies the name (or key) for the property.

Each property name must be unique. If the same name is used for multiple properties, the value specified for the first property is used.

Do not start your property names with `was.` because this prefix is reserved for properties that are predefined in the application server.

Value:

Specifies the value paired with the specified name.

Description:

Provides information about the name-value pair.

Security custom property settings:

Use this page to configure arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

The administrative console contains several custom property settings pages that work similarly. To view one of these administrative pages, click **Custom properties**.

Name:

Specifies the name (or key) for the property.

Each property name must be unique. If the same name is used for multiple properties, the value specified for the first property is used.

Do not start your property names with `was.` because this prefix is reserved for properties that are predefined in the product.

Data type String

Value:

Specifies the value paired with the specified name.

Data type String

Description:

Provides information about the name and value pair.

Data type String

Testing security after enabling it

Basic tests are available that show whether the fundamental security components are working properly. Use this task to validate your security configuration.

Before you begin

After configuring administrative security and restarting all of your servers in a secure mode, validate that security is properly enabled.

Basic tests are available that show whether the fundamental security components are working properly. Complete the following steps to validate your security configuration:

Procedure

1. After enabling security, verify that your system comes up in secure mode.

2. Test the Web-based form login by starting the administrative console: `http://hostname.domain:port_number/ibm/console`. A form-based login page is displayed. If a login page does not appear, try accessing the administrative console by typing `https://myhost.domain:9043/ibm/console`.
3. Test Java Client BasicAuth with `dumpNameSpace`.
Use the `app_server_root/bin/dumpNameSpace.sh` file. A login panel appears. If a login panel does not appear, there is a problem. Type in any valid user ID and password (or password phrase) in your configured user registry.
4. Test all of your applications in secure mode.
5. If all the tests pass, proceed with more rigorous testing of your secured applications. If you have any problems, review the SYSOUT and SYSPRINT logs. For more information on common problems, see Troubleshooting security configurations.

Note: Testing synchronizing of the node agent is a good test. To do so, make a small change to the configuration and save and synchronize those changes. If there are no errors, proceed.

Results

The results of these tests, if successful, indicate that security is fully enabled and working properly.

Example

To test the Snoop application, do the following:

1. Enable security while installing the Base Application Server.
2. Log onto the administrative console with a wsadmin user ID and password.
3. Navigate to **Applications > Enterprise Applications > DefaultApplication > Security role to user/group mapping**.
4. Add a user. Select the role All Role, and click **Lookup User**.
5. Map one of the users (for example, TESTER1) with the role All Role. For more information on mapping, see `../ae/usec_rmapuser.dita`.
6. Save the configuration.
7. Run Resource Access Control Facility (RACF) commands for the role All Role to find those that are associated with the TESTER1 user ID.

Note: In the RACF command, enter All Role as All#Role, as in the following example:

```
RDEFINE EJBROLE S30CSA1.All#Role UACC(NONE) APPLDATA('TESTER1')
PERMIT S30CSA1.All#Role CLASS(EJBROLE) ID(TESTER1) ACCESS(READ)
SETROPTS RACLIST(EJBROLE) REFRESH
PE S30CSA1 CLASS(APPL) ID(TESTER1) ACCESS(READ)
```

8. Access the application with the user ID TESTER1 at `http://localhost:port/snoop`.

Security Configuration Wizard

The Security Configuration Wizard guides you through the process of completing the basic requirements to secure your application serving environment.

This wizard is available from the Security menu from the left pane of the admin console. To get to the wizard, navigate to **Security > Global security > Security Configuration Wizard**.

Step one of the configuration wizard allows you to choose the level of security desired. application-level security is selected by default. You also have the option of selecting Java 2 security.

Step two of the configuration wizard allows you to select a user repository. You have the following options:

- “Federated repository wizard settings” on page 1420

- “Local operating system wizard settings” on page 1352
- “Stand-alone custom registry wizard settings” on page 1384
- “Standalone LDAP registry wizard settings” on page 1359

Step three of the configuration wizard allows you to specify the local operating system user and group definitions as the repository, and, if necessary, to provide the name of a user with administrator privileges.

Step four of the configuration wizard provides a summary of the results of the configuration process.

Security configuration report

The security configuration report gathers and displays the current security settings of the application server. Information is gathered about core security settings, administrative users and groups, CORBA naming roles, and cookie protection. When multiple security domains are configured, each security domain has its own report with a subset of the sections shown in the global security report that apply to the domain.

Note: The security configuration report now includes information about session security, web Attributes, and the HttpOnly setting to enable you to get a more complete view of your server security settings.

The report is a table with four columns: **Console Name**, **Security Configuration Name**, **Value** and **Console Path Name**. The security information gathered is divided into sections, and groups common security information. A row highlighted in blue with a title in the first column starts a new section.

The Security Configuration Report can be run from the administrative console by selecting **Security > Global Security** and then clicking **Security Configuration Report**. A new window displays the report information.

The columns

Console Name

Contains the name of the security attribute as found in the administrative console. If the value in this column is on a row highlighted in blue, and is the only entry on the row, then it is the start of a new section.

Security Configuration Name

Contains the security attribute as found in the configuration file.

Value Contains the value of the security attribute.

Console Path Name

Contains the path where the attribute is found on the console.

The sections

Security Settings

Displays information about the top-level security attributes. These attributes set the default for administrative security for the server, such as whether security is enabled, the default user registry, or if Java security is enabled.

For more information, read the Global security settings article.

Authentication Mechanisms and expirations

Contains all the attributes associated with each authentication mechanisms and trust associations as defined in the configuration.

User Registry

Displays the attributes for the default user registry for the server.

Authorization configuration

Displays attributes configured for an external Java Authorization Contract for Containers (JACC) provider.

Application login configuration

Displays application JAAS login entries and their login modules attributes.

For more information, read the SSL configurations collection article.

CSI Displays the attributes that define the inbound and outbound information for the Common Secure Interoperability (CSI) protocol.

SSL configuration repertoires

Displays the attributes that make up the Secure Sockets Layer (SSL) configuration used by the server. There can be multiple SSL configurations defined, and information about each is displayed. This object is often referenced by an SSL configuration group object used to associate it with an inbound or an outbound connection.

For more information, read the SSL configurations collection article.

Key stores

Displays the keystore attributes for each keystore in the configuration. Keystore objects in the configuration are often referenced by an SSL configuration object in the configuration.

For more information, read the Personal certificates collection article.

Trust managers

Displays the attributes that make up trust managers that can be used by the server. Trust manager objects in the configuration are typically referenced by an SSL configuration object.

For the more information, read the Trust managers collection article.

Key managers

Displays the attributes that make up the key managers that are used by the server. Key manager objects in the configuration are typically referenced by an SSL configuration object.

For more information, read the Key managers collection article.

SSL configuration group

Displays the attributes that make up an SSL configuration that are used for an outbound or an inbound connection.

Management scope

Displays the attributes that make up a management scope. The SSL configuration-related objects in the security configuration are defined within a management scope to reference the management scope object.

For more information, read the Management scope configurations article.

Key set groups

Displays the attributes that make up a group of key sets, which are used to manage public, private and shared keys.

For more information, read the Key set groups collection article.

Key set

Displays the attributes that make up the key set, which is used to manage public, private, and shared keys.

For more information, read the Key sets collection article.

Schedules

Displays the attributes that make up the scheduled process in the security configuration.

Notifications

Displays the attributes that make up notification objects in the security configuration.

Manage certificate expiration

Displays the attributes that define how startCertificateExpMonitor is run on the server.

System login configuration

Displays the attributes that define the System login entries and their login modules.

For more information, read the System login configuration entry settings for Java Authentication and Authorization Service article.

Custom properties

Displays all the custom properties that are defined in the security configuration.

For more information, read the Custom properties article.

Web Authentication

Displays properties that are used to define web authentication used by the server.

For more information, read the web authentication settings article.

Administrative Users and Groups

Displays the attributes that define roles and the users and groups associated with them as found in the admin-authz.xml file. The column titled **Administrative Role Name** contains the name of the administrative role. A column titled **Administrative Role Value** contains the user ID associated with the role (if one exists).

For more information, read the Administrative roles article.

Corba Naming Console Names

Displays the defined CORBA naming roles and the users that are assigned to the roles.

For more information, read the Administrative group roles and CORBA naming service groups article.

Console Name for Certificate Management

Lists all the certificate in keystore that are defined in the security configuration. There is also information about the certificates location and their validity period.

Cookie Protection

Displays attributes that pertain to HTTP Cookies. This section differs from other sections since information is gathered from different configuration files. The HttpOnly custom property, the web authentication com.ibm.wsspi.security.web.webAuthReq property, and the session security setting on each server are displayed on the report.

Java Authorization SPI Configuration

Displays the attributes that are defined for the Java Authorization SPI (JASPI) configuration. If there is a JASPI configuration object in the security configuration, information is included concerning whether JASPI is enabled, the name of the default JASPI provider, and a list of defined providers and their authentication modules.

Note: If JASPI has not been configured, this section is not shown in the security configuration report.

Adding a new custom property in a global security configuration or in a security domain configuration

Custom properties are arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure settings beyond those that are available in the administrative console. You can add new security custom properties in a security configuration or in a security domain configuration.

About this task

Adding a new custom property in a global security configuration using the administrative console

1. Click **Security > Global security > Custom properties**.
2. Click **New**,
3. Enter the property key name in the **Name** field.

Each property key name must be unique. If the same name is used for multiple properties, the value specified for the first property is used.

Do not start your property names with `was`, because this prefix is reserved for properties that are predefined in the application server.

4. Enter the property value in the **Value** field.
5. Click **Apply** or **Save**.

You can also use the `-customProperties` flag in the `setAdminActiveSecuritySettings wsadmin` command to add a new custom property in a global security configuration. See the `SecurityConfigurationCommands` command group for the `AdminTask` object article for more information about this command. For example:

```
wsadmin>AdminTask.setAdminActiveSecuritySettings(['-customProperties ["com.ibm.websphere.security.test=false"]'])
```

Adding a new custom property in a security domain configuration using the administrative console

1. Click **Security > Security domains**.
2. Select the global security domain you want to add a new custom property to.
3. Click **Custom properties**.
4. Click **New**.
5. Enter the property key name in the **Name** field.

Each property key name must be unique. If the same name is used for multiple properties, the value specified for the first property is used.

Do not start your property names with `was`, because this prefix is reserved for properties that are predefined in the application server.

6. Enter the property value in the **Value** field
7. Click **Apply** or **Save**.

You can also use the `-customProperties` flag in the `setAppActiveSecuritySettings wsadmin` command to add a new custom property in a global security domain configuration. See the `SecurityConfigurationCommands` command group for the `AdminTask` object article for more information about this command. Use the `-securityDomainName` flag to specify the security domain where the custom property is located. For example:

```
wsadmin>AdminTask.setAppActiveSecuritySettings(['-securityDomainName testDomain -customProperties ["com.ibm.websphere.security.test=false"]'])
```

Modifying an existing custom property in a global security configuration or in a security domain configuration

Custom properties are arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure settings beyond those that are available in the administrative console. You can modify existing security custom properties in a global security configuration or in a security domain configuration.

About this task

Modifying an existing custom property in a global security configuration using the administrative console

1. Click **Security > Global security > Custom properties**.
2. Select the custom property you want to modify.
3. Click **Edit** in the **Value** field, and then enter the value you want to modify.
4. Click **Apply** or **Save**.

You can also use the `-customProperties` flag in the `setAdminActiveSecuritySettings` `wsadmin` command to modify an existing custom property in a global security configuration. See the `SecurityConfigurationCommands` command group for the `AdminTask` object article for more information about this command. For example:

```
wsadmin>AdminTask.setAdminActiveSecuritySettings('[-customProperties  
["com.ibm.websphere.security.test=false"]']')
```

Modifying an existing custom property in a security domain configuration using the administrative console

1. Click **Security > Security domains**.
2. Select the global security domain you want to modify.
3. Click **Custom properties**.
4. Select the custom property you want to modify.
5. Click **Edit**. In the **Value** field, and then enter the value you want to modify.
6. Click **Apply** or **Save**.

You can also use the `-customProperties` flag in the `setAppActiveSecuritySettings` `wsadmin` command to modify an existing custom property in a global security domain configuration. See the `SecurityConfigurationCommands` command group for the `AdminTask` object article for more information about this command. Use the `-securityDomainName` flag to specify the security domain where the custom property is located. For example:

```
wsadmin>AdminTask.setAppActiveSecuritySettings('[-securityDomainName  
testDomain -customProperties ["com.ibm.websphere.security.test=false"]']')
```

Deleting an existing custom property in a global security configuration or in a security domain configuration

Custom properties are arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure settings beyond those that are available in the administrative console. You can delete existing security custom properties in a global security configuration or in a security domain configuration.

About this task

Deleting an existing custom property in a global security configuration using the administrative console

1. Click **Security > Global security > Custom properties**.
2. Select the custom property you want to delete.
3. Click **Delete**.
4. Click **Apply** or **Save**.

You can also use the `-customProperties` flag in the `setAdminActiveSecuritySettings` `wsadmin` command to delete an existing custom property in a global security configuration. See the `SecurityConfigurationCommands` command group for the `AdminTask` object article for more information about this command. For example:

```
wsadmin>AdminTask.setAdminActiveSecuritySettings('[-customProperties  
["com.ibm.websphere.security.test="]]')
```

Deleting an existing custom property in a security domain configuration using the administrative console

1. Click **Security > Security domains**.
2. Click **Custom properties**.
3. Select the custom property you want to delete.
4. Click **Delete**.
5. In the **Value** field, enter the value you want to delete.
6. Click **Apply** or **Save**.

You can also use the `-customProperties` flag in the `setAppActiveSecuritySettings wsadmin` command to delete an existing custom property in a global security domain configuration. See the `SecurityConfigurationCommands` command group for the `AdminTask` object article for more information about this command. Use the `-securityDomainName` flag to specify the security domain where the custom property is located. For example:

```
wsadmin>AdminTask.setAppActiveSecuritySettings('[ -securityDomainName testDomain  
-customProperties ["com.ibm.websphere.security.test="]]')
```

Securing specific application servers

You can customize security to some extent at the application server level. You can disable administrative security on an application server.

Before you begin

Note: Server level security has been deprecated in this release of WebSphere Application Server. Multiple security domain support has been added in its place. You can create different security configurations and assign them to different applications in WebSphere Application Server processes. By creating multiple security domains, you can configure different security attributes for both administrative and user applications within a cell environment. You can configure different applications to use different security configurations by assigning the servers or clusters or SIBuses that host these applications to the security domains. Read about “Multiple security domains” on page 1310 for more detailed information.

You can also modify Java 2 Security and some of the other security attributes that are found on the Global security panel. This panel provides access to the cell-level security settings. You cannot configure a different authentication mechanism or user registry on an individual server basis. This feature is limited to cell-level configuration only.

By default, server security inherits all of the values that are configured for cell-level security. To override the cell-level security configuration at the server level, click **Servers > Application Servers > server_name**. Under Security, click **Server Security** and click any of the following links:

- CSiv2 inbound authentication
- CSiv2 outbound authentication
- CSiv2 inbound transport
- CSiv2 outbound transport
- z/SAS authentication
- Server-level security

Note: z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

After modifying the configuration in any of these panels and clicking **OK** or **Apply**, the security configuration for that panel or set of panels now overrides cell-level security. Other panels that are not

overridden continue to be inherited at the cell-level. However, you can always revert back to the cell-level configuration at any time. You can revert back to the cell-level security configuration by clearing the check box next to any of the following options on the Server security panel:

- Security settings for this server override cell settings
- RMI/IIOP security for this server overrides cell settings
- SAS security for this server overrides cell settings

A number of additional Secure Authentication Services for z/OS (z/SAS) attributes can be considered for security at a server level, such as:

- Local identity
- Remote identity
- Sync to thread allowed

For more information, see “Server and administrative security” on page 1235.

Procedure

1. Start the administrative console for the deployment manager. To get to the administrative console, go to `http://host.domain:port_number/ibm/console`. If security is disabled, you can enter any ID. If security is enabled, you must enter a valid user ID and password, which is either the administrative ID that is configured for the user registry or a user ID that is entered as an administrative user. To add a user ID as an administrative user, click **System Administration > Console settings > Console users**.

2. Configure cell-level security if you have not configured it previously. Go to “Enabling security” on page 1230 for detailed steps. After security is configured, configure server-level security.

Attention: Server-level security is not enabled when you select the Enable application security option on the Server-level security settings of the administrative console. You also must enable cell-level security by selecting the Enable administrative security option on the Global security settings panel of the administrative console.

3. To configure server-level security, click **Servers > Application Servers > server name**. Under Security, click **Server security**. The status of the security level that is in use for this application server is displayed.

By default, you can see that your cell-level security configuration, Common Secure Interoperability (CSI), and z/SAS have not been overridden at the server level. CSI and z/SAS are authentication protocols for RMI/IIOP security requests. The server-level security panel lists attributes that are on the Global security panel and can be overridden at the server level. Not all of the attributes on the Global security panel can be overridden at the server level, including the user account repository.

4. To enable administrative security for this application server, go to the Server-level security panel, select the **Security settings for this server override cell settings** and the **Enable application security** options. By modifying the Server-level security panel, these settings override the settings for cell-level security.

5. Click **Apply** and **Save**.

6. To enable RMI/IIOP security for the application server, go to the Server-level security panel, select the **RMI/IIOP security for this server overrides cell settings** option and click **Apply**. If you select the **RMI/IIOP security for this server overrides cell settings** option, any changes that you make to the CSIv2 authentication or transport settings override the same settings on the cell level.

What to do next

Typically, server-level security is used to disable user security for a specific application server. However, this can also be used to disable or enable the Java 2 security manager, and to configure the authentication requirements for RMI/IIOP requests both incoming and outgoing from this application server.

After you modify the configuration for a particular application server, you must restart the application server for the changes to become effective. To restart the application server, go to **Servers > Application servers** and click the server name that you recently modified. Click **Stop** and then **Start**.

If you disabled security for the application server, you can typically test a web address that is protected when security is enabled.

Server-level security settings

Use this page to enable server-level security and specify other server-level security configurations.

Note: Server level security has been deprecated in this release of WebSphere Application Server. Multiple security domain support has been added in its place. You can create different security configurations and assign them to different applications in WebSphere® Application Server processes. By creating multiple security domains, you can configure different security attributes for both administrative and user applications within a cell environment. You can configure different applications to use different security configurations by assigning the servers or clusters or SIBuses that host these applications to the security domains. Read about “Multiple security domains” on page 1310 for more detailed information.

To view this administrative console page, complete the following steps:

1. Click **Servers > Server Types > WebSphere application servers > server_name**.
2. Click **Security > Security domain**.

Security settings for this server override cell settings:

Specifies that the settings on this panel override the settings on the Security > Security applications, administration, and infrastructure panel.

Enable application security:

Specifies that server security is disabled, by default, when application security is enabled. Administrative (administrative console and wsadmin) and naming security remain enabled while application security is enabled, regardless of the status of this flag.

Default Disabled

Use Java 2 security to restrict application access to local resources:

Specifies that the server enforces Java 2 security permission checking at the server level. When cleared, the Java 2 server-level security manager is not installed and all of the Java 2 security permission checking is disabled at the server level.

If your application policy file is not set up correctly, see Configuring the was.policy file for Java 2 security in the information center.

Default Disabled

Warn if applications are granted custom permissions:

Specifies whether a warning is issued during application installation when an application requires a Java 2 permission that is normally not granted to an application.

The application server provides support for policy file management. A number of policy files are included in the application server. Some of these policy files are static and some of them are dynamic. Dynamic policy

is a template of permissions for a particular type of resource. In dynamic policy files, the code bases are evaluated at runtime using the configuration data. You can add or remove permissions, as needed, for each code base.

However, do not add, remove, or modify the existing code bases. The real code base is dynamically created from the configuration and run-time data. The `filter.policy` file contains a list of permissions that an application does not have, according to the J2EE 1.4 Specification. For more information on permissions, see the documentation on the Java 2 security policy files.

Default Enabled

Restrict access to resource authentication data:

Enable this option to restrict application access to sensitive Java EE Connector Architecture (JCA) mapping authentication data.

Default Disabled

Use domain-qualified user names:

Specifies whether user IDs that are returned by `getUserPrincipal()` are qualified with the server level security domain within which they reside.

Default Disabled

Note that WebSphere APIs such as `WSSubject.getPrincipal()` always return the unqualified user names irrespective of this property.

Authentication cache timeout:

Specifies the time period during which the authenticated credential in the cache is valid. This time period must be less than the time period specified for the Timeout value for forwarded credentials between servers field.

Data type	Integer
Units	Minutes and seconds
Default	10 minutes and 0 seconds
Range	Greater than 30 seconds. Avoid setting Authentication cache timeout value to 30 seconds or less.

Active protocol:

Specifies the active server level security authentication protocol when server level security is enabled.

You can use an Object Management Group (OMG) protocol called Common Secure Interoperability Version 2 (CSIv2) for more vendor interoperability and additional features. If all of the servers in your entire security domain are Version 6.1 servers, it is best to specify CSI as your protocol.

This field displays if a version 6.0.x server exists in your environment.

Data type	String
Default	CSI and SAS
Range	CSI, CSI and SAS

RMI/IIOP security for this server overrides cell settings:

Specifies that the Remote Method Invocation over Internet InterORB Protocol (RMI/IIOP) settings on this panel override the settings on the Security > Security applications, administration, and infrastructure panel.

Default Enabled

Controlling application environments with RACF server class profiles

The Resource Access Control Facility (RACF) server class profiles are used to control dynamic application environments. Dynamic application environments are displayed and controlled separately from static application environments.

Before you begin

To set up both the three-part or four-part RACF server class profiles for the application server or cluster for your dynamic application environment, the user ID for the servant must be given read access to both of the profiles.

About this task

The Resource Access Control Facility (RACF) server class profiles are used to:

1. Permit the unauthorized WebSphere Application Server servant access to controller services
2. Control dynamic application environments, which are displayed and controlled differently from static application environments

Choose between two SERVER class profiles. You need one of these profiles, and which profile you need correlates to dynamic application environment (DAE) support.

Procedure

- Use the profile for dynamic application environments.

When Dynamic Application Environments are supported, use:

```
RDEFINE SERVER CB.<server>.<cluster>.<cell> UACC(NONE)
PERMIT <SR_userid> ACC(READ)
```

- Use the profile for static application environments.

When Dynamic application environments are not supported (static application environments), use:

```
RDEFINE SERVER CB.<server>.<cluster> UACC(NONE)
PERMIT <SR_userid> ACC(READ)
```

Three-part profile

The existing three-part profile has the form:

`<subsystem_type>.<subsystem_name>.<application_environment_name>`

where:

- `<subsystem_type>` is **CB**
- `<subsystem_name>` is the application server short name.
- `<application_environment_name>` is the application server generic short name, as specified in the WebSphere Application Server variables. If the server resides in a cluster, the name specified here must match the cluster short name. If the server does not reside in a cluster, the name must match the name specified on the ClusterTransitionName custom property for the server .

The four-part profile adds the cell name to avoid ambiguities with existing profile names. The four-part profile has the form:

<subsystem_type>.<subsystem_name>.<application_environment_name>.<cell_name>

where:

- <cell_name> is the short name of the cell containing this application server.

Three-part profile names:

- CB.T5SRV1.T5CL1 (the application server with the short name T5SRV1 and generic short name T5CL1)
- CB.*.T5CL1 (all application servers in the generic short name of T5CL1)
- CB.*.* (any application server in the sysplex)

Four-part profile names:

- CB.T5SRV1.T5CL1.T5CELL (the application server with the short name T5SRV1, and generic short name T5CL1 that resides in the cell T5CELL)
- CB.*.T5CL1.T5CELL (all servers in the generic short name of T5CL1 in the T5CELL)
- CB.*.*.T5CELL (any server in the cell named T5CELL)

If you do not want to discriminate between any of the application servers, you can eliminate all the specified profiles and use a generic form to cover the three and four-part names for all the servers in the sysplex:

- CB.*.T5*
- CB.*.T5*.*

Resource Access Control Facility Tools

The following tools and techniques help you to manage the security definitions used for WebSphere Application Server for z/OS:

- RACF ISPF panels for listing all the profiles in a class
- ISHELL for listing UIDs in UID or user-id order
- EXEC for listing GIDs in GID or group-id order
- EXEC for backing out RACF definitions

RACF ISPF panels

To list all profiles in a specific class, use the RACF ISPF panels. You must have RACF SPECIAL or AUDITOR authority to complete the following steps:

- Select *General Resource Profiles* (option 2).
- Search (option S or 9).
- Type in a class name.
- Press enter two more times.

```
-----  
RACF - SERVICES OPTION MENU  
OPTION ==> 2  
SELECT ONE OF THE FOLLOWING:  
1 DATA SET PROFILES  
2 GENERAL RESOURCE PROFILES  
3 GROUP PROFILES AND USER-TO-GROUP CONNECTIONS  
4 USER PROFILES AND YOUR OWN PASSWORD  
5 SYSTEM OPTIONS  
6 REMOTE SHARING FACILITY  
7 DIGITAL CERTIFICATES AND KEY RINGS  
99 EXIT  
-----
```

```
-----  
RACF - GENERAL RESOURCE PROFILE SERVICES  
SELECT ONE OF THE FOLLOWING:  
1 ADD Add a profile  
2 CHANGE Change a profile
```

```

3 DELETE Delete a profile
4 ACCESS Maintain access list
5 AUDIT Monitor access attempts (Auditors only)
D or 8 DISPLAY Display profile contents
S or 9 SEARCH Search the RACF data base for profiles
-----

```

```

-----
RACF - GENERAL RESOURCE SERVICES - SEARCH
OPTION ==>
ENTER THE FOLLOWING PROFILE INFORMATION:
CLASS ==> STARTED
PROFILE ==>
-----

```

```

-----
BROWSE - RACF COMMAND OUTPUT ----
COMMAND ==>
T5ACR.* (G)
T5DMN.* (G)
T5SRVND5.* (G)
T5SRV1S.* (G)
T5SRV2S.* (G)
T5SRV3S.* (G)
WMQX.* (G)
WSCWTRC.*
-----

```

You can also obtain a list of all profiles in a class using the RACF SEARCH command: SEARCH CLASS(class_name).

Listing all user IDs in UID order

When defining new user IDs with OMVS segments in RACF, you should assign unique UIDs. WebSphere does not yet support the RACF AUTOUID function. To find unassigned (and duplicate) UIDs, use the ISPF ISHELL (option 3.4) to obtain a list of all user IDs in UID order. You must be a superuser (UID=0), and you must follow these steps:

1. Select the *Setup* pull-down and the *User list* option.
2. Browse the list of users.
3. While browsing the list of users, select the *File* pull-down.
4. Select the *Sort UID* option. (Note that a UID of -1 means that the user has no OMVS segment.)

Below is an example of the panels involved:

```

-----
File  Directory  Special_file  Tools  File_systems  Options  Setup  Help
-----
UNIX System Services ISPF Shell
Command ==> _____
-----

-----
1. User...
2. User list...
3. All users...
4. All groups...
5. Permit field access...
6. Character Special...
7. Reset UID to 847039
-----

-----
File  Help
-----
-----
User List
-----
Command ==> _____
-----
User ID          UID          Group
-----
ADMOORE          1024996      $USERS /u/admoore
AHMAD             2            DFSGRP /u/ahmad
AKILOV           125406       $USERS /u/akilov
ALLMOND          36           DFSGRP /u/allmond
AOPUSER          99129934     AOPOPER /u/aopuser
ASTLEY           787202       DFSGRP /u/astley
A5USR            112501       A5GRP /tmp
BAGWELL          342832       DFSGRP /u/bagwell
-----

```

- ```

1. Sort name
2. Sort UID
3. Sort Group
4. Print
5. Exit User ID UID Group

```

```

User ID UID Group

```

| User ID  | UID  | Group   |
|----------|------|---------|
| CBASRUH  | 2336 | CBASRH  |
| CBIVPH   | 2337 | CBIVPGH |
| T5GUEST  | 2402 | T5GUESG |
| T5ADMIN  | 2403 | T5CFG   |
| T5DMNU   | 2411 | T5CFG   |
| T5ACRNDU | 2421 | T5CFG   |
| T5DMGSU  | 2422 | T5SVRG  |
| T5ASRNDU | 2422 | T5SVRG  |
| T5ACRU   | 2431 | T5CFG   |
| T5ASRU   | 2432 | T5SVRG  |
| WSPETSC  | 2701 | WSCNTLG |

```

```

## Listing all Group IDs in GID order

You should also assign unique GIDs to new groups. There is no system-supplied tool for listing groups in GID order (as there is for UIDs), so that you can identify duplicates and assign new GIDs that are unique. Specify GID as the sole parameter to list them in GID order. The default is to list them in group ID order. (You must have RACF SPECIAL, AUDITOR, or other specific authority.)

```
/* Rexx ----- */
/* This exec uses the ishell bpxwirac service to display the group */
/* with OMVS segments and there group IDs. B. Pierce & MJ Loos */
/* ----- */
/* Syntax: LISTGRP Name (default) | GID */
/* ----- */
order = "N" /* set default to name */
Arg parm /* get argument for sort order */
if Abbrev("NAME",parm,1) then order = "N"
if Abbrev("GID",parm,1) then order = "I"

call bpxwirac "OMVSGROUP" /* call the service */

Address ISPEXEC /* using ISPF services */
if order = "N" then do /* already sorted */
 do ix=1 by 1 while queued()>0
 parse pull gname gid
 say left(gname,8) right(gid,8)
 end
end
else do /* sort the results */
 "TBCREATE grptable names(tbgrpnm tbgrpuid) replace nowrite"
 rows = 0
 do ix=1 by 1 while queued()>0 /* populate the table */
 parse pull gname gid
 tbgrpnm = left(gname,8)
 tbgrpuid = right(gid,8)
 "TBADD grptable"
 rows = rows + 1
 end
 "TBSORT grptable FIELDS(tbgrpuid,C,A,tbgrpnm,C,A)" /* sort it */
 "TBTOP grptable"
 do ix = 1 to rows by 1 /* display the results */
 "TBSKIP grptable"
 say tbgrpnm tbgrpuid
 end
 "TBEND grptable" /* throw out the table */
end
say
exit 0
/***** end of EXEC *****/
```

## Backing out RACF Definitions

When you are setting up servers, nodes and cells (and then deleting them), it would be convenient to have a simple way to delete the RACF definitions that you create in the process.

The attached exec reads the generated RACF commands from the BB0WBRAK member of the target .DATA partitioned data set, and creates RACF DELUSER, DELGROUP, RDELETE, and other RACF commands (in reverse order).

Before running the resulting RACF commands, you should review the output and delete any commands that delete users, groups, or profiles used by other servers that you want to retain.

**Tip:** Be very careful not to delete users and generic profiles used by others.

```

/* REXX - UNDO2 - Create backout RACF commands to uninstall Server*/
Read RACF commands into linein.in, parse verb & Obj, push
"delete/undo" commands to cmdOut.out, then write out in rev order */
out = 1 /* Output line number for stem var. cmdOut. */
"EXECIO * DISKR RACFCMDS (STEM linein."
do in = 1 to linein.0 /* See what we read; call the appropriate rtne */
 if pos('/**',linein.in) <> 0 then iterate
 if pos('say',linein.in) = 1 then iterate
 parse var linein.in ''' cmdVerb cmdObj '''
 select
 when cmdVerb = "ADDGROUP" then call DelGrp
 when cmdVerb = "ADDUSER" then call DelUsr
 when cmdVerb = "CONNECT" then call ConUsr
 when cmdVerb = "RDEFINE" then call DelPro
 when cmdVerb = "PERMIT" then call PerUsr
 when cmdVerb = "RACDCERT" then call RdCert
 otherwise iterate
 end /* select */
end /* in=1 to n */
call WriteCmds
exit 1
return

/***** Subroutines: *****/

DelUsr: /* DelUsr: Delete User */
 parse var cmdObj user .
 cmdOut.out = "DELUSER " || user
 out = out + 1
return

DelGrp: /* DelGrp: Delete Group */
 parse var cmdObj group .
 cmdOut.out = "DELGROUP " || group
 out = out + 1
return

ConUsr: /* ConUsr: Remove user from a group */
 cmdOut.out = "REMOVE " || cmdObj
 out = out + 1
return

DelPro: /* DelPro: Delete Profile */
 parse var cmdObj class profile acc .
 cmdOut.out = "RDELETE " || class profile
 out = out + 1
return

PerUsr: /* PerUsr: Remove permission from a profile */
 parse var cmdObj profile class ID acc
 parse value cmdObj with 'ID(' id ')' acc
 cmdOut.out = 'PERMIT ||profile class|| ID(||ID||) DELETE'
 out = out + 1
return

RdCert: /* RdCert: Remove Certificates */
if pos('GENCERT',cmdObj) <> 0 then
DO
 if pos('CERTAUTH',cmdObj) <> 0
 then
 DO
 parse value cmdObj with 'WITHLABEL(' cert ')'
 cmdOut.out = 'RACDCERT CERTAUTH DELETE(LABEL(' || cert || '))'
 out = out + 1
 END
 ELSE DO
 parse value cmdObj with 'WITHLABEL(' cert ')'
 parse value cmdObj with 'ID(' id ')'
 cmdOut.out = 'RACDCERT ID(||id||) DELETE(LABEL(' || cert || '))'
 out = out + 1
 END
 END
END
if pos('ADDRING',cmdObj) <> 0 then
DO
 parse value cmdObj with 'ADDRING(' ringname ')'
 parse value cmdObj with 'ID(' user ')'
 cmdOut.out = 'RACDCERT DELRING(||ringname) ID(||user)'
 out = out + 1
 END
return

/* Finished - pull LIFO stack and Write it out *****/
WriteCmds:

```

```

DO i = out-1 to 1 by -1
 QUEUE cmdOut.i
 EXECIO 1 DISKW RACFUNDO
END
return

```

## RACF keyring setup

### Using Java to create a RACFInputStream for a RACF keystore

During the SSL authentication process, WebSphere Application Server considers a certificate that connects as a PERSONAL certificate as a KeyEntry. You can use the certificate as an end-user certificate in a Secure Sockets Layer (SSL) handshake because the private key is available.

WebSphere Application Server considers a certificate that connects as a CERTAUTH certificate as a TrustedCertEntry and treats the certificate as a Certificate Authority (CA). Keyrings require certificates that connect as PERSONAL and CA certificates that connect as CERTAUTH. Certificates that connect as SITE are not supported in this release.

A RACF keyring that a Java Secure Socket Extension (JSSE) client and server can use for both trust and key information is shown in the following sample code:

```

Certificate Label Name Cert Owner USAGE DEFAULT

PersonalEndUserCert ID(USERID) PERSONAL YES
PersonalEndUserCACert CERTAUTH CERTAUTH NO

```

You must add the certification path provider to your Java environment to construct certificate chains from certificates that WebSphere Application Server reads from the Resource Access Control Facility (RACF). Add the following line to your `java.security` file provider list:

```
security.provider.X=com.ibm.security.cert.IBMCertPath
```

If one of the RACF certificates fails to load, the keystore is not loaded. You must remove any unwanted certificates from the keyring.

The RACFInputStream contains three parameters:

- `userid` - a string containing the ID of the user that owns the keyring
- `ringid` - a string containing the name of the RACF key ring
- `password` - a character array containing the password for the keystore

The following code example shows the RACFInputStream script passing in a user ID, a ring ID, and a null password directly:

```

import com.ibm.crypto.provider.RACFInputStream;

String ksfname;
char[] storePass = null;

RACFInputStream riStream = new RACFInputStream(System.getProperty("user.name"),
 ksfname,
 storePass);
KeyStore racfKeyStore = KeyStore.getInstance("JCERACFKS");
racfKeyStore.load(riStream, storePass);

riStream.close();

```

In the above example, the system property `user.name` is referenced to provide the `userID` that WebSphere Application Server passes to RACF. This example is not typical.

For more information about running the RACFInputStream script, see the document *z/OS Unique Considerations for the Java 2 SDK, Standard Edition, v 6.0*. A link to this z/OS document is provided in the Related Links section of this topic.

## Accessing a RACFInputStream using URLStreamHandler

In this release, you can access data through user-defined classes with the `URLStreamHandler` object. WebSphere Application Server can define the classes that access the data with the system property `java.protocol.handler.pkgs`. To access data that resides in a Service Authorization Facility (SAF) RACF keyring, use the safkeyring URL with the associated classes.

To use the `URLStreamHandler` class to create a `RACFInputStream`, define the following Java property :

```
-Djava.protocol.handler.pkgs
```

If you are using the IBM Java Cryptography Extension (IBMJCE) provider to provide cryptographic support, set the property to the following value:

```
-Djava.protocol.handler.pkgs=com.ibm.crypto.provider
```

If you are using the IBMJCE4758 provider to provide cryptographic support, set the property to the following value:

```
-Djava.protocol.handler.pkgs=com.ibm.crypto.hwCCA.provider
```

You can use a URL to specify a stream handler in the `java.policy` file. The `jarsigner` utility also accepts a URL for the `-keystore` parameter. When certificates from a RACF keyring verify signed jar files, you can specify that WebSphere Application Server must use the keyring as an input stream to the keystore in the `java.policy` file, as shown in the following example code:

```
keystore "safkeyring://myracfid/my_key_ring", "JCERACFKS";
```

In this example,

- `safkeyring` is the URL keyword that the server uses to access the `URLStreamHandler` code to read data from the keyring
- `myracfid` is the RACF userid that has authority to read data from the keyring
- `my_key_ring` is the name of the keyring from which the data is read
- `JCERACFKS` is the keystore type defined for a SAF (RACF) keyring keystore

The Java Virtual Machine (JVM) must be started with the `java.protocol.handler.pkgs` property set to one of the values described previously, so that WebSphere Application Server can call the appropriate `URLStreamHandler`. The following example shows the `jarsigner` utility using a safkeyring URL:

```
jarsigner -keystore safkeyring://myracfid/my_key_ring -signedjar
ibmjceproviders.jar ibmjceprovider.jar ibmprovider -storetype JCERACFKS
```

For more information on inserting or updating information in the RACF External Security Manager, refer to the **RACDCERT** command in the following publications:

- *z/OS SecureWay Security Server RACF Command Language Reference - SA22-7687*

## Controlling access to console users when using a Local OS Registry

Adding console users and authorizing them for a cell involves adjusting the user registry and authorization settings. A user registry custom property governs the form of authorization of console users. Regardless of the form of authorization used, the outcome is that an MVS user ID for the WebSphere administrator identity is able to access all administrative console functions and use the administrative scripting tool when security is first enabled.

### About this task

If non-local operating system registries and System Authorization Facility (SAF) authorization are used, you must use identity mapping to map WebSphere Application Server identities to SAF user IDs. To have the console roles managed by SAF authorization, you must turn on SAF authorization for the cell. To

enable SAF authorization, click **Security > Global security > External Authorization providers >**, and click **System Authorization Facility (SAF) authorization** to enable SAF authorization. If you enable the option, the SAF EJBROLE profiles are used to authorize console users. Otherwise, the administrative console, by default, is used to authorize console users and groups.

Regardless of which type of registry or authorization setting is chosen, the configuration process authorizes the WebSphere configuration group (to which all WebSphere Server identities are permitted), and an MVS user ID for the WebSphere administrator identity to do the following tasks:

- Access all administrative console functions
- Use the administrative scripting tool when security is first enabled

When SAF authorization is selected on z/OS, the special subject of server is not used as the administrative user ID. (Note that using the WebSphere z/OS Profile Management Tool or the **zpm** command generates an administrative user, who is a member of the administrative group, which can be used for authorization.)

### Using SAF Authorization to control access to administrative functions

When SAF Authorization is selected during systems customization, administrative EJBROLE profiles for all administrative roles are defined by the RACF jobs generated using the z/OS Profile Management Tool. If SAF Authorization is selected subsequently, issue the following RACF commands (or equivalent security server commands) to enable your servers and administrator to administer WebSphere Application Server:

**Note:** You can additionally specify a value for the SAF profile prefix (previously referred to as the z/OS security domain).

```
RDEFINE EJBROLE (optionalSAFProfilePrefix.)administrator UACC(NONE)
RDEFINE EJBROLE (optionalSAFProfilePrefix.)monitor UACC(NONE)
RDEFINE EJBROLE (optionalSAFProfilePrefix.)configurator UACC(NONE)
RDEFINE EJBROLE (optionalSAFProfilePrefix.)operator UACC(NONE)
RDEFINE EJBROLE (optionalSAFProfilePrefix.)deployer UACC(NONE)
RDEFINE EJBROLE (optionalSAFProfilePrefix.)adminsecuritymanager UACC(NONE)
RDEFINE EJBROLE (optionalSAFProfilePrefix.)auditor UACC(NONE)

PERMIT (optionalSAFProfilePrefix.)administrator CLASS(EJBROLE) ID(adminGroup) ACCESS(READ)
PERMIT (optionalSAFProfilePrefix.)monitor CLASS(EJBROLE) ID(monitorGroup) ACCESS(READ)
PERMIT (optionalSAFProfilePrefix.)configurator CLASS(EJBROLE) ID(configuratorGroup) ACCESS(READ)
PERMIT (optionalSAFProfilePrefix.)operator CLASS(EJBROLE) ID(operatorGroup) ACCESS(READ)
PERMIT (optionalSAFProfilePrefix.)deployer CLASS(EJBROLE) ID(deployerGroup) ACCESS(READ)
PERMIT (optionalSAFProfilePrefix.)adminsecuritymanager CLASS(EJBROLE) ID(adminSecurityGroup) ACCESS(READ)
PERMIT (optionalSAFProfilePrefix.)auditor CLASS(EJBROLE) ID(auditorGroup) ACCESS(READ)
```

If additional users require access to administrative functions, you can permit a user to any of the above roles as follows by issuing the following RACF command:

```
PERMIT (optionalSAFProfilePrefix.)rolename CLASS(EJBROLE) ID(mvsid) ACCESS(READ)
```

You can give a user access to all administrative functions by connecting it to the configuration group:

```
CONNECT mvsid GROUP(configGroup)
```

### Using WebSphere Authorization to control access to administrative functions:

To assign users to administrative roles, complete the following steps.

#### Procedure

1. In the administrative console, expand **System Administration > Console settings**.
2. Click **Console Users > Add** or **Console Groups > Add**.
3. Add the user identities as desired. For more information on console user roles, see “Administrative roles and naming service authorization” on page 1700.

**Note:**

- When SAF authorization is in effect, WebSphere Application Server authorization, as specified in the administrative console, is ignored.
- SAF role names are case-sensitive.

## Using CBIND to control access to clusters

You can use the CBIND class in RACF to restrict a client's ability to access clusters from Java Application Clients or J2EE compliant servers. You must have READ permission to access clusters.

### Before you begin

You can also use this class to specify which servers are trusted to assert identities (with no authenticator).

**Remember:** When using the server trusted identity, the RACF server id needs to be granted CONTROL permission to the profile.

- z/OS Secure Authentication Services (z/SAS) identity assertion accepted
- Common Secure Interoperability Version 2 (CSIv2) identity assertion
- Web container HTTP transport

**Important:** z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

### About this task

This validates an intermediate server to send certificates (MutualAuthCBindCheck=true). You can deactivate the class if you do not require this kind of access control.

Servers are either clustered or not clustered. The value of cluster\_name is:

1. For a clustered server, the cluster\_name used in these profiles is the cluster short name.
2. For an unclustered server, instead of a cluster\_name a server custom property (ClusterTransitionName) is used.

**Note:** When you convert a server into a clustered server the ClusterTransitionName becomes the short name of the cluster.

The following steps explain the CBIND authorization checking by WebSphere Application Server for z/OS.

### Procedure

1. You can use the CBIND class in RACF to restrict the ability of a client to access clusters, or you can deactivate the class if you do not require this kind of access control. WebSphere Application Server for z/OS uses two types of profiles in the CBIND class. One type of profile controls whether a local or remote client can access clusters. The name of the profile has the following form, where *cluster\_name* is the name of the cluster, and *SAF\_profile\_prefix* is the prefix used for SAF profiles.

```
CB.BIND.<optional SAF_profile_prefix>.<cluster_name>
```

**Note:** When you add a new cluster, you must authorize all Java Client user IDs and Servers to have read access to the CB.**cluster\_name** and CB.BIND.**cluster\_name** RACF profiles.

**Example:** WSADMIN needs read authority to the CB.BBOC001 and CB.BIND.BBOC001 profiles:

```
PERMIT CB.BBOC001 CLASS(CBIND) ID(WSADMIN) ACCESS(READ)
PERMIT CB.BIND.BBOC001 CLASS(CBIND) ID(WSADMIN) ACCESS(READ)
```

2. You can also use the System Authorization Facility (SAF) CBIND class to indicate that a process is trusted to assert identities to WebSphere Application Server for z/OS. This usage is primarily intended for use by trusted intermediate servers who have already authenticated their callers. The intermediate server (or process) must establish its network identity to WebSphere Application Server for z/OS using

SSL client certificates. This network identity is mapped to an MVS user ID by SAF security service. This mapped identity must be granted CONTROL access to the CB.BIND.<optional SAF\_profile\_prefix>.<cluster\_name> process to be authorized to assert identities. The use of CBIND profiles to establish trust is used by the following authentication mechanisms:

- Web container HTTP transport (which validates unencrypted client certificates when the property: MutualAuthCBindCheck=true is set)
- CSiv2 identity assertion for IIOP
- z/SAS identity assertion accepted

For example, WEBSERV must assert client certificates that are received from its callers: PERMIT CB.BIND.BBOC001 CLASS(CBIND) ID(WEBSERV) ACCESS(CONTROL)

---

## Configuring multiple security domains

By default, all administrative and user applications in WebSphere Application Server use the global security configuration. For example, a user registry defined in global security is used to authenticate users for every application in the cell. Out-of-the-box, this behavior is the same as it was in previous releases of WebSphere Application Server. You can create additional WebSphere security domains if you want to specify different security attributes for some or all of your user applications. This section describes how to configure a security domain by using the administrative console.

### Before you begin

Only users assigned to the administrator role can configure or create new multiple security domains. Enable global security in your environment before configuring multiple security domains.

Read about “Multiple security domains” on page 1310 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

### About this task

Security domains enable you to define multiple security configurations for use in your environment. For example, you can define different security (such as a different user registry) for user applications than for administrative applications. You can also define separate security configurations for user applications deployed to different servers and clusters.

Perform the following steps to configure a new security domain by using the administrative console:

### Procedure

1. Click **Security > Security domains**.
2. If you are creating a new multiple security domain, click **New**. Supply a unique name and description for the domain and click **Apply**. If you want to configure an existing multiple security domain, select one to edit. Once you click **Apply** the domain name and additional sections are displayed. One section enables you to define the security attributes for the domain, and another section enables you to select the scopes to which the domain applies.
3. Under Assigned Scopes, select whether you want to assign the security domain to the entire cell or if you want to select the specific servers, clusters, and service integration buses to be included in the security domain. The Assigned Scopes section has two views. The default view is a cell topology. To assign the security domain to the entire cell, click the check box for the cell and then click **Apply** or **OK**.

The name of the security domain appears next to the cell name, which indicates that the domain is now assigned to the cell. You can expand the topology and assign the domain to one or more servers and clusters. When an item in the topology is already assigned to another security domain, the check

box is disabled and the name of the assigned domain is displayed to the right of the scope name. If you want to assign one of these scopes to the domain, you must first disassociate it with its current domain.

Select **All assigned scopes** to view a list of only those resources that are currently assigned to the security domain.

4. Customize your security configuration by specifying security attributes for your new domain. Attributes that are not listed can not be customized at the domain level. Domains inherit attributes from the global security configuration.

There are twelve individually configurable security attribute sections. You can expand and collapse each section. In the collapsed state, the name and a summary value for the section are displayed. Additionally, the summary value text indicates whether the attribute is defined in global security and is reused by the domain (as indicated by gray text) or if it is customized for the domain (as indicated by black text prefixed by the word “Customized”).

Initially, each security attribute is set to use the global security settings. When an attribute is set to use global security, there is no domain-specific configuration for that attribute. Applications that use the domain use the global configuration for these security attributes.

Only configure the security attributes that you want to change. To configure a security attribute for a domain, expand the security attribute section. The key properties of the global configuration display beneath the **Use global security** option. These properties are provided for convenience.

To customize the configuration for the domain, select **Customize for this domain**. Configure the property and then click **OK** or **Apply**.

**Note:** In general, when you select **Customize for this domain**, you override all of the security configurations that are defined for that section in global security. Application logins, system logins, and J2C authentication data entries are some exceptions. When you define entries for a domain, applications in the domain are able to access the global entries in addition to the domain-specific entries.

For example, you might want to use a different user registry for applications that use the security domain but also want to use the global security configuration for all of the other security properties. In this case, expand the User Realm section and select **Customize for this domain**. Select a user registry type, click **Configure**, and provide the appropriate configuration details on the subsequent panel.

You can change security attributes such as the following:

### **Application Security**

Specifies the settings for application security and Java 2 security. You can use the global security settings or customize the settings for a domain.

Select **Enable application security** to enable or disable security this choice for user applications. When this selection is disabled, all of the EJBs and web applications in the security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

### **Java 2 Security**

Select **Java 2 security** to enable or disable Java 2 security at the domain level. This choice enables or disables Java 2 security at the process (JVM) level so that all applications (both administrative and user) can enable or disable Java 2 security.

### **User realm**

This section enables you to configure the user registry for the security domain. You can separately configure any registry that is used at the domain level. Read about “Multiple security domains” on page 1310 for more information.

### Trust association

When you configure the trust association interceptor (TAI) at a domain level, the interceptors configured at the global level are copied to the domain level for convenience. You can modify the interceptor list at the domain level to fit your needs. Only configure those interceptors that are to be used at the domain level.

### SPNEGO Web Authentication

The SPNEGO web authentication, which enables you to configure SPNEGO for web resource authentication, can be configured at the domain level.

**Note:** In WebSphere Application Server Version 6.1, a TAI that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated in WebSphere Application Server 7.0. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

### RMI/IOP Security

The RMI/IOP security attribute refers to the CSIV2 (Common Secure Interoperability version 2) protocol properties. When you configure these attributes at the domain level, the RMI/IOP security configuration at the global level is copied for convenience.

You can change the attributes that need to be different at the domain level. The Transport layer settings for CSIV2 inbound communications should be the same for both the global and the domain levels. If they are different, the domain level attributes are applied to all of the application in the process.

### JAAS application logins

Specifies the configuration settings for the Java Authentication and Authorization Service (JAAS) application logins. You can use the global security settings or customize the settings for a domain.

**Note:** The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

### JAAS system logins

Specifies the configuration settings for the JAAS system logins. You can use the global security settings or customize the configuration settings for a domain.

### JAAS J2C authentication

Specifies the configuration settings for the JAAS J2C authentication data. You can use the global security settings or customize the settings for a domain.

### Java Authentication SPI (JASPI)

Specifies the configuration settings for a Java Authentication SPI (JASPI) authentication provider and associated authentication modules. You can use the global security settings or customize the settings for a domain. To configure JASPI authentication providers for a domain, select **Customize for this domain** and then enable JASPI. Select **Providers** to define providers for the domain.

**Note:** The JASPI authentication provider can be enabled with providers configured at the domain level. By default, all of the applications in the system have access to the JASPI authentication providers configured at the global level. The security runtime first checks

for the JASPI authentication providers at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure JASPI authentication providers at a domain only when the provider is to be used exclusively by the applications in that security domain.

### Authentication Mechanism Attributes

Specifies the various cache settings that need to be applied at the domain level.

Select **Authentication cache settings** to specify your authentication cache settings. The configuration specified on this panel is applied only to this domain.

Select **LTPA Timeout** to configure a different LTPA timeout value at the domain level. The default timeout value is 120 minutes, which is set at the global level. If the LTPA timeout is set at the domain level, any token that is created in the security domain when accessing user applications is created with this expiration time.

When **Use realm-qualified user names** is enabled, user names returned by methods such as `getUserPrincipal()` are qualified with the security realm (user registry) used by applications in the security domain.

### Authorization Provider

You can configure an external third party JACC (Java Authorization Contract for Containers) provider at the domain level. Tivoli Access Manager's JACC provider can only be configured at the global level. Security domains can still use it if they do not override the authorization provider with another JACC provider or with the built-in native authorization.

On z/OS, you can enable or disable the System Authorization Facility (SAF) based authorization at the domain level.

You can additionally configure the SAF authorization options at the security domain level, which are the following:

- The unauthenticated user id
- The SAF profile mapper
- Whether to enable SAF delegation
- Whether to use the APPL profile to restrict access to WebSphere Application Server
- Whether to suppress authorization failed messages
- The SMF audit record strategy
- The SAF profile prefix

For more information on the SAF authorization options, read about “z/OS System Authorization Facility authorization” on page 1734.

### z/OS security options

You can set z/OS specific security options at the process (JVM) level so that all applications (both administrative and user) can enable or disable these options. These properties are:

- Enabling application server and z/OS thread identity synchronization
- Enabling the connection manager RunAs thread identity.

For more information on the z/OS security options, read about “z/OS security options” on page 1264

### Custom properties

Set custom properties at the domain level that are either new or different from those at the global level. By default, all of the custom properties at the global security configuration can be accessed by all of the applications in the cell. The security runtime code first checks for the custom property at the domain level. If it does not find it, it then attempts to obtain the custom property from the global security configuration.

5. Once you have configured the security attributes and assigned the domain to one or more scopes, click **Apply** or **OK**.
6. Restart all servers and clusters for your changes to take effect.

## Multiple security domains

The WebSphere Security Domains (WSD) provide the flexibility to use different security configurations in WebSphere Application Server. The WSD is also referred to as multiple security domains, or simply, security domains. You can configure different security attributes, such as the UserRegistry, for different applications.

**Note:** Multiple security domain support was introduced in WebSphere Application Server Version 7.0. You can create different security configurations and assign them to different applications in WebSphere Application Server processes. By creating multiple security domains, you can configure different security attributes for both administrative and user applications within a cell environment. You can configure different applications to use different security configurations by assigning the servers or clusters or service integration buses that host these applications to the security domains. Only users assigned to the administrator role can configure multiple security domains.

The following sections describe multiple security domains in more detail:

- “Why security domains are useful”
- “Relationship between global security and security domains” on page 1311
- “Contents of a security domain” on page 1312
- “Creating security domains” on page 1313
- “Configuring attributes for security domains” on page 1314
- “Associating scopes to security domains” on page 1315
- “Relationship between old server level security and the new security domains” on page 1316
- “How domain level security attributes are used by security runtime and applications” on page 1316
- “Client and application security programming model when using security domains” on page 1320
- “Application deployment in multiple domains configurations” on page 1322
- “Cross realm communication” on page 1322
- “Federating a node with security domains” on page 1325
- “Security domains in a mixed-version environment” on page 1326
- “Modifying security domains” on page 1326
- “Toleration PTFs required for mixed-release environments” on page 1327

## Why security domains are useful

WebSphere Security Domains provide two major benefits:

- WebSphere Application Server administrative applications can be configured with a different set of security configurations from those for user applications.
- They enable one set of applications to have a different set of security configurations from another set of applications.

For example, WebSphere Application Server administration can be configured to a user registry of RACF while the applications can be configured to a user registry of LDAP.

In previous versions of WebSphere Application Server, all administrative and user applications use security attributes different from those attributes that are defined in global security. All administrative and user applications in WebSphere Application Server use global security attributes by default. For example, a user registry defined in global security is used to authenticate a user for every application in the cell.

In this release of WebSphere Application Server, however, you can use multiple security attributes for user applications other than the global security attributes, create a security domain for those security attributes that must differ, and associate them with the servers and clusters that host those user applications. You also can associate a security domain with the cell. All of the user applications in the cell use this security domain if they do not have a domain previously associated with them. However, global security attributes are still required for administrative applications such as the administrative console, naming resources and MBeans.

If you have used server level security in previous releases of WebSphere Application Server, you should now use multiple security domains since they are more flexible and easier to configure.

Server level security is deprecated in this release. Read “Relationship between global security and security domains” for more information.

## **Relationship between global security and security domains**

Global Security applies to all administrative functions and the default security configuration for user applications. Security domains can be used to define a customized configuration for user applications.

You must have a global security configuration defined before you can create security domains. The global security configuration is used by all of the administrative applications such as the administrative console, naming resources, and Mbeans. If no security domains are configured, all of the applications use information from the global security configuration. User applications such as Enterprise JavaBeans (EJBs), servlets and administrative applications use the same security configuration.

When you create a security domain and associate it with a scope, only the user applications in that scope use the security attributes that are defined in the security domain. The administrative applications as well as the naming operations in that scope use the global security configuration. Define the security attributes at the domain level that need to be different from those at the global level. If the information is common, the security domain does not need to have the information duplicated in it. Any attributes that are missing in the domain are obtained from the global configuration. The global security configuration data is stored in the `security.xml` file, which is located in the `$WAS_HOME/profiles/$ProfileName/cells/$CellName` directory.

The following figure provides an example of a security multiple domain where the cell, a server and a cluster are associated with different security domains. As shown in the figure, the user applications in server S1.1 as well as the cluster use security attributes that are defined in Domain2 and Domain3 respectively (since these scopes are associated with these domains). Server S2.2 is not associated with a domain. As a result, the user application in S2.2 uses the domain that is associated with the cell (Domain1) by default . Security attributes that are missing from the domain level are obtained from the global configuration.

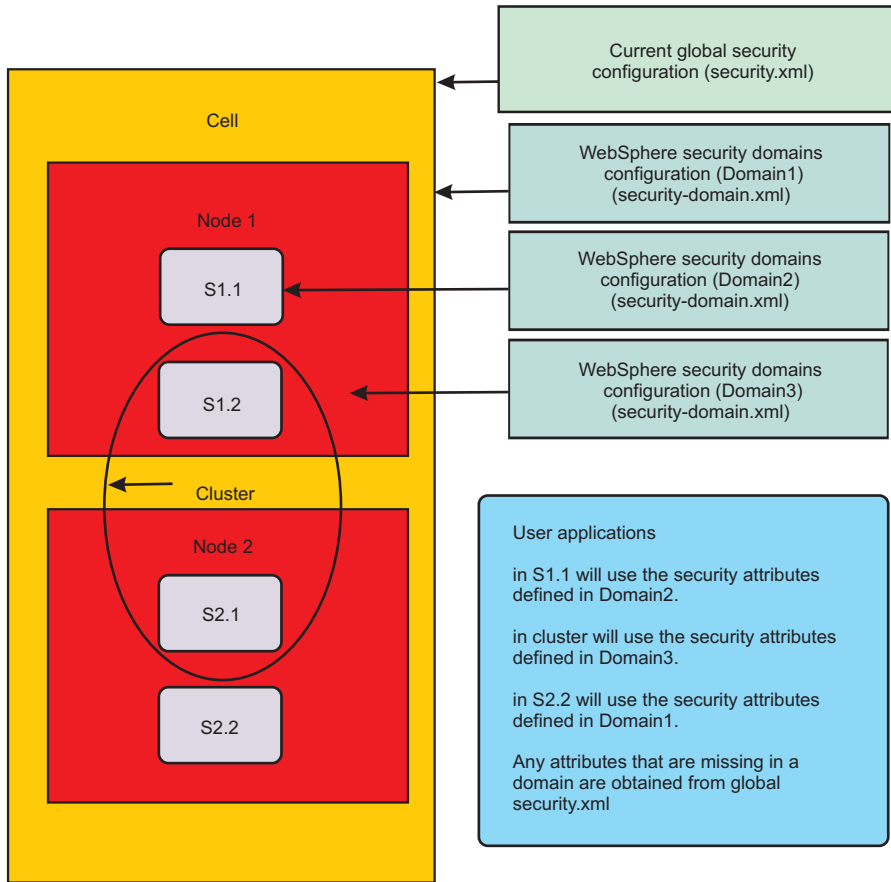

Figure 4. Scopes that can be associated to a security domain

The following figure shows the various high-level security attributes that can be defined at the global security configuration and those that can be overridden at the domain level.

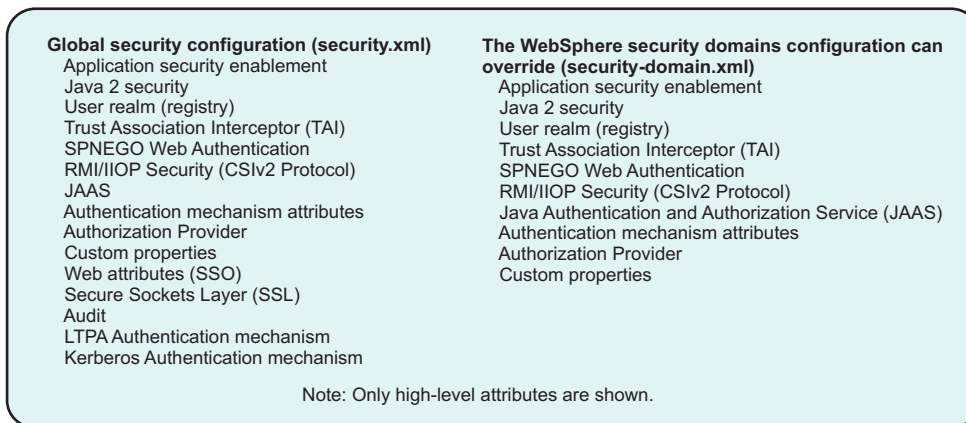

Figure 5. Security attributes that can be configured at the security domain

## Contents of a security domain

A security domain is represented by two configuration files. One configuration file contains the list of attributes that are configured in the security domain. The other configuration file contains the scopes that use the security domain. The security domain information is stored in the \$WAS\_HOME/profiles/

`$ProfileName/config/waspolicies/default/securitydomains/$SecurityDomainName` directory. For every security domain that is configured, a `$SecurityDomainName` directory is created with two files in it: the `security-domain.xml` file contains the list of security attributes configured for the security domain, and the `security-domain-map.xml` file contains the scopes that use the security domain.

The following figure indicates the location of the main security domain related files and the contents of those files.

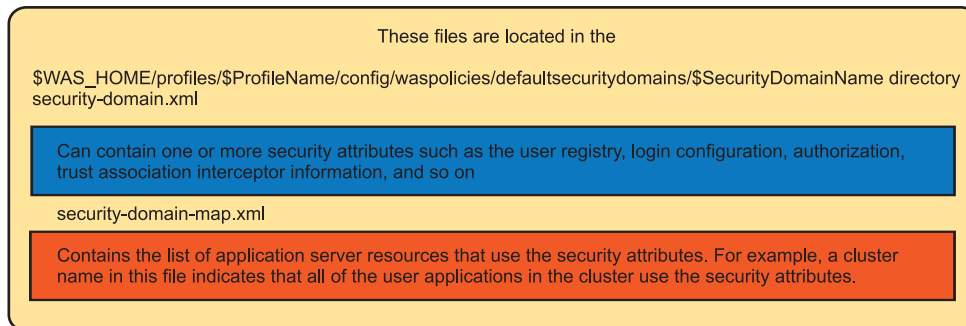

Figure 6. Location and contents of the main security domain related files

**Note:** You should not modify these files manually. Use administrative console tasks or scripting commands to modify the files instead. For a complete list of administrative tasks and scripting commands, see the links in "Related tasks" at the bottom of this document.

## Creating security domains

Use the administrative console tasks or scripting commands to create security domains. In the administrative console, access security domains by clicking **Security > Security domains**. Help is available for each administrative console panel.

For a complete list of administrative console tasks and scripting commands, see the links in "Related tasks" at the bottom of this document.

When you create a security domain you must supply a unique name for the domain, the security attributes you want to configure for the security domain, and the scopes that need to use the security domain. Once configured, the servers that use the security domain must be restarted. The user applications in those scopes then use the attributes that are defined in the security domain. Any attributes that are not configured at the domain level are obtained from the global security configuration. Administrative applications and naming operations in the scopes always use the security attributes from the global security configuration. You must actively manage these attributes.

Any new security domain attributes must be compatible with those global security attributes that are inherited by the user applications that are assigned to the domain.

Other than for JAAS and custom properties, once global attributes are customized for a domain they are no longer used by user applications.

The security domains panel in the administrative console enables you to assign resources and to select the appropriate security attributes for your domain. The panel displays the key security attributes at the global configuration; you can make the decision to override them at the domain level if necessary. Once you have configured and saved the attributes at the domain level, the summary value on the panel displays the customized value for the domain (tagged with the word "customized" in black text).

A scope (a server, cluster, service integration bus or a cell) can be associated with only one domain. For example, you cannot define two domains that both have the cell-wide scope. Multiple scopes, however, can be defined in the same security domain. For example, a domain can be scoped to Server1 and to Server2 only within the cell.

The assigned scopes section on the security domain panel displays two views: one view that enables you to select and assign scopes to the domain, and another view that enables you to see a list of the currently assigned scopes. For convenience, you also have the flexibility to copy all of the security attributes from an existing security domain or the global configuration into a new security domain, and then modify only those attributes that must be different. You must still associate the scopes to these copied domains.

Scripting commands also provide you with the ability to create, copy and modify security domains. Once you create a domain, you must run the appropriate commands to associate security attributes and scopes to it.

## Configuring attributes for security domains

Security attributes that can be configured at the domain level in WebSphere Application Server Version 8.0 are:

- Application security
- Java 2 security
- User realm (registry)
- Trust association
- Simple and Protected GSS-API Negotiation (SPNEGO) web authentication
- RMI/IIOP security (CSIv2)
- JAAS logins (Application, System and J2C Authentication Data)
- Java Authentication SPI
- Authentication mechanism attributes
- Authorization provider
- Federated repositories
- z/OS properties
- Custom properties

The security domains panels in the administrative console display all of these security attributes.

Some of the other well-known attributes that you cannot override at the domain level are Kerberos, Audit, Web Single Sign-on (SSO) and Tivoli Access Manager (TAM). The Secure Socket Layer (SSL) attribute already supports different scopes, but it is not part of the domain configuration. For all of the attributes that are not supported at the domain level, user applications in a domain share their configuration from the global level.

Any new security domain attributes must be compatible with those global security attributes that are inherited by the user applications that are assigned to the domain. You must actively manage these attributes. For example, if you customize only a JAAS configuration at the domain level you must make sure that it works with the user registry configured at the global level (if the user registry is not customized at the domain level).

Other than for JAAS and custom properties, once global attributes are customized for a domain they are no longer used by user applications.

The Tivoli Access Manager client runtime is used to provide authentication (used by TrustAssociationInterceptor and PDLoginModule) and authorization (used for JACC) by contacting TAM

servers. There is only one Tivoli Access Manager runtime shared by all servers in a cell. Read the Tivoli Access Manager JACC provider configuration topic for more information.

You cannot have a different Tivoli Access Manager configuration at the security domain level to override the configuration at the cell level. However, you can to some degree specify Trust Association Interceptor (TAI) and JACC configuration at the security domain level. For example, you can use a different TAI or a different authorization provider. Since TAM server connectivity can only be defined at the global level, you can have a variety of TAIs defined and configured at the security domain level. Some of these TAIs might not use the TAM user repository, while others do. The TAIs that do need to connect to TAM will also connect to the globally-defined TAM server. Similarly, for authorization, you can have a variety of external authorization providers configured at the domain level. However, if any of these external authorization providers require connection to TAM they end up talking to the singular globally-configured TAM server.

## Associating scopes to security domains

In WebSphere Application Server Version 8.0, you can associate a security domain at the cell level, the server level, the cluster level and the service integration bus level.

**Note:** For more information about the service integration bus and bus security in multiple security domains for WebSphere Application Server Version 8.0, see `./ae/cjr_sec_dom.dita`.

When a security domain is associated with a server that is not part of a cluster, all user applications in that server use the attributes from the security domain. Any missing security attributes are obtained from the global security configuration. If the server is part of a cluster, you can associate the security domain with the cluster but not with the individual members in that cluster. The security behavior then remains consistent across all of the cluster members.

If a server is to be part of a cluster, create a cluster first and associate the security domain to it. You might have associated a domain to a server before it was a member of a cluster. If so, even though the domain is associated with the server directly, the security runtime code does not look at the domain. When a server is a cluster member, the security runtime disregards any security domains associated directly to the server. Remove the server scope from the security domain and associate the cluster scope to it instead.

A security domain can also be associated to the cell. This is usually done when you want to associate all user applications in WebSphere Application Server to a security domain. In this scenario, all of the administrative applications and the naming operations use the global security configuration while all of the user applications use the domain level configuration. If you want to split the security configuration information for administrative and user applications, this is all that is needed.

If you have a mixed-version environment, or plan to have one in future, and you want to associate security domains at the cell level, read “Security domains in a mixed-version environment” on page 1326 for more information.

If you are on a base profile server that has its own security domain defined, which is then federated to a deployment manager, associate the server scope to the security domain and not the cell scope. When you federate that node, the security domain information is propagated to the deployment manager. If the cell scope is associated to it, the network deployment configuration uses this security configuration, which might impact existing applications. During federation, the cell scope is changed to the server scope that is being federated. If the server scope is associated with the security domain, only that server uses the security domain after the federation. Other applications in other servers and clusters are not impacted. However, if this base profile server is registered to the Administrative Agent process you can associate the cell scope to the security domain if you want all of the servers from the base profile to use the same security domain for all of their user applications. Read about “Federating a node with security domains” on page 1325 for more information.

You can have a security domain associated at the cell level and also other security domains associated to various clusters or individual servers (those that are not part of any clusters). In this case, the security runtime first checks if any security domains are associated with the server or a cluster. If there is a security domain associated with the server or a cluster, the security attributes defined in it are used for all of the applications in that server or cluster. Any security attributes missing from this server or cluster domain are obtained from the global security configuration, and not from the domain configuration associated with the cell.

If the server or cluster does not have its own domain defined, the security runtime code uses the security attributes from the domain associated with the cell (if one is defined). Any security attributes missing from the cell domain are inherited from the global security configuration.

## Relationship between old server level security and the new security domains

In previous releases of WebSphere Application Server, you could associate a small set of security attributes at a server level. These attributes were used by all of the applications at the server level. The previous way of configuring the security attributes was deprecated in WebSphere Application Server 7.0, and will be removed in a future release.

You should now use the new security domains support starting in WebSphere Application Server 7.0, as these security domains are more easily managed and much more flexible. For example, in previous versions of WebSphere Application Server, you must manually associate the same security configuration to all of the cluster members by configuring the same security attributes for every server in a cluster.

The migration tool migrates the existing server level security configuration information to the new security domain configuration when the script compatibility mode is `false` (`-scriptCompatibility="false"`). A new security domain is created for every server security configuration if it is not part of a cluster. If it is part of a cluster, a security domain is associated with the cluster instead of with all of the servers in that cluster. In both cases, all of the security attributes that were configured at the server level in previous releases are migrated to the new security domain configuration, and the appropriate scope is assigned to the security domains.

If the script compatibility mode is set to `true`, the server level security configuration is not migrated to the new security domains configuration. The old server security configuration is migrated without any changes. The security runtime detects that the old security configuration exists and uses that information, even if a security domain is associated either directly or indirectly to the server. If the script compatibility mode is set to `true`, remove the security configuration from the server level and then create a security domain with the same set of security attributes.

## How domain level security attributes are used by security runtime and applications

This section describes how the individual attributes at the domain level are used by the security runtime and how that impacts the user application security. Since all of these security attributes are also defined at the global level, more information about these attributes can be obtained elsewhere. For the purposes of this section, the emphasis is on domain level behavior.

### 1. Application Security:

Select **Enable application security** to enable or disable security for user applications. When this selection is disabled, all of the EJBs and web applications in the security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

### 2. Java 2 Security:

Select **Use Java 2 security** to enable or disable Java 2 security at the domain level or to assign or add properties related to Java 2 security. This choice enables or disables Java 2 security at the process (JVM) level so that all applications (both administrative and user) can enable or disable Java 2 security.

### 3. **User Realm (User Registry):**

This section enables you to configure the user registry for the security domain. You can separately configure any registry that is used at the domain level. Read about “Configuring attributes for security domains” on page 1314 for more information.

When configuring a registry at the domain level you can choose to define your own realm name for the registry. The realm name distinguishes one user registry from another. The realm name is used in multiple places – in the Java client login panel to prompt the user, in the authentication cache, and when using native authorization.

At the global configuration level, the system creates the realm for the user registry. In previous releases of WebSphere Application Server, only one user registry is configured in the system. When you have multiple security domains you can configure multiple registries in the system. For the realms to be unique in these domains, configure your own realm name for a security domain. You also can choose the system to create a unique realm name if it is certain to be unique. In the latter case, the realm name is based on the registry that is being used.

For LDAP registries, the host:port of the LDAP server is the system-generated realm name. For localOS, the name of the localOS machine is the realm name. For custom user registries, the realm is the one returned by the `getRealm()` method of the custom registry implementation.

If the system generated realm names are unique enough, you can choose the option for the system to generate the realm name. If not, choose a unique realm name for each security domain where you have the user registry configured. If the underlying user repository is the same, use the same realm name in different domains. From a security runtime perspective, same realm names have the same set of users and groups information. For example, when users and groups information is required from a realm, the first user repository that matches the realm is used.

If a localOS registry that is not centralized is configured for any domain, and that domain is associated with servers or clusters in nodes not on the same system as the deployment manager, the realm name has to be provided. This realm name has to be the same as it would be if it were generated on the node. This realm name can be obtained by calling the `getRealm()` method on the SecurityAdmin MBean on that node. Typically, the realm name for localOS registries is the hostname of the machine. In this case, you should not let the system generate the realm name but rather get the realm name that is used by the processes in the node.

If you select the system to generate the realm for the localOS registry at the time of the user registry configuration, it chooses the localOS registry that is used by the deployment manager. If the realm configured does not match the realm used by the servers then there are authorization issues. Also note that in this case, the domain using this local registry can only be associated with servers and clusters that belong to nodes on the same machine.

**Note:** In WebSphere Application Server Version 7.0, the federated repositories user registry can only be configured at the global level and have only one instance per cell, but any domain can use it by configuring it as the active registry. In WebSphere Application Server Version 8.0, you can configure a unique instance of a federated repository at the domain level in a multiple security domain environment.

When a security domain is copied from the global level, the users and groups defined at the global level are also copied to the security domain. This is also true when copying from an existing domain. A newly-created security domain that uses the file-based VMM repository requires that the user populate the repository with users and groups.

Also new in this release of WebSphere Application Server, a new checkbox on the Realm configurations settings administrative console page, Use global schema for model, sets the

global schema option for the data model in a multiple security domain environment. Global schema refers to the schema of the admin domain.

When more than one user registry is in a process, the naming lookup that uses “UserRegistry” as the lookup name returns the user registry that is used by user applications. The user registry used by administrative applications is bound by the lookup name, “AdminUserRegistry”.

As described in “Cross realm communication” on page 1322, when an application in one realm communicates with an application in another realm using LTPA tokens, the realms have to be trusted. The trust relationship can be established using the **Trusted authentication realms – inbound** link in the user registry panel or by using the **addTrustedRealms** command. You can establish trust between different realms. A user logged into one realm can access resources in another realm. If no trust is established between the two realms the LTPA token validation fails.

**Note:** The realm name used in the web.xml file is not related to the user registry realm.

#### 4. **Trust Association:**

When you configure the trust association interceptor (TAI) at a domain level, the interceptors configured at the global level are copied to the domain level for convenience. You can modify the interceptor list at the domain level to fit your needs. Only configure those interceptors that are to be used at the domain level.

Tivoli Access Manager's trust association interceptors can only be configured at the global level. The domain configuration can also use them, but cannot have a different version of the trust association interceptor. Only one instance of Tivoli Access Manager's trust association interceptors can exist in the cell.

#### 5. **SPNEGO web authentication:**

The SPNEGO web authentication, which enables you to configure SPNEGO for web resource authentication, can be configured at the domain level.

**Note:** In WebSphere Application Server Version 6.1, a TAI that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function was deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

#### 6. **RMI/IIOP Security (CSlv2):**

The RMI/IIOP security attribute refers to the CSlv2 (Common Secure Interoperability version 2) protocol properties. When you configure these attributes at the domain level, the RMI/IIOP security configuration at the global level is copied for convenience.

You can change the attributes that need to be different at the domain level. The Transport layer settings for CSlv2 inbound communications should be the same for both the global and the domain levels. If they are different, the domain level attributes are applied to all of the application in the process.

When a process communicates with another process with a different realm, the LTPA authentication and the propagation tokens are not propagated to the downstream server unless that server is listed in the outbound trusted realms list. This can be done using the **Trusted authentication realms – outbound** link on the **CSlv2 outbound communication** panel, or by using the **addTrustedRealms** command task. Read about “Cross realm communication” on page 1322 for more information.

#### 7. **JAAS (Java Authentication and Authorization Service):**

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

For JAAS and custom properties only, once global attributes are customized for a domain they can still be used by user applications.

#### 8. **Java Authentication SPI (JASPI)**

Specifies the configuration settings for a Java Authentication SPI (JASPI) authentication provider and associated authentication modules to be applied at the domain level.

Select **Providers** to create or to edit a JASPI authentication provider.

**Note:** The JASPI authentication provider can be enabled with providers configured at the domain level. By default, all of the applications in the system have access to the JASPI authentication providers configured at the global level. The security runtime first checks for the JASPI authentication providers at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure JASPI authentication providers at a domain only when the provider is to be used exclusively by the applications in that security domain.

#### 9. **Authentication Mechanism Attributes:**

Specifies the various cache settings that must be applied at the domain level.

- a. Authentication cache settings - use to specify your authentication cache settings. The configuration specified on this panel is applied only to this domain.
- b. LTPA Timeout - You can configure a different LTPA timeout value at the domain level. The default timeout value is 120 minutes, which is set at the global level. If the LTPA timeout is set at the domain level, any token that is created in the security domain when accessing user applications is created with this expiration time.
- c. Use realm-qualified user names - When this selection is enabled, user names returned by methods such as `getUserPrincipal()` are qualified with the security realm (user registry) used by applications in the security domain.

#### 10. **Authorization Provider:**

You can configure an external third party JACC (Java Authorization Contract for Containers) provider at the domain level. Tivoli Access Manager's JACC provider can only be configured at the global level. Security domains can still use it if they do not override the authorization provider with another JACC provider.

The JACC attributes, for example the Policy object, are based at the JVM level. This implies that there can be only be one JACC policy object in a JVM process. However, when you have multiple JACC providers configured, the deployment manager process has to handle all these providers in the same JVM because it has to propagate the authorization policy of applications to the respective provider based on the application name.

If your JACC provider can handle propagating the authorization policy to multiple providers, you can configure it at the global level. In this case, when an application is installed, this JACC provider is called in the deployment manager process and it is the responsibility of this JACC provider to propagate the information to the corresponding JACC provider based on the application name passed in the contextID.

Another way to achieve this is to set the custom property, `com.ibm.websphere.security.allowMultipleJaccProviders=true`, at the global security level. When this property is set, WebSphere Application Server propagates the authorization policy information to the JACC provider associated with the domain that corresponds to the target server where the application is installed. This property is only used at the deployment manager process since the managed servers do not host multiple JACC providers.

On z/OS, you can enable or disable the System Authorization Facility (SAF) based authorization at the domain level.

You can additionally configure the SAF authorization options at the security domain level, which are the following:

- The unauthenticated user id
- The SAF profile mapper

- Whether to enable SAF delegation
- Whether to use the APPL profile to restrict access to WebSphere Application Server
- Whether to suppress authorization failed messages
- The SMF audit record strategy
- The SAF profile prefix

CBIND checks are considered administrative operations, and therefore the global level value of the SAF profile prefix that is specified, is used when determining the name of the CBIND resource to check. For example: CB.BIND.<cluster\_name or SAF\_profile\_prefix>.

For more information about the SAF authorization options, read about “z/OS System Authorization Facility authorization” on page 1734.

#### 11. z/OS options:

You can set z/OS specific security options at the process (JVM) level so that all applications (both administrative and user) can enable or disable these options. These properties are:

- Enabling application server and z/OS thread identity synchronization
- Enabling the connection manager RunAs thread identity.

For more information, read about z/OS security options.

#### 12. Custom properties:

Set custom properties at the domain level that are either new or different from those at the global level. By default, all of the custom properties at the global security configuration can be accessed by all of the applications in the cell. The security runtime code first checks for the custom property at the domain level. If it does not find it, it then attempts to obtain the custom property from the global security configuration.

For JAAS and custom properties only, once global attributes are customized for a domain they can still be used by user applications.

## Client and application security programming model when using security domains

A Java client or an application acting as a client that accesses an EJB typically does a naming lookup first. The naming resource, which is used by both administrative and the user applications, is considered an administrative resource. It is protected by the global security configuration information. In a multiple domain setup where the global security is using one realm (the *user registry*) and a domain is using a different realm, the Java client must authenticate to two different realms. The first authentication is required for the realm in the global security configuration for the naming operation to succeed, and the second authentication is required to access the EJB, which uses a different realm.

The CosNamingRead role protects all naming read operations. This role is usually assigned the **Everyone** special subject. This implies that any user, valid or not, can look up the name space. When a multiple domain is defined, if the CosNamingRead role has the **Everyone** special subject the security runtime code in the client side does not prompt you to log in. It uses the UNAUTHENTICATED subject to access the naming operation instead. Once the naming lookup operation is completed, when the client attempts to access the EJB it is prompted with a login panel that indicates the realm that is currently used by that EJB application (that is, the realm used in the domain). The client then presents the appropriate user credentials for that realm, which can then access the EJB. This logic applies to all variations of login source, including properties and stdin, not just when the login source is set to prompt.

If the **Everyone** special subject is removed from the CosNamingRead role, you are prompted twice. If the login source is properties, you can uncomment the com.ibm.CORBA.loginRealm property in the \$WAS\_HOME/profiles/\$ProfileName/properties/sas.client.props file and add the appropriate realms using “|” as the separator. You must also enter the corresponding users and passwords in the com.ibm.CORBA.loginUserid and com.ibm.CORBA.loginPassword properties respectively. When you are using the programmatic logon in the Java client code you must authenticate twice with different user

credentials; once prior to do a naming lookup for the EJB (the user should be in the global realm), and later prior to calling any method in the EJB (the user should be in the EJB domain's realm).

The CosNamingRead role defined in the z/OS security server is not referenced for determining if naming read operations are protected in a multi-security domain environment, even when SAF authorization is enabled. Instead, the settings in the `admin-Authz.xml` file are used. Alternatively, you can use the custom property `com.ibm.security.multiDomain.setNamingReadUnprotected` to control if naming read operations are protected. This property will override any assignments made to the CosNamingRead role, regardless of which authorization provider is used.

In general, when a Java client needs to authenticate to multiple and different realms it has to provide the credential information for all of those realms. If the login source is `prompt` or `stdin` it is prompted to login multiple times, once for each realm. If the login source is set to `properties`, the appropriate properties in the **`sas.client.props`** file (or any related file) are used for authenticating to different realms.

In certain scenarios, a client might make multiple calls to the same realm. For example, the Java client can access a resource using `realm1` followed by access to a resource using `realm2`, and then come back to access a resource in `realm1` again. In this case, the client is prompted three times; first for `realm1`, secondly for `realm2` and finally for `realm1` again.

By default, the subject that is used to login at a realm is not cached by the client side code. If you have this scenario, and you want the client to cache the subject based on the realm, set the `com.ibm.CSI.isRealmSubjectLookupEnabled` property to `true` in the **`sas.client.props`** file. If the `com.ibm.CSI.isRealmSubjectLookupEnabled` property is set, the client code caches the subject based on the realm name. The next time the Java client needs to authenticate to this realm, the cache is located to obtain the subject and the client is not prompted. Also, when the `com.ibm.CSI.isRealmSubjectLookupEnabled` property is set, the same subject that was logged in the first time is used for subsequent logins. If the subject information needs to change then this property should not be set.

If the client is doing a programmatic login it can pass the realm along with the user and password that it needs to authenticate. In this case, when the `com.ibm.CORBA.validateBasicAuth` property is set to `true` (the default value) in the **`sas.client.props`** file, the registry that matches the realm name is used for login. That realm must be supported in the process where the authentication takes place.

When using the WSLLogin JAAS configurations, you also must set the `use_realm_callback` option in the **`wsjaas_client.config`** file in `$WAS_HOME/profiles/$ProfileName/properties` for the realm name to be passed to the call back handler. If you want to specify a different provider URL for the name server, set the `use_appcontext_callback` option and pass in the provider URL properties in a hash map to WSLLogin.

If you do not know the realm name, use `<default>` as the realm name. The authentication is performed against the application realm. If the naming read operation does not have the **Everyone** special subject assigned, you must provide the realm that is used by the administrative applications (the registry used in the global security configuration), as well as the appropriate user and password information in that registry for the lookup operation to succeed.

After the lookup operation succeeds, perform another programmatic login by providing the application realm (or `<default>`) and the user and password information for the appropriate user in the registry that is used by the application. This is similar to the case where the login source is `prompt`. You must authenticate twice, once for the registry used by the global security configuration (for the naming lookup operation) and again for the registry used by the application to access the EJB.

If `com.ibm.CORBA.validateBasicAuth` is set to `false` in the `$WAS_HOME/profiles/$ProfileName/properties/sas.client.props` file then the programmatic login can use `<default>` as the realm name for

both the lookup and the EJB operations. The actual authentication occurs only when the resource is accessed on the server side, in which case the realm is calculated based on the resource that is accessed.

The new security domain support starting in WebSphere Application Version 7.0 does not change the current application security programming model. However, it provides more flexibility and capabilities such as the following:

- User applications can still find the user registry object by using the naming lookup for “UserRegistry”. For the registry object used by administrative applications, the naming lookup for “AdminUserRegistry” can be used.
- The application usage of the JAAS login configuration does not change in a multiple domain setup. However, if an application must refer to the JAAS configuration that is specified at the domain level, the administrator and the deployer of that application must make sure that this domain is configured with the JAAS configurations that are required by the application.
- If an application needs to communicate with other applications using different realms, trust relationship should be established for both inbound and outbound communications when using the LTPA tokens. Read about “Cross realm communication” for more information.
- When using programmatic login in the applications, if you want to login to the realm used by the application, use `<default>` as the realm name or provide the realm name that the application is using. If you need to login to the global realm, you must provide the global realm name. If you provide any other realm, only a basic authentication subject is created. When the request actually flows to the server hosting that realm, the actual authentication of the user occurs if that server hosts the realm. If the server does not host the realm, the login fails.

## Application deployment in multiple domains configurations

When deploying an application in a multiple domain setup, all of the modules in the application should be installed in the servers or clusters that belong to the same security domain. If not, depending on the security attributes configured in these security domains, inconsistent behavior can result. For example, if the domains contain different user registries, the users and groups information can be different, which can cause inconsistent behavior when accessing the modules. Another example is when the JAAS data is different between the security domains. The JAAS configurations is not accessible from all of the modules in the application. The security runtime code and the command tasks rely on one domain being associated with an application when dealing with attributes such as user registry, JAAS login configurations, J2C authentication data, and authorization.

In most cases, application deployment fails when an application is deployed across different domains. However, since this was possible in earlier releases of WebSphere Application Server when only a few attributes were supported at the server level, the deployment tool first checks for attributes that are configured at the domains. If the attributes in the domain are the same as those supported in previous releases, the administrative console requests confirmation to ensure that you want to deploy application modules across multiple security domains. Unless there is an absolute requirement to deploy the applications across different domains, stop the deployment and select the servers and clusters in the same security domain.

## Cross realm communication

When applications communicate using the RMI/IIOP protocol and LTPA is the authentication mechanism, the LTPA token is passed between the servers involved. The LTPA token contains the realm-qualified uniqueId, (also called the *accessId*), of the user who is logging into the front-end application. When this token is received by the downstream server it attempts to decrypt the token. If the LTPA keys are shared between the two servers, decryption succeeds and the accessId of the user is obtained from the token. The realm in the accessId is checked with the current realm that is used by the application. If the realms match, the LTPA token validation succeeds and it proceeds with the authorization. If the realms do not match, the token validation fails since the user from the foreign realm cannot be validated in the current

realm of the application. If applications are not supposed to communicate with each other when using RMI/IIOP and the LTPA authentication mechanism, you do not have to do anything further.

If you do want the cross realm communication to succeed when using RMI/IIOP and LTPA tokens, you must first establish trust between the realms involved, both for inbound and outbound communications.

For the server originating the request, its realm must have the realms that it can trust to send the token to. This is referred to as `outboundTrustedRealms`. For the server receiving the request, its realm needs to trust the realms that it can receive LTPA tokens from. This is referred to as `inboundTrustedRealms`.

Outbound trusted realms can be established using the `addTrustedRealms` command with the `-communicationType` option set to `outbound`. It can also be established in the administrative console by clicking **Trusted authentication realms - outbound** on the **CSiv2 outbound communications** panel.

Inbound trusted realms can be established using the same `addTrustedRealms` command task with the `-communicationType` option set to `inbound`. It can also be established by using the administrative console.

The figure below shows the communication between applications that use different user realms (registries) using RMI/IIOP. In this example, application `app1` (for example, a servlet) is configured to use the `realm1` user registry. The `app2` application (for example, an EJB) is configured to use the `realm2` user registry. The user (`user1`) initially logs into the servlet in `app1`, which then attempts to access an EJB in `app2`. The following must be set:

- In `Domain1`, `realm1` should trust `realm2` for the outbound communication.
- In `Domain2`, `realm2` should trust `realm1` for the inbound communication.
- The `accessId` for `user1` should be configured in the authorization table for `app2`.

When the LTPA token that contains the `accessId` of `user1` is received by `app2`, it decrypts the token. Both of the servers share the same LTPA keys. The LTPA token then ensures that the foreign realm is a trusted realm, and performs the authorization based on the `accessId` of `user1`. If security attribute propagation is not disabled, then the group information of `user1` is also propagated to `app2`. The groups can be used for the authorization check, provided that the authorization table contains the group information. You can associate a special subject, `AllAuthenticatedInTrustedRealms`, to the roles instead of adding individual users and groups to the authorization table.

If the applications in the above example are deployed in different cells, you must do the following:

- Share the LTPA keys between the cells.
- Update the authorization table for `app2` with foreign users and groups `accessIds` by using the **`wsadmin`** utility. The administrative console does not have access to the realms outside of the scope of the cell.

Figure 7. Cross realm communication in a multiple realm environment

Once trust has been established between the realms, when the server receives the LTPA token and the token is decrypted, it checks to see if the foreign realm is in its inbound trusted realms list. If it is trusted, the authentication succeeds. However, since it is a foreign realm, it does not go search the user registry to gather information about the user. Whatever information is in the LTPA token is used to authorize the user.

The only information in the LTPA token is the unique id of the user. This unique id of the user should exist in the authorization table for this application. If it does, authorization succeeds. However, if attribute propagation is enabled, additional authorization attributes (groups that this user belongs to) for the user are sent from the originating server to the receiving server. These additional attributes are used to make the access decisions. If the groups information exists in the propagation tokens it is used when making the authorization decision.

As previously mentioned, the information about the users and or the groups from the trusted realms should exist in the authorization table of the receiving application. Specifically, the accessId of the users and or groups should exist in the binding file of the application. This must be the case when the application is deployed. In the administrative console, when an application is deployed in a domain you can add the accessIds of the users and groups from any of its trusted realms to the authorization table.

You also have an option to associate a special subject, `AllAuthenticatedInTrustedRealms`, to the roles instead of adding individual users and groups. This is similar to the `AllAuthenticated` special subject that is currently supported. The difference is that the `AllAuthenticated` special subject refers to users in the same realm as the application while the `AllAuthenticatedInTrustedRealms` special subject applies to all of the users in the trusted realms and in the realm of the application.

You can associate the accessId by using the `$AdminApp` install script. Because the accessId takes a unique format, use the command `task listRegistryUsers` with `displayAccessIds` set to `true`. If an invalid name or format is entered in this field, the authorization fails.

User and group information from the trusted realms is obtained by the deployment manager since it has access to all of the user registry configurations in all domains. However, in certain situations it is not possible to obtain the users and group information.

For example, if a server hosted on an external node is using localOS as the registry for its domain, the deployment manager cannot obtain the users and groups information unless it is running in the same operating system setup. The external operating system should be contacted to obtain this information. This can be done by directly invoking the registry in the server associated with that domain. The servers associated with the domain have to be started for this to work. You also must set the property, `com.ibm.websphere.allowRegistryLookupOnProcess`, to `true` in the top-level security custom properties. When this property is set, the deployment manager code searches one of the servers that is associated with the security domain and obtains the users and groups information directly from it. This is possible by calling an MBean in one of the servers.

If the MBean in any of the servers that are using that domain cannot be accessed, the administrative console displays a panel where you can enter the user and `accessId` information manually for each user and group. It is important that the correct `accessId` format be entered in this field. The `accessId` format for the user is `user:realmName/userUniqueId`. The `realmName` is the name of the realm where the user resides, and the `userUniqueId` is the `uniqueId` that represents the user, depending on the registry that is used.

For example, for LDAP, the `uniqueUserId` is the Distinguished Name (DN), for the Windows localOS registry and is the SID of the user. For Unix platforms, it is the UID. For custom registries, it depends on the implementation.

Similarly, for groups, the `accessId` format is `group:realmName/groupUniqueId`. As previously mentioned, use the `listRegistryUsers` and `listRegistryGroups` command with the `-displayAccessIds` option set to `true` so that you can obtain the correct format for the domain or realm that you are interested in.

Once users and groups from the trusted realms or the `AllAuthenticatedInTrustedRealms` special subject is added to the authorization table of the application, it is ready to accept requests from other applications that are using any of its trusted realms. The LTPA token validation on the receiving server first checks to make sure that the realm is trusted. The authorization engine then checks to see if the external user and/or the groups or the `AllAuthenticatedInTrustedRealms` special subject are given access to the roles needed to access the resource. If true, access is granted.

Cross realm communication is only applicable when using the WebSphere built-in authorization. If you are using other authorization engines including SAF for z/OS, any cross realm authorization can be achieved by implementing custom login modules that map external users to users in its own repository.

## Federating a node with security domains

When a security domain is configured in the base version and is federated to a cell, the security domain configured at the base version is also configured for that server in the cell. The same domain security configuration can be used by the server before and after the federation. If a base server is to be federated to a cell, the resource assigned to the security domain should be the server scope instead of the cell scope.

If the base server is expected to be registered with an Administrative Agent process, use the cell scope as the resource if the intention is to have all of the servers in the base profile use this security domain.

If during federation the security domain at the base already exists at the cell level, the `addNode` command fails. You can use the `-excludesecuritydomains` option not to include the security domain during federation.

When the federated node is removed from a cell, the resources in that node should be removed from the security domains. If security domains have clusters associated with them that span nodes, the nodes are not removed. You can always remove resources from the security domains or any domains that are not used by using scripting commands or the administrative console.

## Security domains in a mixed-version environment

You should create security domains once all of the nodes have been migrated to the latest version. This is especially true if there is a need to associate the cell with a domain. However, if you want to create security domains in a mixed-version environment, be aware of the following:

- If a cell-wide domain is created in a mixed version setup, a domain called *PassThroughToGlobalSecurity* is created automatically. All mixed clusters are assigned to this domain at the time of the creation of the cell-wide domain. This *PassThroughToGlobalSecurity* domain is special in the sense that attributes cannot be added to it, only resources can be assigned to it.

All resources assigned to the *PassThroughToGlobalSecurity* domain use the global security configuration information. Whenever a node in the mixed version setup is migrated to the latest version, the servers and clusters in these nodes are added to this domain. Applications in all of the servers and clusters in these nodes do not use the cell-wide domain; they instead use the global security configuration before and after migration.

If any of these servers need to use the cell-wide domain, you must remove these resources from this *PassThroughToGlobalSecurity* domain. New servers and clusters that are created in the migrated node use the cell-wide domain, not the *PassThroughToGlobalSecurity* domain. As a result, you have a mix of servers and clusters, some of them using global security configuration and some using the cell-wide domain.

- Once a cell-wide domain is created, adding any old version cluster members to a WebSphere Application Server Version 8.0 cluster is restricted since this action makes it a mixed cluster. This restriction also holds true when a WebSphere Application Server Version 8.0 cluster is associated with a domain, and a previous version cluster member is added to this cluster. This restriction is needed to avoid associating a security domain to a mixed cluster.
- If possible, you should create a cell-wide domain after all of the nodes have been migrated. In this case, the cell-wide domain is applicable to the entire cell and not just to parts of it. This also eliminates the need to create the *PassThroughToGlobalSecurity* domain and the mixed cluster scenario with security domains.

## Modifying security domains

Use the administrative console tasks or scripting commands to modify security domains. For a complete list of administrative tasks and scripting commands, see the links in "Related tasks" at the bottom of this document.

Once a security domain is created and associated to a set of scopes, the servers associated with this new domain must be restarted. After the restart, the applications in the scopes associated with the new domain use the security attributes defined in the domain.

Changes to any of the domain attributes requires the restart of all of the scopes assigned to it. If new scopes are added they also need to be restarted. Any modifications to the domain configuration, either to the security attributes or to the scopes, has impacts on those applications that are using the domain configuration.

Before you make modifications to an existing domain, consider the following potential impacts. For example, if a user registry that is configured at a domain is removed, and the servers restarted, the user registry from the cell-wide domain (if one is defined), or the global security configuration is then used. This can impact application authentication and authorization. Users and groups associated with an application might no longer be valid in the new registry. Another example to consider is when JAAS configurations are removed from a domain. Applications that rely on this are no longer be able to use the JAAS configurations. Whenever a security configuration is changed it might impact your applications, so all security configuration changes should be made with the utmost care.

## Toleration PTFs required for mixed-release environments

Toleration PTFs are required for mixed-release environments in which previous versions of WebSphere Application Server for z/OS IIOp clients inter-operate with a WebSphere Application Server Version 8.0 for z/OS application server that hosts multiple security domains.

The pre-Version 8.0 IIOp client requires an update to its IIOp locate processing code to perform IIOp locates across the security domains of a Version 8.0 application server.

The toleration PTFs for all affected service releases are listed below. The pre-Version 8.0 IIOp client must be at or above the given service level to successfully inter-operate with a Version 8.0 application server that contains multiple security domains.

WebSphere Application Server for z/OS 5.1: W510246

WebSphere Application Server for z/OS v6.0: 602.29

WebSphere Application Server for z/OS v6.1: 610.17

This requirement applies only to WebSphere for z/OS IIOp clients that invoke requests against a WebSphere for z/OS application server with multiple security domains configured and enabled.

## Creating new multiple security domains

You can create multiple security domains in your configuration. By creating multiple security domains, you can configure different security attributes for administrative and user applications within a cell environment.

### Before you begin

Only users assigned to the administrator role can create new multiple security domains. Enable global security in your environment before creating new multiple security domains.

Read about “Multiple security domains” on page 1310 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

### About this task

Security domains provide a mechanism to use different security settings for administrative applications and user applications. They also provide the ability to support multiple security settings so different applications can use different security attributes like user registry or login configurations.

Use multiple security domains to achieve the following goals:

- Configure different security attributes for administrative and user applications within a cell
- Consolidate server configurations by managing different security configurations within a cell
- Restrict access between applications with different user registries, or configure trust relationships between applications to support communication across registries

Perform the following steps to create a new security domain using the administrative console:

### Procedure

1. Click **Security > Security domains**.
2. On the Security domains collection page, click **New**.
3. Specify a unique name for the domain. A domain name must be unique within a cell and cannot contain an invalid character. This field is required.
4. Specify a unique description for the domain. After you click **Apply** you are returned to the Security domains detail page

5. Under Assigned Scopes, assign the security domain to the entire cell or select the specific servers, clusters, and service integration buses to include in the security domain.
6. Customize your security configuration by specifying security attributes for your new domain and by assigning it to cell resources.

You can change security attributes such as the following:

### **Application Security**

Specifies the settings for application security and Java 2 security. You can use the global security settings or customize the settings for a domain.

Select **Enable application security** to enable or disable security this choice for user applications. When this selection is disabled, all of the EJBs and web applications in the security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

### **Java 2 Security**

Select **Java 2 security** to enable or disable Java 2 security at the domain level. This choice enables or disables Java 2 security at the process (JVM) level so that all applications (both administrative and user) can enable or disable Java 2 security.

### **User realm**

This section enables you to configure the user registry for the security domain. You can separately configure any registry that is used at the domain level. Read about “Multiple security domains” on page 1310 for more information.

### **Trust association**

When you configure the trust association interceptor (TAI) at a domain level, the interceptors configured at the global level are copied to the domain level for convenience. You can modify the interceptor list at the domain level to fit your needs. Only configure those interceptors that are to be used at the domain level.

### **SPNEGO Web Authentication**

The SPNEGO web authentication, which enables you to configure SPNEGO for web resource authentication, can be configured at the domain level.

**Note:** In WebSphere Application Server Version 6.1, a TAI that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated in WebSphere Application Server Version 7.0. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

### **RMI/IIOP Security**

The RMI/IIOP security attribute refers to the CSIV2 (Common Secure Interoperability version 2) protocol properties. When you configure these attributes at the domain level, the RMI/IIOP security configuration at the global level is copied for convenience.

You can change the attributes that need to be different at the domain level. The Transport layer settings for CSIV2 inbound communications should be the same for both the global and the domain levels. If they are different, the domain level attributes are applied to all of the application in the process.

### **JAAS application logins**

Specifies the configuration settings for the Java Authentication and Authorization Service (JAAS) application logins. You can use the global security settings or customize the settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

### **JAAS system logins**

Specifies the configuration settings for the JAAS system logins. You can use the global security settings or customize the configuration settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

**Note:** For both JAAS application logins and JAAS system logins, the collections are not populated until one is created first. You can do this by selecting **customize for this domain** under JAAS application logins or JAAS system logins and then by selecting **Apply** or **OK**.

### **JAAS J2C authentication**

Specifies the configuration settings for the JAAS J2C authentication data. You can use the global security settings or customize the settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

### **Java Authentication SPI (JASPI)**

Specifies the configuration settings for a Java Authentication SPI (JASPI) authentication provider. You can use the global security settings or customize the settings for a domain. To configure JASPI authentication providers for a domain, select **Customize for this domain** and then enable JASPI. Select **Providers** to define providers for the domain.

**Note:** The JASPI authentication provider can be enabled with providers configured at the domain level. By default, all of the applications in the system have access to the JASPI authentication providers configured at the global level. The security runtime first checks for the JASPI authentication providers at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure JASPI authentication providers at a domain only when the provider is to be used exclusively by the applications in that security domain.

### **Authentication Mechanism Attributes**

Specifies the various cache settings that need to be applied at the domain level.

Select **Authentication cache settings** to specify your authentication cache settings. The configuration specified on this panel is applied only to this domain.

Select **LTPA Timeout** to configure a different LTPA timeout value at the domain level. The default timeout value is 120 minutes, which is set at the global level. If the LTPA timeout is set at the domain level, any token that is created in the security domain when accessing user applications is created with this expiration time.

When **Use realm-qualified user names** is enabled, user names returned by methods such as `getUserPrincipal()` are qualified with the security realm (user registry) used by applications in the security domain.

### Authorization Provider

You can configure an external third party JACC (Java Authorization Contract for Containers) provider at the domain level. Tivoli Access Manager's JACC provider can only be configured at the global level. Security domains can still use it if they do not override the authorization provider with another JACC provider or with the built-in native authorization.

On z/OS, you can enable or disable the System Authorization Facility (SAF) based authorization at the domain level.

You can additionally configure the SAF authorization options at the security domain level, which are the following:

- The unauthenticated user id
- The SAF profile mapper
- Whether to enable SAF delegation
- Whether to use the APPL profile to restrict access to WebSphere Application Server
- Whether to suppress authorization failed messages
- The SMF audit record strategy
- The SAF profile prefix

For more information on the SAF authorization options, read about “z/OS System Authorization Facility authorization” on page 1734.

### z/OS security options

You can set z/OS specific security options at the process (JVM) level so that all applications (both administrative and user) can enable or disable these options. These properties are:

- Enabling application server and z/OS thread identity synchronization
- Enabling the connection manager RunAs thread identity.

For more information on the z/OS security options, read about “z/OS security options” on page 1264

### Custom properties

Set custom properties at the domain level that are either new or different from those at the global level. By default, all of the custom properties at the global security configuration can be accessed by all of the applications in the cell. The security runtime code first checks for the custom property at the domain level. If it does not find it, it then attempts to obtain the custom property from the global security configuration.

7. Click **Apply**.
8. After you have saved your configuration changes, restart the server for your changes to take effect.

## Deleting multiple security domains

You can delete multiple security domains from your configuration. You must remove the resources assigned to the security domains before deleting them. Only remove those security domains that are not needed in your security configuration.

## Before you begin

Only users assigned to the administrator role can delete security domains. Enable global security in your environment before deleting security domains.

Read about “Multiple security domains” on page 1310 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

## About this task

Security domains provide a mechanism to use different security settings for administrative applications and user applications. They also provide the ability to support multiple security settings so different applications can use different security attributes like user registry or login configurations.

Perform the following steps to delete an existing security domain using the administrative console:

**Note:** Only delete the security domains after first removing any resources associated with them. The servers impacted should be restarted.

## Procedure

1. Click **Security > Security domains**.
2. On the Security domains collection page, select a domain to delete.
3. Click **Delete**.

## Copying multiple security domains

You can copy selected multiple security domains from the domain collection to create a new domain. This is useful if you want to create a domain that is similar to a previous domain. However, you might want to make a few slight adjustments. When copying an existing domain, you must supply a unique domain name for the new one.

## Before you begin

Only users assigned to the administrator role can copy or create new multiple security domains. Enable global security in your environment before copying multiple security domains.

Read about “Multiple security domains” on page 1310 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

## About this task

Security domains provide a mechanism to use different security settings for administrative applications and user applications. They also provide the ability to support multiple security settings so different applications can use different security attributes like user registry or login configurations.

Use multiple security domains to achieve the following goals:

- Configure different security attributes for administrative and user applications within a cell
- Consolidate server configurations by managing different security configurations within a cell
- Restrict access between applications with different user registries, or configure trust relationships between applications to support communication across registries

Perform the following steps to copy an existing security domain using the administrative console:

## Procedure

1. Click **Security > Security domains**.

- Optional: From Preferences, you can select the maximum number of rows to display when the domain collection is large. The default number of rows is 20. Rows that exceed that number appear on subsequent pages.
- Select a domain to copy.
- Click **Copy Selected Domain...** to copy an existing domain from the collection. You can optionally select **Copy Global Security..** to copy an existing domain and have it maintain its global security settings (collection selections are ignored). A new domain name is also required if you choose this option.
- Specify a unique name for the domain. This field is required. A domain name must be unique within a cell and cannot contain an invalid character.
- Specify a unique description for the domain.
- Click **Apply**. After you click **Apply** you are returned to the Security domains detail page
- Under Assigned Scopes, assign the security domain to the entire cell or select the specific servers, clusters, and service integration buses to include in the security domain.
- Customize your security configuration by specifying security attributes for your new domain and by assigning it to cell resources.

You can change security attributes such as the following:

### **Application Security**

Specifies the settings for application security and Java 2 security. You can use the global security settings or customize the settings for a domain.

Select **Enable application security** to enable or disable security this choice for user applications. When this selection is disabled, all of the EJBs and web applications in the security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

### **Java 2 Security**

Select **Java 2 security** to enable or disable Java 2 security at the domain level. This choice enables or disables Java 2 security at the process (JVM) level so that all applications (both administrative and user) can enable or disable Java 2 security.

### **User realm**

This section enables you to configure the user registry for the security domain. You can separately configure any registry that is used at the domain level. Read about “Multiple security domains” on page 1310 for more information.

### **Trust association**

When you configure the trust association interceptor (TAI) at a domain level, the interceptors configured at the global level are copied to the domain level for convenience. You can modify the interceptor list at the domain level to fit your needs. Only configure those interceptors that are to be used at the domain level.

### **SPNEGO Web Authentication**

The SPNEGO web authentication, which enables you to configure SPNEGO for web resource authentication, can be configured at the domain level.

**Note:** In WebSphere Application Server Version 6.1, a TAI that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated in WebSphere Application Server 7.0. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

## RMI/IIOP Security

The RMI/IIOP security attribute refers to the CSv2 (Common Secure Interoperability version 2) protocol properties. When you configure these attributes at the domain level, the RMI/IIOP security configuration at the global level is copied for convenience.

You can change the attributes that need to be different at the domain level. The Transport layer settings for CSv2 inbound communications should be the same for both the global and the domain levels. If they are different, the domain level attributes are applied to all of the application in the process.

## JAAS application logins

Specifies the configuration settings for the Java Authentication and Authorization Service (JAAS) application logins. You can use the global security settings or customize the settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

## JAAS system logins

Specifies the configuration settings for the JAAS system logins. You can use the global security settings or customize the configuration settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

## JAAS J2C authentication

Specifies the configuration settings for the JAAS J2C authentication data. You can use the global security settings or customize the settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

## Java Authentication SPI (JASPI)

Specifies the configuration settings for a Java Authentication SPI (JASPI) authentication provider. You can use the global security settings or customize the settings for a domain. To configure JASPI authentication providers for a domain, select **Customize for this domain** and then enable JASPI. Select **Providers** to define providers for the domain.

**Note:** The JASPI authentication provider can be enabled with providers configured at the domain level. By default, all of the applications in the system have access to the JASPI authentication providers configured at the global level. The security runtime first checks for the JASPI authentication providers at the domain level. If it does not find

them, it then checks for them in the global security configuration. Configure JASPI authentication providers at a domain only when the provider is to be used exclusively by the applications in that security domain.

### Authentication Mechanism Attributes

Specifies the various cache settings that need to be applied at the domain level.

Select **Authentication cache settings** to specify your authentication cache settings. The configuration specified on this panel is applied only to this domain.

Select **LTPA Timeout** to configure a different LTPA timeout value at the domain level. The default timeout value is 120 minutes, which is set at the global level. If the LTPA timeout is set at the domain level, any token that is created in the security domain when accessing user applications is created with this expiration time.

When **Use realm-qualified user names** is enabled, user names returned by methods such as `getUserPrincipal()` are qualified with the security realm (user registry) used by applications in the security domain.

### Authorization Provider

You can configure an external third party JACC (Java Authorization Contract for Containers) provider at the domain level. Tivoli Access Manager's JACC provider can only be configured at the global level. Security domains can still use it if they do not override the authorization provider with another JACC provider or with the built-in native authorization.

On z/OS, you can enable or disable the System Authorization Facility (SAF) based authorization at the domain level.

You can additionally configure the SAF authorization options at the security domain level, which are the following:

- The unauthenticated user id
- The SAF profile mapper
- Whether to enable SAF delegation
- Whether to use the APPL profile to restrict access to WebSphere Application Server
- Whether to suppress authorization failed messages
- The SMF audit record strategy
- The SAF profile prefix

For more information on the SAF authorization options, read about “z/OS System Authorization Facility authorization” on page 1734.

### z/OS security options

You can set z/OS specific security options at the process (JVM) level so that all applications (both administrative and user) can enable or disable these options. These properties are:

- Enabling application server and z/OS thread identity synchronization
- Enabling the connection manager RunAs thread identity.

For more information on the z/OS security options, read about “z/OS security options” on page 1264

### Custom properties

Set custom properties at the domain level that are either new or different from those at the global level. By default, all of the custom properties at the global security configuration can be accessed by all of the applications in the cell. The security runtime code first checks for the custom property at the domain level. If it does not find it, it then attempts to obtain the custom property from the global security configuration.

10. Click **Apply**.

11. After you have saved your configuration changes, restart the server for your changes to take effect.

## Configuring inbound trusted realms for multiple security domains

You can configure which realms to grant inbound trust to for multiple security domains. The trust relationship between realms is used when communicating with Lightweight Third-Party Authentication (LTPA) tokens. Once a LTPA token is decrypted by the receiving server, the realm in the token is checked to see if it is trusted. If it is not, the validation of the token fails. A *realm* represents a user registry in WebSphere Application Server.

### Before you begin

For information on cross realm communications, read the section in “Multiple security domains” on page 1310.

Only users assigned to the administrator role can configure multiple security domains. Enable global security in your environment before configuring multiple security domains.

Perform the following steps to grant inbound trusted realms for multiple security domains using the administrative console:

### Procedure

1. Click **Security > Security domains**.
2. Select a domain to edit or create a new one. Under Security Attributes, click **User realm**.
3. Click **Customize for this domain**.
4. Under Related Items, select **Trusted authentication realms - inbound**.
5. Select **Trust all realms (including those external to this cell)** or **Trust realms as indicated below**.  
If Kerberos authentication is enabled, and you have cross realms or trusted realms, you must add the Kerberos trusted realm by selecting **Trust realms as indicated below**.
6. Click **Apply**.

### What to do next

The realms you selected to trust accept messages from other trusted realms but do not accept messages from untrusted realms. Select **Add External Realm** to add trust for realms that are external to this cell.

## Configure security domains

Use this page to configure the security attributes of a domain and to assign the domain to cell resources. For each security attribute, you can use the global security settings or customize settings for the domain.

To view this administrative console page, click **Security > Security domains**. On the Security domains collection page, select an existing domain to configure, create a new one, or copy an existing domain.

Read about “Multiple security domains” on page 1310 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

### Name

Specifies a unique name for the domain. This name can not be edited after the initial submission.

A domain name must be unique within a cell and cannot contain an invalid character.

### Description

Specifies a description for the domain.

## Assigned Scopes

Select to display the cell topology. You can assign the security domain to the entire cell or select the specific clusters, nodes and service integration buses to include in the security domain.

If you select **All scopes**, the entire cell topology is displayed.

If you select **Assigned scopes**, the cell topology is displayed with those servers and clusters that are assigned to the current domain.

The name of an explicitly assigned domain appears next to any resource. Checked boxes indicate resources that are currently assigned to the domain. You also can select other resources and click **Apply** or **OK** to assign them to the current domain.

A resource that is not checked (disabled) indicates that it is not assigned to the current domain and must be removed from another domain before it can be enabled for the current domain.

If a resource does not have an explicitly-assigned domain, it uses the domain assigned to the cell. If no domain is assigned to the cell, then the resource uses global settings.

Cluster members cannot be individually assigned to domains; the entire cluster uses the same domain.

## Application Security:

Select **Enable application security** to enable or disable security for user applications. You can use the global security settings or customize the settings for a domain.

When this selection is disabled, all of the EJBs and web applications in the security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

### Enable application security

Enables security for the applications in your environment. This type of security provides application isolation and requirements for authenticating application users

In previous releases of WebSphere Application Server, when a user enabled global security, both administrative and application security were enabled. In WebSphere Application Server Version 6.1, the previous notion of global security were split into administrative security and application security, each of which you can enable separately.

As a result of this split, WebSphere Application Server clients must know whether application security is disabled at the target server. Administrative security is enabled, by default. Application security is disabled, by default. To enable application security, you must enable administrative security. Application security is in effect only when administrative security is enabled.

When this selection is disabled, all of the EJBs and web applications in the security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

## Java 2 security:

Select **Use Java 2 security** to enable or disable Java 2 security at the domain level or to assign or add properties related to Java 2 security. You can use the global security settings or customize the settings for a domain.

This choice enables or disables Java 2 security at the process (JVM) level so that all applications (both administrative and user) can enable or disable Java 2 security.

### Use global security settings

Select to specify the global security settings that are being used.

### Customize for this domain

Select to specify the settings that are defined in the domain, such as options to enable application and Java 2 security and to use realm-qualified authentication data.

### Use Java 2 security to restrict application access to local resources

Select to specify whether to enable or disable Java 2 security permission checking. By default, access to local resources is not restricted. You can choose to disable Java 2 security, even when application security is enabled.

When the **Use Java 2 security to restrict application access to local resources** option is enabled and if an application requires more Java 2 security permissions than are granted in the default policy, the application might fail to run properly until the required permissions are granted in either the `app.policy` file or the `was.policy` file of the application. AccessControl exceptions are generated by applications that do not have all the required permissions.

### Warn if applications are granted custom permissions

Specifies that during application deployment and application start, the security runtime issues a warning if applications are granted any custom permissions. Custom permissions are permissions that are defined by the user applications, not Java API permissions. Java API permissions are permissions in the `java.*` and `javax.*` packages.

The application server provides support for policy file management. A number of policy files are available in this product, some of them are static and some of them are dynamic. Dynamic policy is a template of permissions for a particular type of resource. No code base is defined and no relative code base is used in the dynamic policy template. The real code base is dynamically created from the configuration and run-time data. The `filter.policy` file contains a list of permissions that you do not want an application to have according to the J2EE 1.4 specification.

**Important:** You cannot enable this option without enabling the **Use Java 2 security to restrict application access to local resources** option.

### Restrict access to resource authentication data

This option is disabled if Java 2 security has not been enabled.

Consider enabling this option when both of the following conditions are true:

- Java 2 security is enforced.
- The application code is granted the `accessRuntimeClasses WebSphereRuntimePermission` permission in the `was.policy` file found within the application enterprise archive (EAR) file. For example, the application code is granted the permission when the following line is found in your `was.policy` file:

```
permission com.ibm.websphere.security.WebSphereRuntimePermission "accessRuntimeClasses";
```

The **Restrict access to resource authentication data** option adds fine-grained Java 2 security permission checking to the default principal mapping of the `WSPrincipalMappingLoginModule` implementation. You must grant explicit permission to Java 2 Platform, Enterprise Edition (J2EE) applications that use the `WSPrincipalMappingLoginModule` implementation directly in the Java Authentication and Authorization Service (JAAS) login when **Use Java 2 security to restrict application access to local resources** and the **Restrict access to resource authentication data** options are enabled.

**Default:** Disabled

## User Realm:

This section enables you to configure the user registry for the security domain. You can separately configure any registry that is used at the domain level.

When configuring a registry at the domain level you can choose to define your own realm name for the registry. The realm name distinguishes one user registry from another. The realm name is used in multiple places – in the Java client login panel to prompt the user, in the authentication cache, and when using native authorization.

At the global configuration level, the system creates the realm for the user registry. In previous releases of WebSphere Application Server, only one user registry is configured in the system. When you have multiple security domains you can configure multiple registries in the system. For the realms to be unique in these domains, configure your own realm name for a security domain. You also can choose the system to create a unique realm name if it is certain to be unique. In the latter case, the realm name is based on the registry that is being used.

## Trust Association:

Select to specify the settings for the trust association. Trust association is used to connect reversed proxy servers to the application servers.

Trust association enables the integration of IBM WebSphere Application Server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials that are passed by the proxy server.

Tivoli Access Manager's trust association interceptors can only be configured at the global level. The domain configuration can also use them, but cannot have a different version of the trust association interceptor. Only one instance of Tivoli Access Manager's trust association interceptors can exist in the system.

**Note:** The use of trust association interceptors (TAIs) for Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) authentication is deprecated. The SPNEGO web authentication panels provide a much easier way to configure SPNEGO.

## Interceptors

Select to access or to specify the trust information for reverse proxy servers.

## Enable trust association

Select to enable the integration of IBM WebSphere Application Server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials that are passed by the proxy server.

## SPNEGO Web Authentication:

Specifies the settings for Simple and Protected GSS-API Negotiation (SPNEGO) as the web authentication mechanism.

The SPNEGO web authentication, which enables you to configure SPNEGO for web resource authentication, can be configured at the domain level.

**Note:** In WebSphere Application Server Version 6.1, a TAI that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is

deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

### **RMI/IIOP Security:**

Specifies the settings for Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP).

An Object Request Broker (ORB) manages the interaction between clients and servers, using the Internet InterORB Protocol (IIOP). It enables clients to make requests and receive responses from servers in a network-distributed environment.

When you configure these attributes at the domain level, the RMI/IIOP security configuration at the global level is copied for convenience. You can change the attributes that need to be different at the domain level. The Transport layer settings for CSiv2 inbound communications should be the same for both the global and the domain levels. If they are different, the domain level attributes are applied to all of the applications in the process.

When a process communicates with another process with a different realm, the LTPA authentication and the propagation tokens are propagated to the downstream server unless that server is listed in the outbound trusted realms list. This can be done using the **Trusted authentication realms – outbound** link on the **CSiv2 outbound communication** panel.

### **CSiv2 inbound communications**

Select to specify authentication settings for requests that are received and transport settings for connections that are accepted by this server using the Object Management Group (OMG) Common Secure Interoperability (CSI) authentication protocol.

WebSphere Application Server enables you to specify Internet Inter-ORB Protocol (IIOP) authentication for both inbound and outbound authentication requests. For inbound requests, you can specify the type of accepted authentication, such as basic authentication.

### **CSiv2 outbound communications**

Select to specify authentication settings for requests that are sent and transport settings for connections that are initiated by the server using the Object Management Group (OMG) Common Secure Interoperability (CSI) authentication protocol.

WebSphere Application Server enables you to specify Internet Inter-ORB Protocol (IIOP) authentication for both inbound and outbound authentication requests. For outbound requests, you can specify properties such as type of authentication, identity assertion or login configurations that are used for requests to downstream servers.

### **JAAS Application logins**

Select to define login configurations that are used by JAAS.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

For JAAS and custom properties only, once global attributes are customized for a domain they can still be used by user applications.

Do not remove the ClientContainer, DefaultPrincipalMapping, and WSLogin login configurations because other applications might use them. If these configurations are removed, other applications might fail.

## Use global and domain-specific logins

Select to specify the settings that are defined in the domain, such as options to enable application and Java 2 security and to use realm-qualified authentication data.

### JAAS System Logins:

Specifies the configuration settings for the JAAS system logins. You can use the global security settings or customize the configuration settings for a domain.

### System Logins

Select to define the JAAS login configurations that are used by system resources, including the authentication mechanism, principal mapping, and credential mapping

### JAAS J2C Authentication Data:

Specifies the settings for the JAAS J2C authentication data. You can use the global security settings or customize the settings for a domain.

Java 2 Platform, Enterprise Edition (J2EE) Connector authentication data entries are used by resource adapters and Java DataBase Connectivity (JDBC) data sources.

## Use global and domain-specific entries

Select to specify the settings that are defined in the domain, such as options to enable application and Java 2 security and to use realm-qualified authentication data.

### Java Authentication SPI (JASPI)

Specifies the configuration settings for a Java Authentication SPI (JASPI) authentication provider and associated authentication modules. You can use the global security settings or customize the settings for a domain. To configure JASPI authentication providers for a domain, select **Customize for this domain** and then you can enable JASPI. Select **Providers** to create or to edit a JASPI authentication provider.

**Note:** The JASPI authentication provider can be enabled with providers configured at the domain level. By default, all of the applications in the system have access to the JASPI authentication providers configured at the global level. The security runtime first checks for the JASPI authentication providers at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure JASPI authentication providers at a domain only when the provider is to be used exclusively by the applications in that security domain.

### Authentication Mechanism Attributes:

Specifies the various cache settings that must be applied at the domain level.

- Authentication cache settings - use to specify your authentication cache settings. The configuration specified on this panel is applied only to this domain.
- LTPA Timeout - You can configure a different LTPA timeout value at the domain level. The default timeout value is 120 minutes, which is set at the global level. If the LTPA timeout is set at the domain level, any token that is created in the security domain when accessing user applications is created with this expiration time.
- Use realm-qualified user names - When this selection is enabled, user names returned by methods such as `getUserPrincipal()` are qualified with the security realm (user registry) used by applications in the security domain.

### Authorization Provider:

Specifies the settings for the authorization provider. You can use the global security settings or customize the settings for a domain.

You can configure an external third party JACC (Java Authorization Contract for Containers) provider at the domain level. Tivoli Access Manager's JACC provider can only be configured at the global level. Security domains can still use it if they do not override the authorization provider with another JACC provider or with the built-in native authorization.

Select either the **Default authorization** or **External authorization using a JAAC provider**. The **Configure** button is only enabled when **External authorization using a JAAC provider** is selected.

For System Authorization Facility (SAF) authorization, if you set the SAF profile prefix at the domain level, it is applied at the server level so that all applications (both administrative and user) will enable or disable it in that server

### **z/OS security options:**

Specifies the settings for z/OS. You can use the global security settings or customize the settings for a domain.

### **Enable application server and z/OS thread identity synchronization**

Select to indicate if an operating system thread identity should be enabled for synchronization with the Java 2 Platform, Enterprise Edition (J2EE) identity that is used in the application server runtime if an application is coded to request this function.

Synchronizing the operating system identity to the J2EE identity causes the operating system identity to synchronize with the authenticated caller, or delegated RunAs identity in a servlet or Enterprise JavaBeans (EJB) file. This synchronization or association means that the caller or security role identity, rather than the server region identity, is used for z/OS system service requests such as access to files.

If this value is set at the domain level, it is applied at the server level so that all applications (both administrative and user) will enable or disable it in that server.

### **Custom properties**

Select to specify name-value pairs of data, where the name is a property key and the value is a string.

Set custom properties at the domain level that are either new or different from those at the global level. By default, all of the custom properties at the global security configuration can be accessed by all of the applications in the system. The security runtime code first checks for the custom property at the domain level. If it does not find it, it then attempts to obtain the custom property from the global security configuration.

### **Web Services Bindings**

Click **Default policy set bindings** to set the domain default provider and client bindings.

### **External realm name**

Use this page to add a WebSphere Application Server realm that is external to this cell. The realm is initially not trusted. Use the Trusted authentication realms - inbound page to establish trust.

To view this administrative console page, click **Security > Security domains**. Select a domain to edit or create a new one. Under Security Attributes, click **User realm**. Click **Customize for this domain** and then select a **Realm type**. Click **Configure**. Under Related items, click **Trusted authentication realms - inbound** or **Trusted authentication realms - outbound**. Click **Add External Realm...**

### **External realm name**

Use to specify the name of the realm that is external to the list of realms that are available to receive trust.

### **Trust all realms**

Use this page to configure which realms to grant inbound or outbound trust to.

The inbound trust is required to validate LTPA tokens that contain a foreign realm. The outbound trust is required to send the credential tokens to the trusted realms. For example, if an application using realmA needs to communicate using LTPA with an application using realmB, realmA should have realmB in its outbound trust list and realmB should have realmA in its inbound trust list.

To view this administrative console page, click **Security > Security domains**. Select a domain to edit or create a new one. Under Security Attributes, click **User realm**. Click **Customize for this domain**. Select a realm type and then click **Configure**.

Under Related items, click **Trusted authentication realms - inbound** or **Trusted authentication realms - outbound**.

### **Trust all realms (including those external to this cell)**

Select to trust all of the realms listed on this page, including those external to the cell.

### **Trust realms as indicated below**

Select to trust only those realms that you have selected from the list of realms that are available to receive inbound trust.

### **Add External Realm...**

Select to add realms that are external to this cell to the list of realms that are available to receive inbound trust. When an external realm is added, it is trusted by default. If it is not trusted it is removed from the list.

## **Security domains collection**

Security domains provide a mechanism to use different security settings for administrative applications and user applications. They also provide the ability to support multiple security settings so different application servers can use different security attributes like user registry or login configurations.

To view this administrative console page, click **Security > Security domains**.

Read about “Multiple security domains” on page 1310 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

### **Maximum rows**

Specifies the maximum number of rows that display when the collection is large. The rows that are not displayed appear on the next page.

The default is 20. Rows that exceed the maximum number display on subsequent pages.

### **Retain filter criteria**

Specifies whether to use the same filter criteria entered in the show filter function to display this page the next time you visit it.

### **Copy selected domain**

Select to copy a selected domain from the collection (a new name is required)

### **Copy global security**

Select to create a domain with a copy of the global security settings (collection selections are ignored). A domain name is required.

## **Authentication cache settings**

Use this page to specify your authentication cache settings.

To view this administrative console page, click **Security > Global security > Authentication cache settings**.

### **Enable authentication cache**

Specifies whether to disable the authentication cache.

Leave the authentication cache enabled for performance reasons. However, you can disable the authentication cache for debug or measurement purposes. When this choice is disabled, the performance

is impacted since whenever a user is authenticated the user registry is accessed to gather information about the user. New tokens are then created for the user.

**Default:** Enabled

### Cache timeout:

Specifies the time period at which the authenticated credential in the cache expires. Verify that this time period is less than the value for the **Timeout value for forwarded credentials between servers** field (the LTPA timeout).

If the application server infrastructure security is enabled, the security cache timeout can influence performance. The timeout setting specifies how often to refresh the security-related caches. Security information pertaining to beans, permissions, and credentials is cached. When the cache timeout expires, all cached information not accessed within the timeout period is purged from the cache. Subsequent requests for the information result in a database lookup. On occasion, acquiring the information requires invoking a Lightweight Directory Access Protocol (LDAP)-bind or native authentication. Both invocations are relatively costly operations for performance. Determine the best trade-off for the application by looking at usage patterns and security needs for the site.

You must consider the following effects of this value on your configuration:

- Larger authentication cache timeout values can increase the security risk. For example, you might revoke a user in the user registry or repository. However, the revoked user can log into the administrative console using the credential that is cached in the authentication cache until the cache is refreshed.
- Smaller authentication cache timeout values can affect performance. When this value is smaller, the application server accesses the user registry or repository more frequently.
- Larger numbers of entries in the authentication cache, which is due to an increased number of users, increases the memory usage by the authentication cache. Thus, the application server might slow down and affect performance.

You can limit the size of the authentication cache by setting the maximum cache size value. Set both the maximum cache size and the authentication cache timeout values to balance your security risk and performance needs.

The LTPA timeout value should not be set lower than the security cache timeout value. The LTPA timeout value should be set higher than the ORB request timeout value. However, there is no relation between the security cache timeout value and the ORB request timeout value. For more information on the LTPA timeout value, see the documentation about authentication mechanisms and expiration. For more information on the ORB request timeout value, see the documentation about the Object Request Broker service settings.

**Default:** 10 minutes

### Initial cache size:

Specifies the initial size of the hash table caches.

A higher number of available hash values might decrease the occurrence of hash collisions. A hash collision results in a linear search for the hash bucket, which might decrease the retrieval time. If several entries compose a hash table cache, create a table with a larger capacity that supports more efficient hash entries instead of allowing automatic rehashing determine the growth of the table. Rehashing causes every entry to move each time.

**Default:** 50

## Maximum cache size

Indicates the maximum size of the cache.

After this limit is reached, the least used entries are removed from the cache to make space for the new entries.

**Default:** 25000

## Use basic authentication cache keys (password one-way hashed):

Caches the userName and the one-way hashed password as the key lookup in the cache.

Disable this only if you do not want this information to be stored in the cache. If this is disabled, every time a user logs in with userName and password, the user registry is accessed, which impacts performance.

**Default:** True

---

## Authenticating users

The process of authenticating users involves a user registry and an authentication mechanism. Optionally, you can define trust between WebSphere Application Server and a proxy server, configure single sign-on capability, and specify how to propagate security attributes between application servers.

### About this task

The following security topics are covered in this section:

#### User registries

For information on local operating system, Lightweight Directory Access Protocol (LDAP), custom user registries, and user repositories such as virtual member manager, see “Selecting a registry or repository” on page 1345.

#### Trust associations

For more information on trust associations, see “Trust associations” on page 1528.

#### Single sign-on

For more information on single sign-on, see “Single sign-on for authentication using LTPA cookies” on page 1533.

#### Security attribute propagation

For more information on propagation tokens, authorization tokens, single sign-on tokens, and authentication tokens, see “Security attribute propagation” on page 1629.

The following information is covered in this section:

### Procedure

- Configure a user registry. For more information, see “Selecting a registry or repository” on page 1345.
- Configure WebSEAL or a custom trust association interceptor. For more information see, “Integrating third-party HTTP reverse proxy servers” on page 1527.
- Configure single sign-on. For more information, see “Implementing single sign-on to minimize web user authentications” on page 1536.
- Propagate security attributes. For more information, see “Propagating security attributes among application servers” on page 1634.
- Configure the authentication cache. For more information, see “Configuring the authentication cache” on page 1646.

## What to do next

After completing the configuring the authentication process, you must authorize access to resources. For more information, see “Authorizing access to resources” on page 1699.

## Selecting a registry or repository

Information about users and groups reside in a user registry. In WebSphere Application Server, a user registry authenticates a user and retrieves information about users and groups to perform security-related functions, including authentication and authorization.

### Before you begin

**Note:** During profile creation, either during installation or post-installation, administrative security is enabled by default. The file-based federated user repository is configured as the active user registry. Decide if you want a different user registry.

Before configuring the user registry or repository, decide which user registry or repository to use. You can configure one Active default registry for the Cell.

### About this task

WebSphere Application Server provides implementations that support multiple types of registries and repositories including the local operating system registry, a stand-alone Lightweight Directory Access Protocol (LDAP) registry, a stand-alone custom registry, and federated repositories.

With WebSphere Application Server, a user registry or a repository, such as a federated repository, authenticates a user and retrieves information about users and groups to perform security-related functions including authentication and authorization.

With WebSphere Application Server, a user registry or repository is used for:

- Authenticating a user using basic authentication, identity assertion, or client certificates
- Retrieving information about users and groups to perform security-related administrative functions, such as mapping users and groups to security roles

WebSphere Application Server is designed with the capability to support multiple operating systems or operating environment-based user registries, such as the z/OS SAF registry, and most of the major Lightweight Directory Access Protocol (LDAP)-based registries. You can use the custom LDAP feature to support any LDAP server by setting up the correct configuration information, such as user and group filters. However, support is not extended to these custom LDAP servers because there are many possibilities that cannot be tested.

Configuring the correct registry or repository is a prerequisite to assigning users and groups to roles for applications. By default, when a user registry or repository is not configured, the local operating system SAF-based user registry is used. If your choice of user registry or repository is not the local operating system, you must first configure the user registry or repository. Configuring the user registry or repository is normally done as part of enabling administrative security, restarting the servers, and then assigning users and groups to roles for all of your applications.

In addition to local operating system, LDAP, and Federated repository registries, WebSphere Application Server also provides a plug-in to support any registry by using the custom registry feature. The custom registry feature enables you to configure any user registry that is not made available through the security configuration panels of the WebSphere Application Server.

Configuring the correct registry or repository is a prerequisite to assigning users and groups to roles for applications. When a user registry or repository is not configured, the local operating system registry is

used by default. If your choice of user registry is not the local operating system registry, you need to first configure the registry or repository, which is normally done as part of enabling security, restart the servers, and then assign users and groups to roles for all your applications.

WebSphere Application Server supports the following types of user registries:

- Federated repository
- Local operating system such as SAF-based
- Standalone Lightweight Directory Access Protocol (LDAP) registry
- Stand-alone custom registry

The `UserRegistry` interface is used to implement both the custom registry and the federated repository options for the user account repository. The interface is very helpful in situations where the current user and group information exists in some other formats, for example, a database, and cannot move to local operating system or LDAP registries. In such a case, you can implement the `UserRegistry` interface so that WebSphere Application Server can use the existing registry for all the security-related operations. The process of implementing a custom registry is a software implementation effort, and it is expected that the implementation does not depend on WebSphere Application Server resource management for its operation. For example, you cannot use an Application Server data source configuration; generally you must invoke database connections and dictate their behavior directly in your code.

**Note:** WebSphere Application Server has implemented a user registry proxy by using the `UserRegistry` interface. However, the return values are little different from the interface. For example, `getUniqueUserId` returns the `uniqueID` with the realm name wrapped. You cannot use the return value to pass to `getUserSecurityName`, as shown in the following example:

```
// Retrieves the default InitialContext for this server.
javax.naming.InitialContext ctx = new javax.naming.InitialContext();

// Retrieves the local UserRegistry object.
com.ibm.websphere.security.UserRegistry reg =
 (com.ibm.websphere.security.UserRegistry) ctx.lookup("UserRegistry");

// Retrieves the registry uniqueID based on the userName that is specified
// in the NameCallback.
String uniqueid = reg.getUniqueUserId(userName);
// Strip the realm name and get real uniqueID
String uid = com.ibm.wsspi.security.token.WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);

// Retrieves the security name from the user registry based on the uniqueID.
String securityName = reg.getUserSecurityName(uid);
```

You can use a Service Provider Interface (SPI) for this parsing function.

After the applications are assigned users and groups and you need to change the user registries, delete all the users and groups, including any `RunAs` role, from the applications, and reassign them after changing the registry through the administrative console or by using `wsadmin` scripting. The following **`wsadmin`** command, which uses `Jacl`, removes all of the users and groups from any application:

```
$AdminApp deleteUserAndGroupEntries yourAppName
```

where *yourAppName* is the name of the application. Backing up the old application is advised before performing this operation. However, if both of the following conditions are true, you might be able to switch the registries without having to delete the users and groups information:

- All of the user and group names, including the password for the `RunAs` role users, in all of the applications match in both user registries.
- The application bindings file does not contain the access IDs which are unique for each user registry even for the same user or group name.

By default, an application does not contain access IDs in the bindings file. These IDs are generated when the applications start. However, if you migrated an existing application from an earlier release, or if you

used the wsadmin script to add access IDs for the applications to improve performance, you have to remove the existing user and group information and add the information after configuring the new user registry.

For more information on updating access IDs, see updateAccess IDs in the Commands for the AdminApp object article.

**Attention:** WebSphere Application Server supports a variety of user registries and repositories on different operating systems. During the user authentication process, you might use non-alphanumeric characters in your user name or password. Restrictions on the use of these non-alphanumeric characters depends on both the underlying operating system and the user registry type. For more information on which non-alphanumeric characters are not supported, see your operating system and user registry or repository documentation.

For a comprehensive list of the non-alphanumeric characters that are not supported, see the IBM AIX operating system documentation.

Complete one of the following steps to configure your user registry:

### Procedure

- “Configuring local operating system registries”
- “Configuring Lightweight Directory Access Protocol user registries” on page 1352
- “Configuring stand-alone custom registries” on page 1379.
- “Managing the realm in a federated repository configuration” on page 1410

### What to do next

1. If you are enabling security, make sure that you complete the remaining steps. Verify that the User account repository on the Global security panel is set to the appropriate registry or repository. As the final step, validate the user ID and the password by clicking **Apply** on the Global security panel. Save, stop and start all WebSphere Application Servers.
2. For any changes in user registry panels to be effective, you must validate the changes by clicking **Apply** on the Global security panel. After validation, save the configuration and stop and start all WebSphere Application Servers, including the cells, nodes and all of the application servers. To avoid inconsistencies between the WebSphere Application Server processes, make sure that any changes to the registry or repository are done when all of the processes are running. If any of the processes are down, force synchronization to make sure that the process can start later.

If the server or servers start without any problems, the setup is correct.

3. If System Authorization Facility (SAF) through local operating system is selected as the registry or repository, the values in the bindings file are ignored with the exception of the user ID and password (or password phrase) for RunAs role users.

### Configuring local operating system registries

Use these steps to configure local operating system registries.

#### Before you begin

For detailed information about using the local operating system user registry, see “Local operating system registries” on page 1349. These steps set up security based on the local operating system user registry on which WebSphere Application Server is installed.

When a local operating system registry is chosen, the started task identity is chosen as the server identity. A user ID and password are not required to configure the server.

**Important:** Each started task, for example, a controller, servant, or daemon might have a different identity. Because you should give differing resource authorizations to each, you should give differing user IDs to controllers and servants. The z/OS Profile Management Tool sets up these identities.

## About this task

When you set up a user registry for WebSphere Application Server, the System Authorization Facility (SAF) works in conjunction with the user registry to authorize applications to run on the server. For more information on the SAF capabilities, see “System Authorization Facility user registries” on page 1733. Complete the following steps to configure additional properties that are associated with the local OS user registry and SAF configuration.

**Important:** The local operating system is not a valid user account repository when you have a mixed cell environment that includes both z/OS platform and non-z/OS platform nodes.

## Procedure

1. Click **Security > Global security**.
2. Under User account repository, select **Local operating system** and click **Configure**.
3. If SAF authorization is not enabled, enter a valid user name in the **Primary administrative user name** field. This value is the name of a user with administrative privileges that is defined in the registry. This user name is used to access the administrative console or used by wsadmin.
4. Optional: Select the **Ignore case for authorization** option to enable WebSphere Application Server to perform a case insensitive authorization check when you use the default authorization.
5. Click **Apply**.
6. Select either the **Automatically generated server identity** or **User identity for the z/OS started task**.
7. Optional: Enable and configure SAF authorization.
  - a. Click **Security > Global security > External authorization provider**.
  - b. Select the **System Authorization Facility (SAF) authorization** option to enable SAF as the authorization provider.
  - c. Under Related items, click **z/OS SAF authorization** to configure SAF authorization. To see an explanation of the SAF authorization options, see “z/OS System Authorization Facility authorization” on page 1734.
8. Click **OK**.

The administrative console does not validate the user ID and password when you click **OK**. Validation is only done when you click **OK** or **Apply** in the Global security panel. First, make sure that you select **Local operating system** as the available realm definition in the User account repository section, and click **Set as current**. If security was already enabled and you had changed either the user or the password information in this panel, make sure to go to the Global security panel and click **OK** or **Apply** to validate your changes. If your changes are not validated, the server might not start.

**Important:** Until you authorize other users to perform administrative functions, you can only access the administrative console with the server user ID and password that you specified. For more information, see “Authorizing access to administrative roles” on page 1782.

## Results

For any changes in this panel to be effective, you need to save, stop, and start all the product servers, including deployment managers, nodes and application servers. If the server comes up without any problems, the setup is correct.

After completed these steps, you have configured WebSphere Application Server to use the local operating system registry to identify authorized users.

## What to do next

Complete any remaining steps for enabling security. For more information, see “Enabling security” on page 1230.

### *Local operating system registries:*

With the registry implementation for the local operating system, the WebSphere Application Server authentication mechanism can use the user accounts database of the local operating system.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log`, `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

A local operating system registry is a centralized registry within a sysplex.

WebSphere Application Server uses the System Authorization Facility (SAF) interfaces. SAF interfaces are defined by MVS to enable applications to use system authorization services or registries to control access to resources such as data sets and MVS commands. SAF allows security authorization requests to be processed directly through the Resource Access Control Facility (RACF) or a third party z/OS security provider. You must provide a mapping from a user registry identity to a SAF user ID unless you select local operating system as the user registry. For more information, see Custom System Authorization Facility mapping modules.

Web client certificate authentication is supported when using the local operating system user registry. Digital certificates can be mapped to MVS identities by both web and Java clients when you select Local OS. A certificate name filter can be used to simplify the mapping. If you are using RACF as the security server, the **RACDCERT MAP** command creates a resource profile that maps multiple user identities to a digital certificate to simplify administration of certificates, conserve storage space in the RACF database, maintain accountability, or maintain access control granularity.

## Using system user registries

The following notes apply when you use system user registries:

### *Password sensitivity using a local operating system registry:*

Allowing for a larger number of password combinations benefits WebSphere Application Security. Passwords restricted to 8 characters have limits on how secure they can be. Hacking attempts often are successful with 8 character passwords. WebSphere Application Server expands the possible combinations beyond the 8 character password by providing the ability to additionally use a password phrase from 9 to 100 characters long. The password phrase gives you an exponentially larger number of combinations for securing any given user ID to an application.

## **z/OS Version 1.9 RACF**

In z/OS Version 1.9, RACF allows you to use password phrases in securing a user ID to an application. Password phrase support for WebSphere Application Server provides infrastructure changes that you (or other applications) can exploit to facilitate authentication information across environments and applications.

A password phrase can be from 9 to 100 characters in length and provide a far greater number of possible combinations of characters and numbers than do passwords. A password phrase is a character string made up of mixed-case letters, numbers, and special characters. A user ID can have both a password and a password phrase associated with it. The user ID uses the password for existing applications that accept an eight-character password and the password phrase for those applications that are sensitive to the longer character string.

If you want to also use mixed-case password phrases, or password phrases that have trailing blank spaces, you must use the RACF mixed case password option and enable it by using the SETROPTS PASSWORD(MIXEDCASE) RACF command. See "Password case sensitivity using a local operating system registry" for more information about mixed case passwords.

**Remember:** After initializing the use of RACF mixed case passwords, you **MUST** restart the WebSphere Application Server.

To use password phrases in WebSphere Application Server, you must comply with all of the following requirements:

1. Use z/OS Version 1.9 or higher
2. Use the local operating system registry as your active registry
3. Use the System Authorization Facility (SAF) as your authorization provider.
4. Install the WebSphere Application Server Fix Pack 6.1.0.15 or later.
5. If you want to specify a password phrase that is between 9 and 13 characters, inclusive, then you must also install the ICHPWX11 RACF exit routine.

**Important:** All of these requirements must be met; otherwise, WebSphere Application Server password phrases are not recognized and do not take effect.

For more information about password phrases in z/OS Version 1.9, see Z/OS V1R9.0 Security Server RACF Security Administrator's Guide. This guide is available under "**Security Server and Integrated Security Services**". Within the guide, see section 3.4.14.

*Password case sensitivity using a local operating system registry:*

Knowing when a password is interpreted as case sensitive or not can directly affect how you use a local operating system registry. WebSphere Application Server exploits the mixed case password option for the Resource Access Control Facility (RACF) and allows you to use case sensitive passwords.

### **z/OS Version 1.7 RACF**

In z/OS Version 1.7, RACF supports the option of a mixed case password. You select this option for RACF by using the SETROPTS PASSWORD(MIXEDCASE) command. To use case sensitive passwords in WebSphere Application Server for a local operating system registry, you must comply with all of the following requirements:

1. Use z/OS Version 1.7 or higher
2. Use the local operating system registry
3. Turn on the RACF mixed case option with the SETROPTS PASSWORD(MIXEDCASE) command

**Important:** All three of these requirements must be met; otherwise, WebSphere Application Server password will not be sensitive to case.

If you use a Lightweight Directory Access Protocol (LDAP) configuration, you can use mixed case passwords.

For more information on the mixed case password feature in z/OS Version 1.7, see Z/OS V1R7.0 Security Server RACF Security Administrator's Guide. This guide is available under "**Security Server and Integrated Security Services**". Within the guide, see section 5.2.1.

**Local operating system settings:**

Use this page to configure local operating system registry settings.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Local operating system**.
3. Click **Configure**.

WebSphere Application Server Version 7.0 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

**Note:** Any settings that are related to the System Authorization Facility (SAF) might not be visible on this panel. To modify these settings:

1. Go to the panel for SAF by clicking **Security > Global security > External authorization providers**.
2. Select **System Authorization Facility (SAF)** from the drop-down list under the Authorization provider option.
3. Click **Configure**.

*Primary administrative user name:*

Specifies the name of a user with administrative privileges that is defined in your local operating system.

The user name is used to log on to the administrative console when administrative security is enabled..

**Attention:** In WebSphere Application Server, Version 6.1 and above, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1 and above, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

**Important:** If System Authorization Facility (SAF) authorization is enabled on the External authorization providers panel, this field does not display.

*Automatically generated server identity:*

Enables the application server to generate the server identity, which is recommended for environments that contain only Version 6.1 or later nodes. Automatically generated server identities are not stored in a user repository.

**Default:** Enabled

*User identity for the z/OS started task:*

Specifies the user identity that is associated with the z/OS system started task. Each controller and server can have its own identity.

*Ignore case for authorization:*

Indicates that a case-insensitive authorization check is performed when you use the default authorization.

**Default:** Disabled  
**Range:** Enabled or Disabled

### ***Local operating system wizard settings:***

Use this security wizard page to configure local operating system registry settings.

To view this security wizard page, complete the following steps:

1. Click **Security > Global security > Security configuration wizard**.
2. Select your protection settings and click **Next**.
3. Select the **Local operating system** option and click **Next**.

*Primary administrative user name:*

Specifies the name of a user with administrative privileges that is defined in your local operating system.

The user name is used to log on to the administrative console when administrative security is enabled..

**Attention:** In WebSphere Application Server, Version 6.1 and above, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1 and above, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

**Important:** If System Authorization Facility (SAF) authorization is enabled on the External authorization providers panel, this field does not display.

## **Configuring Lightweight Directory Access Protocol user registries**

To access a user registry using the Lightweight Directory Access Protocol (LDAP), you must know a valid user name (ID) and password, the server host and port of the registry server, the base distinguished name (DN) and, if necessary, the bind DN and the bind password. You can choose any valid user in the user registry that is searchable. You can use any user ID that has the administrative role to log in.

### **Before you begin**

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log , SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

There are two different identities that are used for security purposes: the user ID for administrative functions and the server identity. When administrative security is enabled, the user ID and password for administrative functions is authenticated with the registry. If authentication fails, access to the administrative console is not granted or tasks with wsadmin scripts are not completed. It is important to choose an ID and password that do not expire or change often. If this user ID or password need to change in the registry, make sure that the changes are performed when all the application servers are up and running. When changes are to be made in the registry, review the article on “Standalone Lightweight Directory Access Protocol registries” on page 1501 (LDAP) before beginning this task.

The server identity is used for internal process communication. As part of this task, you can change the server identity from the default automatically generated ID to a server ID and password from the LDAP repository.

## Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Enter a valid user name in the **Primary administrative user name** field. Typically, the user name is the short name of the user and is defined by the user filter in the Advanced LDAP settings panel.
4. Determine whether to specify the user identity that is used for internal process communication. Cells that contain Version 5.1 or 6.x nodes require a server user identity that is defined in the active user repository. By default, the **Automatically generated server identity** option is enabled, and the application server generates the server identity. However, you can select the **Server identity that is stored in the repository** option to specify both the server identity and its associated password.
5. Select the type of LDAP server to use from the **Type** list. The type of LDAP server determines the default filters that are used by WebSphere Application Server. These default filters change the **Type** field to **Custom**, which indicates that custom filters are used. This action occurs after you click **OK** or **Apply** in the Advanced LDAP settings panel. Choose the **Custom** type from the list and modify the user and group filters to use other LDAP servers, if required.

IBM Tivoli Directory Server users can choose IBM Tivoli Directory Server as the directory type. Use the IBM Tivoli Directory Server directory type for better performance. For a list of supported LDAP servers, see the Supported hardware, software, and APIs website.

**Attention:** IBM SecureWay Directory Server has been renamed to IBM Tivoli Directory Server in WebSphere Application Server version 6.1.

6. Enter the fully qualified host name of the LDAP server in the **Host** field. You can enter either the IP address or domain name system (DNS) name.
7. Enter the LDAP server port number in the **Port** field. The host name and the port number represent the realm for this LDAP server in the WebSphere Application Server cell. So, if servers in different cells are communicating with each other using Lightweight Third Party Authentication (LTPA) tokens, these realms must match exactly in all the cells.

The default value is 389. If multiple WebSphere Application Servers are installed and configured to run in the same single sign-on domain, or if the WebSphere Application Server interoperates with a previous version of the WebSphere Application Server, then it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as 389 in a version 5.x configuration, and a WebSphere Application Server at version 6.0.x is going to interoperate with the version 5.x server, then verify that port 389 is specified explicitly for the version 6.0.x server.

You can set the `com.ibm.websphere.security.ldap.logicRealm` custom property to change the value of the realm name that is placed in the token. For more information, see the security custom properties topic.

8. Enter the base distinguished name (DN) in the **Base distinguished name** field. The base DN indicates the starting point for searches in this LDAP directory server. For example, for a user with a DN of `cn=John Doe, ou=Rochester, o=IBM, c=US`, specify the base DN as any of the following options, assuming a suffix of `c=us`:
  - `ou=Rochester, o=IBM, c=us`
  - `o=IBM, c=us`
  - `c=us`

For authorization purposes, this field is case sensitive by default. Match the case in your directory server. If a token is received (for example, from another cell or Lotus Domino) the base DN in the server must match exactly the base DN from the other cell or Domino. If case sensitivity is not a consideration for authorization, enable the **Ignore case for authorization** option.

In WebSphere Application Server, the distinguished name is normalized according to the Lightweight Directory Access Protocol (LDAP) specification. Normalization consists of removing spaces in the base distinguished name before or after commas and equal symbols. An example of a non-normalized base distinguished name is `o = ibm, c = us` or `o=ibm, c=us`. An example of a normalized base distinguished name is `o=ibm,c=us`.

To interoperate between WebSphere Application Server Version 6.0 and later versions, you must enter a normalized base distinguished name in the **Base Distinguished Name** field. In WebSphere Application Server, Version 6.0 or later, the normalization occurs automatically during runtime.

This field is required for all LDAP directories except the Lotus Domino Directory. The **Base Distinguished Name** field is optional for the Domino server.

9. Optional: Enter the bind DN name in the **Bind distinguished name** field. The bind DN is required if anonymous binds are not possible on the LDAP server to obtain user and group information. If the LDAP server is set up to use anonymous binds, leave this field blank. If a name is not specified, the application server binds anonymously. See the **Base Distinguished Name** field description for examples of distinguished names.
10. Optional: Enter the password corresponding to the bind DN in the **Bind password** field.
11. Optional: Modify the Search time out value. This timeout value is the maximum amount of time that the LDAP server waits to send a response to the product client before stopping the request. The default is 120 seconds.
12. Ensure that the **Reuse connection** option is selected. This option specifies that the server should reuse the LDAP connection. Clear this option only in rare situations where a router is used to send requests to multiple LDAP servers and when the router does not support affinity. Leave this option selected for all other situations.
13. Optional: Verify that the **Ignore case for authorization** option is enabled. When you enable this option, the authorization check is case insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the LDAP server and is case sensitive. However, when you use either the IBM Directory Server or the Sun ONE (formerly iPlanet) Directory Server LDAP servers, you must enable this option because the group information that is obtained from the LDAP servers is not consistent in case. This inconsistency affects the authorization check only. Otherwise, this field is optional and can be enabled when a case sensitive authorization check is required. For example, you might select this option when you use certificates and the certificate contents do not match the case of the entry in the LDAP server.

You can also enable the **Ignore case for authorization** option when you are using single sign-on (SSO) between the product and Lotus Domino. The default is enabled.

14. Optional: Select the **SSL enabled** option if you want to use Secure Sockets Layer communications with the LDAP server.

**Important:** This step will only be successful provided that the Signer certificate for the LDAP is first added to the truststore that will be eventually used. If the Signer certificate from the LDAP is not added to the truststore, then

- An error will be issued by the Administrative console.
- the deployment manager (DMGR) systemout.log will show the **CWPKI0022E: SSL HANDSHAKE FAILURE** message indicating that the Signer certificate needs to be added to the truststore.

To ensure an error free operation for this step, You need to first extract to a file the Signer certificate of the LDAP and send that file to the WebSphere Application Server machine. You can then add the certificate to the truststore being defined for the LDAP. In this way, you are assured that the remaining actions for this step will be successful.

If you select the **SSL enabled** option, you can select either the **Centrally managed** or the **Use specific SSL alias** option.

### Centrally managed

Enables you to specify an SSL configuration for particular scope such as the cell, node, server, or cluster in one location. To use the **Centrally managed** option, you must specify the SSL configuration for the particular set of endpoints. The Manage endpoint security configurations and trust zones panel displays all of the inbound and outbound endpoints that use the SSL protocol. If you expand the Inbound or Outbound section of the panel and click the name of a node, you can specify an SSL configuration that is used for every endpoint on that node. For an LDAP registry, you can override the inherited SSL configuration by specifying an SSL configuration for LDAP. To specify an SSL configuration for LDAP, complete the following steps:

- a. Click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones**.
- b. Expand **Outbound > cell\_name > Nodes > node\_name > Servers > server\_name > LDAP**.

### Use specific SSL alias

Select the **Use specific SSL alias** option if you intend to select one of the SSL configurations in the menu below the option.

This configuration is used only when SSL is enabled for LDAP. The default is *DefaultSSLSettings*. You can click the name of an existing configuration to modify it or complete the following steps to create a new SSL configuration:

- a. Click **Security > SSL certificate and key management**.
- b. Under Configuration settings, click **Manage endpoint security configurations**.
- c. Select a Secure Sockets Layer (SSL) *configuration\_name* for selected scopes, such as a cell, node, server, or cluster.
- d. Under Related items, click **SSL configurations**.
- e. Click **New**.

15. Click **OK** and either **Apply** or **Save** until you return to the Global security panel.

## Results

This set of steps is required to set up the LDAP user registry. This step is required as part of enabling security in the WebSphere Application Server.

### What to do next

1. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1254.
2. If you want to use System Authorization Facility (SAF) authorization with your LDAP registry, then read about “System Authorization Facility considerations for the operating system and application levels” on page 1201 for more information.
3. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect. If the server comes up without any problems the setup is correct.

### **Standalone LDAP registry settings:**

Use this page to configure Lightweight Directory Access Protocol (LDAP) settings when users and groups reside in an external LDAP directory.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.

When security is enabled and any of these properties change, go to the Global security panel and click **Apply** to validate the changes.

WebSphere Application Server Version 7.0 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

**Note:** Any settings that are related to the System Authorization Facility (SAF) might not be visible on this panel. To modify these settings:

1. Go to the panel for SAF by clicking **Security > Global security > External authorization providers**.
2. Select **System Authorization Facility (SAF)** from the drop-down list under the Authorization provider option.
3. Click **Configure**.

**Note:** The initial profile creation configures WebSphere Application Server to use a federated repositories security registry option with the file-based registry. This security registry configuration can be changed to use other options, including the stand-alone LDAP registry. Instead of changing from the federated repositories option to the stand-alone LDAP registry option under the User account repository configuration, consider employing the federated repositories option, which provides for LDAP configuration. Federated repositories provide a wide range of capabilities, including the ability to have one or multiple user registries. It supports federating one or more LDAPs in addition to file-based and custom registries. It also has improved failover capabilities, and a robust set of member (user and group) management capabilities. Federated repositories is required when you are using the new member management capabilities in WebSphere Portal 6.1 and above, and Process Server 6.1 and above. The use of federated repositories is required for following LDAP referrals, which is a common requirement in some LDAP server environments (such as Microsoft Active Directory).

It is recommended that you migrate from stand-alone LDAP registries to federated repositories. If you move to WebSphere Portal 6.1 and above, and or WebSphere Process Server 6.1 and above, you should migrate to federated repositories prior to these upgrades. For more information about federated repositories and its capabilities, read the Federated repositories topic. For more information about how to migrate to federated repositories, read the Migrating a stand-alone LDAP repository to a federated repositories LDAP repository configuration topic.

*Primary administrative user name:*

Specifies the name of a user with administrative privileges that is defined in your user registry.

The user name is used to log onto the administrative console when administrative security is enabled. Versions 6.1 and later require an administrative user that is distinct from the server user identity so that administrative actions can be audited.

**Attention:** In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When you migrate to Version 7.0, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

**Note:** When you configure LDAP as a user registry and SAF is enabled, if the property `com.ibm.security.SAF.authorization`, is set to true, then the Primary administrative user name field is not displayed on the administrative console.

*Automatically generated server identity:*

Enables the application server to generate the server identity, which is recommended for environments that contain only Version 6.1 or later nodes. Automatically generated server identities are not stored in a user repository.

**Default:** Enabled

*Type of LDAP server:*

Specifies the type of LDAP server to which you connect.

IBM SecureWay Directory Server is supported by the application server for z/OS as well as many other LDAP servers.

*Host:*

Specifies the host ID (IP address or domain name service (DNS) name) of the LDAP server.

*Port:*

Specifies the host port of the LDAP server.

If multiple application servers are installed and configured to run in the same single sign-on domain or if the application server interoperates with a previous version, it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as 389 in a Version 6.1 configuration, and a WebSphere Application Server at Version 7.0 is going to interoperate with the Version 6.1 server, verify that port 389 is specified explicitly for the Version 7.0 server.

**Default:** 389  
**Type:** Integer

*Base distinguished name (DN):*

Specifies the base distinguished name (DN) of the directory service, which indicates the starting point for LDAP searches of the directory service. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed.

For example, for a user with a DN of `cn=John Doe , ou=Rochester, o=IBM, c=US`, specify the Base DN as any of the following options: `ou=Rochester, o=IBM, c=US` or `o=IBM c=US` or `c=US`. For authorization purposes, this field is case sensitive. This specification implies that if a token is received, for example, from another cell or Lotus Domino, the base DN in the server must match the base DN from the other cell or Lotus Domino server exactly. If case sensitivity is not a consideration for authorization, enable the **Ignore case for authorization** option. This option is required for all Lightweight Directory Access Protocol (LDAP) directories, except for the Lotus Domino Directory, IBM Tivoli Directory Server V6.0, and Novell eDirectory, where this field is optional.

*Bind distinguished name (DN):*

Specifies the DN for the application server to use when binding to the directory service.

If no name is specified, the application server binds anonymously. See the Base distinguished name (DN) field description for examples of distinguished names.

*Bind password:*

Specifies the password for the application server to use when binding to the directory service.

*Search timeout:*

Specifies the timeout value in seconds for a Lightweight Directory Access Protocol (LDAP) server to respond before stopping a request.

**Default:** 120

*Reuse connection:*

Specifies whether the server reuses the LDAP connection. Clear this option only in rare situations where a router is used to distribute requests to multiple LDAP servers and when the router does not support affinity.

**Default:** Enabled  
**Range:** Enabled or Disabled

**Important:** Disabling the **Reuse connection** option causes the application server to create a new LDAP connection for every LDAP search request. This situation impacts system performance if your environment requires extensive LDAP calls. This option is provided because the router is not sending the request to the same LDAP server. The option is also used when the idle connection timeout value or firewall timeout value between the application server and LDAP is too small.

If you are using WebSphere Edge Server for LDAP failover, you must enable TCP resets with the Edge server. A TCP reset causes the connection to immediately closed and a backup server to failover. For more information, see "Sending TCP resets when server is down" at <http://www.ibm.com/software/webservers/appserv/doc/v50/ec/infocenter/edge/LBguide.htm#HDRRESETSERVER> and the Edge Server V2 - TCP Reset feature in PTF #2 described in: <ftp://ftp.software.ibm.com/software/websphere/edgeserver/info/doc/v20/en/updates.pdf>.

*Ignore case for authorization:*

Specifies that a case insensitive authorization check is performed when using the default authorization.

This option is required when IBM Tivoli Directory Server is selected as the LDAP directory server.

This option is required when Sun ONE Directory Server is selected as the LDAP directory server. For more information, see "Using specific directory servers as the LDAP server" in the documentation.

This option is optional and can be enabled when a case-sensitive authorization check is required. For example, use this option when the certificates and the certificate contents do not match the case that is used for the entry in the LDAP server. You can enable the **Ignore case for authorization** option when using single sign-on (SSO) between the application server and Lotus Domino.

**Default:** Enabled  
**Range:** Enabled or Disabled

*SSL enabled:*

Specifies whether secure socket communication is enabled to the Lightweight Directory Access Protocol (LDAP) server.

When enabled, the LDAP Secure Sockets Layer (SSL) settings are used, if specified.

*Centrally managed:*

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations rather than spreading them across the configuration documents.

**Default:** Enabled

*Use specific SSL alias:*

Specifies the SSL configuration alias to use for LDAP outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI platform.

**Standalone LDAP registry wizard settings:**

Use this security wizard page to provide the basic settings to connect the application server to an existing Lightweight Directory Access Protocol (LDAP) registry.

To view this security wizard page, click **Security > Global security > Security configuration wizard**. You can modify your LDAP registry configuration by completing the following steps:

1. Click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.

*Primary administrative user name:*

Specifies the name of a user with administrative privileges that is defined in your user registry.

The user name is used to log onto the administrative console when administrative security is enabled. Versions 6.1 and later require an administrative user that is distinct from the server user identity so that administrative actions can be audited.

**Attention:** In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When you migrate to Version 7.0, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

**Note:** When you configure LDAP as a user registry and SAF is enabled, if the property `com.ibm.security.SAF.authorization` is set to true, then the Primary administrative user name field is not displayed on the administrative console.

*Type of LDAP server:*

Specifies the type of LDAP server to which you connect.

IBM SecureWay Directory Server is supported by the application server for z/OS as well as many other LDAP servers.

*Host:*

Specifies the host ID (IP address or domain name service (DNS) name) of the LDAP server.

*Port:*

Specifies the host port of the LDAP server.

If multiple application servers are installed and configured to run in the same single sign-on domain or if the application server interoperates with a previous version, it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as 389 in a Version 6.1 configuration, and a WebSphere Application Server at Version 7.0 is going to interoperate with the Version 6.1 server, verify that port 389 is specified explicitly for the Version 7.0 server.

|                 |         |
|-----------------|---------|
| <b>Default:</b> | 389     |
| <b>Type:</b>    | Integer |

*Base distinguished name (DN):*

Specifies the base distinguished name (DN) of the directory service, which indicates the starting point for LDAP searches of the directory service. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed.

For example, for a user with a DN of cn=John Doe , ou=Rochester, o=IBM, c=US, specify the Base DN as any of the following options: ou=Rochester, o=IBM, c=US or o=IBM, c=US or c=US. For authorization purposes, this field is case sensitive. This specification implies that if a token is received, for example, from another cell or Lotus Domino, the base DN in the server must match the base DN from the other cell or Lotus Domino server exactly.

*Bind distinguished name (DN):*

Specifies the DN for the application server to use when binding to the directory service.

If no name is specified, the application server binds anonymously. See the Base distinguished name (DN) field description for examples of distinguished names.

*Bind password:*

Specifies the password for the application server to use when binding to the directory service.

***Advanced Lightweight Directory Access Protocol user registry settings:***

Use this page to configure the advanced Lightweight Directory Access Protocol (LDAP) user registry settings when users and groups reside in an external LDAP directory.

To view this administrative page, complete the following steps:

1. Click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.

Default values for all the user and group related filters are already completed in the appropriate fields. You can change these values depending on your requirements. These default values are based on the type of LDAP server that is selected in the Standalone LDAP registry settings panel. If this type changes, for example from Netscape to Secureway, the default filters automatically change. When the default filter

values change, the LDAP server type changes to Custom to indicate that custom filters are used. When security is enabled and any of these properties change, go to the Global security panel and click **Apply** or **OK** to validate the changes.

**Note:** The initial profile creation configures WebSphere Application Server to use a federated repositories security registry option with the file-based registry. This security registry configuration can be changed to use other options, including the stand-alone LDAP registry. Instead of changing from the federated repositories option to the stand-alone LDAP registry option under the User account repository configuration, consider employing the federated repositories option, which provides for LDAP configuration. Federated repositories provide a wide range of capabilities, including the ability to have one or multiple user registries. It supports federating one or more LDAPs in addition to file-based and custom registries. It also has improved failover capabilities, and a robust set of member (user and group) management capabilities. Federated repositories is required when you are using the new member management capabilities in WebSphere Portal 6.1 and above, and Process Server 6.1 and above. The use of federated repositories is required for following LDAP referrals, which is a common requirement in some LDAP server environments (such as Microsoft Active Directory).

It is recommended that you migrate from stand-alone LDAP registries to federated repositories. If you move to WebSphere Portal 6.1 and above, and or WebSphere Process Server 6.1 and above, you should migrate to federated repositories prior to these upgrades. For more information about federated repositories and its capabilities, read the Federated repositories topic. For more information about how to migrate to federated repositories, read the Migrating a stand-alone LDAP repository to a federated repositories LDAP repository configuration topic.

*User filter:*

Specifies the LDAP user filter that searches the user registry for users.

This option is typically used for security role-to-user assignments and specifies the property by which to look up users in the directory service. For example, to look up users based on their user IDs, specify `(&(uid=%v)(objectclass=inetOrgPerson))`. For more information about this syntax, see the LDAP directory service documentation.

**Data type:** String

*Group filter:*

Specifies the LDAP group filter that searches the user registry for groups

This option is typically used for security role-to-group assignments and specifies the property by which to look up groups in the directory service. For more information about this syntax, see the LDAP directory service documentation.

**Data type:** String

*User ID map:*

Specifies the LDAP filter that maps the short name of a user to an LDAP entry.

Specifies the piece of information that represents users when users display. For example, to display entries of the object class = inetOrgPerson type by their IDs, specify `inetOrgPerson:uid`. This field takes multiple objectclass:property pairs delimited by a semicolon (;).

**Data type:** String

*Group ID map:*

Specifies the LDAP filter that maps the short name of a group to an LDAP entry.

Specifies the piece of information that represents groups when groups display. For example, to display groups by their names, specify \*:cn. The asterisk (\*) is a wildcard character that searches on any object class in this case. This field takes multiple objectclass:property pairs, delimited by a semicolon (;).

**Data type:** String

*Group member ID map:*

Specifies the LDAP filter that identifies user-to-group relationships.

For directory types SecureWay, and Domino, this field takes multiple objectclass:property pairs, delimited by a semicolon (;). In an objectclass:property pair, the object class value is the same object class that is defined in the group filter, and the property is the member attribute. If the object class value does not match the object class in the group filter, authorization might fail if groups are mapped to security roles. For more information about this syntax, see your LDAP directory service documentation.

For IBM Directory Server, Sun ONE, and Active Directory, this field takes multiple group attribute:member attribute pairs delimited by a semicolon (;). These pairs are used to find the group memberships of a user by enumerating all the group attributes that are possessed by a given user. For example, attribute pair memberof:member is used by Active Directory, and ibm-allGroup:member is used by IBM Directory Server. This field also specifies which property of an object class stores the list of members belonging to the group represented by the object class. For supported LDAP directory servers, see "Supported directory services".

**Data type:** String

*Perform a nested group search:*

Specifies a recursive nested group search.

Select this option if the Lightweight Directory Access Protocol (LDAP) server does not support recursive server-side group member searches and if recursive group member search is required. It is not recommended that you select this option to locate recursive group memberships for LDAP servers.

Application server security leverages the recursive search functionality of the LDAP server to search a user's group memberships, including recursive group memberships. For example:

- IBM Directory Server is preconfigured by the application server security to recursively calculate a user's group memberships using the `ibm-allGroup` attribute.
- SunONE directory server is preconfigured to calculate nested group memberships using the `nsRole` attribute.

**Data type:** String

*Kerberos user filter:*

Specifies the Kerberos user filter value. This value can be modified when Kerberos is configured and is active as one of the preferred authentication mechanisms.

**Data type:** String

### *Certificate map mode:*

Specifies whether to map X.509 certificates into an LDAP directory by EXACT\_DN or CERTIFICATE\_FILTER. Specify CERTIFICATE\_FILTER to use the specified certificate filter for the mapping.

**Data type:** String

### *Certificate filter:*

Specifies the filter certificate mapping property for the LDAP filter. The filter is used to map attributes in the client certificate to entries in the LDAP registry.

If more than one LDAP entry matches the filter specification at runtime, authentication fails because the result is an ambiguous match. The syntax or structure of this filter is:

(&(uid=\${SubjectCN})(objectclass=inetOrgPerson)). The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. The right side must begin with a dollar sign (\$) and open bracket ({} and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:

- \${UniqueKey}
- \${PublicKey}
- \${IssuerDN}
- \${Issuer<xx>}

where <xx> is replaced by the characters that represent any valid component of the Issuer Distinguished Name. For example, you might use \${IssuerCN} for the Issuer Common Name.

- \${NotAfter}
- \${NotBefore}
- \${SerialNumber}
- \${SigAlgName}
- \${SigAlgOID}
- \${SigAlgParams}
- \${SubjectDN}
- \${Subject<xx>}

where <xx> is replaced by the characters that represent any valid component of the Subject Distinguished Name. For example, you might use \${SubjectCN} for the Subject Common Name.

- \${Version}

**Data type:** String

### ***Configuring Lightweight Directory Access Protocol search filters:***

Use this topic to configure the LDAP search filters. These steps are required to modify existing user and group filters for a particular LDAP directory type, and also to set up certificate filters to map certificates to entries in the LDAP server.

#### **Before you begin**

WebSphere Application Server uses Lightweight Directory Access Protocol (LDAP) filters to search and obtain information about users and groups from an LDAP directory server. A default set of filters is provided for each LDAP server that the product supports. You can modify these filters to fit your LDAP configuration. After the filters are modified and you click **OK** or **Apply** the directory type in the Standalone LDAP registry panel changes to custom, which indicates that custom filters are used. Also, you can develop filters to support any additional type of LDAP server. The effort to support additional LDAP

directories is optional and other LDAP directory types are not supported. Complete the following steps in the administrative console.

## Procedure

1. Click **Security > Global security**.
2. Under User account repository, select **Standalone LDAP registry** and click **Configure**.
3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
4. Modify the user filter, if necessary. The user filter is used for searching the registry for users and is typically used for the security role-to-user assignment. The filter is also used to authenticate a user with the attribute that is specified in the filter. The filter specifies the property that is used to look up users in the directory service.

In the following example, the property that is assigned to %v, which is the short name of the user, must be a unique key. Two LDAP entries with the same object class cannot have the same short name. To look up users based on their user IDs (uid) and to use the inetOrgPerson object class, specify the following syntax:

```
(&(uid=%v)(objectclass=inetOrgPerson))
```

For more information about this syntax, see the “Using specific directory servers as the LDAP server” on page 1367 documentation.

5. Modify the Kerberos user filter, if necessary. The Kerberos user filter name is used for searching the registry for the Kerberos principal name. Specify the LDAP attribute that holds the Kerberos principal name.

### **IBM Lotus Domino default krbuser filter:**

```
(&(krbPrincipalName=%v)(objectcategory=Person))
```

### **IBM SecureWay Directory Server default krbuser filter:**

```
(&(krbPrincipalName=%v)(objectcategory=ePerson))
```

### **Microsoft Active Directory default krbuser filter:**

```
(&(userprincipalname=%v)(objectcategory=user))
```

### **Sun Java System Directory Server default krbuser filter:**

```
(&(krbPrincipalName=%v)(objectcategory=inetOrgPerson))
```

### **Novell eDirectory default krbuser filter:**

```
(&(krbPrincipalName=%v)(objectcategory=Person))
```

6. Optional: If your using Federated Repositories, modify the Kerberos attribute name if necessary. The Kerberos attribute name is used for searching the registry for Kerberos principal. Specify the LDAP attribute that holds the Kerberos principal name.

### **IBM Lotus Domino default krbuser filter:**

```
krbPrincipalName
```

### **IBM SecureWay Directory Server default krbuser filter:**

```
krbPrincipalName
```

### **Microsoft Active Directory default krbuser filter:**

```
userprincipalname
```

### **Sun Java System Directory Server default krbuser filter:**

```
krbPrincipalName
```

### **Novell eDirectory default krbuser filter:**

```
krbPrincipalName
```

7. Modify the group filter, if necessary. The group filter is used in searching the registry for groups and is typically used for the security role-to-group assignment. Also, the filter is used to specify the property by which to look up groups in the directory service.

In the following example, the property that is assigned to %v, which is the short name of the group, must be a unique key. Two LDAP entries with the same object class cannot have the same short name. To look up groups based on their common names (CN) and to use either the groupOfNames object class or the groupOfUniqueNames object class, specify the following syntax:

```
(&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))
```

For more information about this syntax, see the “Using specific directory servers as the LDAP server” on page 1367 documentation.

8. Modify the user ID map, if necessary. This filter maps the short name of a user to an LDAP entry and specifies the piece of information that represents users when these users are displayed with their short names. For example, to display entries of object class = inetOrgPerson by their IDs, specify inetOrgPerson:uid. This field takes multiple objectclass:property pairs, delimited by a semicolon (;). To provide a consistent value for methods like the getCallerPrincipal method and the getUserPrincipal method, the short name that is obtained by using this filter is used. For example, the CN=Bob Smith, ou=austin.ibm.com, o=IBM, c=US user can log in using any attributes that are defined, for example, email address, social security number, and so on, but when these methods are called, the bob user ID is returned no matter how the user logs in.
9. Modify the group ID map filter, if necessary. This filter maps the short name of a group to an LDAP entry and specifies the piece of information that represents groups when groups display. For example, to display groups by their names, specify \*:cn. The asterisk (\*) is a wildcard character that searches on any object class in this case. This field takes multiple objectclass:property pairs, delimited by a semicolon (;).
10. Modify the group member ID map filter, if necessary. This filter identifies user-to-group memberships. For SecureWay, and Domino directory types, this field is used to query all the groups that match the specified object classes to see if the user is contained in the specified attribute. For example, to get all the users that belong to groups with the groupOfNames object class and the users that are contained in the member attributes, specify groupOfNames:member. This syntax, which is a property of an object class, stores the list of members that belong to the group that is represented by the object class. This field takes multiple objectclass:property pairs that are delimited by a semicolon (;). For more information about this syntax, see the “Using specific directory servers as the LDAP server” on page 1367.

For the IBM Tivoli Directory Server, Sun ONE, and Active Directory, this field is used to query all users in a group with the information that is stored in the user object. For example, the memberof:member filter (for Active Directory) is used to get the memberof attribute of the user object to obtain all the groups to which the user belongs. The member attribute is used to get all the users in a group that use the Group object. Using the User object to obtain the group information improves performance.

11. Select the **Perform a nested group search** option if your LDAP server does not support recursive server-side searches.
12. Modify the Certificate map mode, if necessary. You can use the X.590 certificates for user authentication when LDAP is selected as the registry. This field is used to indicate whether to map the X.509 certificates into an LDAP directory user by **EXACT\_DN** or **CERTIFICATE\_FILTER**. If **EXACT\_DN** is selected, the DN in the certificate must exactly match the user entry in the LDAP server, including case and spaces.

Select the **Ignore case for authorization** option on the Standalone LDAP registry settings to make the authorization case insensitive. To access the Standalone LDAP registry settings panel, complete the following steps:

- a. Click **Security > Global security**.
  - b. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**.
13. If you select **CERTIFICATE\_FILTER**, specify the LDAP filter for mapping attributes in the client certificate to entries in LDAP. If more than one LDAP entry matches the filter specification at run time,

authentication fails because an ambiguous match results. The syntax or structure of this filter is: LDAP attribute=\${Client certificate attribute} (for example, uid=\${SubjectCN}).

The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. Note that the right side must begin with a dollar sign (\$), open bracket ({), and end with a close bracket (}). Use the following certificate attribute values on the right side of the filter specification. The case of the strings is important.

- \${UniqueKey}
- \${PublicKey}
- \${IssuerDN}
- \${Issuer<xx>}

where <xx> is replaced by the characters that represent any valid component of the Issuer Distinguished Name. For example, you might use \${IssuerCN} for the Issuer Common Name.

- \${NotAfter}
- \${NotBefore}
- \${SerialNumber}
- \${SigAlgName}
- \${SigAlgOID}
- \${SigAlgParams}
- \${SubjectDN}
- \${Subject<xx>}

where <xx> is replaced by the characters that represent any valid component of the Subject Distinguished Name. For example, you might use \${SubjectCN} for the Subject Common Name.

- \${Version}

To enable this field, select **CERTIFICATE\_FILTER** for the certificate mapping.

#### 14. Click **Apply**.

When any LDAP user or group filter is modified in the Advanced LDAP Settings panel click **Apply**. Clicking **OK** navigates you to the Standalone LDAP registry panel, which contains the previous LDAP directory type, rather than the custom LDAP directory type. Clicking **OK** or **Apply** in the Standalone LDAP registry panel saves the back-level LDAP directory type and the default filters of that directory. This action overwrites any changes to the filters that you made. To avoid overwriting changes, you can take either of the following actions:

- Click **Apply** in the Advanced Lightweight Directory Access Protocol (LDAP) user registry settings panel. Click **Security > Global security** and change the User account repository type to Stand-alone custom registry.
- Select **Custom** type from the Standalone LDAP registry panel. Click **Apply** and then change the filters by clicking the Advanced Lightweight Directory Access Protocol (LDAP) user registry settings panel. After you complete your changes, click **Apply** or **OK**.

The validation of the changes does not take place in this panel. Validation is done when you click **OK** or **Apply** on the Global security panel. If you are in the process of enabling security for the first time, complete the remaining steps and go to the Global security panel. Select **Standalone LDAP registry** as the user account repository. If security is already enabled and any information on this panel changes, go to the Global security panel and click **OK** or **Apply** to validate your changes. If your changes are not validated, the server might not start.

## Results

These steps result in the configuration of the LDAP search filters. These steps are required to modify existing user and group filters for a particular LDAP directory type. The steps are also used to set up certificate filters to map certificates to entries in the LDAP server.

## What to do next

1. Validate this setup by clicking **OK** or **Apply** on the Global security panel.

2. Save, stop, and start all the product servers, including the cell, nodes and all of the application servers for any changes in this panel to become effective.
3. After the server starts, go through all the security-related tasks (getting users, getting groups, and so on) to verify that the changes to the filters function.

### ***Using specific directory servers as the LDAP server:***

This article provides important information about the directory servers that are supported as Lightweight Directory Access Protocol (LDAP) servers in WebSphere Application Server.

### **Before you begin**

Microsoft Active Directory forests are not supported with the stand-alone LDAP Registry. The Federated Repository Registry, when configured to use an Active Directory LDAP does support the use of forests.

### **About this task**

For a list of supported LDAP servers, refer to the Supported hardware and software website.

It is expected that other LDAP servers follow the LDAP specification. Support is limited to these specific directory servers only. You can use any other directory server by using the custom directory type in the list and by filling in the filters that are required for that directory.

To improve performance for LDAP searches, the default filters for IBM Tivoli Directory Server, Sun ONE, and Active Directory are defined such that when you search for a user, the result contains all the relevant information about the user (user ID, groups, and so on). As a result, the product does not call the LDAP server multiple times. This definition is possible only in these directory types, which support searches where the complete user information is obtained.

If you use the IBM Directory Server, select the **Ignore case for authorization** option. This option is required because when the group information is obtained from the user object attributes, the case is not the same as when you get the group information directly. For the authorization to work in this case, perform a case insensitive check and verify the requirement for the **Ignore case for authorization** option.

The LDAP Security Server for the z/OS platform is supported when the DB2 Technical Database Management (TDBM) back-end is used. Use the SecureWay Directory Server filters to connect to the LDAP Security Server for the z/OS platform.

#### **• Using IBM Tivoli Directory Server as the LDAP server**

You can select either the **IBM Tivoli Directory Server** or **SecureWay** directory type for the IBM Directory Server.

The difference between these two types is group membership lookup. It is recommended that you choose the IBM Tivoli Directory Server for optimum performance during runtime. In the IBM Tivoli Directory Server, the group membership is an operational attribute. With this attribute, a group membership lookup is done by enumerating the `ibm-allGroups` attribute for the entry. All group memberships, including the static groups, dynamic groups, and nested groups, can be returned with the `ibm-allGroups` attribute.

WebSphere Application Server supports dynamic groups, nested groups, and static groups in IBM Tivoli Directory Server using the `ibm-allGroups` attribute. To utilize this attribute in a security authorization application, use a case-insensitive match so that attribute values returned by the `ibm-allGroups` attribute are all in uppercase.

**Important:** It is recommended that you do not install IBM Tivoli Directory Server Version 6.0 on the same machine that you install Version 8.0. IBM Tivoli Directory Server Version 6.0 includes WebSphere Application Server, Express Version 5.1.1, which the directory server uses for its administrative console. Install the Web Administration tool Version 6.0 and WebSphere

Application Server, ExpressVersion 5.1.1, which are both bundled with IBM Tivoli Directory Server Version 6.0, on a different machine from Version 8.0. You cannot use Version 8.0 as the administrative console for IBM Tivoli Directory Server. If IBM Tivoli Directory Server Version 6.0 and Version 8.0 are installed on the same machine, you might encounter port conflicts.

If you must install IBM Tivoli Directory Server Version 6.0 and Version 8.0 on the same machine, consider the following information:

- During the IBM Tivoli Directory Server installation process, you must select both the **Web Administration tool** and **WebSphere Application Server, Express Version 5.1.1**.
- Install Version 8.0.
- When you install Version 8.0, change the port number for the application server.
- You might need to adjust the WebSphere Application Server environment variables on Version 8.0 for *WAS\_HOME* and *WAS\_INSTALL\_ROOT* (or *APP\_SERVER\_ROOT* for IBM i). To change the variables using the administrative console, click **Environment > WebSphere Variables**.

- **Using a Lotus Domino Enterprise Server as the LDAP server**

If you select the Lotus Domino Enterprise Server Version 6.5.4 or Version 7.0 and the attribute short name is not defined in the schema, you can take either of the following actions:

- Change the schema to add the short name attribute.
- Change the user ID map filter to replace the short name with any other defined attribute (preferably to UID). For example, change `person:shortname` to `person:uid`.

The userID map filter is changed to use the uid attribute instead of the shortname attribute as the current version of Lotus Domino does not create the shortname attribute by default. If you want to use the shortname attribute, define the attribute in the schema and change the userID map filter.

User ID Map :    person:shortname

- **Using Sun ONE Directory Server as the LDAP server**

You can select **Sun ONE Directory Server** for your Sun ONE Directory Server system. In Sun ONE Directory Server, the object class is the default `groupOfUniqueName` when you create a group. For better performance, WebSphere Application Server uses the User object to locate the user group membership from the `nsRole` attribute. Create the group from the role. If you want to use the `groupOfUniqueName` attribute to search groups, specify your own filter setting. Roles unify entries. Roles are designed to be more efficient and easier to use for applications. For example, an application can locate the role of an entry by enumerating all the roles that are possessed by a given entry, rather than selecting a group and browsing through the members list. When using roles, you can create a group using a:

- Managed role
- Filtered role
- Nested role

All of these roles are computable by the `nsRole` attribute.

- **Using Microsoft Active Directory server as the LDAP server**

To use Microsoft Active Directory as the LDAP server for authentication with WebSphere Application Server you must take specific steps. By default, Microsoft Active Directory does not permit anonymous LDAP queries. To create LDAP queries or to browse the directory, an LDAP client must bind to the LDAP server using the distinguished name (DN) of an account that has the authority to search and read the values of LDAP attributes, such as user and group information, needed by the Application Server. A group membership search in the Active Directory is done by enumerating the `memberof` attribute for a given user entry, rather than browsing through the member list in each group. If you change the default behavior to browse each group, you can change the **Group Member ID Map** field from `memberof:member` to `group:member`.

The following steps describe how to set up Microsoft Active Directory as your LDAP server.

### Procedure

1. Determine the full distinguished name (DN) and password of an account in the administrators group.
2. Determine the short name and password of any account in the Microsoft Active Directory.
3. Use the WebSphere Application Server administrative console to set up the information that is needed to use Microsoft Active Directory.
  - a. Click **Security > Global security**.
  - b. Under User account repository, select **Standalone LDAP registry** and click **Configure**.
  - c. Set up LDAP with Active Directory as the type of LDAP server. Based on the information that is determined in the previous steps, you can specify the following values on the LDAP settings panel:

#### Primary administrative user name

Specify the name of a user with administrative privileges that is defined in the registry. This user name is used to access the administrative console or used by wsadmin.

**Type** Specify Active Directory

**Host** Specify the domain name service (DNS) name of the machine that is running Microsoft Active Directory.

#### Base distinguished name (DN)

Specify the domain components of the DN of the account that is chosen in the first step.  
For example: dc=ibm, dc=com

#### Bind distinguished name (DN)

Specify the full distinguished name of the account that is chosen in the first step. For example: cn=adminUsername, cn=users, dc=ibm, dc=com

#### Bind password

Specify the password of the account that is chosen in the first step.

- d. Click **OK** and **Save** to save the changes to the master configuration.
4. Click **Security > Global security**.
  5. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
  6. Select either the **Automatically generated server identity** or **Server identity that is stored in the repository** option. If you select the **Server identity that is stored in the repository** option, enter the following information:

#### Server user ID or administrative user on a Version 6.0.x node

Specify the short name of the account that is chosen in the second step.

#### Server user password

Specify the password of the account that is chosen in the second step.

7. Optional: Set ObjectCategory as the filter in the Group member ID map field to improve LDAP performance.
  - a. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
  - b. Add ;objectCategory:group to the end of the Group member ID map field.
8. Click **OK** and **Save** to save the changes to the master configuration.
9. Stop and restart the administrative server so that the changes take effect.

### **Locating user group memberships in a Lightweight Directory Access Protocol registry:**

You can configure WebSphere Application Server security to use Lightweight Directory Access Protocol (LDAP) servers. The LDAP specifications allow for different mechanisms to define group memberships.

Depending on your LDAP server implementation, you can use methods to determine group memberships. WebSphere Application Server can search group memberships directly or indirectly. Also, you can configure the product to search one or more static groups, recursive or nested groups, and dynamic groups for some Lightweight Directory Access Protocol (LDAP) servers.

## Procedure

- Evaluate group memberships.
  - **Static group membership:** All LDAP server implementations support static group membership. The group object contains a list of users or groups that are members of the group. To determine the groups in which a user is a member, you must get the list of all groups, and then query each group in turn to see if the user is a member of that group. This operation results in (0)zero groups and does not scale well.

Several LDAP servers enable user objects in the LDAP server to contain information about the groups to which they belong. Examples of LDAP servers that support direct group searches include Microsoft Active Directory Server and the owner of eDirectory.

- **Dynamic group memberships**

Some user group memberships are computable from attributes within the user object. IBM Directory Server and Sun ONE Directory Server are two examples of LDAP servers that support dynamic group membership. In some LDAP servers, you can use an attribute to include a user's dynamic group memberships, nesting group memberships, and static group memberships to determine all the group memberships from a single attribute.

For example, in IBM Directory Server, you can return all group memberships including the static groups, dynamic groups, and nested groups using the `ibm-allGroups` attribute. In the Sun ONE directory server you can use the `nsRole` attribute to calculate, all roles, including managed roles, filtered roles, and nested roles. If an LDAP server has such an attribute in a User object to include dynamic groups, nested groups, and static groups, you can configure WebSphere Application Server security to use this attribute to determine these groups.

Depending on the implementation, and LDAP server can calculate dynamic group membership. In this case, this dynamic computation is performed entirely by the LDAP server under a single LDAP query and is invisible to WebSphere Application Server. While this approach is not as efficient as direct groups, server-side dynamic queries are more efficient than determining group membership using static group queries.

Dynamic group membership, when it is supported by the LDAP server, is frequently reflected back to the LDAP client, which is the WebSphere Application Server. In this configuration, WebSphere Application Server is required to compose the appropriate dynamic query against LDAP for each group. This operation results in 0(zero) groups and does not scale well.

### Tips:

- Use the efficient direct group membership where possible.
- Use the relatively efficient dynamic group membership where the LDAP computes membership within a single query.
- Use static group membership, or client side dynamic group membership as a secondary alternative. This option only performs well on systems where the number of groups within the LDAP server is "small".

The configurations for the supported, listed LDAP servers are pre-defined to use the optimal group membership mechanisms. They assume that the standard object types and schemas for that LDAP vendor are in use on the LDAP server.

- Evaluate the LDAP registry configuration.
  - **Standalone LDAP registry**

If you are configuring an LDAP server outside of the list of pre-configured types, you must configure the appropriate value in the Group Member ID map field on the Advanced LDAP Settings panel using the following methods.

- If you use static group membership, you must specify objectclass:attribute pairs. If the objectclass for the group object is, **groupOfUniquePersons**, and within that objectclass, members are listed as **persons**, then the static group membership **Group Member ID map** is **groupOfUniquePersons:persons**.
- If direct group membership is used, attributes exist in the objectclass, you must use attribute:attribute pairs. For example, if the objectclass for the user is **user** and the objectclass contains attributes called **ingroup**, which contains each group membership, then the direct group membership **Group Member ID map** is **ingroup:member**.

– **LDAP Registry within a Federated Repositories Registry**

If you are configuring an LDAP server outside of the list of pre-configured types, you must configure the appropriate value in the **Group attribute definition** properties for the repository.

- If static group membership is used, you must specify the name of the object class, and the attribute that is used for indicating membership in **Group attribute definition -> Member attributes**. If the group objectclass for the user is, **groupOfUniquePersons**, and within that objectclass, members are listed as **persons**, then the static group **Member attributes** property is set follows:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Member attributes**.
7. Click **New** to specify a new member attribute.

Set the **Name of member attribute** field to persons

Set the **Object class field** to groupOfUniquePersons

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

- If direct group membership is used, then attributes exist in the objectclass for the user and you must use the attribute. For example, if the objectclass for the user is **user**, and it contains attributes called **ingroup** that contain each group membership, then you specify the direct group membership in the **Group attribute definition** property for the repository. Perform the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.

Set the **Name of group membership attribute** field to ingroup.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

- Use the sample entries of objectClass:attribute pairs in the Group member ID map field.
  - dominoGroup:member for Lotus Domino
  - groupOfNames:member for eDirectory
- Evaluate Nested Groups.
  - **Nested Groups**

Depending on the LDAP server implementation, groups can contain only users, or can contain other groups, which is known as a nested group. You configure WebSphere Application Server to properly discover all groups by following this nesting as it applies to either a stand-alone LDAP registry or a LDAP Registry within a Federated Repositories Registry.

- **Standalone LDAP Registry** The stand-alone LDAP registry default setting performs only a single group membership query. If the groups returned are in fact subgroups of other groups, you must enable the **Perform a nested group search** property on the Advanced LDAP Settings panel of the LDAP registry as follows:
  1. Click **Security > Global security**.
  2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
  3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.

Put a check mark in the **Perform a nested group search** check box.

- **LDAP Registry within a Federated Repositories Registry** Within Federated repositories, you must configure what you expect the results of the query to return. Based on this information, the Federated repository makes the appropriate calls to establish all group membership. If the LDAP server returns all nested group information within a single direct group query, then you set the **Scope of group membership** attribute property in the group attribute definition to **Nested**. as follows:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.

Set the **Scope of group membership** attribute property in the group attribute definition to **Nested**.

- If the LDAP server returns only the direct membership, then the registry must then make subsequent queries to establish complete membership. To force the Federated Repository to issue subsequent queries, set the **Scope of group membership** attribute property in the **Group attribute definition** for the repository to **Direct**.

## Results

While using the direct method, dynamic groups, recursive groups, and static groups can be returned as multiple values of a single attribute. For example, in IBM Directory Server all group memberships, including the static groups, dynamic groups, and nested groups, can be returned using the `ibm-allGroups` attribute. In Sun ONE, all roles, including managed roles, filtered roles, and nested roles, are calculated using the `nsRole` attribute. If an LDAP server can use the `nsRole` attribute, dynamic groups, nested groups, and static groups are all supported by WebSphere Application Server.

Some LDAP servers do not have recursive computing functionality. For example, although Microsoft Active Directory server has direct group search capability using the `memberOf` attribute, this attribute lists the groups beneath, which the group is directly nested only and does not contain the recursive list of nested predecessors. The Lotus Domino LDAP server only supports the indirect method to locate the group memberships for a user. You cannot obtain recursive group memberships from a Domino server directly. For LDAP servers without recursive searching capability, WebSphere Application Server security provides a recursive function that is enabled by clicking **Perform a Nested Group Search** in the Advanced LDAP user registry settings. Select this option only if your LDAP server does not provide recursive searches and you want a recursive search.

### *Configuring dynamic and nested group support for the SunONE or iPlanet Directory Server:*

Configure dynamic and nested groups to simplify WebSphere Application Server security management and increase its effectiveness and flexibility.

#### **Before you begin**

To use dynamic and nested groups with WebSphere Application Server security, you must be running WebSphere Application Server Version 6.1 or later. Refer to “Dynamic groups and nested group support for LDAP” on page 1502 for more information on this topic.

#### **Procedure**

1. In the administrative console for WebSphere Application Server, click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Select SunONE for the type of LDAP server.
4. Select the **Ignore case for authorization** option.
5. Under Additional Properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
6. Change the Group filter setting to `&(cn=%v)(objectclass=ldapsubentry)`.
7. Change the Group member ID map setting to `nsRole:nsRole`.
8. Click **Apply** or **OK** to validate the changes.

### *Configuring dynamic and nested group support for the IBM Tivoli Directory Server:*

Configure dynamic and nested groups to simplify WebSphere Application Server security management and increase its effectiveness and flexibility.

#### **Before you begin**

When creating groups, ensure that nested and dynamic group memberships work correctly.

#### **Procedure**

1. In the administrative console for WebSphere Application Server, click **Security > Global security**.
2. Under User account repository, click **Standalone LDAP registry**, and click **Configure**.
3. Select IBM Tivoli Directory Server for the type of LDAP server.
4. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
5. Change the Group filter value to `(&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)(objectclass=groupOfURLs)))`.
6. Change the Group member ID map value to `ibm-allGroups:member;ibm-allGroups:uniqueMember`.
7. Click **Apply** or **OK** to validate the changes.
8. Verify that Auxiliary object class field on the Add an LDAP entry panel for your IBM Tivoli Directory server has the appropriate value. When you create a nested group, the Auxiliary object class value is `ibm-nestedGroup`. When you create a dynamic group, the Auxiliary object class value is `ibm-dynamicGroup`.

### **Configuring multiple LDAP servers for user registry failover:**

WebSphere Application Server security can be configured to attempt failovers between multiple Lightweight Directory Access Protocol (LDAP) hosts.

## Before you begin

The multiple LDAP servers involved in the failover can be replicas that are replicated from the same master LDAP server, or they can be any LDAP host with the same schema. That is any LDAP host that contains data that is imported from the same LDAP data interchange format (LDIF) file.

**Note:** When WebSphere Application Server attempts failovers between multiple Lightweight Directory Access Protocol (LDAP) hosts, system properties are exchanged. WebSphere Application Server Version 6.1.0 manages the SSL configuration and these system properties. You cannot expect to set system properties yourself and expect the failover to succeed.

## Procedure

1. Start the deployment manager process.
  - a. Start the Command Prompt application.
  - b. Change directories to *profile\_root*\bin.
  - c. Enter startManager.
2. Start the wsadmin Command Prompt application.
  - a. Start the Command Prompt application.
  - b. Change directories to *profile\_root*\bin.
  - c. Enter the following command:

```
wsadmin -user username -password password
```
3. Configure a second LDAP server for failover.
  - a. Enter the following command to set the failover LDAP server hostname:

```
set ldapServer [ldap server hostname]
```
  - b. Enter the following command to set the LDAP server port number:

```
set ldapPort [ldap server port]
```
  - c. Enter the following command to set the WebSphere LDAP failover variable:

```
set Attrs2 [list [list hosts [list [list [list host $ldapServer] [list port $ldapPort]]]]]
```
  - d. Modify the LDAP configuration to add the failover LDAP server by entering the following command:

```
set result [$AdminConfig list LDAPUserRegistry]
```
  - e. Find the LDAP server configID by entering the following command:

```
$AdminConfig modify $result $Attrs2
```
  - f. Enter the following command to save the configuration change:

```
$AdminConfig save
```
  - g. Enter exit to quit the Command Prompt application. The following is an example of the Command Prompt application output:

```
wsadmin>set ldapServer [list xxxx.xxxx.xxx.com]
xxxx.xxxx.xxx.com
wsadmin>set ldapPort [list NNN]
NNN
wsadmin>set Attrs2 [list [list hosts [list [list [list host $ldapServer] [list port $ldapPort]]]]]
{hosts {{{host xxxx.xxxx.xxx.com} {port NNN}}}}
wsadmin> set result [$AdminConfig list LDAPUserRegistry]
(cells/Father2Cell101|security.xml#LDAPUserRegistry_1)
wsadmin>$AdminConfig modify $result $Attrs2

wsadmin>$AdminConfig save
```
4. Review the configuration change by opening the security.xml file with a text editor and review the new entry.
5. Stop the deployment manager.
  - a. Start the Command Prompt application.

- b. Change directories to *profile\_root\bin*.
- c. To stop the deployment manager, enter the following command:  
`stopManager -user username -password password`

### **Testing an LDAP server for user registry failover:**

After configuring a Lightweight Directory Access Protocol (LDAP) host for failover you should test the failover server by stopping the main LDAP server.

### **Before you begin**

This task assumes the following setup:

- Deployment Manager is installed on the primary LDAP server running Application Server version 6.0.2 or higher.
- All other LDAP hosts are Active Directory machines with similar user registry designs.
- At least one of the other LDAP hosts has been configured for failover.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log`, `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

### **Procedure**

1. Stop the Active Directory Server on the failover server.
2. Start the deployment manager process.
  - a. Start the Command Prompt application.
  - b. Change directories to *profile\_root\bin*.
  - c. Enter `startManager`.
3. Review the `SystemOut.log` file to see if the LDAP failover happened. The sample text is an example of a `SystemOut.log` file that records a successful failover:
 

```
[7/11/05 15:38:31:324 EDT] 0000000a LdapRegistryI A SECJ0418I:
Cannot connect to the LDAP server ldap://xxx.xxxx.xxx.com:NNN. {primary LDAP server}
[7/11/05 15:38:32:486 EDT] 0000000a UserRegistryI A SECJ0136I:
Custom Registry:com.ibm.ws.security.registry.ldap.LdapRegistryImpl has been initialized
[7/11/05 15:38:53:787 EDT] 0000000a LdapRegistryI A SECJ0419I:
The user registry is currently connected to the LDAP server ldap://xxx.xxxx.xxx.com:NNN. {failover LDAP server}
...
[7/11/05 15:39:35:667 EDT] 0000000a WsServerImpl A WSVR0001I: Server dmgr open for e-business
```
4. Log into the console to see working and non-working cases.
  - a. Start a browser.
  - b. Browse to `http://localhost:9060/admin`.
  - c. Type in your user ID and password and click **OK**.
  - d. Log out of the Administrative Console.
  - e. Type in `DummyAdmin` as the user ID and `dummy1admin` as your password and click **OK**. This should fail proving WebSphere Application Server is connected to the other LDAP server. Please make sure that on a production system the user registries are identical so this problem does not happen when switching between LDAP servers.
5. Stop the deployment manager.
  - a. Start the Command Prompt application.
  - b. Change directories to *profile\_root\bin*.

- c. To stop the deployment manager, enter the following command:

```
stopManager -user username -password password
```

### **Deleting LDAP endpoints using wsadmin:**

You can delete Lightweight Directory Access Protocol (LDAP) endpoints for a user registry by using the WebSphere Application Server administrative tool (wsadmin).

#### **Procedure**

1. Start the wsadmin scripting tool.
2. Set the LDAP variable and display a list of LDAP endpoint objects. Enter the following commands:

Using Jacl:

```
set ldap [$AdminConfig list LDAPUserRegistry]
```

```
$AdminConfig list EndPoint $ldap
```

Using Jython:

```
ldap=AdminConfig.list["LDAPUserRegistry"]
```

```
print AdminConfig.show(ldap)
```

For the Jython language, you can obtain the endpoint from the host variable after running the previous command.

3. Display a list of LDAP endpoint objects. Enter the following command for each object:

Using Jacl:

```
$AdminConfig showall End_Point_Object
```

Using Jython:

```
AdminConfig.showall("End_Point_Object")
```

4. Delete an LDAP endpoint object. Enter the following command:

Using Jacl:

```
$AdminConfig remove End_Point_Object
```

Using Jython:

```
AdminConfig.remove ("End_Point_Object")
```

5. Save your configuration changes: Enter the following command:

Using Jacl:

```
$AdminConfig save
```

Using Jython:

```
AdminConfig.save()
```

### **Updating LDAP binding information:**

Use this information to dynamically update security LDAP binding information by switching to a different binding identity.

#### **About this task**

You can dynamically update Lightweight Directory Access Protocol (LDAP) binding information without first stopping and restarting WebSphere Application Server by using the **wsadmin** tool.

The `resetLdapBindInfo` method in `SecurityAdmin` MBean is used to dynamically update LDAP binding information at WebSphere Application Server security runtime, and it takes the bind distinguished name (DN) and bind password parameters as input. The `resetLdapBindInfo` method validates the bind

information against the LDAP server. If validation passes, new binding information is stored in `security.xml`, and a copy of the information is placed in WebSphere Application Server security runtime.

The MBean method also synchronizes the binding information change in `security.xml` from cell to nodes.

If the new binding information is `null`, `null`, the `resetLdapBindInfo` method first extracts LDAP binding information, including bind DN, bind password, and target binding host from WebSphere Application Server security configuration in `security.xml`. It then pushes the binding information to WebSphere Application Server security runtime.

There are two ways to dynamically update WebSphere Application Server security LDAP binding information using the SecurityAdmin MBean through `wsadmin`:

- “Switching to a different binding identity”
- “Switching to a failover LDAP host”

*Switching to a different binding identity:*

#### **About this task**

To dynamically update security LDAP binding information by switching to a different binding identity:

#### **Procedure**

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Create a new bind DN. It must have the same access authority as the current bind DN.
4. Run the SecurityAdmin MBean across all of the processes (deployment manager, nodes, and application servers) to validate the new binding information, to save it to `security.xml`, and to push the new binding information to the runtime.

#### **Example**

The following is a sample Jacl file for step 4:

```
proc LDAPReBind {args} {
 global AdminConfig AdminControl ldapBindDn ldapBindPassword
 set ldapBindDn [lindex $args 0]
 set ldapBindPassword [lindex $args 1]
 set secMBeans [AdminControl queryNames type=SecurityAdmin,*]
 set plist [list $ldapBindDn $ldapBindPassword]
 foreach secMBean $secMBeans {
 set result [AdminControl invoke $secMBean resetLdapBindInfo $plist]
 }
}
```

*Switching to a failover LDAP host:*

#### **About this task**

To dynamically update security LDAP binding information by switching to a failover LDAP host:

#### **Procedure**

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Standalone LDAP registry** and click **Configure**.
3. Change the password for bind DN on one LDAP server (it can be the primary or the backup).
4. Update the new bind DN password to WebSphere Application security runtime by calling `resetLdapBindInfo` with the bind DN and by using its new password as a parameter.
5. Use the new bind DN password for all of the other LDAP servers. The binding information is now consistent across WebSphere Application Server and the LDAP servers.

If you call `resetLdapBindInfo` with `null`, `null` as input parameters, WebSphere Application Server security runtime completes the following steps:

- a. Reads the bind DN, bind password, and target LDAP hosts from `security.xml`.
- b. Refreshes the cached connection to the LDAP server.

If you configure security to use multiple LDAP servers, this MBean call forces WebSphere Application Server security to reconnect to the first available LDAP host in the list. For example, if three LDAP servers are configured in the order of L1, L2, and L3, the reconnection process always starts with the L1 server.

When LDAP failover is configured by associating a single hostname to multiple IP addresses, entering an invalid password can cause multiple LDAP bind retries. With the default settings, the number of LDAP bind retries is equal to one more than the number of associated IP addresses. This means a single invalid login attempt can cause the LDAP account to be locked. If the `com.ibm.websphere.security.ldap.retryBind` custom property is set to `false`, LDAP bind calls are not retried.

**gotcha:** Federated repository does not support failover by associating a single hostname to multiple IP addresses. This feature is only available in stand-alone LDAP.

### **Configuring to secure Lightweight Directory Access Protocol user registry using Resource Access Control Facility based on z/OS:**

You can secure the application server by configuring Lightweight Access Directory Protocol (LDAP) on z/OS with an existing Resource Access Control Facility (RACF) back end. This integrates the native z/OS security settings defined in RACF with the WebSphere Application Server security environment.

#### **Before you begin**

The following requirements exist when implementing these steps:

- You must have an LDAP server configured with RACF based on z/OS. See z/OS Internet Library for more information about this configuration..
- You must use LDAP on z/OS v1r3 or higher. For v1r3 or v1r4, you must apply APAR 0A03857 - PTF UA06622 before following these steps.
- The user logs into WebSphere security with RACF user ID and is authenticated with the LDAP using a password and a Distinguished Name, the Bind DN. The Bind DN incorporates the RACF user ID and the SDBM suffix in the LDAP server configuration file. If the RACF user is *john*doe, and the suffix value in the SDBM section of the LDAP configuration file is *cn=myRACF*, then the bind DN is: *racfid=johndoe, profiletype=user, cn=myRACF*.
- Each RACF group, including WebSphere security groups, a user belongs to is stored in a multi-value **racfconnectgroupname** attribute in the LDAP entry for the user. The attribute is returned when a base or subtree search is performed with the user's DN as the Base DN.
- The Bind DN must represent an RACF user with *Special* or *Auditor* privileges. For more information about the required RACF authority, see the z/OS Security Server RACF Command Language Reference for your z/OS version in the z/OS Internet Library.
- You must define the **racfconnectgroupname** attribute in the LDAP default schema.

**Remember:** If you have TBDM defined in the LDAP server configuration file in addition to SDBM, the schema in TBDM is the default schema for the LDAP server. If the TBDM schema does not include the **racfconnectgroupname** attribute, remove TBDM from the LDAP server configuration file or add the schema in the `schema.user.ldif` file and `schema.IBM.ldif` file to the TBDM schema. For more information about TBDM and SDBM, see Native authentication with RACF and Tivoli Access Manager.

## Procedure

1. Click **Security > Global security**.
2. Under User account repository, select **Standalone LDAP registry** and then click **Configure**.
3. Under the Type of LDAP server, click **Custom**.
4. Complete the fields for your LDAP environment. For more information, see “Configuring Lightweight Directory Access Protocol user registries” on page 1352. The users and groups must be in the sub tree of the Base DN.
5. Make sure that **Ignore case for authorization** is selected. RACF user names and group names are not case-sensitive.
6. Click **Apply** and then click **Save**.
7. Under Additional Properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry setting**.
8. Change User filter and Group filter to `racfid=%v`.
9. Change User ID map and Group ID Map to `*:racfid`.
10. Change Group member ID map to `racfconnectgroupname:racfgroupuserids`.
11. Click **Apply** and click **Save**.
12. Assign the administrative role to a user. See “Authorizing access to administrative roles” on page 1782 for more information.
13. Restart WebSphere Application Server.

## Results

Your environment is now protected by LDAP on z/OS with a RACF back end.

## Configuring stand-alone custom registries

Use the following information to configure stand-alone custom registries through the administrative console.

### Before you begin

Before you begin this task, implement and build the UserRegistry interface. For more information on developing stand-alone custom registries refer to Developing stand-alone custom registries. The following steps are required to configure stand-alone custom registries through the administrative console.

## Procedure

1. Click **Security > Global security**.
2. Under User account repositories, select **Stand-alone custom registry** and click **Configure**.
3. Enter a valid user name in the Primary administrative user name field. This ID is the security server ID, which is only used for WebSphere Application Server security and is not associated with the system process that runs the server. The server calls the local operating system registry to authenticate and obtain privilege information about users by calling the native APIs in that particular registry.
4. Enter the dot-separated class name that implements the `com.ibm.websphere.security.UserRegistry` interface in the Custom registry class name field. For the sample, this file name is `com.ibm.websphere.security.FileRegistrySample`.  
This file exists in all the product processes. Thus, this file exists in the cell class path and in all of the node class paths.  
**Attention:** The sample provided is intended to familiarize you with this feature. Do not use this sample in an actual production environment.
5. Add your custom registry class name to the class path. It is recommended that you add the Java Archive (JAR) file that contains your custom user registry implementation to the following directory:

- `app_server_root/lib/ext`
6. Optional: Select the **Ignore case for authorization** option for the authorization to perform a case insensitive check. Enabling this option is necessary only when your user registry is case insensitive and does not provide a consistent case when queried for users and groups.
  7. Click **Apply** if you have any other additional properties to enter for the registry initialization.
  8. Optional: Enter additional properties to initialize your implementation.
    - a. Click **Custom properties > New**.
    - b. Enter the property name and value.
 

For the sample, enter the following two properties. It is assumed that the `users.props` file and the `groups.props` file are in the `customer_sample` directory under the product installation directory. You can place these properties in any directory that you choose and reference their locations through custom properties. However, make sure that the directory has the appropriate access permissions.

Table 89. Additional properties.

This table lists additional custom properties when configuring stand-alone custom registries.

| Property name | Property value                                                   |
|---------------|------------------------------------------------------------------|
| usersFile     | <code>\${USER_INSTALL_ROOT}/customer_sample /users.props</code>  |
| groupsFile    | <code>\${USER_INSTALL_ROOT}/customer_sample /groups.props</code> |

Samples of these two properties are available in “users.props file” on page 1402 and “groups.props file” on page 1402.

To use the `users.props` and the `groups.props` files on the z/OS platform, save these files in the ASCII format before calling them from the administrative console.

The **Description**, **Required**, and **Validation Expression** fields are not used and can remain blank.

In a WebSphere Application Server, Network Deployment environment where multiple WebSphere Application Server processes exist, such as cell and multiple nodes in different machines, these properties are available for each process. Use the `USER_INSTALL_ROOT` relative name to locate any files, as this name expands to the product installation directory. If this name is not used, ensure that the files exist in the same location in all the nodes.

WebSphere Application Server version 4-based custom user registry is migrated to the custom user registry based on the `com.ibm.websphere.security.UserRegistry` interface.

- c. Click **Apply**.
  - d. Repeat this step to add other additional properties.
9. Click **Security > Global security**.
10. Under User account repository, click the **Available realm definitions** drop-down list, select **Stand-alone custom registry**, and click **Configure**.
11. Select either the **Automatically generated server identity** or **Server identity that is stored in the repository** option. If you select the **Server identity that is stored in the repository** option, enter the following information:
  - Server user ID or administrative user on a Version 6.0.x node**  
Specify the short name of the account that is chosen in the second step.
  - Server user password**  
Specify the password of the account that is chosen in the second step.
12. Click **OK** and complete the required steps to turn on security.

## Results

This set of steps is required to set up the stand-alone custom registry and to enable security in WebSphere Application Server.

**Note:** The security component of WebSphere Application Server expands a selected list of variables when enabling security. See the information about variable settings for more details.

### What to do next

1. Complete the remaining steps, if you are enabling security.
2. Validate the user and password. Save and synchronize in the cell environment.
3. After security is turned on, save, stop, and start all the product servers, including cell, nodes, and all of the application servers, for any changes to take effect. If the server comes up without any problems, the setup is correct.

### **Stand-alone custom registries:**

A *stand-alone custom registry* is a customer-implemented registry that implements the UserRegistry Java interface, as provided by the product. A custom-implemented registry can support virtually any type of an account repository from a relational database, flat file, and so on. The custom user registry provides considerable flexibility in adapting product security to various environments where some form of a registry or repository other than federated repositories, stand-alone Lightweight Directory Access Protocol (LDAP) registry or local operating system registry already exists in the operational environment.

WebSphere Application Server security provides an implementation that uses various local operating system-based registries and various stand-alone Lightweight Directory Access Protocol (LDAP)-based registries. However, situations can exist where your user and group data resides in other repositories or custom user registries, such as a database, and moving this information to either a local operating system registry or a stand-alone LDAP registry implementation might not be feasible. For these situations, WebSphere Application Server security provides a service provider interface (SPI) that you can implement to interact with your current registry. The custom registry feature supports any user registry that is not implemented by WebSphere Application Server.

The SPI is the UserRegistry interface. The *UserRegistry interface* is a collection of methods that are required for authorization purposes. These methods authenticate individual users using either a password or certificates and collect information about the user, which are called privilege attributes. This interface also includes methods that obtain user and group information so that they can be given access to resources. When implementing the methods in the interface, you must decide how to map the information that is manipulated by the UserRegistry interface to the information in your registry.

This interface has a set of methods to implement for the product security to interact with your registries for all security-related tasks. The local operating system and LDAP registry implementations that are provided also implement this interface. Custom user registries are sometimes called the *pluggable user registries* or *custom registries* for short. Your custom user registry implementation is expected to be thread-safe.

Building a custom registry is a software implementation effort. The implementation does not depend on other WebSphere Application Server resources, for example, data sources, for its operation.

Make sure that your implementation of the custom registry does not depend on any WebSphere Application Server components such as data sources, enterprise beans, and so on. Do not have this dependency because security is initialized and enabled prior to most of the other WebSphere Application Server components during startup. If your previous implementation used these components, make a change that eliminates the dependency.

The methods in the UserRegistry interface operate on the following information for users:

### User security name

The user name is similar to the user name in the local operating system registries.

This name is used to log in when prompted by a secured application. By default, the Enterprise JavaBeans (EJB) `getCallerPrincipal` method and the `getRemoteUser` and `getUserPrincipal` servlet methods return this name. The user security name is also referred to as *userSecurityName*, *userName*, or *user name*.

### WAS\_UseDisplayName

This is a custom property of User Registries. This property defines the returning value of the `getCallerPrincipal()`, `getUserPrincipal()`, and `RemoteUser()` methods. The following shows acceptable values for `WAS_UseDisplayName`:

- `false` This is default. Security Name is returned.
- `true` The display name is returned. This setting requires that the custom property `com.ibm.websphere.security.useLoggedSecurityName` be set to `true`.

### Unique user ID

This ID represents a unique identifier for the user, which is required by the `UserRegistry` interface. The unique ID is similar to the system ID (SID) in Windows systems, the Unique ID (UID) in Linux and UNIX systems, and the distinguished name (DN) in Lightweight Directory Authentication Protocol (LDAP). This ID is also referred to as *uniqueUserId*. The unique ID is used to make the authorization decisions for protected resources.

### Display user name

This name is an optional string that describes a user. The implementation can use display names for informational purposes only; these names are not required to exist or to be unique. The user interface can use the display name to present more information about the user.

### Group security name

This name, which represents the security group, is also referred to as *groupSecurityName*, *groupName*, and *group name*.

### Unique group ID

The unique ID is the identifier for a group. This name is also referred to as *uniqueGroupId* ID.

### Display group name

The display name is an optional string that describes a group.

The topic on `UserRegistry` interface describes each of the methods in the interface that need implementing. An explanation of each of the methods and their usage in the sample and any changes from the Version 4 interface are provided. The Related references section provides links to all other custom user registries documentation, including a file-based registry sample. The Sample provided is very simple and is intended to familiarize you with this feature. Do not use this sample in an actual production environment.

### Stand-alone custom registry settings:

Use this page to configure the stand-alone custom registry.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Stand-alone custom registry**, and click **Configure**.

After the properties are set in this panel, click **Apply**. Under Additional Properties, click **Custom properties** to include additional properties that the custom user registry requires.

**Note:** Custom properties might include information such as specifying lists of users or groups.

When security is enabled and any of these custom user registry settings change, go to the Global security panel and click **Apply** to validate the changes.

WebSphere Application Server Version 7.0 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

**Note:** Any settings that are related to the System Authorization Facility (SAF) might not be visible on this panel. To modify these settings:

1. Go to the panel for SAF by clicking **Security > Global security > External authorization providers**.
2. Select **System Authorization Facility (SAF)** from the drop-down list under the Authorization provider option.
3. Click **Configure**.

*Primary administrative user name:*

Specifies the name of a user with administrative privileges that is defined in your custom user registry.

The user name is used to log onto the administrative console when administrative security is enabled. Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

**Attention:** In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

*Automatically generated server identity:*

Enables the application server to generate the server identity, which is recommended for environments that contain only Version 6.1 or later nodes. Automatically generated server identities are not stored in a user repository.

**Default:** Enabled

*User identity for the z/OS started task:*

Specifies the user identity that is associated with the z/OS system started task. Each controller and server can have its own identity.

*Custom registry class name:*

Specifies a dot-separated class name that implements the `com.ibm.websphere.security.UserRegistry` interface.

Put the custom registry class name in the class path. A suggested location is the following directory.

- `%install_root%/lib/ext`

**Data type:** String  
**Default:** `com.ibm.websphere.security.FileRegistrySample`

*Ignore case for authorization:*

Indicates that a case-insensitive authorization check is performed when you use the default authorization.

**Default:** Disabled

**Range:**

Enabled or Disabled

### ***Stand-alone custom registry wizard settings:***

A wizard page exists in the administrative console to aid in viewing the basic settings necessary to connect the application server to an existing stand-alone custom registry. After you have viewed the basic settings, you can also modify the existing stand-alone customer registry configuration using the administrative console.

To view this security wizard page, complete the following steps:

1. Click **Security > Global security > Security configuration wizard**.
2. Select your protection settings and click **Next**.
3. Select the **Stand-alone custom registry** option and click **Next**.

You can modify your stand-alone custom registry configuration by completing the following steps:

1. Click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Stand-alone custom registry**, and click **Configure**.
3. Enter additional properties to initialize your implementation
  - Click **Custom properties > New**.
  - Enter the property name and value. For the sample, enter the following two properties. It is assumed that the `users.props` file and the `groups.props` file are in the `customer_sample` directory under the product installation directory. You can place these properties in any directory that you choose and reference their locations through Custom properties. However, make sure that the directory has the appropriate access permissions.

*Table 90. Custom properties.*

*This table lists additional custom properties when changing stand-alone custom registry wizard settings.*

| Property name | Property value                                                   |
|---------------|------------------------------------------------------------------|
| usersFile     | <code>\${USER_INSTALL_ROOT}/customer_sample /users.props</code>  |
| groupsFile    | <code>\${USER_INSTALL_ROOT}/customer_sample /groups.props</code> |

Samples of these two properties are available in reference topics for the `users.props` file and the `groups.props` file. See the related links below for more information.

The Description, Required, and Validation Expression fields are not used and can remain blank.

WebSphere Application Server Version 4 based custom user registry is migrated to the custom user registry based on the `com.ibm.websphere.security.UserRegistry` interface.

- Click **Apply**.

### *Primary administrative user name:*

Specifies the name of a user with administrative privileges that is defined in your custom user registry.

The user name is used to log onto the administrative console when administrative security is enabled. Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

**Attention:** In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

*Custom registry class name:*

Specifies a dot-separated class name that implements the com.ibm.websphere.security.UserRegistry interface.

Put the custom registry class name in the class path. A suggested location is the following directory.

- %install\_root%/lib/ext

**Data type:** String  
**Default:** com.ibm.websphere.security.FileRegistrySample

*Ignore case for authorization:*

Indicates that a case-insensitive authorization check is performed when you use the default authorization.

**Default:** Disabled  
**Range:** Enabled or Disabled

***FileRegistrySample.java file:***

This provides an example of the FileRegistrySample.java file.

The user and group information required by this sample is contained in the "users.props file" on page 1402 and "groups.props file" on page 1402 files.

**Attention:** The samples that are provided are intended to familiarize you with this feature. Do not use these samples in an actual production environment.

The contents of the FileRegistrySample.java file:

 * (for example if there are a large number of users) you can create
 * the NotImplementedException for that particular group. Make sure
 * that if the process choreographer is installed (or if installed later)
 * the staff assignments are not modeled using these particular groups.
 * If there is no concern about returning the users from groups
 * in the registry it is recommended that this method be implemented
 * without creating the NotImplementedException.
 * @param groupSecurityName the name of the group
 * @param Limits the maximum number of users that should be
 * returned. This is very useful in situations where there
 * are lots of users in the registry and getting all of
 * them at once is not practical. A value of 0 implies

```

```

* get all the users and hence must be used with care.
* @return A Result object that contains the list of users
* requested and a flag to indicate if more users exist.
* @deprecated This method will be deprecated in future.
* @exception NotImplementedException create this exception in rare
* situations if it is not practical to get this information
* for any of the group or groups from the registry.
* @exception EntryNotFoundException if the group does not exist in
* the registry
* @exception CustomRegistryException if there is any registry-specific
* problem

### **Using a DB2 database to hold custom user registry data:**

A custom user registry can use a DB2 database to maintain the user and password information.

#### **About this task**

However, to maintain the user and password information, you must adhere to the following configuration requirements and restrictions:

- You must use the DB2 Universal Java database connectivity (JDBC) Driver to access the DB2 database that is used by the custom user registry. Also, the driver must be a type 4 driver.  
You cannot use the legacy DB2 for z/OS JDBC Driver or a type 2 DB2 Universal JDBC Driver because both of these drivers use Resource Recovery Services (RRS). If you use these drivers, the custom user registry DB2 server requests interfere with the user application processing under the same thread.
- Because you must use the DB2 Universal JDBC Driver, do not define any JDBC resources under the server that require the legacy DB2 for z/OS JDBC Driver.  
For example, do not define a DB2 for z/OS JDBC Provider (RRS) because the legacy DB2 for z/OS JDBC Driver cannot coexist with the DB2 Universal JDBC Driver.
- You must have an unmanaged DB2 data source or connection that is used by the custom user registry. The data source or connection must not rely on any WebSphere Application Server resource management. For example, the data source or connection cannot rely on Java Naming and Directory Interface (JNDI) lookup, pooling, datastore helpers, XA resource or transaction processing, connection management, and so on.
- To connect a custom user registry to a DB2 database, you can use one of the following approaches:
  - Use the Java Platform DriverManager to register an instance of the `com.ibm.db2.jcc.DB2Driver` class, which is packaged in the DB2 Universal JDBC Driver. Then, invoke the DriverManager to get a DB2 connection using a DB2 Type 4 URL that defines the target DB2 database.
  - Use the `com.ibm.db2.jcc.DB2DataSource` class, which that is packaged in the DB2 Universal JDBC Driver, to set up a data source. Set the data source properties to specify the target DB2 database and other options. Then, get a connection from the data source.

**Important:** For more information on how to use these approaches, see DB2 UDB for z/OS Version 8 Application Programming Guide and Reference for Java.

Complete the following steps to define the JDBC driver for WebSphere Application Server. You must set up the following DB2 JDBC Universal Driver configuration before you define your custom user registry for the WebSphere Application Server for z/OS security component.

#### **Procedure**

1. Define the DB2 Universal JDBC Driver in the `ws.ext.dirs` class path for the servant. To define the driver, complete the following steps in the administrative console:
  - a. Click **Servers > Application servers > *server\_name***.
  - b. Under Server Infrastructure, click **Java and Process Management > Process definition > Servant**.
  - c. Under Additional properties, click **Java Virtual Machine**.
  - d. Under Additional properties, click **Custom properties**.
  - e. Click **New** and define the driver. Create the new property using the following information:

**Property name**

ws.ext.dirs

**Property value**

```
db2jcc.jar_directory_path/db2jcc.jar:license_jar_directory_path/
db2jcc_license_cisuz.jar
```

2. Define the DB2 Universal JDBC Driver in the ext.dirs class path for the controller. To define the driver, complete the following steps in the administrative console:
  - a. Click **Servers > Application servers > server\_name**.
  - b. Under Server Infrastructure, click **Java and Process Management > Process definition > Controller**.
  - c. Under Additional properties, click **Java Virtual Machine**.
  - d. Under Additional properties, click **Custom properties**.
  - e. Click **New** and define the driver. Create the new property using the following information:

**Property name**

ws.ext.dirs

**Property value**

```
db2jcc.jar_directory_path/db2jcc.jar:license_jar_directory_path/
db2jcc_license_cisuz.jar
```

3. Recycle the server.

***Developing the UserRegistry interface for using custom registries:***

Implementing this interface enables WebSphere Application Server security to use custom registries. This capability extends the java.rmi file. With a remote registry, you can complete this process remotely.

**About this task**

Provide implementations of the following methods.

**Procedure**

- Initialize the UserRegistry method, with initialize(java.util.Properties).

```
public void initialize(java.util.Properties props)
 throws CustomRegistryException,
 RemoteException;
```

This method is called to initialize the UserRegistry method. All the properties that are defined in the Custom User Registry panel propagate to this method.

For the FileRegistrySample.java sample file, the initialize method retrieves the names of the registry files that contain the user and group information.

This method is called during server bringup to initialize the registry. This method is also called when validation is performed by the administrative console, when security is on. This method remains the same as in Version 4.x.

- Authenticate users with checkPassword(String,String).

```
public String checkPassword(String userSecurityName, String password)
 throws PasswordCheckFailedException
 CustomRegistryException,
 RemoteException;
```

The checkPassword method is called to authenticate users when they log in using a name or user ID and a password. This method returns a string which, in most cases, is the user security name. A credential is created for the user for authorization purposes. This user name is also returned for the getCallerPrincipal enterprise bean call and the servlet calls the getUserPrincipal and getRemoteUser

methods. See the `getUserDisplayName` method for more information if you have display names in your registry. In some situations, if you return a user other than the one who is logged in, you must verify that the user is valid in the registry.

For the `FileRegistrySample.java` sample file, the `mapCertificate` method gets the distinguished name (DN) from the certificate chain and makes sure it is a valid user in the registry before returning the user. For the sample, the `checkPassword` method checks the name and password combination in the user registry and, if they match, the method returns the user being authenticated.

This method is called for various scenarios, for example, by the administrative console to validate the user information after the user registry is initialized. This method is also called when you access protected resources in the product for authenticating the user and before proceeding with the authorization. This method is the same as in Version 4.x.

- Obtain user names from X.509 certificates with `mapCertificate(X509Certificate[])`.

```
public String mapCertificate(X509Certificate[] cert)
 throws CertificateMapNotSupportedException,
 CertificateMapFailedException,
 CustomRegistryException,
 RemoteException;
```

The `mapCertificate` method is called to obtain a user name from an X.509 certificate chain that is supplied by the browser. The complete certificate chain is passed to this method and the implementation can validate the chain if needed and get the user information. A credential is created for this user for authorization purposes. If browser certificates are not supported in your configuration, you can create the `CertificateMapNotSupportedException` exception. The consequence of not supporting certificates is authentication failure if the challenge type is certificates, even if valid certificates are in the browser.

This method is called when certificates are provided for authentication. For web applications, when the authentication constraints are set to `CLIENT-CERT` in the `web.xml` file of the application, this method is called to map a certificate to a valid user in the registry. For Java clients, this method is called to map the client certificates in the transport layer, when using transport layer authentication. When the identity assertion token, using the `CSlv2` authentication protocol, is set to contain certificates, this method is called to map the certificates to a valid user.

In WebSphere Application Server Version 4.x, the input parameter is the `X509Certificate` certificate. In WebSphere Application Server Version 5.x and later, this parameter changes to accept an array of `X509Certificate` certificates such as a certificate chain. In Version 4.x, this parameter is called for web applications only, but in version 5.x and later, you can call this method for both web and Java clients.

- Obtain the security realm name with `getRealm`.

```
public String getRealm()
 throws CustomRegistryException,
 RemoteException;
```

The `getRealm` method is called to get the name of the security realm. The name of the realm identifies the security domain for which the registry authenticates users. If this method returns a null value, a `customRealm` default name is used.

For the `FileRegistrySample.java` sample file, the `getRealm` method returns the `customRealm` string. One of the calls to this method occurs when the user registry information is validated. This method is the same method as in Version 4.x.

- Obtain the list of users from the registry with `getUsers(String,int)`.

```
public Result getUsers(String pattern, int limit)
 throws CustomRegistryException,
 RemoteException;
```

The `getUsers` method returns the list of users from the registry. The names of users depend on the pattern parameter. The number of users are limited by the limit parameter. In a registry that has many users, getting all the users is not practical. So the limit parameter is introduced to limit the number of users retrieved from the registry. A limit of zero (0) indicates to return all the users that match the pattern and might cause problems for large registries. Use this limit with care.

The custom registry implementations are expected to support at least the wildcard search (\*). For example, a pattern of asterisk (\*) returns all the users and a pattern of (b\*) returns the users starting with *b*.

The return parameter is an object with a `com.ibm.websphere.security.Result` type. This object contains two attributes, a `java.util.List` and a `java.lang.Boolean` attribute. The list contains the users that are returned and the Boolean flag indicates if more users are available in the user registry for the search pattern. This Boolean flag is used to indicate to the client whether more users are available in the registry.

In the `FileRegistrySample.java` sample file, the `getUsers` method retrieves the required number of users from the user registry and sets them as a list in the Result object. To find out if more users are presented than requested, the sample gets one more user than requested and if it finds the additional user, it sets the Boolean flag to `true`. For pattern matching, the `match` method in the `RegExpSample` class is used, which supports wildcard characters such as the asterisk (\*) and the question mark (?).

This method is called by the administrative console to add users to roles in the various map-users-to-roles panels. The administrative console uses the Boolean set in the Result object to indicate that more entries matching the pattern are available in the user registry.

In WebSphere Application Server Version 4.x, this method specifies to take only the pattern parameter. The return is a list. In WebSphere Application Server Version 5.x or later, this method is changed to take one additional parameter, the limit. Ideally, your implementation changes to take the limit value and limits the users that are returned. The return is changed to return a Result object, which consists of the list and a flag that indicates if more entries exist. When the list returns, use the `Result.setList(List)` method to set the list in the Result object. If more entries exist than requested in the limit parameter, set the Boolean attribute to `true` in the result object, using the `Result.setHasMore` method. The default for the Boolean attribute in the result object is `false`.

- Obtain the display name of a user with `getUserDisplayName(String)`.

```
public String getUserDisplayName(String userSecurityName)
 throws EntryNotFoundException,
 CustomRegistryException,
 RemoteException;
```

The `getUserDisplayName` method returns a display name for a user, if one exists. The display name is an optional string that describes the user that you can set in some registries. This descriptive name is for the user and does not have to be unique in the registry.

For example in Windows systems, you can display the full name of the user.

If you do not need display names in your registry, return null or an empty string for this method.

If display names existed for any user in WebSphere Application Server Version 4.x, these names were useful for the Enterprise JavaBean (EJB) method call `getCallerPrincipal` and the servlet calls `getUserPrincipal` and `getRemoteUser`. If the display names are not the same as the security name for any user, the display names are returned for the previously mentioned enterprise beans and servlet methods. Returning display names for these methods might become problematic in some situations because the display names might not be unique in the user registry. Avoid this problem by changing the default behavior to return the user security name instead of the user display name in this version of the product. For more information on how to set properties for the custom registry, see the section on *Setting Properties for Custom Registries*.

In the `FileRegistrySample.java` sample file, this method returns the display name of the user whose name matches the user name that is provided. If the display name does not exist, this method returns an empty string.

This method can be called by the product to present the display names in the administrative console, or by using the command line and the **wsadmin** tool. Use this method for display purposes only. This method is the same as in Version 4.x.

- Obtain the unique ID of a user with `getUniqueId(String)`.

```
public String getUniqueId(String userSecurityName)
 throws EntryNotFoundException,
 CustomRegistryException,
 RemoteException;
```

This method returns the unique ID of the user, given the security name.

In the `FileRegistrySample.java` sample file, this method returns the `uniqueUserId` value of the user whose name matches the supplied name. This method is called when forming a credential for a user and also when creating the authorization table for the application.

- Obtain the security name of a user with `getUserSecurityName(String)`.

```
public String getUserSecurityName(String uniqueUserId)
 throws EntryNotFoundException,
 CustomRegistryException,
 RemoteException;
```

This method returns the security name of a user given the unique ID. In the `FileRegistrySample.java` sample file, this method returns the security name of the user whose unique ID matches the supplied ID.

This method is called to make sure a valid user exists for a given `uniqueUserId`. This method is called to get the security name of the user when the `uniqueUserId` is obtained from a token.

- Check whether a given user is a valid user in the registry with `isValidUser(String)`.

```
public boolean isValidUser(String userSecurityName)
 throws CustomRegistryException,
 RemoteException;
```

This method indicates whether the given user is a valid user in the registry.

In the `FileRegistrySample.java` sample file, this method returns `true` if the user is found in the registry, otherwise this method returns `false`. This method is primarily called in situations where knowing if the user exists in the directory prevents problems later. For example, in the `mapCertificate` call, when the name is obtained from the certificate if the user is not found as a valid user in the user registry, you can avoid trying to create the credential for the user.

- Return the list of groups from the user registry with `getGroups(String,int)`.

```
public Result getGroups(String pattern, int limit)
 throws CustomRegistryException,
 RemoteException;
```

The `getGroups` method returns the list of groups from the user registry. The names of groups depend on the pattern parameter. The number of groups is limited by the limit parameter. In a registry that has many groups, getting all the groups is not practical. So, the limit parameter is introduced to limit the number of groups retrieved from the user registry. A limit of zero (0) implies to return all the groups that match the pattern and can cause problems for large user registries. Use this limit with care. The custom registry implementations are expected to support at least the wildcard search (\*). For example, a pattern of asterisk (\*) returns all the users and a pattern of (b\*) returns the users starting with *b*.

The return parameter is an object of the `com.ibm.websphere.security.Result` type. This object contains the `java.util.List` and `java.lang.Boolean` attributes. The list contains the groups that are returned and the Boolean flag indicates whether more groups are available in the user registry for the pattern searched. This Boolean flag is used to indicate to the client if more groups are available in the registry.

In the `FileRegistrySample.java` sample file, the `getUsers` method retrieves the required number of groups from the user registry and sets them as a list in the Result object. To find out if more groups are presented than requested, the sample gets one more user than requested and if it finds the additional user, it sets the Boolean flag to `true`. For pattern matching, the `match` method in the `RegExpSample` class is used, which supports the asterisk (\*) and question mark (?) characters.

This method is called by the administrative console to add groups to roles in the various `map-groups-to-roles` panels. The administrative console uses the boolean set in the Result object to indicate that more entries matching the pattern are available in the user registry.

In WebSphere Application Server Version 4, this method is used to take the pattern parameter only and returns a list. In WebSphere Application Server Version 5.x or later, this method is changed to take the limit parameter. Change to take the limit value and limit the users that are returned. The return is changed to return a Result object, which consists of the list and a flag that indicates whether more entries exist. Use the `Result.setList(List)` method to set the list in the Result object. If more entries exist

than requested in the limit parameter, set the Boolean attribute to true in the Result object using the Result.setHasMore method. The default for the Boolean attribute in the Result object is false.

- Obtain the display name of a group with `getGroupDisplayName(String)`.

```
public String getGroupDisplayName(String groupSecurityName)
 throws EntryNotFoundException,
 CustomRegistryException,
 RemoteException;
```

The `getGroupDisplayName` method returns a display name for a group if one exists. The display name is an optional string that describes the group that you can set in some user registries. This name is a descriptive name for the group and does not have to be unique in the registry. If you do not need to have display names for groups in your registry, return null or an empty string for this method.

In the `FileRegistrySample.java` sample file, this method returns the display name of the group whose name matches the group name that is provided. If the display name does not exist, this method returns an empty string.

The product can call this method to present the display names in the administrative console or through the command line using the **wsadmin** tool. This method is used for display purposes only.

- Obtain the unique ID of a group with `getUniqueGroupId(String)`.

```
public String getUniqueGroupId(String groupSecurityName)
 throws EntryNotFoundException,
 CustomRegistryException,
 RemoteException;
```

This method returns the unique ID of the group that is given the security name.

In the `FileRegistrySample.java` sample file, this method returns the security name of the group whose unique ID matches the supplied ID. This method verifies that a valid group exists for a given `uniqueGroupId` ID.

- Obtain the unique IDs of all groups to which a user belongs with `getUniqueGroupIds(String)`.

```
public List getUniqueGroupIds(String uniqueUserId)
 throws EntryNotFoundException,
 CustomRegistryException,
 RemoteException;
```

This method returns the unique IDs of all the groups to which a user belongs.

In the `FileRegistrySample.java` sample file, this method returns the unique ID of all the groups that contain this `uniqueUserId` ID. This method is called when creating the credential for the user. As part of creating the credential, all the `groupUniqueIds` IDs in which the user belongs are collected and put in the credential for authorization purposes when groups are given access to a resource.

- Obtain the security name of a group with `getGroupSecurityName(String)`.

```
public String getGroupSecurityName(String uniqueGroupId)
 throws EntryNotFoundException,
 CustomRegistryException,
 RemoteException;
```

This method returns the security name of a group given its unique ID.

In the `FileRegistrySample.java` sample file, this method returns the security name of the group whose unique ID matches the supplied ID. This method verifies that a valid group exists for a given `uniqueGroupId` ID.

- Determine whether a group is a valid group in the registry with `isValidGroup(String)`.

```
public boolean isValidGroup(String groupSecurityName)
 throws CustomRegistryException,
 RemoteException;
```

This method indicates if the given group is a valid group in the registry.

In the `FileRegistrySample.java` sample file, this method returns true if the group is found in the registry, otherwise the method returns false. This method can be used in situations where knowing whether the group exists in the directory might prevent problems later.

- Obtain all groups to which a user belongs with `getGroupsForUser(String)`.

```
public List getGroupsForUser(String userSecurityName)
 throws EntryNotFoundException,
 CustomRegistryException,
 RemoteException;
```

This method returns all the groups to which a user belongs whose name matches the supplied name. This method is similar to the `getUniqueGroupIds` method with the exception that the security names are used instead of the unique IDs.

In the `FileRegistrySample.java` sample file, this method returns all the group security names that contain the `userSecurityName` name.

This method is called by the administrative console or the scripting tool to verify that the users entered for the RunAs roles are already part of that role in the users and groups-to-role mapping. This check is required to ensure that a user cannot be added to a RunAs role unless that user is assigned to the role in the users and groups-to-role mapping either directly or indirectly through a group that contains this user. Because a group in which the user belongs can be part of the role in the users and groups-to-role mapping, this method is called to check if any of the groups that this user belongs to mapped to that role.

- Retrieve users from a specified group with `getUsersForGroup(String,int)`.

```
public Result getUsersForGroup(String groupSecurityName, int limit)
 throws NotImplementedException,
 EntryNotFoundException,
 CustomRegistryException,
 RemoteException;
```

This method retrieves users from the specified group. The number of users returned is limited by the limit parameter. A limit of zero (0) indicates to return all of the users in that group. This method is not directly called by the WebSphere Application Server security component. However, this method can be called by other components. In rare situations, if you are working with a user registry where getting all the users from any of your groups is not practical, you can create the `NotImplementedException` exception for the particular groups. In this case, verify that if the process choreographer is installed the staff assignments are not modeled using these particular groups. If no concern exists about returning the users from groups in the user registry, it is recommended that you do not create the `NotImplemented` exception when implementing this method.

The return parameter is an object with a `com.ibm.websphere.security.Result` type. This object contains the `java.util.List` and `java.lang.boolean` attributes. The list contains the users that are returned and the Boolean flag, which indicates whether more users are available in the user registry for the search pattern. This Boolean flag indicates to the client whether users are available in the user registry.

In the example, this method gets one user more than the requested number of users for a group, if the limit parameter is not set to zero (0). If the method succeeds in getting one more user, the Boolean flag is set to `true`.

In WebSphere Application Server Version 4, this `getUsers` method is mandatory for the product. For WebSphere Application Server Version 5.x or later, this method can create the `NotImplementedException` exception in situations where it is not practical to get the requested set of users. However, create this exception in rare situations when as other components can be affected. In Version 4, this method accepts only the pattern parameter and returns a list. In Version 5, this method accepts the limit parameter. Change your implementation to take the limit value and limit the users that are returned. The return changes to return a `Result` object, which consists of the list and a flag that indicates whether more entries exist. When the list is returned, use the `Result.setList(List)` method to set the list in the `Result` object. If more entries than requested are in the limit parameter, set the Boolean attribute to `true` in the `Result` object using `Result.setHasMore` method. The default for the Boolean attribute in the `Result` object is `false`.

- Implement the `createCredential(String)` method.

**Attention:** The first two lines of the following code sample are split for illustrative purposes only.

```
public com.ibm.websphere.security.cred.WSCredential createCredential(String userSecurityName)
 throws NotImplementedException,
 EntryNotFoundException,
 CustomRegistryException,
 RemoteException;
```

In this release the WebSphere Application Server, the `createCredential` method is not called. You can return `null`. In the example, a `null` value is returned.

## What to do next

### Managing the realm in a federated repository configuration

Follow this topic to manage the realm in a federated repository configuration.

#### Before you begin

The realm can consist of identities in:

- The file-based repository that is built into the system
- One or more external repositories
- Both the built-in, file-based repository and in one or more external repositories

Before you configure your realm, review “Federated repositories limitations” on page 1416.

#### Procedure

1. Configure your realm by using one of the following topics. You might be configuring your realm for the first time or changing an existing realm configuration.
  - “Using a single built-in, file-based repository in a new configuration under Federated repositories” on page 1419
  - “Changing a federated repository configuration to include a single built-in, file-based repository only” on page 1424
  - “Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories” on page 1425
  - “Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only” on page 1426
  - “Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1427
  - “Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1429
2. Configure supported entity types using the steps described in “Configuring supported entity types in a federated repository configuration” on page 1471. You must configure supported entity types before you can manage this account with Users and Groups. The Base entry for the default parent determines the repository location where entities of the specified type are placed on a create operation.
3. Optional: Use one or more of the following tasks to extend the capabilities of storing data and attributes in your realm:
  - a. Configure an entry mapping repository using the steps described in “Configuring an entry mapping repository in a federated repository configuration” on page 1468. An entry mapping repository is used to store data for managing profiles on multiple repositories.
  - b. Configure a property extension repository using the steps described in “Configuring a property extension repository in a federated repository configuration” on page 1447. A property extension repository is used to store attributes that cannot be stored in your Lightweight Directory Access Protocol (LDAP) server.
    - a. Set up a database repository using `wsadmin` commands as described in “Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using `wsadmin` commands” on page 1452
4. Optional: Use one or more of the following advanced user tasks to extend the capabilities of LDAP repositories in your realm:
  - “Increasing the performance of the federated repository configuration” on page 1477

- “Configuring Lightweight Directory Access Protocol entity types in a federated repository configuration” on page 1490
  - “Configuring group attribute definition settings in a federated repository configuration” on page 1493
5. Optional: Manage repositories that are configured in your system by following the steps described in “Managing repositories in a federated repository configuration” on page 1474.
  6. Optional: Add an external repository into your realm by following the steps described in “Adding an external repository in a federated repository configuration” on page 1445.
  7. Optional: Change the password for the repository that is configured under federated repositories by the following steps described in “Changing the password for a repository under a federated repositories configuration” on page 1417.

### What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** in the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

### **Federated repositories:**

*Federated repositories* enable you to use multiple repositories with WebSphere Application Server. These repositories, which can be file-based repositories, LDAP repositories, or a sub-tree of an LDAP repository, are defined and theoretically combined under a single realm. All of the user repositories that are configured under the federated repository functionality are invisible to WebSphere Application Server.

When you use the federated repositories functionality, all of the configured repositories, which you specify as part of the federated repository configuration, become active. It is required that the user ID, and the distinguished name (DN) for an LDAP repository, be unique in multiple user repositories that are configured under the same federated repository configuration. For example, there might be three different repositories that are configured for the federated repositories configuration: Repository A, Repository B, and Repository C. When user1 logs in, the federated repository adapter searches each of the repositories for all of the occurrences of that user. If multiple instances of that user are found in the combined repositories, an error message displays.

In addition, the federated repositories functionality in WebSphere Application Server supports the logical joining of entries across multiple user repositories when the Application Server searches and retrieves entries from the repositories. For example, when an application calls for a sorted list of people whose age is greater than twenty, WebSphere Application searches all of the repositories in the federated repositories configuration. The results are combined and sorted before the Application Server returns the results to the application.

### **Restrictions:**

- WebSphere Application Server federated repositories **DO NOT** support a z/OS LDAP server with an SDBM backend (resource access control facility (RACF)).

Unlike the local operating system, stand-alone LDAP registry, or custom registry options, federated repositories provide user and group management with read and write capabilities. When you configure federated repositories, you can use one of the following methods to add, create, and delete users and groups:

**Important:** If you configure multiple repositories under the federated repositories realm, you must also configure supported entity types and specify a base entry for the default parent. The base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management. See “Configuring supported entity types in a federated repository configuration” on page 1471 for details.

- Use the user management application programming interfaces (API). For more information, refer to articles under "Developing with virtual member manager" in this information center.
- Use the administrative console. To manage users and groups within the administrative console, click **Users and Groups > Manage Users** or **Users and Groups > Manage Groups**. For information on user and group management, click the Help link that displays in the upper right corner of the window. From the left navigation pane, click **Users and Groups**.
- Use the wsadmin commands. For more information, see the WIMManagementCommands command group for the AdminTask object topic.

If you do not configure the federated repositories functionality or do not enable federated repositories as the active repository, you cannot use the user management capabilities that are associated with federated repositories. You can configure an LDAP server as the active user registry and configure the same LDAP server under federated repositories, but not select federated repositories as the active user repository. With this scenario, authentication takes place using the LDAP server, and you can use the user management functionality for the LDAP server that is available for federated repositories.

The following table compares the federated repository functionality that is available in WebSphere Application Server Version 8.0 with the registry functionality that remains unchanged from previous versions of the Application Server.

*Table 91. Federated repositories versus user registry implementations.*

*This table lists federated repositories versus user registry implementations.*

| Federated repositories                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | User registry                                                                                                                             |

| Supports multiple types of repositories such as file-based, LDAP, database, and custom. In WebSphere Application Server Version 8.0, file-based and LDAP repositories are supported by the administrative console. However, the federated repositories functionality does not support local operating system implementations.<br><br>With this service release, the federated repositories functionality supports local operating system implementations.<br><br>For database and custom repositories, you can use the wsadmin command-line interface or the configuration application programming interfaces (API).<br><b>Restriction:</b> WebSphere Application Server federated repositories <b>DO NOT</b> support a z/OS LDAP server with an SDBM backend (resource access control facility (RACF)). | Supports multiple types of registries such as the local operating system, a stand-alone LDAP registry, and a stand-alone custom registry. |
| Supports multiple repositories in a realm within a cell.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Supports one registry only in a realm within a cell.                                                                                      |
| Provides read and write capabilities for the repositories that are defined in the federated repository configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Provides read only capability for the registries.                                                                                         |
| Provides account and password policy support as defined by the registry type. However, this support is not provided by the federated repository functionality.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Provides account and password policy support as defined by the registry type.                                                             |
| Supports identity profiles.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Does not support identity profiles.                                                                                                       |
| Uses the custom UserRegistry implementation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Uses the custom UserRegistry implementation.                                                                                              |

### **Realm configuration settings:**

Use this page to manage the realm. The realm can consist of identities in the file-based repository that is built into the system, in one or more external repositories, or in both the built-in, file-based repository and one or more external repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Security domains**.
2. Under User realm, select **Customize for this domain**. Select **Federated repositories** from the Realm type field and click **Configure**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

A single built-in, file-based repository is built into the system and included in the realm by default.

You can configure one or more Lightweight Directory Access Protocol (LDAP) repositories to store identities in the realm. Click **Add base entry to realm** to specify a repository configuration and a base entry into the realm. You can configure multiple different base entries into the same repository.

Click **Remove** to remove selected repositories from the realm. Repository configurations and contents are not destroyed. The following restrictions apply:

- The realm must always contain at least one base entry; therefore, you cannot remove every entry.
- If you plan to remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.

WebSphere Application Server Version 7.0 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

*Realm name:*

Specifies the name of the realm. You can change the realm name.

*Primary administrative user name:*

Specifies the name of the user with administrative privileges that is defined in the repository, for example, adminUser.

The user name is used to log on to the administrative console when administrative security is enabled. Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

**Attention:** In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

*Automatically generated server identity:*

Enables the application server to generate the server identity, which is recommended for environments that contain only Version 6.1 or later nodes. Automatically generated server identities are not stored in a user repository.

**Default:** Enabled

*User identity for the z/OS started task:*

Specifies the user identity that is associated with the z/OS system started task. Each controller and server can have its own identity.

*Ignore case for authorization:*

Specifies that a case-insensitive authorization check is performed.

If case sensitivity is not a consideration for authorization, enable the **Ignore case for authorization** option.

*Allow operations if some of the repositories are down:*

Specifies whether operations (such as login, search, or get) are allowed even if the repositories in the realm are down.

*Use global schema for model:*

Sets the global schema option for the data model in a multiple security domain environment. Global schema refers to the schema of the admin domain.

**Note:** Application domains that are set to use global schema share the same schema of the admin domain. If you extend the schema for an application in one domain, you must also consider how that might affect applications of other domains, as they are bound by the same schema. For example, adding a mandatory property for one application might cause other applications to fail.

*Base entry:*

Specifies the base entry within the realm. This entry and its descendents are part of the realm.

*Repository identifier:*

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

*Repository type:*

Specifies the repository type, such as File or LDAP.

***User attribute mapping for federated repositories:***

Use this panel to set or to modify the mapping for a user registry's user or group attribute to a federated repository property.

To view this administrative console page, click **Security > Global security**. Under Available realm definitions, click **Federated repositories**, and then **Configure**. On the next panel and under Additional Properties, click **User repository attribute mapping**.

*Attribute mappings:*

Select an attribute to set or to modify the mapping for a user registry's user or group attribute to a federated repository property, and then click **Edit**.

***Custom properties details for federated repositories:***

Use this panel to specify the configuration for access to a custom repository.

To view this administrative console page, click **Security > Global security**. Under Available realm definitions, click **Federated repositories**, and then **Configure**. On the next panel and under Additional Properties, click **Manage repositories**. Under Add, select **Custom repository**.

*Repository identifier:*

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

*Repository adapter class name:*

Specifies the implementation class name for the repository adapter. For a User Registry bridge, use `com.ibm.ws.wim.adapter.urbridge.URBridge`.

*Login properties:*

Specifies the property names to use to log into the application server.

*Custom properties:*

Specifies arbitrary name and value pairs of data. The name is a property key and the value is a string value that can be used to set internal system configuration properties.

***File details for federated repositories:***

Use this panel to specify the configuration for access to a file repository.

To view this administrative console page, click **Security > Global security**. Under Available realm definitions, click **Federated repositories**, and then **Configure**. On the next panel and under Additional Properties, click **Manage repositories**. Under Add, select **File repository**.

*Repository identifier:*

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

*Repository adapter class name:*

Specifies the implementation class name for the repository adapter. For a User Registry bridge, use `com.ibm.ws.wim.adapter.urbridge.URBridge`.

*Base directory:*

The base directory where the files are to be created. This directory must already exist.

*File name:*

The file name for the repository.

The default value is `fileRegistry.xml`.

*Salt length:*

Specifies the salt length of the randomly generated salt for password hashing.

The default value is 12.

### *Message digest algorithm:*

Specifies the message digest algorithm to use for hashing the password.

Select one of the following: SHA-1, SHA-256, SHA-384 or SHA-512.

The default value is SHA-1.

### *Login properties:*

Specifies the property names to use to log into the application server.

### *Custom properties:*

Specifies arbitrary name and value pairs of data. The name is a property key and the value is a string value that can be used to set internal system configuration properties.

### **Federated repositories limitations:**

This topic outlines known limitations and important information for configuring federated repositories.

### **Configuring federated repositories in a mixed-version environment**

In a mixed-version deployment manager cell that contains both Version 6.1.x and Version 5.x or 6.0.x nodes, the following limitations apply for configuring federated repositories:

- You can configure only one Lightweight Directory Access Protocol (LDAP) repository under federated repositories, and the repository must be supported by Version 5.x or 6.0.x.
- You can specify a realm name that is compatible with prior versions only. The host name and the port number represent the realm for the LDAP server in a mixed-version nodes cell. For example, machine1.austin.ibm.com:389.
- You must configure a stand-alone LDAP registry; the LDAP information in both the stand-alone LDAP registry and the LDAP repository under the federated repositories configuration must match. During node synchronization, the LDAP information from the stand-alone LDAP registry propagates to the Version 5.x or 6.0.x nodes.

**Important:** Before node synchronization, verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. Do not set the stand-alone LDAP registry as the current realm definition.

- You cannot configure an entry mapping repository or a property extension repository in a mixed-version deployment manager cell.

### **Configuring LDAP servers in a federated repository**

The LDAP connection `connectTimeout` default value is 20 seconds. LDAP should respond within 20 seconds for any request from WebSphere Application Server. If you cannot connect to your LDAP within this time, make sure that your LDAP is running. A connection error displays at the top of the LDAP configuration panel when the connection timeout exceeds 20 seconds.

### **Coexisting with Tivoli Access Manager**

For Tivoli Access Manager to coexist with a federated repositories configuration, the following limitations apply:

- You can configure only one LDAP repository under federated repositories, and that LDAP repository configuration must match the LDAP server configuration under Tivoli Access Manager.

- The distinguished name for the realm base entry must match the LDAP distinguished name (DN) of the base entry within the repository. In WebSphere Application Server, Tivoli Access Manager recognizes the LDAP user ID and LDAP DN for both authentication and authorization. The federated repositories configuration does not include additional mappings for the LDAP user ID and DN.
- The federated repositories functionality does not recognize the metadata that is specified by Tivoli Access Manager. When users and groups are created under user and group management, they are not formatted using the Tivoli Access Manager metadata. The users and groups must be manually imported into Tivoli Access Manager before you use them for authentication and authorization.

### Limitation for configuring active directories with their own federated repository realms

In order to use the administrative console to perform a wildcard search for all available users on two Active Directories, and to prevent multiple entries exceptions with all built-in IDs, you must first configure each Active Directory with its own federated repository realm.

However, you cannot use the administrative console to configure each Active Directory with its own federated repository realm. You can instead use a wsadmin script similar to the following:

```
$AdminTask createIdMgrRealm {-name AD1realm}
$AdminTask addIdMgrRealmBaseEntry {-name AD1realm -baseEntry o=AD1}

$AdminTask createIdMgrRealm {-name AD2realm}
$AdminTask addIdMgrRealmBaseEntry {-name AD2realm -baseEntry o=AD2}

$AdminConfig save
```

### Changing the password for a repository under a federated repositories configuration:

Passwords allow security control over the repositories under a federated repositories configuration. As part of managing the realm in a federated repository configuration, one of the optional tasks you can perform is to change the password of an individual repository that is under a federated repositories configuration.

### Before you begin

Before you change the password for the repository that is configured under federated repositories, ensure that the WebSphere Application Server is running and the target repository for the password change is configured under the federated repositories configuration. In a WebSphere Application Server, Network Deployment environment, you must complete these steps on the deployment manager.

### Procedure

- Changing the password for a repository using the dynamic **updateIdMgrLDAPBindInfo** command Use the following steps to change the Lightweight Directory Access Protocol (LDAP) bind distinguished name (DN) or bind password of an LDAP repository.
 

From a **wsadmin** prompt, you can enter the following command to display a list of arguments for the **updateIdMgrLDAPBindInfo** command: `$AdminTask help UpdateIdMgrLDAPBindInfo`

  1. Start the wsadmin command-line utility. The wsadmin command is found in the `app_server_root/bin` directory. The WebSphere Application Server and wsadmin must remaining running.
  2. Use an LDAP tool to change the password of the LDAP repository. Some LDAP repositories require a stop and start of the LDAP server to change the password.
  3. From the **wsadmin** prompt, enter the **updateIdMgrLDAPBindInfo** command to update the LDAP password under the federated repository. The change is also reflected in the `wimconfig.xml` file.
- Changing the password for a repository using the **updateIdMgrDBRepository** command
  1. Start the wsadmin command-line utility. The wsadmin command is found in the `app_server_root/bin` directory. The wsadmin command session must remain running. If WebSphere Application Server is not started, you need to open a wsadmin command session in local mode. `wsadmin -conntype none`
  2. Log in to the Administrative Console for WebSphere Application Server.
  3. Change the password for the repository.

4. From the Administrative Console, change the data source (J2C) password. You access the proper console page by clicking **Resources > JDBC > Data sources > data\_source > JAAS - J2C authentication data**.
  5. From the Administrative Console, save your changes to the master configuration.
  6. From the **wsadmin** prompt, use the `updateIdMgrDBRepository` command to update the password in the `wimconfig.xml` file.
  7. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
  8. Restart the WebSphere Application Server.
- Changing the password for a repository using the **setIdMgrPropertyExtensionRepository** command
    1. Start the `wsadmin` command-line utility. The `wsadmin` command is found in the `app_server_root/bin` directory. The `wsadmin` command session must remain running. If WebSphere Application Server is not started, you need to open a `wsadmin` command session in local mode.
 

```
wsadmin -conntype none
```
    2. Log in to the Administrative Console for WebSphere Application Server.
    3. Change the password for the repository.
    4. From the Administrative Console, change the data source (J2C) password. You access the proper console page by clicking **Resources > JDBC > Data sources > data\_source > JAAS - J2C authentication data**.
    5. From the Administrative Console, save your changes to the master configuration.
    6. From the **wsadmin** prompt, use the `setIdMgrPropertyExtensionRepository` command to update the password in the `wimconfig.xml` file.
    7. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
    8. Restart the WebSphere Application Server.
  - Changing the password for a repository using the **setIdMgrEntryMappingRepository** command
    1. Start the `wsadmin` command-line utility. The `wsadmin` command is found in the `app_server_root/bin` directory. The `wsadmin` command session must remain running. If WebSphere Application Server is not started, you need to open a `wsadmin` command session in local mode.
 

```
wsadmin -conntype none
```
    2. Log in to the Administrative Console for WebSphere Application Server.
    3. Change the password for the repository.
    4. From the Administrative Console, change the data source (J2C) password. You access the proper console page by clicking **Resources > JDBC > Data sources > data\_source > JAAS - J2C authentication data**.
    5. From the Administrative Console, save your changes to the master configuration.
    6. From the **wsadmin** prompt, use the `setIdMgrEntryMappingRepository` command to update the password in the `wimconfig.xml` file.
    7. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
    8. Restart the WebSphere Application Server.
  - Changing the password for a repository using the **updateIdMgrLDAPServer** command
    1. Start the `wsadmin` command-line utility. The `wsadmin` command is found in the `app_server_root/bin` directory. The `wsadmin` command session must remain running. If WebSphere Application Server is not started, you need to open a `wsadmin` command session in local mode.
 

```
wsadmin -conntype none
```
    2. Change the password for the repository.
    3. From the **wsadmin** prompt, use the `updateIdMgrDBRepository` command to update the password in the `wimconfig.xml` file.

4. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
5. Restart the WebSphere Application Server.

## Results

The password for the repository has been changed.

### ***Using a single built-in, file-based repository in a new configuration under Federated repositories:***

Follow this task to use a single built-in, file-based repository in a new configuration under Federated repositories.

## Before you begin

To use the default configuration under Federated repositories that includes a single built-in, file-based repository only, you need to know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

## Restriction:

Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

WebSphere Application Server federated repositories **DO NOT** support a z/OS LDAP server with an SDBM backend (resource access control facility (RACF)).

## Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Leave the Realm name field value as `defaultWIMFileBasedRealm`.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, `adminUser`.
5. Leave the **Ignore case for authorization** option enabled.
6. Click **OK**.
7. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, the panel does not display. If a built-in, file-based repository is included, complete the following steps:
  - a. Supply a password for the administrative user in the Password field.
  - b. Confirm the password of the primary administrative user in the Confirm password field.
  - c. Click **OK**.

## Results

After completing these steps, your new configuration under Federated repositories includes a single built-in, file-based repository only.

## What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1471.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If

Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.

3. If you are enabling security, complete the remaining steps, as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

#### *Administrative user password settings:*

Use this page to set a password for the administrative user who manages the product resources and user accounts.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. If your federated repository configuration includes a built-in, file-based repository, then the **Administrative user password** panel displays when changes are applied.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

#### *Password:*

Specifies the password of the administrative user who manages the product resources and user accounts.

#### *Confirm password:*

Confirms the password of the administrative user who manages the product resources and user accounts.

#### *Federated repository wizard settings:*

Use this security wizard page to complete the basic requirements to connect the application server to a federated repository.

To view this security wizard page, complete the following steps

1. Click **Security > Global security > Security configuration wizard**.
2. Select your protection settings and click **Next**.
3. Select the **Federated repositories** option and click **Next**.

You can modify your federated repository configuration by completing the following steps:

1. Click **Security > Global security**.
2. Under User account repository, select Federated repository and click **Configure**.

**Note:** This wizard is used for the initial configuration of a built-in, file-based repository. The user name and password do not have to be in the federated repository because they will be created. If you have previously configured federated repositories, do not use the Security configuration wizard to modify your configuration. Instead, modify your configuration using the Federated repositories selection under User account repository on the Global security panel.

*Primary administrative user name:*

Specifies the name of the user with administrative privileges that is defined in the repository, for example, adminUser.

The user name is used to log on to the administrative console when administrative security is enabled. Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

**Attention:** In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

*Password:*

Specifies the password of the administrative user who manages the product resources and user accounts.

*Confirm password:*

Confirms the password of the administrative user who manages the product resources and user accounts.

### ***Configuring a single built-in, file-based repository in a new configuration under federated repositories using wsadmin:***

You can use the Jython or Jacl scripting language with the wsadmin tool to configure a single built-in, file-based repository in a new configuration under Federated repositories.

### **Before you begin**

Shut down the application server and ensure you have the primary administrator id and password.

### **About this task**

The federated repositories configuration file, wimconfig.xml, is supported by WebSphere Application Server 6.1.x and is located in the *app\_server\_root/profiles/profile\_name/config/cells/cell\_name/wim/config* directory.

Use the following steps to configure for use a single built-in, file-based repository in a new configuration for federated repositories.

### **Procedure**

1. Start the wsadmin scripting tool.
2. Create the fileRegistry.xml file, which is the user registry itself, if it does not already exist. If the fileRegistry.xml file does exist, this step just adds the user to registry.

Using Jython:

```
AdminTask.addFileRegistryAccount('-userId isoet01s01 -password oets01')
```

Using Jacl:

```
$AdminTask addFileRegistryAccount {-userId isoet01s01 -password oets01}
```

For more information on the addFileRegistryAccount command, see the documentation about the FileRegistryCommands command group for the AdminTask object.

3. Update the security.xml file to enable administrative security, set the activeUserRegistry to use federated repositories, and update the primaryAdmin and its password.

Using Jython:

```
AdminTask applyWizardSettings('-secureApps false
-secureLocalResources false
-userRegistryType WIMUserRegistry
-customRegistryClass com.ibm.ws.wim.registry.WIMUserRegistry
-adminName isoet01s01 -adminPassword oets01')
```

Using Jacl:

```
$AdminTask applyWizardSettings {-secureApps false
-secureLocalResources false
-userRegistryType WIMUserRegistry
-customRegistryClass com.ibm.ws.wim.registry.WIMUserRegistry
-adminName isoet01s01
-adminPassword oets01}
```

For more information on the `applyWizardSettings` command, see the documentation about the `WizardCommands` command group for the `AdminTask` object.

4. Save your configuration changes. Enter the following commands to save the new configuration and close the `wsadmin` tool:

Using Jython:

```
AdminConfig.save()
```

Using Jacl:

```
$AdminConfig save
```

5. Restart the application server.

*FileRegistryCommands* command group for the *AdminTask* object:

Federated repositories provides a file registry. Use the commands in the `FileRegistryCommands` command group to administer the file registry using the `wsadmin` tool.

**Note:** If the `Use global security settings` option is selected for the user realm or the `Global federated repositories` option is selected as the realm type for the specified domain, the user and group management commands are executed on the federated repository of the admin domain. For example, if you run the `createUser` command for the specified domain, the user is created in the admin domain. However, configuration changes that are performed on the domain are applied to the security domain-specific configuration.

Use the following commands in the `FileRegistryCommands` group to modify the federated repository file registry:

- “`addFileRegistryAccount` command”
- “`changeFileRegistryAccountPassword` command” on page 1423

### **addFileRegistryAccount** command

The `addFileRegistryAccount` command adds an account to the file registry. You must save your configuration changes after running this command to save the new account to the master repository.

Target object

None

Required parameters

**-userId**

Specifies the ID of the user to add to the file registry. (String, required)

**-password**

Specifies the password of the user to add to the file registry. (String, required)

Optional parameters

**-securityDomainName**

Specifies the name that uniquely identifies the security domain. The default value is admin. (String, optional)

**-parent**

Specifies the parent of the entity. (String, optional)

.

Return value

This command returns a message that indicates that the command ran successfully, as the following example displays:

```
'CWNIM4544I Account newAcct(uid=newAcct,o=defaultWIMFileBasedRealm) is stored in the file registry in the temporary workspace. You must use the "$AdminConfig save" command to save it in the master repository.'
```

Batch mode example usage

- Using Jython string:

```
AdminTask.addFileRegistryAccount(['-userId newAcct -password new2password'])
```

Interactive mode example usage

- Using Jython string:

```
AdminTask.addFileRegistryAccount(['-userId', 'newAcct', '-password', 'new2password'])
```

## changeFileRegistryAccountPassword command

The changeFileRegistryAccountPassword changes the password for the file registry account.

Target object

None.

Required parameters

**-userId**

Specifies the user ID of interest. (String, required)

**-password**

Specifies the new password. (String, required)

Optional parameters

**-securityDomainName**

Specifies the name that uniquely identifies the security domain. The default value is admin. (String, optional)

**-uniqueName**

Specifies the fully-qualified unique name of the administrator. (String, optional)

Return value

This command returns a message that indicates that the command ran successfully, as the following example displays:

```
'CWNIM4545I The password is changed for newAcct(uid=newAcct,o=defaultWIMFileBasedRealm) in the file registry in the temporary workspace. You must use the "$AdminConfig save" command to save it in the master repository.'
```

## Batch mode example usage

- Using Jython string:

```
AdminTask.changeFileRegistryAccountPassword(['-userId newAcct -password newPassword -uniqueName uid=newAcct,o=defaultWIMFileBasedRealm'])
```

## Interactive mode example usage

- Using Jython string:

```
AdminTask.changeFileRegistryAccountPassword(['-userId', 'newAcct', '-password', 'newPassword', '-uniqueName', 'uid=newAcct,o=defaultWIMFileBasedRealm'])
```

## ***Changing a federated repository configuration to include a single built-in, file-based repository only:***

Follow this task to change your federated repository configuration to include a single built-in, file-based repository only.

### **Before you begin**

To change your federated repository configuration to include a single built-in, file-based repository only, you need to know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

**Restriction:** Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

### **Procedure**

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. If the realm contains a single built-in, file-based repository only, you must specify defaultWIMFileBasedRealm as the realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Enable the **Ignore case for authorization** option.
6. Click **Use built-in repository** if the built-in, file-based repository is not listed in the collection.
7. Select all repositories in the collection that are not of type File and click **Remove**.
8. Click **OK**.
9. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, it does not display. If a built-in, file-based repository is included, complete the following steps:
  - a. Supply a password for the primary administrative user in the Password field.
  - b. Confirm the password of the primary administrative user in the Confirm password field.
  - c. Click **OK**.

### **Results**

After completing these steps, your federated repository configuration, which includes a single built-in, file-based repository only, is configured.

### **What to do next**

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1471.

2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps, as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

### **Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories:**

Follow this task to configure a single, Lightweight Directory Access Protocol (LDAP) repository in a new configuration under Federated repositories.

#### **Before you begin**

To configure an LDAP repository in a new configuration under Federated repositories, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as the WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log in to the administrative console after you turn on security. You can use other users to log in, if those users are part of the administrative roles.

#### **Procedure**

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. On the Federated repositories panel, complete the following steps:
  - a. Enter the name of the realm in the Realm name field. You can change the existing realm name.
  - b. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
  - c. Optional: Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

**Restriction:** Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

- d. Click **Add base entry to realm** to add a base entry that uniquely identifies the external repository in the realm. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1445.
4. On the Federated repositories panel, complete the following steps:
    - a. Select the built-in, file-based repository in the collection, and click **Remove**.

**Restriction:** Before you remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.

- b. Click **OK**.

## Results

After completing these steps, your new configuration under Federated repositories includes a single, LDAP repository only.

## What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1471.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

## ***Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only:***

Follow this task to change your federated repository configuration to include a single, Lightweight Directory Access Protocol repository (LDAP) repository only.

## Before you begin

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log into the administrative console after you turn on security. You can use other users to log in if those users are part of the administrative roles.

## Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Optional: Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the

complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

**Restriction:** Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

6. Optional: Click **Add base entry to realm** if the LDAP repository that you need is not contained in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1445.
7. On the Federated repositories panel, complete the following steps:
  - a. Optional: Select the repositories in the collection that you do not need in the realm and click **Remove**.

**Restriction:** The realm must always contain at least one base entry; therefore, you cannot remove every entry.

- b. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which includes a single LDAP repository only, is configured.

## What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1471.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

## ***Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration:***

Follow this task to configure multiple Lightweight Directory Access Protocol (LDAP) repositories in a federated repository configuration.

## **Before you begin**

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log into the administrative console

after you turn on security. You can use other users to log in if those users are part of the administrative roles.

## Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Optional: Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

**Restriction:** Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

6. Optional: Click **Add base entry to realm** if the LDAP repository that you need is not listed in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1445.
7. On the Federated repositories panel, complete the following steps:
  - a. Optional: Repeat step 6 if the LDAP repository that you need is not listed in the collection.
  - b. Optional: Select the repositories in the collection that you do not need in the realm and click **Remove**. The following restrictions apply:
    - The realm must always contain at least one base entry; therefore, you cannot remove every entry.
    - If you plan to remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.
  - c. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which includes multiple LDAP repositories, is configured.

## What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1471.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

## ***Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration:***

Follow this task to configure a single built-in, file-based repository and multiple Lightweight Directory Access Protocol (LDAP) repositories in a federated repository configuration.

### **Before you begin**

To configure a built-in, file-based repository in a federated repository configuration, you must know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log in to the administrative console after you turn on security. You can use other users to log in if those users are part of the administrative roles.

**Restriction:** Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

### **Procedure**

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.

**Restriction:** When you configure multiple repositories that includes a single built-in, file-based repository, the primary administrative user name must exist in the file-based repository. If the primary administrative user name does not exist in the file-based repository, then the name is created in the file-based repository. The primary administrative user name cannot exist in other repositories.

5. Select the **Ignore case for authorization** option.

**Attention:** When the realm includes a built-in, file-based repository, you must enable the **Ignore case for authorization** option.

When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

**Restriction:** Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

6. Optional: Click **Add base entry to realm** if the LDAP repository that you need is not contained in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1445.
7. On the Federated repositories panel, complete the following steps:
  - a. Optional: Repeat step 6 if the LDAP repository that you need is not listed in the collection.

- b. Click **Use built-in repository** if the built-in, file-based repository is not listed in the collection.
- c. Optional: Select the repositories in the collection that you do not need in the realm and click **Remove**.

**Restriction:** The realm must always contain at least one base entry; therefore, you cannot remove every entry.

- d. Click **OK**.
8. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, the panel does not display. If a built-in, file-based repository is included, complete the following steps:
- a. Supply a password for the administrative user in the Password field.
  - b. Confirm the password of the primary administrative user in the Confirm password field.
  - c. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which includes a single built-in, file-based repository and one or more LDAP repositories, is configured.

## What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1471.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

## **Manually configuring an Lightweight Directory Access Protocol repository in a federated repository configuration:**

Follow this topic to manually configure Lightweight Directory Access Protocol (LDAP) repository in a federated repository configuration.

## Before you begin

As a prerequisite, you need to add a LDAP repository to your WebSphere Application Server configuration, where you define the following information:

*Table 92. Prerequisite LDAP repository information.*

*This table lists prerequisite LDAP repository information,*

| Item Name             | Example                     |
|-----------------------|-----------------------------|
| Repository identifier | ldaprepo1                   |
| Directory type        | IBM Tivoli Directory Server |
| Primary host name     | localhost                   |
| Port                  | 389                         |

Table 92. Prerequisite LDAP repository information (continued).

This table lists prerequisite LDAP repository information,

| Item Name               | Example                                       |
|-------------------------|-----------------------------------------------|
| Bind distinguished name | cn=ldapadmin                                  |
| Bind password           | yourpwd                                       |
| Login properties        | uid (a property containing login information) |

See “Lightweight Directory Access Protocol repository configuration settings” on page 1436 for the specific steps you must perform to establish this LDAP repository.

### About this task

At this point, you have a valid LDAP repository ready to be manually configured in a federated repository configuration.

### Procedure

1. Map the federated repository entity types to the LDAP object classes.
  - a. Configure the LDAP repository to match the used LDAP object class for users.
    - 1) In the administrative console, click **Security > Global security**.
    - 2) Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
    - 3) Under Related items, click **Manage repositories**.
    - 4) Select the repository (for example, ldaprepo1).
    - 5) Click **LDAP entity types**.
    - 6) Click **PersonAccount**.
    - 7) Insert the *objectclass* name used in our LDAP server, for example, inetOrgPerson.
    - 8) Click **Apply**.
    - 9) Click **Save**.

See “Configuring supported entity types in a federated repository configuration” on page 1471 for an explanation of the supported entity types.

See <http://publib.boulder.ibm.com/infocenter/wasinfo/v6r1/topic/com.ibm.websphere.wim.doc.en/ldap.html> for a description of the LDAP default mappings.
  - b. Configure the LDAP repository to match the used LDAP *objectclass* for groups
    - 1) In the administrative console, click **Security > Global security**.
    - 2) Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
    - 3) Under Related items, click **Manage repositories**.
    - 4) Select ldaprepo1.
    - 5) Click **LDAP entity types**.
    - 6) Click **Group**.
    - 7) Insert the objectclass name used for your LDAP server, for example, groupOfUniqueNames.
    - 8) Click **Apply**.
    - 9) Click **Save**.

See “Group attribute definition settings” on page 1494 for an explanation of group attribute definitions.
2. Map the federated repository property names to the LDAP attribute names.
  - a. Configure the LDAP repository to match the used LDAP attributes for a user.

1) Edit the file

```
{WAS_HOME}\profiles\{profileName}\config\cells\{cellName}\wim\config\wimconfig.xml
```

2) Look for the section in this file containing the LDAP repository configuration, For example,

a)

```
<config:repositories
xsi:type="config:LdapRepositoryType"
adapterClassName="com.ibm.ws.wim.adapter.ldap.LdapAda
pter" id="ldaprepo1" ...>
```

b)

```
<config:attributeConfiguration>
```

c)

```
...
```

d)

```
<config:attributes name="anLDAPAttribute"
propertyName="aVMMAttribute"/>
```

e)

```
...
```

```
<config:attributeConfiguration>
```

3) Add an element of type `config:attributes` to define the mapping between a given federated depository property name, such as `departmentNumber`, to a desired LDAP attribute name, such as `warehouseSection`.

**Note:** For all given federated depository properties, a one-to-one mapping is assumed. If no explicit mapping of the above type is defined, for example the federated repository property `departmentNumber`, the underlying LDAP attribute name, `departmentNumber` is assumed.

b. Configure the unsupported properties of the federated repository.

To indicate that a given federated repository property, such as `departmentNumber` is not supported by any LDAP attributes, you need to define the following type of element:

```
<config:repositories xsi:type="config:LdapRepositoryType"
adapterClassName="com.ibm.ws.wim.adapter.ldap.LdapAdapter"
id="ldaprepo1" ...>
<config:attributeConfiguration>
...
<config:propertiesNotSupported name=" departmentNumber"/>
...
<config:attributeConfiguration>
```

c. Configure the LDAP repository to match the used LDAP user membership attribute in the groups.

1) In the administrative console, click **Security > Global security**.

2) Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.

3) Under Related items, click **Manage repositories**.

4) Select `ldaprepo1`

5) Click **Group attribute defintions**.

6) Click **Member attributes**.

7) Check if your LDAP attributes (for example, `uniqueMember`) is specified for your LDAP objectclass (for example, `groupOfUniqueNames`).

- If not specified, click **New** and add the pair (*objectclass / member attribute name*) that applies to your LDAP schema (for example, `uniqueMember / groupOfUniqueNames`)
- If specified, proceed.

8) Click **Apply**.

9) Click **Save**.

3. Map other LDAP settings by configuring a new base entry for the new LDAP repository.

a. In the administrative console, click **Security > Global security**.

b. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.

c. Click **Add Base Entry to Realm**.

- d. Select `ldaprepo1`.
- e. Specify:
  - The base entry within the federated repository realm, for example, `o=Default Organization`
  - The base entry within the LDAP repository, for example, `o=Default Organization`
- f. Click **Apply**.
- g. Click **Save**.

For an explanation of base entries, see the Configuring supported entity types in a federated repository configuration topic.

## Results

After completing these steps, your federated repository matches the LDAP server settings.

## What to do next

### ***Configuring Lightweight Directory Access Protocol in a federated repository configuration:***

Follow this topic to configure Lightweight Directory Access Protocol (LDAP) settings in a federated repository configuration.

## Before you begin

You have chosen among various ways to configure LDAP:

- “Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories” on page 1425
- “Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only” on page 1426
- “Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1427
- “Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1429
- “Managing repositories in a federated repository configuration” on page 1474

## About this task

At this point, you are viewing the LDAP repository configuration page of the administrative console.

## Procedure

1. Enter a unique identifier for the repository in the Repository identifier field. This identifier uniquely identifies the repository within the cell, for example: `LDAP1`.
2. Select the type of LDAP server that is used from the Directory type list. The type of LDAP server determines the default filters that are used by WebSphere Application Server.  
IBM Tivoli Directory Server users can choose either IBM Tivoli Directory Server or SecureWay as the directory type. Use the IBM Tivoli Directory Server directory type for better performance. For a list of supported LDAP servers, see “Using specific directory servers as the LDAP server” on page 1367.
3. Enter the fully qualified host name of the primary LDAP server in the Primary host name field. You can enter either the IP address or the domain name system (DNS) name.
4. Enter the server port of the LDAP directory in the Port field. The host name and the port number represent the realm for this LDAP server in a mixed version nodes cell. If servers in different cells are communicating with each other using Lightweight Third Party Authentication (LTPA) tokens, these realms must match exactly in all the cells.

The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

If multiple WebSphere Application Servers are installed and configured to run in the same single sign-on domain, or if WebSphere Application Server interoperates with a previous version of WebSphere Application Server, then it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as 389 in a Version 5.x or 6.0.x configuration, and WebSphere Application Server at Version 6.1 is going to interoperate with the Version 5.x or 6.0.x server, then verify that port 389 is specified explicitly for the Version 6.1 server.

5. Optional: Enter the host name of the failover LDAP server in the Failover host name field. You can specify a secondary directory server to be used in the event that your primary directory server becomes unavailable. After switching to a secondary directory server, LDAP repository attempts to reconnect to the primary directory server every 15 minutes.
6. Optional: Enter the port of the failover LDAP server in the Port field and click **Add**. The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.
7. Optional: Select the type of *referral*. A referral is an entity that is used to redirect a client request to another LDAP server. A referral contains the names and locations of other objects. It is sent by the server to indicate that the information that the client requested can be found at another location, possibly at another server or several servers. The default value is ignore.

**ignore**

Referrals are ignored.

**follow** Referrals are followed automatically.

8. Optional: Enter the bind DN name in the Bind distinguished name field, for example, cn=root. The bind DN is required if anonymous binds are not possible on the LDAP server to obtain user and group information or for write operations. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed. If the LDAP server is set up to use anonymous binds, leave this field blank. If a name is not specified, the application server binds anonymously.

**Note:** To create LDAP queries or to browse, an LDAP client must bind to the LDAP server using the distinguished name (DN) of an account that has the authority to search and read the values of LDAP attributes, such as user and group information. The LDAP administrator ensures that **read access privileges** are set for the bind DN. Read access privileges allow access to the subtree of the base DN and ensure that searches of user and group information are successful.

The directory server provides an operational attribute in each directory entry (for example, the IBM Directory Server uses `ibm-entryUuid` as the operational attribute). The value of this attribute is a universally unique identifier (UUID), which is chosen automatically by the directory server when the entry is added, and is expected to be unique: no other entry with the same or different name would have this same value. Directory clients may use this attribute to distinguish objects identified by a distinguished name or to locate an object after renaming.

**Ensure that the bind credentials have the authority to read this attribute.**

9. Optional: Enter the password that corresponds to the bind DN in the Bind password field.
10. Optional: Enter the property names to use to log into WebSphere Application Server in the Login properties field. This field takes multiple login properties, delimited by a semicolon (;). For example, `uid;mail`.

All login properties are searched during login. If multiple entries or no entries are found, an exception is thrown. For example, if you specify the login properties as `uid;mail` and the login ID as Bob, the

search filter searches for uid=Bob or mail=Bob. When the search returns a single entry, then authentication can proceed. Otherwise, an exception is thrown.

**Note:** If you define multiple login properties, then the first login property is programmatically mapped to the federated repositories principalName property. For example, if you set uid;mail as the login properties, the LDAP attribute uid value is mapped to the federated repositories principalName property. If you define multiple login properties, after login, the first login property is returned as the value of the principalName property. For example, if you pass joe@yourco.com as the principalName value and the login properties are configured as uid;mail, the principalName is returned as joe.

11. Optional: Select the certificate map mode in the Certificate mapping field. You can use the X.590 certificates for user authentication when LDAP is selected as the repository. The Certificate mapping field is used to indicate whether to map the X.509 certificates into an LDAP directory user by EXACT\_DN or CERTIFICATE\_FILTER. If EXACT\_DN is selected, the DN in the certificate must exactly match the user entry in the LDAP server, including case and spaces.
12. If you select **CERTIFICATE\_FILTER** in the Certificate mapping field, specify the LDAP filter for mapping attributes in the client certificate to entries in LDAP.

If more than one LDAP entry matches the filter specification at run time, authentication fails because the result is an ambiguous match. The syntax or structure of this filter is:

```
LDAP attribute=${Client certificate attribute}
```

For example, uid=\${SubjectCN}.

The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. The right side must begin with a dollar sign (\$) and open bracket ({} and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:

- \${UniqueKey}
- \${PublicKey}
- \${PublicKey}
- \${Issuer}
- \${NotAfter}
- \${NotBefore}
- \${SerialNumber}
- \${SigAlgName}
- \${SigAlgOID}
- \${SigAlgParams}
- \${SubjectCN}
- \${Version}

13. Optional: Select the **Require SSL communications** option if you want to use Secure Sockets Layer communications with the LDAP server.

If you select the **Require SSL communications** option, you can select either the **Centrally managed** or **Use specific SSL alias** option.

#### **Centrally managed**

Enables you to specify an SSL configuration for a particular scope, such as the cell, node, server, or cluster in one location. To use the Centrally managed option, you must specify the SSL configuration for the particular set of endpoints. The Manage endpoint security configurations and trust zones panel displays all of the inbound and outbound endpoints that use the SSL protocol. If you expand the Inbound or Outbound section of the panel and click the name of a node, you can specify an SSL configuration that is used for every endpoint on that node. For an LDAP registry, you can override the inherited SSL configuration by specifying an SSL configuration for LDAP. To specify an SSL configuration for LDAP, complete the following steps:

- a. Click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones**.
- b. Expand **Outbound > cell\_name > Nodes > node\_name > Servers > server\_name > LDAP**.

#### Use specific SSL alias

Select the **Use specific SSL alias** option if you intend to select one of the SSL configurations in the menu that follows the option.

This configuration is used only when SSL is enabled for LDAP. The default is *DefaultSSLSettings*. To modify or create a new SSL configuration, complete the following steps:

- a. Click **Security > SSL certificate and key management**.
- b. Under Configuration settings, click **Manage endpoint security configurations and trust zones > configuration\_name**.
- c. Under Related items, click **SSL configurations**.

14. Click **OK**.

#### Results

After completing these steps, your LDAP repository settings are configured.

#### What to do next

Return to the appropriate task to complete the steps for your federated repository configuration:

- “Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories” on page 1425
- “Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only” on page 1426
- “Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1427
- “Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1429
- “Managing repositories in a federated repository configuration” on page 1474

#### *Lightweight Directory Access Protocol repository configuration settings:*

Use this page to configure secure access to a Lightweight Directory Access Protocol (LDAP) repository with optional failover servers.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

#### *Repository identifier:*

Specifies a unique identifier for the LDAP repository. This identifier uniquely identifies the repository within the cell, for example: LDAP1.

*Directory type:*

Specifies the type of LDAP server to which you connect.

Expand the drop-down list to display a list of LDAP directory types.

*Primary host name:*

Specifies the host name of the primary LDAP server. This host name is either an IP address or a domain name service (DNS) name.

*Port:*

Specifies the LDAP server port.

The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

|                   |                                                           |                                                       |
|-------------------|-----------------------------------------------------------|-------------------------------------------------------|
| <b>Data type:</b> | Integer                                                   |                                                       |
| <b>Default:</b>   | 389                                                       |                                                       |
| <b>Range:</b>     | 389, which is not a Secure Sockets Layer (SSL) connection | 636, which is a Secure Sockets Layer (SSL) connection |

*Failover host name:*

Specifies the host name of the failover LDAP server.

You can specify a secondary directory server to be used in the event that your primary directory server becomes unavailable. After switching to a secondary directory server, the LDAP repository attempts to reconnect to the primary directory server every 15 minutes.

*Port:*

Specifies the port of the failover LDAP server.

The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

|                   |                                                           |                                                       |
|-------------------|-----------------------------------------------------------|-------------------------------------------------------|
| <b>Data type:</b> | Integer                                                   |                                                       |
| <b>Range:</b>     | 389, which is not a Secure Sockets Layer (SSL) connection | 636, which is a Secure Sockets Layer (SSL) connection |

*Support referrals to other LDAP servers:*

Specifies how referrals that are encountered by the LDAP server are handled.

A referral is an entity that is used to redirect a client request to another LDAP server. A referral contains the names and locations of other objects. It is sent by the server to indicate that the information that the client requested can be found at another location, possibly at another server or several servers. The default value is ignore.

|                 |        |
|-----------------|--------|
| <b>Default:</b> | ignore |
|-----------------|--------|

**Range:****ignore** Referrals are ignored.**follow** Referrals are followed automatically.*Support for repository change tracking:*

Specifies the type of support for repository change tracking, which is one of the following:

**none** Specifies there is no change tracking support for this repository.**native** Specifies that the repository's native change tracking mechanism is used by virtual member manager to return changed entities.*Custom properties:*

Specifies arbitrary name and value pairs of data. The name is a property key and the value is a string value that can be used to set internal system configuration properties.

Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

*Bind distinguished name:*

Specifies the distinguished name (DN) for the application server to use when binding to the LDAP repository.

If no name is specified, the application server binds anonymously. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed.

*Bind password:*

Specifies the password for the application server to use when binding to the LDAP repository.

*Login properties:*

Specifies the property names to use to log into the application server.

This field takes multiple login properties, delimited by a semicolon (;). For example, `uid;mail`. All login properties are searched during login. If multiple entries or no entries are found, an exception is thrown. For example, if you specify the login properties as `uid;mail` and the login ID as Bob, the search filter searches for `uid=Bob` or `mail=Bob`. When the search returns a single entry, then authentication can proceed. Otherwise, an exception is thrown.

**Note:** If you define multiple login properties, then the first login property is programmatically mapped to the federated repositories `principalName` property. For example, if you set `uid;mail` as the login properties, the LDAP attribute `uid` value is mapped to the federated repositories `principalName` property. If you define multiple login properties, after login, the first login property is returned as the value of the `principalName` property. For example, if you pass `joe@yourco.com` as the `principalName` value and the login properties are configured as `uid;mail`, the `principalName` is returned as `joe`.

*LDAP attribute for Kerberos principal name:*

Specifies the LDAP attribute for Kerberos principal name. This field can be modified when Kerberos is configured and it is one of the active or preferred authentication mechanisms.

*Certificate mapping:*

Specifies whether to map X.509 certificates into an LDAP directory by EXACT\_DN or CERTIFICATE\_FILTER. Specify CERTIFICATE\_FILTER to use the specified certificate filter for the mapping.

*Certificate filter:*

Specifies the filter certificate mapping property for the LDAP filter. The filter is used to map attributes in the client certificate to entries in the LDAP repository.

If more than one LDAP entry matches the filter specification at run time, authentication fails because the result is an ambiguous match. The syntax or structure of this filter is:

```
LDAP attribute=${Client certificate attribute}
```

An example of a simple certificate filter is: uid=\${SubjectCN}.

You can also specify multiple properties and values as part of the certificate filter. Two examples of complex certificate filters are:

```
(&(cn=${IssuerCN}) (employeeNumber=${SerialNumber}))
```

```
(& (issuer=${IssuerDN}) (serial=${SerialNumber}) (subjectdn=${SubjectDN}))
```

The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. You can also use the **UniqueKey** certificate variable, which consists of the base64-encoding of the MD5 hash of the subject DN and issuer DN. The right side must begin with a dollar sign (\$) and open bracket ({} and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:

- \${UniqueKey}
- \${PublicKey}
- \${IssuerDN}
- \${Issuerxx} where xx is replaced by the characters that represent any valid component of the Issuer Distinguished Name. For example, you might use \${IssuerCN} for the Issuer Common Name.
- \${NotAfter}
- \${NotBefore}
- \${SerialNumber}
- \${SigAlgName}
- \${SigAlgOID}
- \${SigAlgParams}
- \${SubjectDN}
- \${Subjectxx} where xx is replaced by the characters that represent any valid component of the Subject Distinguished Name. For example, you might use \${SubjectCN} for the Subject Common Name.
- \${Version}

*Require SSL communications:*

Specifies whether secure socket communication is enabled to the LDAP server.

When enabled, the Secure Sockets Layer (SSL) settings for LDAP are used, if specified.

*Centrally managed:*

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations, rather than spreading them across the configuration documents.

**Default:** Enabled  
**Range:** Enabled or Disabled

*Use specific SSL alias:*

Specifies the SSL configuration alias to use for LDAP outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI platform.

***Migrating a stand-alone LDAP repository to a federated repositories LDAP repository configuration:***

When configuring the security for your application server, you might need to migrate a stand-alone LDAP registry to a federated repositories LDAP repository configuration.

**Before you begin**

- | Note the specifications of your stand-alone LDAP repository that you want to migrate, for reference when
- | configuring the LDAP repository in federated repositories. To access these fields, on the administrative
- | console, click **Security > Global security**. To access these fields in a multiple security domain
- | environment, click **Security > Security domains > DomainName**, and then, under Security Attributes,
- | expand User Realm, and click **Customize for this domain**. Select a Realm type. and then click
- | **Configure**.

The following table shows the administrative console panels and fields of the stand-alone LDAP repository configuration and their corresponding fields in a federated repositories LDAP repository configuration for mapping.

*Table 93. Mapping between a stand-alone LDAP repository configuration and a federated repositories LDAP repository configuration. This table illustrates the mapping between a stand-alone LDAP repository configuration and a federated repositories LDAP repository configuration.*

| <b>Stand-alone LDAP repository configuration</b>                                | <b>LDAP repository in a federated repositories configuration</b>                                                                                          |

The User Filter, Group Filter, User ID map, Group ID map, and Group member ID map fields are not listed in the previous table as they do not have a one-to-one correspondence with fields in the federated repositories LDAP repository configuration panel. These LDAP attributes are set differently in the federated repositories LDAP repository configuration and involve multiple steps. These settings are explained in detail in the following sections and procedure.

## About this task

Migrating from a stand-alone LDAP repository configuration to a federated repositories LDAP repository configuration involves migrating the configuration parameters, most of which are straight forward as shown in Table 1 in the previous section. Migrating the search filters is an important part of migrating a stand-alone LDAP repository configuration to a federated repository LDAP configuration; therefore, the concept and migration of LDAP search filters is described here in detail.

Stand-alone LDAP registry search filters follow the LDAP filter syntax, where you specify the attribute on which the search is based and its value.

The user filter is used for searching the registry for users. It is used to authenticate a user by using the attribute specified in the filter.

The group filter is used for searching the registry for groups. It specifies the property by which to look up groups.

**Examples of commonly used LDAP user filters:** In the following examples of search filters, %v is replaced with the corresponding search pattern of the user or group at run time.

```
(&(uid=%v)(objectclass=ePerson))
```

Searches for users where the uid attribute matches the specified search pattern of the ePerson object class.

```
(&(cn=%v)(objectclass=user))
```

Searches for users where the cn attribute matches the specified search pattern of the user object class.

```
(&(sAMAccountName=%v)(objectcategory=user))
```

Searches for users where the sAMAccountName attribute matches the specified search pattern of the user object category.

```
(&(userPrincipalName=%v)(objectcategory=user))
```

Searches for users where the userPrincipalName attribute matches the specified search pattern of the user object category.

```
(&(mail=%v)(objectcategory=user))
```

Searches for users where the mail attribute matches the specified search pattern of the user object category.

```
(&(|(sAMAccountName=%v)(userPrincipalName=%v))(objectcategory=user))
```

Searches for users where the sAMAccountName or the userPrincipalName matches the specified search pattern of the user object category.

Examples of commonly used group filters:

```
(&cn=%v)(objectCategory=group)
```

Looks up groups based on their common names (cn).

```
(&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))
```

Looks up groups based on their common names (cn) and by using the object class of either groupOfNames or groupOfUniqueNames.

As shown in these examples, a stand-alone LDAP registry search filter consists of LDAP attributes and object classes, based on which the search or login is performed.

You can also specify the LDAP attributes and object classes in the LDAP adapter configuration of federated repositories, but they are configured differently and provide more flexibility. In federated repositories the user is represented as PersonAccount entity type and group as Group entity type. Each entity type can have its own RDN (Relative Distinguished Name) property (rdnProperties) and object class. For example, the default RDN property of PersonAccount is uid, and the default RDN property of Group is cn. The default object class mapping depends on the LDAP server type. For example, for Tivoli Directory Server, the object class for PersonAccount is inetOrgPerson and object class for Group is groupOfNames. PersonAccount can also have login properties. When a user logs in or a search is performed for a user in a user registry, these login properties are matched with the pattern. For example, if the login properties are uid and mail, then for the search pattern, a\*, all the users who match uid=a\* or mail=a\* are returned.

**gotcha:** You can specify the value of User ID Map property (userIdMap) of the stand-alone LDAP repository as the RDN property (rdnProperties) or the first login property (loginProperties) in federated repositories. Though you can set both the RDN property and the login property in federated repositories, it is sufficient if you set only the RDN property. The login property is optional and you need to set it only if the login property is different from RDN property or if there are more than one login properties. If both the RDN property and login property are set, the login property takes precedence over RDN property.

Migrating search filters involves one or more of the following steps: setting the correct login properties, mapping the attributes of the back-end repository to the federated repositories properties, setting the object class, setting the search filter by using object class or object category, and setting the member or membership attribute. This mapping and configuration for federated repositories is maintained in the wimconfig.xml file.

The stand-alone LDAP registry search filter can be split into two parts:

- User or group attributes filter
- User or group object class or object category filter

For example, in the search filter, (&(cn=%v)(objectclass=user)):

- The attribute filter is (cn=%v)
- The object class filter is (objectclass=user)

These two filters are mapped separately in a federated repositories configuration:

- The attribute filter is mapped to the RDN properties or login properties configuration for user and to RDN properties configuration for group.
- The object class filter is mapped to the entity type configuration of the LDAP adapter.

The default attribute and object class mapping is set based on the LDAP server type but additional steps might be required to migrate these two filters:

- attribute filter:
  - Setting either or both the RDN property and login properties (if applicable)
  - Mapping the federated repository property to the LDAP attribute (if applicable)
- object class filter:
  - Setting the object class for entity type (if applicable)

- Setting the search filter of entity type (if applicable)

Some of the steps in the following procedure include two examples. In these steps:

- Example 1 is applicable to the scenario where you are migrating the search filter (&(cn=%v)(objectclass=ePerson)) from a stand-alone IBM Tivoli Directory Server LDAP repository to a federated repositories LDAP repository with the identifier LDAPTDS.
- Example 2 is applicable to the scenario where you are migrating the search filter (&(|(sAMAccountName=%v)(userPrincipalName=%v))(objectcategory=user)) from a stand-alone Microsoft Active Directory LDAP repository to a federated repositories LDAP repository with the identifier LDAPAD. sAMAccountName and userPrincipalName attributes are not defined in federated repositories, so these attributes must be mapped to federated repository properties.

## Procedure

1. Add the LDAP repository that you want to migrate to the federated repositories configuration.  
See Table 1 in the Before you begin section of this topic, and follow the steps described in the topic *Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories*. These steps include links to other procedures that you must complete such as:
  - Adding an external repository in a federated repository configuration.
  - Configuring supported entity types in a federated repository configuration.
  - Configuring Lightweight Directory Access Protocol in a federated repository configuration.

After you complete these steps, the LDAP repository that you want to migrate will be successfully configured in the federated repository configuration.

2. Set the login properties (if applicable).

Login properties are the property names that are used to log on to the WebSphere Application Server. You can specify multiple login properties by using the semicolon (;) as a delimiter. The federated repositories properties commonly used as login properties are uid, cn, sn, givenName, mail, and so on. To set login properties on the administrative console, follow the steps in the topic *Lightweight Directory Access Protocol repository configuration settings*, and apply the settings under the section, Login properties.

**Example 1:** In the **Login properties** field, enter cn.

**Example 2:** In the **Login properties** field, enter uid;cn.

Complete Step 3 to map these properties to LDAP attributes.

3. Map the federated repository property to the LDAP attribute (if applicable).  
If the LDAP attribute is not a federated repository property, then the login property that you defined must be mapped to the LDAP attribute.
  - a. In the administrative console, click **Global security > Federated repositories > Manage repositories > repository\_ID**, and then, under Additional properties, click the **LDAP attributes** link.
  - b. If the attribute mapping exists, you must first delete the existing mapping for the LDAP attribute, and then add a new mapping for the attribute. Select the checkbox next to the LDAP attribute name and click **Delete**.
  - c. To add an attribute mapping, click **Add**, and select **Supported** from the drop-down menu. Enter the LDAP attribute name in the **Name** field, the federated repositories property name in the **Property name** field, and the entity type which applies the attribute mapping in the **Entity types** field.

**Example 1:** Because the federated repository property cn is implicitly mapped to the cn LDAP attribute, no additional mapping is required.

**Example 2:** Here the search filter includes two LDAP attributes, sAMAccountName and userPrincipalName.

- For the LDAP server type, Active Directory, the LDAP attribute sAMAccountName is mapped by default to the federated repositories property, uid, as shown in the list of attributes on LDAP attributes panel. Therefore, you do not have to execute the addIdMgrLDAPAttr command to add an attribute configuration for sAMAccountName.
  - If an attribute mapping for the LDAP attribute userPrincipalName exists, then delete the existing attribute mapping before adding a new configuration.
    - a. Select the checkbox next to **userPrincalName** and click **Delete**.
    - b. Click **Add**, and select **Supported** from the drop-down menu.
    - c. In the **Name** field, enter userPrincipalName.
    - d. In the **Property name** field, enter cn.
    - e. In the **Entity types** field, enter PersonAccount.
4. Set the object class for an entity type (if applicable).

**gotcha:** Before executing this step, check the current mapping . If the object class mapping is already set, skip this step.

To set the object class for an entity type on the administrative console, follow the steps in the topic *Lightweight Directory Access Protocol entity types settings*, and apply the following settings under the section, Object classes:

- Specify PersonAccount as the entity type name for user filters
- Specify Group as the entity type name for group filters.

**Example 1:** In the **Entity type** field, enter PersonAccount.

In the **Object classes** field, enter ePerson.

**Example 2:** In the **Entity type** field, enter PersonAccount.

In the **Object classes** field, enter user.

5. Set the search filter for the entity type (if applicable).
- Federated repositories performs the search based on the object class setting. To change this default setting and use object category as the filter, follow the steps in topic *Lightweight Directory Access Protocol entity types settings*, and apply the settings under the section, Search Filter.

**Example 1:** Because the search is based on object class, no additional configuration is required.

**Example 2:** In the **Search filter** field, enter (objectcategory=user).

6. To migrate group filters, you must also configure the group attribute definition settings.
- The steps to configure the group attribute definition settings through the administrative console are specified in the topic *Locating user group memberships in a Lightweight Directory Access Protocol registry*, under the section, LDAP Registry within a Federated Repositories Registry. You can also use the wsadmin commands addIdMgrLDAPGroupDynamicMemberAttr or addIdMgrLDAPGroupMemberAttr that are described in the topic *IdMgrRepositoryConfig command group for the AdminTask object*.
7. Save your configuration changes
8. Restart the application server.

## Results

After completing these steps, your LDAP repository is configured for use within the federated repositories configuration.

***Adding an external repository in a federated repository configuration:***

Follow this task to add an external repository into a federated repository configuration.

## Procedure

1. If the Lightweight Directory Access Protocol (LDAP) repository that you want to add to your federated repository configuration is previously configured, select the corresponding Repository on the Repository reference panel. To access the Repository reference panel, complete the following steps:
  - a. Click **Security > Global security**.
  - b. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
  - c. Click **Add base entry to realm**.
2. Enter a distinguished name for the realm base entry in the Distinguished name that uniquely identifies... field. This base entry must uniquely identify the external repository in the realm. If multiple repositories are included in the realm, use this field to define an additional distinguished name (DN) that uniquely identifies this set of entries within the realm. For example, repositories LDAP1 and LDAP2 might both use o=ibm,c=us as the base entry in the repository. Use the DN in this field to uniquely identify this set of entries in the realm. For example: o=ibm,c=us for LDAP1 and o=ibm2,c=us for LDAP2. The specified DN in this field maps to the LDAP DN of the base entry within the repository.
3. Enter the LDAP DN of the base entry within the repository in the Distinguished name of a base entry... field. The base entry indicates the starting point for searches in this LDAP directory server. This entry and its descendents are mapped to the subtree that is identified by this unique base name entry field. For example, for a user with a DN of cn=John Doe, ou=Rochester, o=IBM, c=US, specify the LDAP base entry as any of the following options:  
ou=Rochester, o=IBM, c=us or o=IBM, c=us or c=us  
In most cases, this LDAP DN is the same as the distinguished name for the realm base entry.  
If this field is left blank, then the subtree defaults to the root of the LDAP repository. Consult your LDAP administrator to determine if your LDAP repository provides support to search from the root, or create users and groups under the root without defining a suffix beforehand.  
In WebSphere Application Server, the distinguished name is normalized according to the LDAP specification. Normalization consists of removing spaces in the base distinguished name before or after commas and equal symbols. An example of a non-normalized base distinguished name is o = ibm, c = us or o=ibm, c=us. An example of a normalized base distinguished name is o=ibm,c=us.
4. If the LDAP repository that you want to add to your realm is not previously configured, complete the following steps:
  - a. Click **Add Repository** on the Repository reference panel to configure the LDAP repository. See step 1 to access the Repository reference panel.
  - b. Configure LDAP on the LDAP configuration panel, as described in “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 1433.
  - c. Select the new Repository on the Repository reference panel.
5. Click **OK**.

## Results

You have added a new or previously configured external repository into your federated repository configuration.

## What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1471.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply**

- on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** in the Global security panel.
  4. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

### **Configuring a property extension repository in a federated repository configuration:**

Follow this task to configure a property extension repository to store attributes that cannot be stored in your Lightweight Directory Access Protocol (LDAP) server.

#### **About this task**

For security and business reasons, you might want to prohibit write operations to your repositories. However, applications calling the federated repository configuration might need to store additional properties for the entities. A federated repository configuration provides a *property extension repository*, which is a database regardless of the type of main profile repositories, for a propertylevel join configuration. For example, a company that uses an LDAP directory for its internal employees and a database for external customers and business partners might not allow write access to its LDAP and its database. The company can use the *property extension repository* in a federated repository configuration to store additional properties for the people in those repositories, excluding the user ID. When an application uses the federated repository configuration to retrieve an entry for a person, the federated repository configuration transparently joins the properties of the person that is retrieved from either the LDAP or the customer's database with the properties of the person that is retrieved from the property extension repository into a single logical person entry.

When you configure a property extension repository, you can supply a valid data source, a direct connection configuration, or both. The system first tries to connect by way of the data source. If the data source is not available, then the system uses the direct access configuration.

**Restriction:** You cannot configure a property extension repository in a mixed version deployment manager cell.

#### **Procedure**

1. Configure the WebSphere Application Server data source. See “Configuring the WebSphere Application Server data source” on page 1467.
2. If you are adding new properties (including properties that are stored in the property extension repository) to the schema, you must do the following before you create the property extension repository.
  - a. Open or create the `wimxmlextension.xml` file under the `profile_root\config\cells\cell_name\wim\model` directory.
 

**Attention:** Make sure the editor is on the deployment manager node.
  - b. Add the schema definition of the new property. The following sample `wimxmlextension.xml` file adds a new property called `ibmotherEmail` to both the `Person` and `PersonAccount` entity types. This new property type is `"String"` and it is `multivalued`.

```
<sdo:datagraph xmlns:sdo="commonj.sdo"
 xmlns:wim="http://www.ibm.com/websphere/wim">
 <wim:schema>
 <wim:propertySchema
 nsURI="http://www.ibm.com/websphere/wim"
 dataType="String"
 multiValued="true"

 </wim:propertySchema>
 <wim:propertySchema
 nsURI="http://www.ibm.com/websphere/wim"
 dataType="String"
 multiValued="false"
 propertyName="ibm-firstWorkDayOfWeek">
 <wim:applicableEntityTypeNames>Person
 </wim:applicableEntityTypeNames>
 <wim:applicableEntityTypeNames>PersonAccount
 </wim:applicableEntityTypeNames>
 </wim:propertySchema>
 <wim:propertySchema
 nsURI="http://www.ibm.com/websphere/wim"
 dataType="String"
 multiValued="false"
 propertyName="ibm-gender">
 <wim:applicableEntityTypeNames>Person
 </wim:applicableEntityTypeNames>
 <wim:applicableEntityTypeNames>PersonAccount
 </wim:applicableEntityTypeNames>
 </wim:propertySchema>
 <wim:propertySchema
 nsURI="http://www.ibm.com/websphere/wim"
 dataType="String"
 multiValued="true"
 propertyName="ibm-hobby">
 <wim:applicableEntityTypeNames>Person
 </wim:applicableEntityTypeNames>
 <wim:applicableEntityTypeNames>PersonAccount
 </wim:applicableEntityTypeNames>
 </wim:propertySchema>
</wim:schema>
</sdo:datagraph>

```

Available data types are defined in `com.ibm.websphere.wim.SchemaConstants`. For example:

```

/**
 * Instance Class: java.lang.String
 */
String DATA_TYPE_STRING = "String";
/**
 * Instance Class: int
 */
String DATA_TYPE_INT = "Int";
/**
 * Instance Class: java.lang.Object
 */
String DATA_TYPE_DATE = "Date";
/**
 * Instance Class: dojava.lang.Object
 */
String DATA_TYPE_ANY_SIMPLE_TYPE = "AnySimpleType";
/**
 * Instance Class: java.lang.String
 */
String DATA_TYPE_ANY_URI = "AnyURI";
/**
 * Instance Class: java.lang.boolean
 */
String DATA_TYPE_BOOLEAN = "Boolean";
/**
 * Instance Class: long
 */
String DATA_TYPE_LONG = "Long";
/**
 * Instance Class: double
 */
String DATA_TYPE_DOUBLE = "Double";
/**
 * Instance Class: short
 */
String DATA_TYPE_SHORT = "Short";

```

- c. Follow the example inside this file to define the new property definitions. The schema file for `wimlaproperties.xml` is `wimdbproperty.xsd` and is in the same directory. It can be used for reference.
3. Run the `setupIdMgrPropertyExtensionRepositoryTables` command to create the property extension repository and to add the new properties.

4. Set up the property extension repository using wsadmin by following the procedure discussed in “Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands” on page 1452; ignore the "Before you begin" options.
5. Configure the property extension repository by completing the following steps:
  - a. In the administrative console, click **Security > Global security**.
  - b. Under User account repository, select **Federated repositories**, and click **Configure**.
  - c. Click **Property extension repository**.
  - d. Supply the name of the data source in the Data source name field.
  - e. Select the type of database that is used for the property extension repository.
  - f. Supply the name of the Java database connectivity (JDBC) driver in the JDBC driver field.

Values include:

**DB2** `com.ibm.db2.jcc.DB2Driver`

**Oracle**  
`oracle.jdbc.driver.OracleDriver`

**Informix**  
`com.informix.jdbc.IfxDriver`

**Microsoft SQL Server**  
`com.microsoft.jdbc.sqlserver.SQLServerDriver`

**Derby** `org.apache.derby.jdbc.EmbeddedDriver`

- g. Supply the database URL that is used to access the property extension repository with JDBC in the Database URL field. Use an alphanumeric text string that conforms to the standard JDBC URL syntax.

Values include:

**DB2** `jdbc:db2://<hostname>:<port>/<DB2location>`

**Oracle**  
`jdbc:oracle:thin:@<hostname>:<port>:<dbname>`

**Derby** `jdbc:derby:c:\derby\wim`

**Microsoft SQL Server**  
`jdbc:microsoft:sqlserver://<hostname>:1433;databaseName=wim;selectmethod=cursor;`

**Informix**  
`jdbc:informixqli://<hostname>:1526/wim:INFORMIXSERVER=<IFXServerName>;`

- h. Supply the user name of the database administrator in the Database administrator user name field.
- i. Supply the password of the database administrator in the Password field.
- j. Specify the entity retrieval limit in the Entity retrieval limit field. The entity retrieval limit is the maximum number of entities that the system can retrieve from the property extension repository with a single database query. The default value is 200.
- k. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which includes a property extension repository, is configured.

## What to do next

1. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** on the Global security panel.

2. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

*Property extension repository settings:*

Use this page to configure a property extension repository that is used to store attributes that cannot be stored in existing repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Property extension repository**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Data source name:*

Specifies the Java Naming and Directory Interface (JNDI) name of the data source that is used to access the property extension repository.

**Default:** jdbc/wimDS

*Database type:*

Specifies the type of database that is used for the property extension repository.

**Default:** DB2

*JDBC driver:*

Specifies the Java Database Connectivity (JDBC) driver that is used to access the entry mapping repository.

Values include:

**DB2** COM.ibm.db2.jcc.DB2Driver

**Oracle**  
oracle.jdbc.driver.OracleDriver

**Informix**  
com.informix.jdbc.IfxDriver

**DataDirect Connect**  
com.ddtek.jdbc.sqlserver.SQLServerDriver

**Derby** org.apache.derby.jdbc.EmbeddedDriver

**Microsoft SQL Server**  
com.microsoft.sqlserver.jdbc.SQLServerDriver

*Database URL:*

Specifies the web address for the property extension repository.

Values include:

**DB2** jdbc:db2:wim

**DB2 for z/OS**

jdbc:db2://hostname:port/DB2location

**Informix**

jdbc:informix-sqli://host\_name:1526/wim:INFORMIXSERVER=IFXServerName;

**DataDirect Connect**

jdbc:datadirect:sqlserver://host\_name:1433;databaseName=wim;selectMethod=cursor;

**Derby** jdbc:derby:c:\derby\wim

**Oracle**

jdbc:oracle:thin:@host\_name:port:dbname

**Microsoft SQL Server**

jdbc:sqlserver://host\_name:1433;databaseName=wim;selectMethod=cursor;

*Database administrator user name:*

Specifies the user name of the database administrator that is used to access the property extension repository.

*Password:*

Specifies the password that is used to enable the database administrator to access the property extension repository.

*Entity retrieval limit:*

Specifies the maximum number of entities that the system can retrieve from the property extension repository with a single database query.

|                   |         |
|-------------------|---------|
| <b>Data type:</b> | Integer |
| <b>Default:</b>   | 200     |

*Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands:*

You can set up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands.

**Before you begin**

If you are setting up an entry mapping repository, begin with the steps described in “Configuring an entry mapping repository in a federated repository configuration” on page 1468.

If you are setting up a property extension repository, begin with the steps described in “Configuring a property extension repository in a federated repository configuration” on page 1447.

**About this task**

When you create a repository, use the appropriate wsadmin commands to define the database schema and to populate the database property definitions.

## Procedure

1. Create the database. You can use any relational database product. The following examples give you tips for specific vendors.

a. For **DB2**, open a DB2 command window or command center and enter the following:

```
db2 create database <name> using codeset UTF-8 territory US
```

Enter the following database tuning commands:

```
db2 update database configuration for <name> using applheapsz 1024
db2 update database configuration for <name> using stmtheap 4096
db2 update database configuration for <name> using app_ctl_heap_sz 2048
db2 update database configuration for <name> using locklist 1024
db2 update database configuration for <name> using indexrec RESTART
db2 update database configuration for <name> using logfilsiz 1000
db2 update database configuration for <name> using logprimary 12
db2 update database configuration for <name> using logsecond 10
db2 update database configuration for <name> using sortheap 2048
db2set DB2_RR_TO_RS=yes
```

b. Optional: For **Informix** databases using dbaccess, enter the following command:

```
CREATE DATABASE <name> WITH BUFFERED LOG
```

c. Optional: For **Oracle** databases, the database should already exist during Oracle installation (for example, orcl).

2. Run the `setupIdMgrEntryMappingRepositoryTables` command, the `setupIdMgrPropertyExtensionRepositoryTables` command, or the `setupIdMgrDBTables` command (for custom registries) by doing the following:

a. Start WebSphere Application Server.

b. Open a command window and go to the `<WAS>/Profiles/<PROFILE_NAME>bin` directory.

c. Start `wsadmin`.

d. Type the necessary commands as described below.

## What to do next

Using these commands, you can:

- Specify the arguments on the command line.
- Specify the arguments in a file.

The `-file` option enables you to specify a file in which some or all of the parameters are specified. To use the `-file` argument on the command line, enter the full path to the file. Parameters in the file must be specified in `key=value` pairs and each must be on its own line. If a parameter is specified on both the command line and in the file, the value on the command line takes precedence.

Tips for diagnosing argument errors:

- If an argument is not properly specified on the command line or in the file, a message is returned which states that the argument was not properly specified. This might mean that the argument was not specified at all or was required for a given configuration but was not specified.
- If the argument was not specified at all, check that the parameter is specified on the command line or in the file, and that it is properly spelled and has matching case.
- If the argument was required for a given configuration but was not specified, it is possible that a value is not required solely by the command but is required for the type of database and configuration you are setting.

For example, if you set the `dn`, `wasAdminId`, or `wasAdminPassword` parameters, you must also specify the `dbDriver` parameter.

Additionally, if the `dn`, `wasAdminId` or `wasAdminPassword` parameters are specified, and the `databaseType` is not a Apache Derby v10.2 database, then the `dbAdminId` and `dbAdminPassword` parameters must also be specified.

**Important:** To use Apache Derby v10.2 for your repository, you must run the Apache Derby Network Server framework. This framework supports multiple concurrent JVM connections with the database, whereas the embedded framework works with only a single JVM, which cannot fulfill most workload-balancing requirements. Running the Network Server framework for Apache Derby v10.2 requires the Derby Client driver files and classes.

### The `setupIdMgrDBTables` command:

The `setupIdMgrDBTables` command creates, and populates the tables in the database that you previously created. Arguments are case-sensitive, both through the command line and the file.

*Parameters:*

**schemaLocation (String, Required)**

The location of the `<WAS>/etc/wim/setup` directory.

**dbPropXML (String)**

The location of database repository property definition XML file.

**databaseType (String, Required)**

The type of database. Supported databases are `db2`, `oracle`, `informix`, `derby`, `sqlserver`, `db2zos`, and `db2iseries`.

**dbURL (String, Required)**

The database URL for direct access mode. For example: `jdbc:db2:wim`.

**dbDriver (String)**

The name of the database driver. For example: `com.ibm.db2.jcc.DB2Driver`.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: `db2admin`.

**Note:** For a Apache Derby v10.2 embedded database, `dbAdminId` is not required.

**dbAdminPassword (String)**

The password associated with the `dbAdminId`.

**Note:** For a Apache Derby v10.2 embedded database, `dbAdminPassword` is not required.

**dn (String)**

The default organization `uniqueName` to replace. For example: `o=yourco`. If it is not set, `o=DefaultOrganization` is used.

**wasAdminId (String)**

The WebSphere Application Server admin user ID. The ID should be a short name, not a `uniqueName`. For example: `wasadmin`. After creation, the `uniqueName` is `uid=wasadmin, <defaultOrg>`.

**wasAdminPassword (String)**

The WebSphere Application Server admin user password. If `wasAdminId` is set, then this parameter is mandatory.

**saltLength (Integer)**

The salt length of the randomly generated salt for password hashing.

**encryptionKey (String)**

The password encryption key. Set the password encryption key to match the encryption key in the `wimconfig.xml` file for the repository. If the encryption key is not set, the default is used.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**tablesBufferPool (String)**

The buffer pool variable of default tables in DB2 for z/OS. The default value is BP0.

**LOBtablesBufferPool (String)**

The buffer pool variable of auxiliary LOB tables in DB2 for z/OS. The default value is BP0.

**indextablesBufferPool (String)**

The buffer pool variable of unique index tables in DB2 for z/OS. The default value is BP0.

**dbSchema (String)**

The database schema where you want to create the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

**tablespacePrefix (String)**

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

**The deleteMgrDBTables command:**

The deleteMgrDBTables command deletes the tables in the database.

*Parameters:***schemaLocation (String, Required)**

The location of the <WAS>/etc/wim/setup directory.

**databaseType (String, Required)**

The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

**dbURL (String, Required)**

The database URL for direct access mode. For example: jdbc:db2:wim.

**dbDriver (String)**

The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: db2admin.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminId is not required.

**dbAdminPassword (String)**

The password associated with the dbAdminId.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**dbSchema (String)**

The database schema from which you want to delete the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

**tablespacePrefix (String)**

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

**The setupIdMgrPropertyExtensionRepositoryTables command:**

The setupIdMgrPropertyExtensionRepositoryTables command sets up the property extension repository. The default behavior includes creating and populating the tables in the database.

This command is available in connected or local mode.

*Parameters:***schemaLocation (String, Required)**

The location of the `app_server_root/etc/wim/setup` directory.

**laPropXML (String)**

The location of the property extension repository definition XML file.

**databaseType (String, Required)**

The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

**dbURL (String, Required)**

The database URL for direct access mode. For example: `jdbc:db2:wim`.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: `db2admin`.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminId is not required.

**dbAdminPassword (String)**

The password associated with the dbAdminId.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**skipDBCcreation (Boolean)**

Specifies whether to create the tables in the property extension repository.

If you set this parameter value to false or do not specify a value, then the command follows the default behavior of creating and populating the tables in the database.

If you set this parameter value to true, manually set up the property extension repository before running this command so that the tables get populated. For more information on this manual process, see the appropriate topic on manually setting up the property extension repository for your database.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**tablesBufferPool (String)**

The buffer pool variable of default tables in DB2 for z/OS. The default value is BP0.

**LOBtablesBufferPool (String)**

The buffer pool variable of auxiliary LOB tables in DB2 for z/OS. The default value is BP0.

**indextablesBufferPool (String)**

The buffer pool variable of unique index tables in DB2 for z/OS. The default value is BP0.

**dbSchema (String)**

The database schema where you want to create the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

**tablespacePrefix (String)**

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

**The deleteIdMgrPropertyExtensionRepositoryTables command:**

The deleteIdMgrPropertyExtensionRepositoryTables command deletes the tables in the property extension database.

This command is available in the connected or local mode.

*Parameters:*

**schemaLocation (String, Required)**

The location of the <WAS>/etc/wim/setup directory.

**databaseType (String, Required)**

The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

**dbURL (String, Required)**

The database URL for direct access mode. For example: jdbc:db2:wim.

**dbDriver (String)**

The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: db2admin.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminId is not required.

**dbAdminPassword (String)**

The password associated with the dbAdminId.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**dbSchema (String)**

The database schema from which you want to delete the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

**tablespacePrefix (String)**

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

**The setupIdMgrEntryMappingRepositoryTables command:**

The setupIdMgrEntryMappingRepositoryTables command sets up the entry mapping repository, which includes creating and populating the tables of the repository.

*Parameters:***schemaLocation (String, Required)**

The location of the <WAS>/etc/wim/setup directory.

**databaseType (String, Required)**

The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

**dbURL (String, Required)**

The database URL for direct access mode. For example: jdbc:db2:wim.

**dbDriver (String)**

The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: db2admin.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminId is not required.

**dbAdminPassword (String)**

The password associated with the dbAdminId.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a

corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**tablesBufferPool (String)**

The buffer pool variable of default tables in DB2 for z/OS. The default value is BP0.

**dbSchema (String)**

The database schema where you want to create the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

**tablespacePrefix (String)**

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

**The deleteIdMgrEntryMappingRepositoryTables command:**

The deleteIdMgrEntryMappingRepositoryTables command deletes the tables in the entry mapping repository.

*Parameters:*

**schemaLocation (String, Required)**

The location of the <WAS>/etc/wim/setup directory.

**databaseType (String, Required)**

The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

**dbURL (String, Required)**

The database URL for direct access mode. For example: jdbc:db2:wim.

**dbDriver (String)**

The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: db2admin.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminId is not required.

**dbAdminPassword (String)**

The password associated with the dbAdminId.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**dbSchema (String)**

The database schema from which you want to delete the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

## tablespacePrefix (String)

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

## Sample command line usage:

To set up a database using the command line, enter the following:

```
$AdminTask setupIdMgrDBTables {-schemaLocation "C:/WAS/etc/wim/setup" -dbPropXML
"C:/WAS/etc/wim/setup/wimdbproperties.xml" -databaseType db2
-dbURL jdbc:db2:wim -dbAdminId db2admin
-dbDriver com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd
-reportSqlError true}
```

To delete database tables using the command line, enter the following:

```
$AdminTask deleteIdMgrDBTables {-schemaLocation "C:/WAS/etc/wim/setup"
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin
-dbDriver com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd
-reportSqlError true}
```

To set up a property extension repository using the command line, enter the following:

```
$AdminTask setupIdMgrPropertyExtensionRepositoryTables {-schemaLocation
"C:/WAS/etc/wim/setup"
-laPropXML "C:/WAS/etc/wim/setup/wimlaproperties.xml" -databaseType db2
-dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver com.ibm.db2.jcc.DB2Driver
-dbAdminPassword db2adminPwd -reportSqlError true}
```

To delete a property extension repository using the command line, enter the following:

```
$AdminTask deleteIdMgrPropertyExtensionRepositoryTables {-schemaLocation "C:/WAS/etc/wim/setup "
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver
com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

To set up an entry mapping repository using the command line, enter the following:

```
$AdminTask setupIdMgrEntryMappingRepositoryTables {-schemaLocation "C:/WAS/etc/wim/setup"
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver
com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

To delete an entry mapping repository using the command line, enter the following:

```
$AdminTask deleteIdMgrEntryMappingRepositoryTables {-schemaLocation "C:/WAS/etc/wim/setup"
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver
com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

## Sample CLI Usage using -file option:

To set up a database with the -file option using the example params.txt file below, enter the following:

```
$AdminTask setupIdMgrDBTables {-file C:/params.txt -dbPropXML
"C:/OverrideDBPropParam/wimdbproperties.xml"}
```

### Params.txt

```
schemaLocation=C:/WAS/etc/wim/setup
dbPropXML=C:/Program Files/IBM/WebSphere/AppServer/profiles/default
/config/cells/mycell1/wim/config/wimdbproperties.xml
laPropXML=C:/Program Files/IBM/WebSphere/AppServer/profiles/default
/config/cells/mycell1/wim/config/wimlaproperties.xml
databaseType=db2
dbURL=jdbc:db2:wim
dbDriver=com.ibm.db2.jcc.DB2Driver
reportSqlError=true
dn=o=db.com
dbAdminId=db2admin
dbAdminPassword=dbPassword
wasAdminId=wasadmin
wasAdminPassword=wasadmin1
```

To set up a database with the -file option using a file only, enter the following:

```
$AdminTask setupIdMgrDBTables {-file C:/params.txt}
```

**Note:** The use of a file only works if `-file` is the only parameter specified on the command line. If other parameters are specified then the file is completely ignored, and only the parameters on the command line are used to execute the command.

*Manually setting up the property extension repository for federated repositories:*

You can use the `createIdMgrPropExtDbTables` script to create tables in the property extension repository for federated repositories.

### **Before you begin**

The following databases are supported by the script when the database exists on a distributed operating system:

- IBM DB2
- Apache Derby
- IBM Informix Dynamic Server
- Oracle 11g
- Microsoft SQL Server

For a list of the supported database versions, see the IBM WebSphere Application Server detailed system requirements.

To use the IBM DB2 on z/OS or IBM DB2 on iSeries database, read about manually setting up the property extension repository in DB2.

If you do not have WebSphere Application Server installed on the same system on which you are setting up the database, you must copy the following files from a system where WebSphere Application Server is installed to the system on which you are setting up the database. Ensure that you replicate the same directory structure within the setup directory. The `db_type` variable represents one of the following directory names: `db2`, `oracle`, `informix`, `derby`, or `sqlserver`.

```
app_server_root\etc\wim\setup\bin\createIdMgrPropExtDbTables.sh
app_server_root\etc\wim\setup\bin\createIdMgrPropExtDbTables.bat
app_server_root\etc\wim\setup\lookaside\db_type\dbclean.sql
app_server_root\etc\wim\setup\lookaside\db_type\schema.sql
app_server_root\etc\wim\setup\lookaside\db_type\primarykeys.sql
app_server_root\etc\wim\setup\lookaside\db_type\indexes.sql
app_server_root\etc\wim\setup\lookaside\db_type\references.sql
app_server_root\etc\wim\setup\lookaside\keys.sql
app_server_root\etc\wim\setup\lookaside\bootstrap.sql
```

### **Specifying the database schema:**

You can specify the database schema where you want to create the federated repository tables when you are manually setting up the property extension repository.

If you want to use the default schema of the database, you must execute the following commands without specifying the `DBSCHEMA` parameter. Typically, the default schema is the namespace of the current database user.

Complete these steps to replace the schema variable in the SQL files with the actual database schema name. If WebSphere Application Server and the database are not on the same system, set the `SCHEMA_LOCATION` value to the location where you copied the SQL files.

### **Windows operating systems:**

1. Open a command window.
2. Change to the `app_server_root\etc\wim\setup` directory.

3. Enter the following commands:

```
set SCHEMA_LOCATION=app_server_root\etc\wim\setup\lookaside
set DBTYPE=<db_type>
set DBSCHEMA=dbschemaname
set SCHEMA_DEST_LOCATION=<location where the updated SQL files with replaced variables should be copied>
ws_ant.bat -f app_server_root\etc\wim\setup\filterbuild.xml
```

where the value of <db\_type> is db2, derby, informix, oracle, or sqlserver.

**Note:** : If SCHEMA\_DEST\_LOCATION is not set, the updated SQL files are copied to a directory with the name as the value not substituted under the current directory. The output shows where the files are copied.

### AIX, HP-UX, Linux, and Solaris operating systems:

1. Open a command window
2. Change to the *app\_server\_root/etc/wim/setup* directory.
3. Enter the following commands:

```
export SCHEMA_LOCATION=app_server_root/etc/wim/setup/lookaside
export DBTYPE=<db_type>
export DBSCHEMA=dbschemaname
export SCHEMA_DEST_LOCATION=<location where the updated SQL files with replaced variables should be copied>
ws_ant.sh -f app_server_root/etc/wim/setup/filterbuild.xml
```

where the value of <db\_type> is db2, derby, informix, oracle, or sqlserver.

**Note:** If SCHEMA\_DEST\_LOCATION is not set, the updated SQL files are copied to a directory with the name as the value not substituted under the current directory. The output shows where the files are copied.

### About this task

The following notes apply to specific databases:

- **Oracle 11g**

- If you did not create the default database when you installed Oracle product, you must manually create the database before you run the `createldMgrPropExtDbTables` script. The value of the `ORACLE_SID` variable is the same value as the name of the database.
- If you want to create the tables in the schema that you specified using `DBSCHEMA` (described in the previous section, *Specifying the database schema*) ensure that you create the specified schema in this database before you run the `createldMgrPropExtDbTables` script.
- On the AIX, HP-UX, Linux, and Solaris operating systems, run the `createldMgrPropExtDbTables` script either as an Oracle user or as a root user with database administrator (dba) rights and appropriate permissions to run SQL queries as a system database administrator (sysdba).

- **IBM DB2**

- On the Windows operating systems, you must initialize the DB2 environment before you run the `createldMgrPropExtDbTables` script. At the Windows command prompt, enter `db2cmd` to open a new DB2 command window and run the `createldMgrPropExtDbTables` batch file from this prompt.

- **Microsoft SQL Server**

- Open a command window, change to the *app\_server\_root\bin* directory, and enter the following commands to replace the variables in the SQL files. If WebSphere Application Server and the database are not on the same system, set the **SCHEMA\_LOCATION** value to the location where you copied the SQL files.

```
set SCHEMA_LOCATION=app_server_root\etc\wim\setup\lookaside
set DBTYPE=sqlserver
set SCHEMA_DEST_LOCATION=<location where the updated SQL files with replaced variables should be copied>
set BOWNER=dbo
ws_ant.bat -f app_server_root\etc\wim\setup\filterbuild.xml
```

**Note:** If `SCHEMA_DEST_LOCATION` is not set, the updated SQL files are copied to a directory with the name as the value not substituted under the current directory. The output shows where the files are copied.

The following default instance is created as a part of the database installation:

- DB2: *DB2*
- Informix: *demo\_on*
- SQL Server: *%computername%*

The Informix database is created with the following environment:

```
CLIENT_LOCALE=EN_US.CP1252
DB_LOCALE=EN_US.8859-1
SERVER_LOCALE=EN_US.CP1252
DBLANG=EN_US.CP125
```

## Procedure

Run the `createIdMgrPropExtDbTables.sh` script or `createIdMgrPropExtDbTables.bat` script to create the tables in the property extension repository.

Run the script from the following location or from the directory to which you previously copied the script file:

### AIX, HP-UX, Linux, and Solaris operating systems

```
app_server_root/etc/wim/setup/bin/createIdMgrPropExtDbTables.sh
```

### Windows

```
app_server_root\etc\wim\setup\bin\createIdMgrPropExtDbTables.bat
```

Use the following parameters to specify the values that you require when you run the script:

- b** Use this parameter to specify the home directory of the database.  
This value is a string value that is required for all database types.
- d** Use this parameter to specify the schema of the database.  
The value of this parameter should be the same value that you specified for `DBSCHEMA` (described in the previous section, *Specifying the database schema*).  
This value is a string value that is optional for DB2, Derby, and SQL Server databases, if you want to specify the database schema where you want to create the federated repository tables. This value is not required for Oracle and Informix databases.
- h** Use this parameter to display the help information. (Optional)
- i** Use this parameter to specify the home directory of the database instance.  
This value is a string value that is required for a DB2 database only; do not specify a value for other database types.  
This parameter applies to the AIX, HP-UX, Linux, and Solaris operating systems.
- n** Use this parameter to specify the name of the database to which you are connecting.  
For an Oracle database, the value of the `ORACLE_SID` variable is the same as the name of the database.  
This value is a string value that is required for all database types.
- p** Use this parameter to specify the password of the database administrator.  
This value is a string value that is required for DB2, Oracle, Informix, and SQL Server databases only; do not specify a value for a Derby database.

**-s** On AIX, HP-UX, Linux, and Solaris operating systems, this parameter specifies the location of the *app\_server\_root/etc/wim/setup* directory, or the location to which the updated files are copied according to the steps in the previous section, Specifying the database schema.

On Windows operating systems, this parameter specifies the location of the *app\_server\_root\etc\wim\setup* directory, or the location to which the updated files are copied according to the steps in the previous section, Specifying the database schema.

This value is a string value that is required for all database types.

**-t** Use this parameter to specify a database type.

- On the AIX, HP-UX, Linux, and Solaris operating systems, specify one of the following valid values: db2, oracle, informix, derby.
- On the Windows operating systems, specify one of the following valid values: db2, oracle, informix, derby, or sqlserver.

This value is a string value that is required for all database types.

**-u** Use this parameter to specify the user ID of the database administrator.

This value is a string value that is required for DB2, Oracle, Informix, and SQL Server databases only; do not specify a value for a Derby database.

## Example

Run the appropriate script for your database and operating system to create tables in the property extension repository. Use the sample values to specify database parameters. If the database exists on a system where WebSphere Application Server is not installed, the following examples assume that your PATH variable includes an entry for the location to which you copied the script files. For the AIX, HP-UX, Linux, and Solaris operating systems, the entry might be the *app\_server\_root/etc/wim/setup/bin/* or the */setup/bin/* directory. For Windows operating systems, the entry might be the *app\_server\_root\etc\wim\setup\bin\* or the *\setup\bin\* directory.

The examples in the following section are organized into multiple lines for illustration purposes only.

On the AIX, HP-UX, Linux, and Solaris operating systems:

### Oracle databases

```
createIdMgrPropExtDbTables.sh
-b /space/oracle/product/10.2.0/Db_1/
-n orcl
-u system
-p manager
-s /opt/IBM/WebSphere/AppServer1/etc/wim/setup
-t oracle
```

### Informix databases

```
createIdMgrPropExtDbTables.sh
-b /opt/IBM/informix/
-n demo_on
-u informix
-p informix
-s /opt/IBM/WebSphere/AppServer/etc/wim/setup
-t informix
```

### DB2 databases

```
createIdMgrPropExtDbTables.sh
-b /opt/ibm/db2/V9.1/
-n db2inst1
-p db2inst1
```

```

-s /opt/IBM/WebSphere/AppServer/etc/wim/setup
-t DB2
-u db2inst1
-i /home/db2inst1/

```

### Derby databases

```

createIdMgrPropExtDbTables.sh
-b /opt/ibm/derby/
-n test11
-s /opt/IBM/WebSphere/AppServer/etc/wim/setup
-t derby

```

On the Windows operating systems:

### Oracle databases

```

createIdMgrPropExtDbTables.bat
-b "c:\oracle\product\10.2.0\Db_1"
-n orcl
-u system
-p manager
-s "c:\Program Files\IBM\WebSphere\AppServer1\etc\wim\setup"
-t oracle

```

### Informix databases

```

createIdMgrPropExtDbTables.bat
-b "c:\Program Files\IBM\informix"
-n demo_on
-u informix
-p informix
-s "c:\Program Files\IBM\WebSphere\AppServer\etc\wim\setup"
-t informix

```

### DB2 databases

```

createIdMgrPropExtDbTables.bat
-t db2
-u db2admin
-p sec001ret#
-n test23
-b "c:\Program Files\IBM\SQLLIB"
-s "c:\Program Files\IBM\WebSphere\AppServer1\etc\wim\setup"

```

### Derby databases

```

createIdMgrPropExtDbTables.bat
-t derby
-b "c:\Derby"
-n test11
-s "c:\Program Files\IBM\WebSphere\AppServer1\etc\wim\setup"

```

### Microsoft SQL Server databases

```

createIdMgrPropExtDbTables.bat
-t sqlserver
-u sa
-p sec001ret#
-n sqlsrv
-b "c:\Progra~1\Micros~1\90\Tools"
-s "C:\Progra~1\IBM\WebSphere\AppServer1\etc\wim\setup"

```

### What to do next

Run the `setupIdMgrPropertyExtensionRepositoryTables` command with the **skipDBCcreation** parameter set to true to populate the tables that are created. For more information, read about setting up an entry mapping repository, a property extension repository, or a custom registry database repository using `wsadmin` commands.

*Manually setting up the property extension repository for DB2 for iSeries or DB2 for z/OS:*

Use this task to set up the property extension repository for DB2 for iSeries or DB2 for z/OS.

## Before you begin

The information in this topic applies in the following scenarios:

- The application server and the database both exist on the IBM i operating system.
- The application server and the database both exist on the z/OS operating system.
- The application server exists on a distributed operating system, but the database exists on either the IBM i or z/OS operating system.

If you do not have WebSphere Application Server installed in the system on which you are setting up the database, copy the following files from a system where WebSphere Application Server is installed to the system on which you are setting up the database:

### DB2 for iSeries

```
app_server_root/etc/wim/setup/lookaside/db2iseries/dbclean.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/schema.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/primarykeys.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/indexes.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/references.sql
app_server_root/etc/wim/setup/lookaside/keys.sql
app_server_root/etc/wim/setup/lookaside/bootstrap.sql
```

### DB2 for z/OS

```
app_server_root/etc/wim/setup/lookaside/db2zos/dbclean.sql
app_server_root/etc/wim/setup/lookaside/db2zos/schema.sql
app_server_root/etc/wim/setup/lookaside/db2zos/primarykeys.sql
app_server_root/etc/wim/setup/lookaside/db2zos/indexes.sql
app_server_root/etc/wim/setup/lookaside/db2zos/references.sql
app_server_root/etc/wim/setup/lookaside/keys.sql
app_server_root/etc/wim/setup/lookaside/bootstrap.sql
```

## About this task

For information about how to create a database and run SQL queries in DB2 for iSeries, see the DB2 Universal Database for iSeries in the IBM iSeries Information Center.

For information about how to create a database and run SQL queries in DB2 for z/OS, see the Information Management Software for z/OS Solutions Information Center.

## Procedure

1. Open a command window.
2. Change to the *app\_server\_root/bin* directory
3. Enter the following commands to replace the variables in the SQL files:
  - a. `export SCHEMA_LOCATION=app_server_root/etc/wim/setup/lookaside`  
Set the `SCHEMA_LOCATION` value to the location where you copied the SQL files if you do not have WebSphere Application Server installed on the same system on which you are setting up the database.
  - b. `export DBTYPE=<db_type>`  
where the value of `<db_type>` is `db2iseries` or `db2zos`
  - c. To specify the database schema where you want to create the federated repository tables use the `DBSCHEMA` command. If you want to use the default schema, which is typically the namespace of the current database user, do not specify the `DBSCHEMA` command.  
`export DBSCHEMA=dbschemaname`
  - d. `export SCHEMA_DEST_LOCATION=<schema_dest_location>`

where `<schema_dest_location>` is the location where the updated SQL files with replaced variables should be copied. If `SCHEMA_DEST_LOCATION` is not set, the updated SQL files are copied to a directory with the name as the unsubstituted value under the current directory. The output indicates where the files are copied to.

- e. Specify the buffer pool to use for creating the federated repository tables. The buffer pool value that you specify should exist in the database. The default buffer pool value in the database is `BP0`. Even if you want to use the default buffer pool value, you must still execute the following commands and specify the default value of `BP0` explicitly:

```
export DEFAULT_TABLE=<buffer pool value for default tables>
export LOB_TABLE=<buffer pool value for LOB tables>
export INDEX_TABLE=<buffer pool value for unique index tables>
```

- f. `export DBNAME=zos`

- g. `./ws_ant.sh -f app_server_root/etc/wim/setup/filterbuild.xml`

4. Start the DB2 server.
5. Create a database.
6. Run the SQL files, which were previously referenced, to create the tables for the property extension repository. If you are setting up the database on the same system on which the application server is installed, the files are located in the following locations:

#### DB2 for iSeries

```
app_server_root/etc/wim/setup/lookaside/db2iseries/dbclean.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/schema.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/primarykeys.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/indexes.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/references.sql
app_server_root/etc/wim/setup/lookaside/keys.sql
app_server_root/etc/wim/setup/lookaside/bootstrap.sql
```

#### DB2 for z/OS

```
app_server_root/etc/wim/setup/lookaside/db2zos/dbclean.sql
app_server_root/etc/wim/setup/lookaside/db2zos/schema.sql
app_server_root/etc/wim/setup/lookaside/db2zos/primarykeys.sql
app_server_root/etc/wim/setup/lookaside/db2zos/indexes.sql
app_server_root/etc/wim/setup/lookaside/db2zos/references.sql
app_server_root/etc/wim/setup/lookaside/keys.sql
app_server_root/etc/wim/setup/lookaside/bootstrap.sql
```

Otherwise, run the SQL files from the location to which you copied the files. If you executed the commands to substitute variables according to the steps in the previous section, Specifying the database schema, the SQL files are copied to the location you specified for `SCHEMA_DEST_LOCATION`. If `SCHEMA_DEST_LOCATION` is not set, the updated SQL files are copied to a directory with the name as the unsubstituted value under the current directory. The output shows where the files are copied.

## What to do next

Run the `setupIdMgrPropertyExtensionRepositoryTables` command with the **skipDBCcreation** parameter set to true to populate the tables that are created. For more information, read about setting up an entry mapping repository, a property extension repository, or a custom registry database repository using `wsadmin` commands.

### *Configuring the WebSphere Application Server data source:*

Installed applications use data sources as resources to obtain connection to relational databases. To create these connections between an application and a relational database, WebSphere Application Server uses the driver implementation classes that are encapsulated by the JDBC provider, which is an object that represents vendor-specific JDBC driver classes to WebSphere Application Server. For access to a relational databases, applications use the JDBC drivers and data sources that you configure for WebSphere Application Server.

## Procedure

1. Start the WebSphere Application Server administrative console.
2. Click **Security -> Global security**.
3. On the Configuration panel, expand Java Authentication and Authorization Service and click **J2C authentication data**.
4. Click **New** and enter the Alias, User ID and Password.
5. Click **Ok**.
6. On the WebSphere Application Server administrative console, expand **Resources**. Expand **JDBC** then click **JDBC Providers**.
7. In the Scope section, choose the **Node level** from the drop-down list.
8. Click **New** to create a new JDBC driver.
9. Select, in this order, the Database type, Provider type, Implementation type and Name. The Name automatically fills based on the implementation type you choose.
10. Click **Next** and configure the database class path. Click **Next**.
11. On the Summary page, click **Finish**.
12. Click **Save** to save your selections. The JDBC providers page then appears.
13. On the WebSphere Application Server administrative console, click **Data sources**.
14. Click **New** to create a new data source. Enter the Data source name and the JNDI name, and choose the authentication alias from the drop-down list in Component-managed authentication alias. The JNDI name should match the dataSourceName value set in wimconfig.xml. By default, it is jdbc/wimDS.  
  
**Note:** For Apache Derby v10.2 embedded databases, leave the Component-managed authentication alias field set to NONE.
15. Click **Next**.
16. Enter the Database name and deselect the checkbox, **Use this data source in container managed persistence (CMP)**. Click **Next**.
17. On the Summary page, click **Finish**.
18. The Data sources page displays. Click **Save**, Then select the check box for the authentication alias previously created. Click **Test Connection**. The message should indicate that the connection is successful. Ignore any warnings, and then click **Next**.
19. Save the configurations, and restart WebSphere Application Server.

### **Configuring an entry mapping repository in a federated repository configuration:**

Follow this task to configure an entry mapping repository that is used to store data for managing profiles on multiple repositories.

#### **About this task**

An *entry-level join* means that the federated repository configuration uses multiple repositories simultaneously and recognizes the entries in the different repositories as entries representing distinct entities. For example, a company might have a Lightweight Directory Access Protocol (LDAP) directory that contains entries for its employees and a database that contains entries for business partners and customers. By configuring an entry mapping repository, a federated repository configuration can use both the LDAP and the database at the same time. The federated repository configuration hierarchy and constraints for identifiers provide the aggregated namespace for both of those repositories and prevent identifiers from colliding.

When you configure an entry mapping repository, you can supply a valid data source, a direct connection configuration, or both. The system first tries to connect by way of the data source. If the data source is not available, then the system uses the direct access configuration.

**Restriction:** You cannot configure an entry mapping repository in a mixed-version deployment manager cell.

### Procedure

1. Configure the WebSphere Application Server data source. See “Configuring the WebSphere Application Server data source” on page 1467.
2. Set up the entry mapping repository using wsadmin. See “Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands” on page 1452; ignore the "Before you begin" options.
3. Configure the entry mapping repository into the federated repository by doing the following:
  - a. In the administrative console, click **Security > Global security**.
  - b. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
  - c. Click **Entry mapping repository**.
  - d. Supply the name of the data source in the Data source name field.
  - e. Select the type of database that is used for the property extension repository.
  - f. Supply the name of the Java database connectivity (JDBC) driver in the JDBC driver field.

Values include:

**DB2** com.ibm.db2.jcc.DB2Driver

#### DB2 for z/OS

com.ibm.db2.jcc.DB2Driver

#### Informix

com.informix.jdbc.IfxDriver

#### DataDirect Connect

com.ddtek.jdbc.sqlserver.SQLServerDriver

**Derby** org.apache.derby.jdbc.EmbeddedDriver

#### Microsoft SQL Server

com.microsoft.sqlserver.jdbc.SQLServerDriver

#### Oracle

oracle.jdbc.driver.OracleDriver

- g. Supply the database URL that is used to access the property extension repository with JDBC in the Database URL field. Use an alphanumeric text string that conforms to the standard JDBC URL syntax.

Values include:

**DB2** jdbc:db2:wim

#### Informix

jdbc:informix-sqli://host\_name:1526/wim:INFORMIXSERVER=IFXServerName;

#### DataDirect Connect

jdbc:datadirect:sqlserver://host\_name:1433;databaseName=wim;selectMethod=cursor;

**Derby** jdbc:derby:c:\derby\wim

#### Microsoft SQL Server

jdbc:sqlserver://host\_name:1433;databaseName=wim;selectMethod=cursor;

## Oracle

`jdbc:oracle:thin:@host_name:port:dbname`

- h. Supply the user name of the database administrator in the Database administrator user name field.
- i. Supply the password of the database administrator in the Password field.
- j. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which includes an entry mapping repository, is configured.

## What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** in the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

### *Entry mapping repository settings:*

Use this page to configure an entry mapping repository that is used to store data for managing profiles on multiple repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Entry mapping repository**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

### *Data source name:*

Specifies the Java Naming and Directory Interface (JNDI) name of the data source that is used to access the entry mapping repository.

**Default:** `jdbc/wimDS`

### *Database type:*

Specifies the type of database that is used to access the entry mapping repository.

**Default:** `DB2`

### *JDBC driver:*

Specifies the Java Database Connectivity (JDBC) driver that is used to access the entry mapping repository.

Values include:

**DB2** `com.ibm.db2.jcc.DB2Driver`

**DB2 for z/OS**

`com.ibm.db2.jcc.DB2Driver`

**DataDirect Connect**

`com.ddtek.jdbc.sqlserver.SQLServerDriver`

**Informix**

`com.informix.jdbc.IfxDriver`

**Oracle**

`oracle.jdbc.driver.OracleDriver`

**Microsoft SQL Server**

`com.microsoft.sqlserver.jdbc.SQLServerDriver`

**Derby** `org.apache.derby.jdbc.EmbeddedDriver`

*Database URL:*

Specifies the web address for the entry mapping repository.

Values include:

**DB2** `jdbc:db2:wim`

**Derby** `jdbc:derby:c:\derby\wim`

**DataDirect Connect**

`datadirect:sqlserver://:host_name1433;databaseName=wim;selectMethod=cursor;`

**Oracle**

`jdbc:oracle:thin:@host_name:port:dbname`

**Microsoft SQL Server**

`jdbc:sqlserver://host_name:1433;databaseName=wim;selectMethod=cursor;`

**Informix**

`jdbc:informix-sqli://host_name:1526/wim:INFORMIXSERVER=IFXServerName;`

*Database administrator user name:*

Specifies the user name of the database administrator that is used to access the entry mapping repository.

*Password:*

Specifies the password that is used to enable the database administrator to access the entry mapping repository.

***Configuring supported entity types in a federated repository configuration:***

Follow this task to configure supported entity types for user and group management.

**About this task**

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The supported entity types are Group, OrgContainer, and PersonAccount. A

Group entity represents a simple collection of entities that might not have any relational context. An OrgContainer entity represents an organization, such as a company or an enterprise, a subsidiary, or an organizational unit, such as a division, a location, or a department. A PersonAccount entity represents a human being. You cannot add or delete the supported entity types, because these types are predefined.

The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

**Note:** To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

**Note:** You must restart the server or dmgr if the federated repository has changed before using the Manage Users option. Otherwise, user or group changes made to the repository could be lost after restart.

### Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Click **Supported entity types** to view a list of predefined entity types.
4. Click the name of a predefined entity type to change its configuration.
5. Supply the distinguished name of a base entry in the repository in the Base entry for the default parent field. This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.
6. Supply the relative distinguished name (RDN<sup>®</sup>) properties for the specified entity type in the Relative Distinguished Name properties field. Possible values are `cn` for Group, `uid` or `cn` for PersonAccount, and `o`, `ou`, `dc`, and `cn` for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

The following list outlines known requirements and limitations that apply to specific Lightweight Directory Access Protocol (LDAP) servers:

#### Using Microsoft Active Directory as the LDAP server

- Unless you modify the LDAP schema to use `uid`, you must specify `cn` in the Relative Distinguished Name (RDN) properties field for the PersonAccount entity type.
- Secure Sockets Layer communications must be enabled to create users with passwords. To select the **Require SSL communications** option, see the topic “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 1433.
- Typically the value of `user` is specified as the value in the Object classes field for the PersonAccount entity type and the value of `group` is specified as the value in the Object classes field for the Group entity type.

#### Using a Lotus Domino Enterprise Server as the LDAP server

- Typically, the value of `cn` is specified in the Relative Distinguished Name (RDN) properties field for the PersonAccount entity type. The value of `uid` is also acceptable.
- Typically, both `inetOrgPerson` and `dominoPerson` are used as values in the Object classes field for the PersonAccount entity type.

#### Using Sun ONE Directory Server as the LDAP server

- Typically, `groupOfUniqueNames` is specified as the value in the Object classes field for the Group entity type.

7. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which uses supported entity types, is configured.

### What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** on the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

### *Supported entity types collection:*

Use this page to list entity types that are supported by the member repositories or to select an entity type to view or change its configuration properties.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Supported entity types**.

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

### *Entity type:*

Specifies the entity type name.

### *Base entry for the default parent:*

Specifies the distinguished name of a base entry in the repository.

This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.

### *Relative Distinguished Name properties:*

Specifies the relative distinguished name (RDN) properties for the specified entity type.

Possible values are `cn` for Group, `uid` or `cn` for PersonAccount, and `o`, `ou`, `dc`, and `cn` for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

### *Supported entity types settings:*

Use this page to configure entity types that are supported by the member repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Supported entity types**.
4. Click the name of a configured entity type to view or change its configuration.

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Entity type:*

Specifies the name of the entity type.

*Base entry for the default parent:*

Specifies the distinguished name of a base entry in the repository.

This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.

*Relative Distinguished Name properties:*

Specifies the relative distinguished name (RDN) properties for the specified entity type.

Possible values are cn for Group, uid or cn for PersonAccount, and o, ou, dc, and cn for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

### ***Managing repositories in a federated repository configuration:***

Follow this topic to manage repositories in a federated repository configuration.

### **Procedure**

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**. Repositories that are configured in the system are listed in the collection panel. This list includes repositories that are configured using the federated repository functionality as well as repositories that are created using wsadmin commands described in the topic `IdMgrRepositoryConfig` command group for the AdminTask object.
4. Optional: Click **Add** to configure a new external repository. The Lightweight Directory Access Protocol (LDAP) repository configuration settings are described in detail in "Configuring Lightweight Directory Access Protocol in a federated repository configuration" on page 1433.

**Restriction:** You cannot add a database repository using the administrative console. This repository configuration is supported by using wsadmin commands only.

5. Optional: Click **Delete** to delete a repository that you specified previously using the administrative console or wsadmin commands.

**Restriction:** You cannot delete the built-in, file-based repository from the collection panel.

- Optional: Select one of the LDAP repository identifier entries to view or update an external repository that is configured in the system previously. The steps to configure LDAP settings are described in detail in “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 1433.

**Restriction:** While database repositories that are configured in the system are listed in the collection panel, you cannot update a database repository using the administrative console. Updates to a database repository are supported by using wsadmin commands only.

- Click **OK**.

## Results

After completing these steps, the collection panel under Managing repositories reflects a current list of repositories that are configured in your system.

## What to do next

- To add one or more external repositories that are listed on this collection panel into the realm, see “Managing the realm in a federated repository configuration” on page 1410.
- After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
- If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1254. As the final step, validate this setup by clicking **Apply** in the Global security panel.
- Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

**Important:** Be aware of any changes made to built-in, file-based repositories that are part of the federated repositories configuration. You must replicate these changes to the managed nodes to ensure that your network deployment configuration is synchronized. See “Replicating changes to a built-in, file-based repository” for the steps needed to perform this replication.

*Replicating changes to a built-in, file-based repository:*

Changes to built-in, file-based repositories are not automatically replicated to managed nodes in a federated repositories configuration. You need to use the administrative console to replicate the changes you make to a built-in, file-based repository.

## About this task

The network deployment support in a federated repositories configuration only updates the in-memory state of the processes that are running on the managed nodes. Because WebSphere Application Server synchronizes the file systems, the network deployment support does not attempt to update the file systems of the managed nodes.

You must synchronize the node configuration to replicate the changes to the built-in, file-based repository.

## Procedure

- In the administrative console, click **System Administration > Nodes**. to access the nodes panel.

2. On the Nodes panel, select all the relevant nodes for which the changes to the built-in, file-based repository need to be made.
3. Click **Full Resynchronize**. The resynchronize operation resolves conflicts among configuration files and can take several minutes to complete.

## Results

After completing these steps, your federated repository configuration of managed nodes reflects the changes to the built-in, file-based repository.

### *Manage repositories collection:*

Use this page to list repositories that are configured in the system or to select a repository to view or change its configuration properties. You can add or delete external repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

### *Repository identifier:*

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

### *Repository type:*

Specifies the repository type, such as File or LDAP.

### *Add:*

Select to add a new LDAP, custom or file repository.

### *Repository reference settings:*

Use this page to configure a repository reference. A repository reference is a single repository that contains a set of identity entries that are referenced by a base entry into the directory information tree.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Click **Add base entry to realm**.
