           RemoteException;
```

This method retrieves users from the specified group. The number of users returned is limited by the limit parameter. A limit of zero (0) indicates to return all of the users in that group. This method is not directly called by the WebSphere Application Server security component. However, this method can be called by other components. In rare situations, if you are working with a user registry where getting all the users from any of your groups is not practical, you can create the `NotImplementedException` exception for the particular groups. In this case, verify that if the process choreographer is installed the staff assignments are not modeled using these particular groups. If no concern exists about returning the users from groups in the user registry, it is recommended that you do not create the `NotImplemented` exception when implementing this method.

The return parameter is an object with a `com.ibm.websphere.security.Result` type. This object contains the `java.util.List` and `java.lang.boolean` attributes. The list contains the users that are returned and the Boolean flag, which indicates whether more users are available in the user registry for the search pattern. This Boolean flag indicates to the client whether users are available in the user registry.

In the example, this method gets one user more than the requested number of users for a group, if the limit parameter is not set to zero (0). If the method succeeds in getting one more user, the Boolean flag is set to `true`.

In WebSphere Application Server Version 4, this `getUsers` method is mandatory for the product. For WebSphere Application Server Version 5.x or later, this method can create the `NotImplementedException` exception in situations where it is not practical to get the requested set of users. However, create this exception in rare situations when as other components can be affected. In Version 4, this method accepts only the pattern parameter and returns a list. In Version 5, this method accepts the limit parameter. Change your implementation to take the limit value and limit the users that are returned. The return changes to return a `Result` object, which consists of the list and a flag that indicates whether more entries exist. When the list is returned, use the `Result.setList(List)` method to set the list in the `Result` object. If more entries than requested are in the limit parameter, set the Boolean attribute to `true` in the `Result` object using `Result.setHasMore` method. The default for the Boolean attribute in the `Result` object is `false`.

- Implement the `createCredential(String)` method.

Attention: The first two lines of the following code sample are split for illustrative purposes only.

```
public com.ibm.websphere.security.cred.WSCredential createCredential(String userSecurityName)
    throws NotImplementedException,
           EntryNotFoundException,
           CustomRegistryException,
           RemoteException;
```

In this release the WebSphere Application Server, the `createCredential` method is not called. You can return `null`. In the example, a `null` value is returned.

What to do next

Managing the realm in a federated repository configuration

Follow this topic to manage the realm in a federated repository configuration.

Before you begin

The realm can consist of identities in:

- The file-based repository that is built into the system
- One or more external repositories
- Both the built-in, file-based repository and in one or more external repositories

Before you configure your realm, review “Federated repositories limitations” on page 1487.

Procedure

1. Configure your realm by using one of the following topics. You might be configuring your realm for the first time or changing an existing realm configuration.
 - “Using a single built-in, file-based repository in a new configuration under Federated repositories” on page 1490
 - “Changing a federated repository configuration to include a single built-in, file-based repository only” on page 1495
 - “Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories” on page 1496
 - “Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only” on page 1497
 - “Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1498
 - “Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1500
2. Configure supported entity types using the steps described in “Configuring supported entity types in a federated repository configuration” on page 1543. You must configure supported entity types before you can manage this account with Users and Groups. The Base entry for the default parent determines the repository location where entities of the specified type are placed on a create operation.
3. Optional: Use one or more of the following tasks to extend the capabilities of storing data and attributes in your realm:
 - a. Configure an entry mapping repository using the steps described in “Configuring an entry mapping repository in a federated repository configuration” on page 1539. An entry mapping repository is used to store data for managing profiles on multiple repositories.
 - b. Configure a property extension repository using the steps described in “Configuring a property extension repository in a federated repository configuration” on page 1518. A property extension repository is used to store attributes that cannot be stored in your Lightweight Directory Access Protocol (LDAP) server.
 - a. Set up a database repository using `wsadmin` commands as described in “Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using `wsadmin` commands” on page 1523
4. Optional: Use one or more of the following advanced user tasks to extend the capabilities of LDAP repositories in your realm:
 - “Increasing the performance of the federated repository configuration” on page 1548

- “Configuring Lightweight Directory Access Protocol entity types in a federated repository configuration” on page 1562
 - “Configuring group attribute definition settings in a federated repository configuration” on page 1564
5. Optional: Manage repositories that are configured in your system by following the steps described in “Managing repositories in a federated repository configuration” on page 1545.
 6. Optional: Add an external repository into your realm by following the steps described in “Adding an external repository in a federated repository configuration” on page 1517.
 7. Optional: Change the password for the repository that is configured under federated repositories by the following steps described in “Changing the password for a repository under a federated repositories configuration” on page 1488.

What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Federated repositories:

Federated repositories enable you to use multiple repositories with WebSphere Application Server. These repositories, which can be file-based repositories, LDAP repositories, or a sub-tree of an LDAP repository, are defined and theoretically combined under a single realm. All of the user repositories that are configured under the federated repository functionality are invisible to WebSphere Application Server.

When you use the federated repositories functionality, all of the configured repositories, which you specify as part of the federated repository configuration, become active. It is required that the user ID, and the distinguished name (DN) for an LDAP repository, be unique in multiple user repositories that are configured under the same federated repository configuration. For example, there might be three different repositories that are configured for the federated repositories configuration: Repository A, Repository B, and Repository C. When user1 logs in, the federated repository adapter searches each of the repositories for all of the occurrences of that user. If multiple instances of that user are found in the combined repositories, an error message displays.

In addition, the federated repositories functionality in WebSphere Application Server supports the logical joining of entries across multiple user repositories when the Application Server searches and retrieves entries from the repositories. For example, when an application calls for a sorted list of people whose age is greater than twenty, WebSphere Application searches all of the repositories in the federated repositories configuration. The results are combined and sorted before the Application Server returns the results to the application.

Restrictions:

- WebSphere Application Server federated repositories **DO NOT** support a z/OS LDAP server with an SDBM backend (resource access control facility (RACF)).

Unlike the local operating system, stand-alone LDAP registry, or custom registry options, federated repositories provide user and group management with read and write capabilities. When you configure federated repositories, you can use one of the following methods to add, create, and delete users and groups:

Important: If you configure multiple repositories under the federated repositories realm, you must also configure supported entity types and specify a base entry for the default parent. The base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management. See “Configuring supported entity types in a federated repository configuration” on page 1543 for details.

- Use the user management application programming interfaces (API). For more information, refer to articles under "Developing with virtual member manager" in this information center.
- Use the administrative console. To manage users and groups within the administrative console, click **Users and Groups > Manage Users** or **Users and Groups > Manage Groups**. For information on user and group management, click the Help link that displays in the upper right corner of the window. From the left navigation pane, click **Users and Groups**.
- Use the wsadmin commands. For more information, see the WIMManagementCommands command group for the AdminTask object topic.

If you do not configure the federated repositories functionality or do not enable federated repositories as the active repository, you cannot use the user management capabilities that are associated with federated repositories. You can configure an LDAP server as the active user registry and configure the same LDAP server under federated repositories, but not select federated repositories as the active user repository. With this scenario, authentication takes place using the LDAP server, and you can use the user management functionality for the LDAP server that is available for federated repositories.

The following table compares the federated repository functionality that is available in WebSphere Application Server Version 8.0 with the registry functionality that remains unchanged from previous versions of the Application Server.

Table 92. Federated repositories versus user registry implementations.

This table lists federated repositories versus user registry implementations.

Federated repositories	User registry
Supports multiple types of repositories such as file-based, LDAP, database, and custom. In WebSphere Application Server Version 8.0, file-based and LDAP repositories are supported by the administrative console. However, the federated repositories functionality does not support local operating system implementations. With this service release, the federated repositories functionality supports local operating system implementations. For database and custom repositories, you can use the wsadmin command-line interface or the configuration application programming interfaces (API). Restriction: WebSphere Application Server federated repositories DO NOT support a z/OS LDAP server with an SDBM backend (resource access control facility (RACF)).	Supports multiple types of registries such as the local operating system, a stand-alone LDAP registry, and a stand-alone custom registry.
Supports multiple repositories in a realm within a cell.	Supports one registry only in a realm within a cell.
Provides read and write capabilities for the repositories that are defined in the federated repository configuration.	Provides read only capability for the registries.
Provides account and password policy support as defined by the registry type. However, this support is not provided by the federated repository functionality.	Provides account and password policy support as defined by the registry type.
Supports identity profiles.	Does not support identity profiles.
Uses the custom UserRegistry implementation.	Uses the custom UserRegistry implementation.

Realm configuration settings:

Use this page to manage the realm. The realm can consist of identities in the file-based repository that is built into the system, in one or more external repositories, or in both the built-in, file-based repository and one or more external repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Security domains**.
2. Under User realm, select **Customize for this domain**. Select **Federated repositories** from the Realm type field and click **Configure**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

A single built-in, file-based repository is built into the system and included in the realm by default.

You can configure one or more Lightweight Directory Access Protocol (LDAP) repositories to store identities in the realm. Click **Add base entry to realm** to specify a repository configuration and a base entry into the realm. You can configure multiple different base entries into the same repository.

Click **Remove** to remove selected repositories from the realm. Repository configurations and contents are not destroyed. The following restrictions apply:

- The realm must always contain at least one base entry; therefore, you cannot remove every entry.
- If you plan to remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.

WebSphere Application Server Version 7.0 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

Realm name:

Specifies the name of the realm. You can change the realm name.

Primary administrative user name:

Specifies the name of the user with administrative privileges that is defined in the repository, for example, adminUser.

The user name is used to log on to the administrative console when administrative security is enabled. Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

Attention: In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

Automatically generated server identity:

Enables the application server to generate the server identity, which is recommended for environments that contain only Version 6.1 or later nodes. Automatically generated server identities are not stored in a user repository.

Default: Enabled

User identity for the z/OS started task:

Specifies the user identity that is associated with the z/OS system started task. Each controller and server can have its own identity.

Ignore case for authorization:

Specifies that a case-insensitive authorization check is performed.

If case sensitivity is not a consideration for authorization, enable the **Ignore case for authorization** option.

Allow operations if some of the repositories are down:

Specifies whether operations (such as login, search, or get) are allowed even if the repositories in the realm are down.

Use global schema for model:

Sets the global schema option for the data model in a multiple security domain environment. Global schema refers to the schema of the admin domain.

Note: Application domains that are set to use global schema share the same schema of the admin domain. If you extend the schema for an application in one domain, you must also consider how that might affect applications of other domains, as they are bound by the same schema. For example, adding a mandatory property for one application might cause other applications to fail.

Base entry:

Specifies the base entry within the realm. This entry and its descendents are part of the realm.

Repository identifier:

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Repository type:

Specifies the repository type, such as File or LDAP.

User attribute mapping for federated repositories:

Use this panel to set or to modify the mapping for a user registry's user or group attribute to a federated repository property.

To view this administrative console page, click **Security > Global security**. Under Available realm definitions, click **Federated repositories**, and then **Configure**. On the next panel and under Additional Properties, click **User repository attribute mapping**.

Attribute mappings:

Select an attribute to set or to modify the mapping for a user registry's user or group attribute to a federated repository property, and then click **Edit**.

Custom properties details for federated repositories:

Use this panel to specify the configuration for access to a custom repository.

To view this administrative console page, click **Security > Global security**. Under Available realm definitions, click **Federated repositories**, and then **Configure**. On the next panel and under Additional Properties, click **Manage repositories**. Under Add, select **Custom repository**.

Repository identifier:

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Repository adapter class name:

Specifies the implementation class name for the repository adapter. For a User Registry bridge, use `com.ibm.ws.wim.adapter.urbridge.URBridge`.

Login properties:

Specifies the property names to use to log into the application server.

Custom properties:

Specifies arbitrary name and value pairs of data. The name is a property key and the value is a string value that can be used to set internal system configuration properties.

File details for federated repositories:

Use this panel to specify the configuration for access to a file repository.

To view this administrative console page, click **Security > Global security**. Under Available realm definitions, click **Federated repositories**, and then **Configure**. On the next panel and under Additional Properties, click **Manage repositories**. Under Add, select **File repository**.

Repository identifier:

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Repository adapter class name:

Specifies the implementation class name for the repository adapter. For a User Registry bridge, use `com.ibm.ws.wim.adapter.urbridge.URBridge`.

Base directory:

The base directory where the files are to be created. This directory must already exist.

File name:

The file name for the repository.

The default value is `fileRegistry.xml`.

Salt length:

Specifies the salt length of the randomly generated salt for password hashing.

The default value is 12.

Message digest algorithm:

Specifies the message digest algorithm to use for hashing the password.

Select one of the following: SHA-1, SHA-256, SHA-384 or SHA-512.

The default value is SHA-1.

Login properties:

Specifies the property names to use to log into the application server.

Custom properties:

Specifies arbitrary name and value pairs of data. The name is a property key and the value is a string value that can be used to set internal system configuration properties.

Federated repositories limitations:

This topic outlines known limitations and important information for configuring federated repositories.

Configuring federated repositories in a mixed-version environment

In a mixed-version deployment manager cell that contains both Version 6.1.x and Version 5.x or 6.0.x nodes, the following limitations apply for configuring federated repositories:

- You can configure only one Lightweight Directory Access Protocol (LDAP) repository under federated repositories, and the repository must be supported by Version 5.x or 6.0.x.
- You can specify a realm name that is compatible with prior versions only. The host name and the port number represent the realm for the LDAP server in a mixed-version nodes cell. For example, machine1.austin.ibm.com:389.
- You must configure a stand-alone LDAP registry; the LDAP information in both the stand-alone LDAP registry and the LDAP repository under the federated repositories configuration must match. During node synchronization, the LDAP information from the stand-alone LDAP registry propagates to the Version 5.x or 6.0.x nodes.

Important: Before node synchronization, verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. Do not set the stand-alone LDAP registry as the current realm definition.

- You cannot configure an entry mapping repository or a property extension repository in a mixed-version deployment manager cell.

Configuring LDAP servers in a federated repository

The LDAP connection `connectTimeout` default value is 20 seconds. LDAP should respond within 20 seconds for any request from WebSphere Application Server. If you cannot connect to your LDAP within this time, make sure that your LDAP is running. A connection error displays at the top of the LDAP configuration panel when the connection timeout exceeds 20 seconds.

Coexisting with Tivoli Access Manager

For Tivoli Access Manager to coexist with a federated repositories configuration, the following limitations apply:

- You can configure only one LDAP repository under federated repositories, and that LDAP repository configuration must match the LDAP server configuration under Tivoli Access Manager.

- The distinguished name for the realm base entry must match the LDAP distinguished name (DN) of the base entry within the repository. In WebSphere Application Server, Tivoli Access Manager recognizes the LDAP user ID and LDAP DN for both authentication and authorization. The federated repositories configuration does not include additional mappings for the LDAP user ID and DN.
- The federated repositories functionality does not recognize the metadata that is specified by Tivoli Access Manager. When users and groups are created under user and group management, they are not formatted using the Tivoli Access Manager metadata. The users and groups must be manually imported into Tivoli Access Manager before you use them for authentication and authorization.

Limitation for configuring active directories with their own federated repository realms

In order to use the administrative console to perform a wildcard search for all available users on two Active Directories, and to prevent multiple entries exceptions with all built-in IDs, you must first configure each Active Directory with its own federated repository realm.

However, you cannot use the administrative console to configure each Active Directory with its own federated repository realm. You can instead use a wsadmin script similar to the following:

```
$AdminTask createIdMgrRealm {-name AD1realm}
$AdminTask addIdMgrRealmBaseEntry {-name AD1realm -baseEntry o=AD1}

$AdminTask createIdMgrRealm {-name AD2realm}
$AdminTask addIdMgrRealmBaseEntry {-name AD2realm -baseEntry o=AD2}

$AdminConfig save
```

Changing the password for a repository under a federated repositories configuration:

Passwords allow security control over the repositories under a federated repositories configuration. As part of managing the realm in a federated repository configuration, one of the optional tasks you can perform is to change the password of an individual repository that is under a federated repositories configuration.

Before you begin

Before you change the password for the repository that is configured under federated repositories, ensure that the WebSphere Application Server is running and the target repository for the password change is configured under the federated repositories configuration. In a WebSphere Application Server, Network Deployment environment, you must complete these steps on the deployment manager.

Procedure

- Changing the password for a repository using the dynamic **updateIdMgrLDAPBindInfo** command Use the following steps to change the Lightweight Directory Access Protocol (LDAP) bind distinguished name (DN) or bind password of an LDAP repository.

From a **wsadmin** prompt, you can enter the following command to display a list of arguments for the **updateIdMgrLDAPBindInfo** command: `$AdminTask help updateIdMgrLDAPBindInfo`

1. Start the wsadmin command-line utility. The wsadmin command is found in the `app_server_root/bin` directory. The WebSphere Application Server and wsadmin must remaining running.
 2. Use an LDAP tool to change the password of the LDAP repository. Some LDAP repositories require a stop and start of the LDAP server to change the password.
 3. From the **wsadmin** prompt, enter the **updateIdMgrLDAPBindInfo** command to update the LDAP password under the federated repository. The change is also reflected in the `wimconfig.xml` file.
- Changing the password for a repository using the **updateIdMgrDBRepository** command
 1. Start the wsadmin command-line utility. The wsadmin command is found in the `app_server_root/bin` directory. The wsadmin command session must remain running. If WebSphere Application Server is not started, you need to open a wsadmin command session in local mode. `wsadmin -conntype none`

gotcha: If you are starting the wsadmin command session in local mode, you must ensure that the location of the database driver is specified in the class path using the `-wsadmin_classpath`

option. For information on using this option, see the topic, *wsadmin scripting tool* in the WebSphere Application Server information center.

2. Log in to the Administrative Console for WebSphere Application Server.
 3. Change the password for the repository.
 4. From the Administrative Console, change the data source (J2C) password. You access the proper console page by clicking **Resources > JDBC > Data sources > data_source > JAAS - J2C authentication data**.
 5. From the Administrative Console, save your changes to the master configuration.
 6. From the **wsadmin** prompt, use the `updateIdMgrDBRepository` command to update the password in the `wimconfig.xml` file.
 7. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
 8. Restart the WebSphere Application Server.
- Changing the password for a repository using the **setIdMgrPropertyExtensionRepository** command
 1. Start the `wsadmin` command-line utility. The `wsadmin` command is found in the `app_server_root/bin` directory. The `wsadmin` command session must remain running. If WebSphere Application Server is not started, you need to open a `wsadmin` command session in local mode.

```
wsadmin -conntype none
```
 2. Log in to the Administrative Console for WebSphere Application Server.
 3. Change the password for the repository.
 4. From the Administrative Console, change the data source (J2C) password. You access the proper console page by clicking **Resources > JDBC > Data sources > data_source > JAAS - J2C authentication data**.
 5. From the Administrative Console, save your changes to the master configuration.
 6. From the **wsadmin** prompt, use the **setIdMgrPropertyExtensionRepository** command to update the password in the `wimconfig.xml` file.
 7. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
 8. Restart the WebSphere Application Server.
 - Changing the password for a repository using the **setIdMgrEntryMappingRepository** command
 1. Start the `wsadmin` command-line utility. The `wsadmin` command is found in the `app_server_root/bin` directory. The `wsadmin` command session must remain running. If WebSphere Application Server is not started, you need to open a `wsadmin` command session in local mode.

```
wsadmin -conntype none
```
 2. Log in to the Administrative Console for WebSphere Application Server.
 3. Change the password for the repository.
 4. From the Administrative Console, change the data source (J2C) password. You access the proper console page by clicking **Resources > JDBC > Data sources > data_source > JAAS - J2C authentication data**.
 5. From the Administrative Console, save your changes to the master configuration.
 6. From the **wsadmin** prompt, use the **setIdMgrEntryMappingRepository** command to update the password in the `wimconfig.xml` file.
 7. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
 8. Restart the WebSphere Application Server.
 - Changing the password for a repository using the **updateIdMgrLDAPServer** command
 1. Start the `wsadmin` command-line utility. The `wsadmin` command is found in the `app_server_root/bin` directory. The `wsadmin` command session must remain running. If WebSphere Application Server is not started, you need to open a `wsadmin` command session in local mode.

- ```
wsadmin -conntype none
```
2. Change the password for the repository.
  3. From the **wsadmin** prompt, use the **updateIdMgrLDAPServer** command to update the password in the wimconfig.xml file.
  4. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
  5. Restart the WebSphere Application Server.

## Results

The password for the repository has been changed.

### *Using a single built-in, file-based repository in a new configuration under Federated repositories:*

Follow this task to use a single built-in, file-based repository in a new configuration under Federated repositories.

## Before you begin

To use the default configuration under Federated repositories that includes a single built-in, file-based repository only, you need to know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

## Restriction:

Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

WebSphere Application Server federated repositories **DO NOT** support a z/OS LDAP server with an SDBM backend (resource access control facility (RACF)).

## Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Leave the Realm name field value as `defaultWIMFileBasedRealm`.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, `adminUser`.
5. Leave the **Ignore case for authorization** option enabled.
6. Click **OK**.
7. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, the panel does not display. If a built-in, file-based repository is included, complete the following steps:
  - a. Supply a password for the administrative user in the Password field.
  - b. Confirm the password of the primary administrative user in the Confirm password field.
  - c. Click **OK**.

## Results

After completing these steps, your new configuration under Federated repositories includes a single built-in, file-based repository only.

### What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1543.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps, as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

### *Administrative user password settings:*

Use this page to set a password for the administrative user who manages the product resources and user accounts.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. If your federated repository configuration includes a built-in, file-based repository, then the **Administrative user password** panel displays when changes are applied.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

### *Password:*

Specifies the password of the administrative user who manages the product resources and user accounts.

### *Confirm password:*

Confirms the password of the administrative user who manages the product resources and user accounts.

### *Federated repository wizard settings:*

Use this security wizard page to complete the basic requirements to connect the application server to a federated repository.

To view this security wizard page, complete the following steps

1. Click **Security > Global security > Security configuration wizard**.
2. Select your protection settings and click **Next**.
3. Select the **Federated repositories** option and click **Next**.

You can modify your federated repository configuration by completing the following steps:

1. Click **Security > Global security**.
2. Under User account repository, select Federated repository and click **Configure**.

**Note:** This wizard is used for the initial configuration of a built-in, file-based repository. The user name and password do not have to be in the federated repository because they will be created. If you have previously configured federated repositories, do not use the Security configuration wizard to modify your configuration. Instead, modify your configuration using the Federated repositories selection under User account repository on the Global security panel.

*Primary administrative user name:*

Specifies the name of the user with administrative privileges that is defined in the repository, for example, adminUser.

The user name is used to log on to the administrative console when administrative security is enabled. Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

**Attention:** In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

*Password:*

Specifies the password of the administrative user who manages the product resources and user accounts.

*Confirm password:*

Confirms the password of the administrative user who manages the product resources and user accounts.

### ***Configuring a single built-in, file-based repository in a new configuration under federated repositories using wsadmin:***

You can use the Jython or Jacl scripting language with the wsadmin tool to configure a single built-in, file-based repository in a new configuration under Federated repositories.

### **Before you begin**

Shut down the application server and ensure you have the primary administrator id and password.

### **About this task**

The federated repositories configuration file, wimconfig.xml, is supported by WebSphere Application Server 6.1.x and is located in the *app\_server\_root/profiles/profile\_name/config/cells/cell\_name/wim/config* directory.

Use the following steps to configure for use a single built-in, file-based repository in a new configuration for federated repositories.

### **Procedure**

1. Start the wsadmin scripting tool.
2. Create the fileRegistry.xml file, which is the user registry itself, if it does not already exist. If the fileRegistry.xml file does exist, this step just adds the user to registry.

Using Jython:

```
AdminTask.addFileRegistryAccount('-userId isoet01s01 -password oets01')
```

Using Jacl:

```
$AdminTask addFileRegistryAccount {-userId isoet01s01 -password oets01}
```

For more information on the `addFileRegistryAccount` command, see the documentation about the `FileRegistryCommands` command group for the `AdminTask` object.

3. Update the `security.xml` file to enable administrative security, set the `activeUserRegistry` to use federated repositories, and update the `primaryAdmin` and its password.

Using Jython:

```
AdminTask applyWizardSettings('-secureApps false
 -secureLocalResources false
 -userRegistryType WIMUserRegistry
 -customRegistryClass com.ibm.ws.wim.registry.WIMUserRegistry
 -adminName isoet01s01 -adminPassword oets01')
```

Using Jacl:

```
$AdminTask applyWizardSettings {-secureApps false
 -secureLocalResources false
 -userRegistryType WIMUserRegistry
 -customRegistryClass com.ibm.ws.wim.registry.WIMUserRegistry
 -adminName isoet01s01
 -adminPassword oets01}
```

For more information on the `applyWizardSettings` command, see the documentation about the `WizardCommands` command group for the `AdminTask` object.

4. Save your configuration changes. Enter the following commands to save the new configuration and close the `wsadmin` tool:

Using Jython:

```
AdminConfig.save()
```

Using Jacl:

```
$AdminConfig save
```

5. Restart the application server.

*FileRegistryCommands* command group for the *AdminTask* object:

Federated repositories provides a file registry. Use the commands in the `FileRegistryCommands` command group to administer the file registry using the `wsadmin` tool.

**Note:** If the `Use global security settings` option is selected for the user realm or the `Global federated repositories` option is selected as the realm type for the specified domain, the user and group management commands are executed on the federated repository of the admin domain. For example, if you run the `createUser` command for the specified domain, the user is created in the admin domain. However, configuration changes that are performed on the domain are applied to the security domain-specific configuration.

Use the following commands in the `FileRegistryCommands` group to modify the federated repository file registry:

- “`addFileRegistryAccount` command”
- “`changeFileRegistryAccountPassword` command” on page 1494

### **addFileRegistryAccount** command

The `addFileRegistryAccount` command adds an account to the file registry. You must save your configuration changes after running this command to save the new account to the master repository.

Target object

None

## Required parameters

### **-userId**

Specifies the ID of the user to add to the file registry. (String, required)

### **-password**

Specifies the password of the user to add to the file registry. (String, required)

## Optional parameters

### **-securityDomainName**

Specifies the name that uniquely identifies the security domain. The default value is admin. (String, optional)

### **-parent**

Specifies the parent of the entity. (String, optional)

.

## Return value

This command returns a message that indicates that the command ran successfully, as the following example displays:

```
'CWNIM4544I Account newAcct(uid=newAcct,o=defaultWIMFileBasedRealm) is stored in the file registry in the temporary workspace. You must use the "$AdminConfig save" command to save it in the master repository.'
```

## Batch mode example usage

- Using Jython string:

```
AdminTask.addFileRegistryAccount(['-userId newAcct -password new2password'])
```

## Interactive mode example usage

- Using Jython string:

```
AdminTask.addFileRegistryAccount(['-userId', 'newAcct', '-password', 'new2password'])
```

## **changeFileRegistryAccountPassword command**

The changeFileRegistryAccountPassword changes the password for the file registry account.

## Target object

None.

## Required parameters

### **-userId**

Specifies the user ID of interest. (String, required)

### **-password**

Specifies the new password. (String, required)

## Optional parameters

### **-securityDomainName**

Specifies the name that uniquely identifies the security domain. The default value is admin. (String, optional)

### **-uniqueName**

Specifies the fully-qualified unique name of the administrator. (String, optional)

## Return value

This command returns a message that indicates that the command ran successfully, as the following example displays:

```
'CWNIM4545I The password is changed for newAcct(uid=newAcct,o=defaultWIMFileBasedRealm)
in the file registry in the temporary workspace. You must use the "$AdminConfig save"
command to save it in the master repository.'
```

## Batch mode example usage

- Using Jython string:

```
AdminTask.changeFileRegistryAccountPassword(['-userId newAcct -password newPassword -uniqueName
uid=newAcct,o=defaultWIMFileBasedRealm'])
```

## Interactive mode example usage

- Using Jython string:

```
AdminTask.changeFileRegistryAccountPassword(['-userId', 'newAcct', '-password', 'newPassword',
'-uniqueName', 'uid=newAcct,o=defaultWIMFileBasedRealm'])
```

## ***Changing a federated repository configuration to include a single built-in, file-based repository only:***

Follow this task to change your federated repository configuration to include a single built-in, file-based repository only.

### **Before you begin**

To change your federated repository configuration to include a single built-in, file-based repository only, you need to know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

**Restriction:** Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

### **Procedure**

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. If the realm contains a single built-in, file-based repository only, you must specify defaultWIMFileBasedRealm as the realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Enable the **Ignore case for authorization** option.
6. Click **Use built-in repository** if the built-in, file-based repository is not listed in the collection.
7. Select all repositories in the collection that are not of type File and click **Remove**.
8. Click **OK**.
9. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, it does not display. If a built-in, file-based repository is included, complete the following steps:
  - a. Supply a password for the primary administrative user in the Password field.
  - b. Confirm the password of the primary administrative user in the Confirm password field.
  - c. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which includes a single built-in, file-based repository only, is configured.

### What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1543.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps, as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

### **Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories:**

Follow this task to configure a single, Lightweight Directory Access Protocol (LDAP) repository in a new configuration under Federated repositories.

### Before you begin

To configure an LDAP repository in a new configuration under Federated repositories, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as the WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log in to the administrative console after you turn on security. You can use other users to log in, if those users are part of the administrative roles.

### Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. On the Federated repositories panel, complete the following steps:
  - a. Enter the name of the realm in the Realm name field. You can change the existing realm name.
  - b. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
  - c. Optional: Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

**Restriction:** Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and

case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

- d. Click **Add base entry to realm** to add a base entry that uniquely identifies the external repository in the realm. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1517.
4. On the Federated repositories panel, complete the following steps:
    - a. Select the built-in, file-based repository in the collection, and click **Remove**.

**Restriction:** Before you remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.

- b. Click **OK**.

## Results

After completing these steps, your new configuration under Federated repositories includes a single, LDAP repository only.

## What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1543.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

## ***Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only:***

Follow this task to change your federated repository configuration to include a single, Lightweight Directory Access Protocol repository (LDAP) repository only.

## Before you begin

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log into the administrative console after you turn on security. You can use other users to log in if those users are part of the administrative roles.

## Procedure

1. In the administrative console, click **Security > Global security**.

2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Optional: Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

**Restriction:** Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

6. Optional: Click **Add base entry to realm** if the LDAP repository that you need is not contained in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1517.
7. On the Federated repositories panel, complete the following steps:
  - a. Optional: Select the repositories in the collection that you do not need in the realm and click **Remove**.

**Restriction:** The realm must always contain at least one base entry; therefore, you cannot remove every entry.

- b. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which includes a single LDAP repository only, is configured.

## What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1543.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

## ***Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration:***

Follow this task to configure multiple Lightweight Directory Access Protocol (LDAP) repositories in a federated repository configuration.

## Before you begin

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log into the administrative console after you turn on security. You can use other users to log in if those users are part of the administrative roles.

## Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Optional: Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

**Restriction:** Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

6. Optional: Click **Add base entry to realm** if the LDAP repository that you need is not listed in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1517.
7. On the Federated repositories panel, complete the following steps:
  - a. Optional: Repeat step 6 if the LDAP repository that you need is not listed in the collection.
  - b. Optional: Select the repositories in the collection that you do not need in the realm and click **Remove**. The following restrictions apply:
    - The realm must always contain at least one base entry; therefore, you cannot remove every entry.
    - If you plan to remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.
  - c. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which includes multiple LDAP repositories, is configured.

## What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1543.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm

definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.

3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

### ***Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration:***

Follow this task to configure a single built-in, file-based repository and multiple Lightweight Directory Access Protocol (LDAP) repositories in a federated repository configuration.

#### **Before you begin**

To configure a built-in, file-based repository in a federated repository configuration, you must know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log in to the administrative console after you turn on security. You can use other users to log in if those users are part of the administrative roles.

**Restriction:** Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

#### **Procedure**

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.

**Restriction:** When you configure multiple repositories that includes a single built-in, file-based repository, the primary administrative user name must exist in the file-based repository. If the primary administrative user name does not exist in the file-based repository, then the name is created in the file-based repository. The primary administrative user name cannot exist in other repositories.

5. Select the **Ignore case for authorization** option.

**Attention:** When the realm includes a built-in, file-based repository, you must enable the **Ignore case for authorization** option.

When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

**Restriction:** Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.

6. Optional: Click **Add base entry to realm** if the LDAP repository that you need is not contained in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1517.
7. On the Federated repositories panel, complete the following steps:
  - a. Optional: Repeat step 6 if the LDAP repository that you need is not listed in the collection.
  - b. Click **Use built-in repository** if the built-in, file-based repository is not listed in the collection.
  - c. Optional: Select the repositories in the collection that you do not need in the realm and click **Remove**.

**Restriction:** The realm must always contain at least one base entry; therefore, you cannot remove every entry.

- d. Click **OK**.
8. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, the panel does not display. If a built-in, file-based repository is included, complete the following steps:
  - a. Supply a password for the administrative user in the Password field.
  - b. Confirm the password of the primary administrative user in the Confirm password field.
  - c. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which includes a single built-in, file-based repository and one or more LDAP repositories, is configured.

## What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1543.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

## *Manually configuring an Lightweight Directory Access Protocol repository in a federated repository configuration:*

Follow this topic to manually configure Lightweight Directory Access Protocol (LDAP) repository in a federated repository configuration.

## Before you begin

As a prerequisite, you need to add a LDAP repository to your WebSphere Application Server configuration, where you define the following information:

Table 93. Prerequisite LDAP repository information.

This table lists prerequisite LDAP repository information,

| Item Name               | Example                                       |
|-------------------------|-----------------------------------------------|
| Repository identifier   | ldaprepo1                                     |
| Directory type          | IBM Tivoli Directory Server                   |
| Primary host name       | localhost                                     |
| Port                    | 389                                           |
| Bind distinguished name | cn=ldapadmin                                  |
| Bind password           | yourpwd                                       |
| Login properties        | uid (a property containing login information) |

See “Lightweight Directory Access Protocol repository configuration settings” on page 1507 for the specific steps you must perform to establish this LDAP repository.

### About this task

At this point, you have a valid LDAP repository ready to be manually configured in a federated repository configuration.

### Procedure

1. Map the federated repository entity types to the LDAP object classes.
  - a. Configure the LDAP repository to match the used LDAP object class for users.
    - 1) In the administrative console, click **Security > Global security**.
    - 2) Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
    - 3) Under Related items, click **Manage repositories**.
    - 4) Select the repository (for example, ldaprepo1).
    - 5) Click **LDAP entity types**.
    - 6) Click **PersonAccount**.
    - 7) Insert the *objectclass* name used in our LDAP server, for example, inetOrgPerson.
    - 8) Click **Apply**.
    - 9) Click **Save**.

See “Configuring supported entity types in a federated repository configuration” on page 1543 for an explanation of the supported entity types.

See <http://publib.boulder.ibm.com/infocenter/wasinfo/v6r1/topic/com.ibm.websphere.wim.doc.en/ldap.html> for a description of the LDAP default mappings.
  - b. Configure the LDAP repository to match the used LDAP *objectclass* for groups
    - 1) In the administrative console, click **Security > Global security**.
    - 2) Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
    - 3) Under Related items, click **Manage repositories**.
    - 4) Select ldaprepo1.
    - 5) Click **LDAP entity types**.
    - 6) Click **Group**.
    - 7) Insert the objectclass name used for your LDAP server, for example, groupOfUniqueNames.
    - 8) Click **Apply**.
    - 9) Click **Save**.

See “Group attribute definition settings” on page 1566 for an explanation of group attribute definitions.

2. Map the federated repository property names to the LDAP attribute names.
  - a. Configure the LDAP repository to match the used LDAP attributes for a user.

- 1) Edit the file

```
{WAS_HOME}\profiles\{profileName}\config\cells\{cellName}\wim\config\wimconfig.xml
```

- 2) Look for the section in this file containing the LDAP repository configuration, For example,
  - a)

```
<config:repositories
xsi:type="config:LdapRepositoryType"
adapterClassName="com.ibm.ws.wim.adapter.ldap.LdapAda
pter" id="ldaprepo1" ...>
```

- b)

```
<config:attributeConfiguration>
```

- c)

```
...
```

- d)

```
<config:attributes name="anLDAPAttribute"
propertyName="aVMMAttribute"/>
```

- e)

```
...
```

```
<config:attributeConfiguration>
```

- 3) Add an element of type `config:attributes` to define the mapping between a given federated depository property name, such as `departmentNumber`, to a desired LDAP attribute name, such as `warehouseSection`.

**Note:** For all given federated depository properties, a one-to-one mapping is assumed. If no explicit mapping of the above type is defined, for example the federated repository property `departmentNumber`, the underlying LDAP attribute name, `departmentNumber` is assumed.

- b. Configure the unsupported properties of the federated repository.

To indicate that a given federated repository property, such as `departmentNumber` is not supported by any LDAP attributes, you need to define the following type of element:

```
<config:repositories xsi:type="config:LdapRepositoryType"
adapterClassName="com.ibm.ws.wim.adapter.ldap.LdapAdapter"
id="ldaprepo1" ...>
<config:attributeConfiguration>
...
<config:propertiesNotSupported name=" departmentNumber"/>
...
<config:attributeConfiguration>
```

- c. Configure the LDAP repository to match the used LDAP user membership attribute in the groups.

- 1) In the administrative console, click **Security > Global security**.
- 2) Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
- 3) Under Related items, click **Manage repositories**.
- 4) Select `ldaprepo1`
- 5) Click **Group attribute defintions**.
- 6) Click **Member attributes**.
- 7) Check if your LDAP attributes (for example, `uniqueMember`) is specified for your LDAP objectclass (for example, `groupOfUniqueNames`).
  - If not specified, click **New** and add the pair (*objectclass / member attribute name*) that applies to your LDAP schema (for example, `uniqueMember / groupOfUniqueNames`)
  - If specified, proceed.
- 8) Click **Apply**.
- 9) Click **Save**.

3. Map other LDAP settings by configuring a new base entry for the new LDAP repository.

- a. In the administrative console, click **Security > Global security**.
- b. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
- c. Click **Add Base Entry to Realm**.
- d. Select ldaprepo1.
- e. Specify:
  - The base entry within the federated repository realm, for example, o=Default Organization
  - The base entry within the LDAP repository, for example, o=Default Organization
- f. Click **Apply**.
- g. Click **Save**.

For an explanation of base entries, see the Configuring supported entity types in a federated repository configuration topic.

## Results

After completing these steps, your federated repository matches the LDAP server settings.

## What to do next

### ***Configuring Lightweight Directory Access Protocol in a federated repository configuration:***

Follow this topic to configure Lightweight Directory Access Protocol (LDAP) settings in a federated repository configuration.

## Before you begin

You have chosen among various ways to configure LDAP:

- “Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories” on page 1496
- “Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only” on page 1497
- “Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1498
- “Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1500
- “Managing repositories in a federated repository configuration” on page 1545

## About this task

At this point, you are viewing the LDAP repository configuration page of the administrative console.

## Procedure

1. Enter a unique identifier for the repository in the Repository identifier field. This identifier uniquely identifies the repository within the cell, for example: LDAP1.
2. Select the type of LDAP server that is used from the Directory type list. The type of LDAP server determines the default filters that are used by WebSphere Application Server.  
IBM Tivoli Directory Server users can choose either IBM Tivoli Directory Server or SecureWay as the directory type. Use the IBM Tivoli Directory Server directory type for better performance. For a list of supported LDAP servers, see “Using specific directory servers as the LDAP server” on page 1438.
3. Enter the fully qualified host name of the primary LDAP server in the Primary host name field. You can enter either the IP address or the domain name system (DNS) name.

4. Enter the server port of the LDAP directory in the Port field. The host name and the port number represent the realm for this LDAP server in a mixed version nodes cell. If servers in different cells are communicating with each other using Lightweight Third Party Authentication (LTPA) tokens, these realms must match exactly in all the cells.

The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

If multiple WebSphere Application Servers are installed and configured to run in the same single sign-on domain, or if WebSphere Application Server interoperates with a previous version of WebSphere Application Server, then it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as 389 in a Version 5.x or 6.0.x configuration, and WebSphere Application Server at Version 6.1 is going to interoperate with the Version 5.x or 6.0.x server, then verify that port 389 is specified explicitly for the Version 6.1 server.

5. Optional: Enter the host name of the failover LDAP server in the Failover host name field. You can specify a secondary directory server to be used in the event that your primary directory server becomes unavailable. After switching to a secondary directory server, LDAP repository attempts to reconnect to the primary directory server every 15 minutes.
6. Optional: Enter the port of the failover LDAP server in the Port field and click **Add**. The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.
7. Optional: Select the type of *referral*. A referral is an entity that is used to redirect a client request to another LDAP server. A referral contains the names and locations of other objects. It is sent by the server to indicate that the information that the client requested can be found at another location, possibly at another server or several servers. The default value is ignore.

**ignore**

Referrals are ignored.

**follow** Referrals are followed automatically.

8. Optional: Enter the bind DN name in the Bind distinguished name field, for example, cn=root. The bind DN is required if anonymous binds are not possible on the LDAP server to obtain user and group information or for write operations. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed. If the LDAP server is set up to use anonymous binds, leave this field blank. If a name is not specified, the application server binds anonymously.

**Note:** To create LDAP queries or to browse, an LDAP client must bind to the LDAP server using the distinguished name (DN) of an account that has the authority to search and read the values of LDAP attributes, such as user and group information. The LDAP administrator ensures that **read access privileges** are set for the bind DN. Read access privileges allow access to the subtree of the base DN and ensure that searches of user and group information are successful.

The directory server provides an operational attribute in each directory entry (for example, the IBM Directory Server uses `ibm-entryUuid` as the operational attribute). The value of this attribute is a universally unique identifier (UUID), which is chosen automatically by the directory server when the entry is added, and is expected to be unique: no other entry with the same or different name would have this same value. Directory clients may use this attribute to distinguish objects identified by a distinguished name or to locate an object after renaming.

**Ensure that the bind credentials have the authority to read this attribute.**

9. Optional: Enter the password that corresponds to the bind DN in the Bind password field.

- Optional: Enter the property names to use to log into WebSphere Application Server in the Login properties field. This field takes multiple login properties, delimited by a semicolon (;). For example, uid;mail.

All login properties are searched during login. If multiple entries or no entries are found, an exception is thrown. For example, if you specify the login properties as uid;mail and the login ID as Bob, the search filter searches for uid=Bob or mail=Bob. When the search returns a single entry, then authentication can proceed. Otherwise, an exception is thrown.

**Note:** If you define multiple login properties, then the first login property is programmatically mapped to the federated repositories principalName property. For example, if you set uid;mail as the login properties, the LDAP attribute uid value is mapped to the federated repositories principalName property. If you define multiple login properties, after login, the first login property is returned as the value of the principalName property. For example, if you pass joe@yourco.com as the principalName value and the login properties are configured as uid;mail, the principalName is returned as joe.

- Optional: Select the certificate map mode in the Certificate mapping field. You can use the X.590 certificates for user authentication when LDAP is selected as the repository. The Certificate mapping field is used to indicate whether to map the X.509 certificates into an LDAP directory user by EXACT\_DN or CERTIFICATE\_FILTER. If EXACT\_DN is selected, the DN in the certificate must exactly match the user entry in the LDAP server, including case and spaces.
- If you select **CERTIFICATE\_FILTER** in the Certificate mapping field, specify the LDAP filter for mapping attributes in the client certificate to entries in LDAP.

If more than one LDAP entry matches the filter specification at run time, authentication fails because the result is an ambiguous match. The syntax or structure of this filter is:

```
LDAP attribute=${Client certificate attribute}
```

For example, uid=\${SubjectCN}.

The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. The right side must begin with a dollar sign (\$) and open bracket ({} and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:

- \${UniqueKey}
- \${PublicKey}
- \${PublicKey}
- \${Issuer}
- \${NotAfter}
- \${NotBefore}
- \${SerialNumber}
- \${SigAlgName}
- \${SigAlgOID}
- \${SigAlgParams}
- \${SubjectCN}
- \${Version}

- Optional: Select the **Require SSL communications** option if you want to use Secure Sockets Layer communications with the LDAP server.

If you select the **Require SSL communications** option, you can select either the **Centrally managed** or **Use specific SSL alias** option.

#### **Centrally managed**

Enables you to specify an SSL configuration for a particular scope, such as the cell, node, server, or cluster in one location. To use the Centrally managed option, you must specify the SSL configuration for the particular set of endpoints. The Manage endpoint security configurations and trust zones panel displays all of the inbound and outbound endpoints that use the SSL protocol. If you expand the Inbound or Outbound section of the panel and click

the name of a node, you can specify an SSL configuration that is used for every endpoint on that node. For an LDAP registry, you can override the inherited SSL configuration by specifying an SSL configuration for LDAP. To specify an SSL configuration for LDAP, complete the following steps:

- a. Click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones**.
- b. Expand **Outbound > cell\_name > Nodes > node\_name > Servers > server\_name > LDAP**.

#### Use specific SSL alias

Select the **Use specific SSL alias** option if you intend to select one of the SSL configurations in the menu that follows the option.

This configuration is used only when SSL is enabled for LDAP. The default is *DefaultSSLSettings*. To modify or create a new SSL configuration, complete the following steps:

- a. Click **Security > SSL certificate and key management**.
- b. Under Configuration settings, click **Manage endpoint security configurations and trust zones > configuration\_name**.
- c. Under Related items, click **SSL configurations**.

14. Click **OK**.

#### Results

After completing these steps, your LDAP repository settings are configured.

#### What to do next

Return to the appropriate task to complete the steps for your federated repository configuration:

- “Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories” on page 1496
- “Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only” on page 1497
- “Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1498
- “Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1500
- “Managing repositories in a federated repository configuration” on page 1545

*Lightweight Directory Access Protocol repository configuration settings:*

Use this page to configure secure access to a Lightweight Directory Access Protocol (LDAP) repository with optional failover servers.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Repository identifier:*

Specifies a unique identifier for the LDAP repository. This identifier uniquely identifies the repository within the cell, for example: LDAP1.

*Directory type:*

Specifies the type of LDAP server to which you connect.

Expand the drop-down list to display a list of LDAP directory types.

*Primary host name:*

Specifies the host name of the primary LDAP server. This host name is either an IP address or a domain name service (DNS) name.

*Port:*

Specifies the LDAP server port.

The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

|                   |                                                           |                                                       |
|-------------------|-----------------------------------------------------------|-------------------------------------------------------|
| <b>Data type:</b> | Integer                                                   |                                                       |
| <b>Default:</b>   | 389                                                       |                                                       |
| <b>Range:</b>     | 389, which is not a Secure Sockets Layer (SSL) connection | 636, which is a Secure Sockets Layer (SSL) connection |

*Failover host name:*

Specifies the host name of the failover LDAP server.

You can specify a secondary directory server to be used in the event that your primary directory server becomes unavailable. After switching to a secondary directory server, the LDAP repository attempts to reconnect to the primary directory server every 15 minutes.

*Port:*

Specifies the port of the failover LDAP server.

The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

|                   |                                                           |                                                       |
|-------------------|-----------------------------------------------------------|-------------------------------------------------------|
| <b>Data type:</b> | Integer                                                   |                                                       |
| <b>Range:</b>     | 389, which is not a Secure Sockets Layer (SSL) connection | 636, which is a Secure Sockets Layer (SSL) connection |

*Support referrals to other LDAP servers:*

Specifies how referrals that are encountered by the LDAP server are handled.

A referral is an entity that is used to redirect a client request to another LDAP server. A referral contains the names and locations of other objects. It is sent by the server to indicate that the information that the client requested can be found at another location, possibly at another server or several servers. The default value is ignore.

|                 |                                                     |
|-----------------|-----------------------------------------------------|
| <b>Default:</b> | ignore                                              |
| <b>Range:</b>   | <b>ignore</b> Referrals are ignored.                |
|                 | <b>follow</b> Referrals are followed automatically. |

*Support for repository change tracking:*

Specifies the type of support for repository change tracking, with is one of the following:

- none** Specifies there is no change tracking support for this repository.
- native** Specifies that the repository's native change tracking mechanism is used by virtual member manager to return changed entities.

*Custom properties:*

Specifies arbitrary name and value pairs of data. The name is a property key and the value is a string value that can be used to set internal system configuration properties.

Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

*Bind distinguished name:*

Specifies the distinguished name (DN) for the application server to use when binding to the LDAP repository.

If no name is specified, the application server binds anonymously. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed.

*Bind password:*

Specifies the password for the application server to use when binding to the LDAP repository.

*Login properties:*

Specifies the property names to use to log into the application server.

This field takes multiple login properties, delimited by a semicolon (;). For example, uid;mail. All login properties are searched during login. If multiple entries or no entries are found, an exception is thrown. For example, if you specify the login properties as uid;mail and the login ID as Bob, the search filter searches for uid=Bob or mail=Bob. When the search returns a single entry, then authentication can proceed. Otherwise, an exception is thrown.

**Note:** If you define multiple login properties, then the first login property is programmatically mapped to the federated repositories principalName property. For example, if you set uid;mail as the login properties, the LDAP attribute uid value is mapped to the federated repositories principalName property. If you define multiple login properties, after login, the first login property is returned as the value of the principalName property. For example, if you pass joe@yourco.com as the principalName value and the login properties are configured as uid;mail, the principalName is returned as joe.

*LDAP attribute for Kerberos principal name:*

Specifies the LDAP attribute for Kerberos principal name. This field can be modified when Kerberos is configured and it is one of the active or preferred authentication mechanisms.

### *Certificate mapping:*

Specifies whether to map X.509 certificates into an LDAP directory by EXACT\_DN or CERTIFICATE\_FILTER. Specify CERTIFICATE\_FILTER to use the specified certificate filter for the mapping.

### *Certificate filter:*

Specifies the filter certificate mapping property for the LDAP filter. The filter is used to map attributes in the client certificate to entries in the LDAP repository.

If more than one LDAP entry matches the filter specification at run time, authentication fails because the result is an ambiguous match. The syntax or structure of this filter is:

```
LDAP attribute=${Client certificate attribute}
```

An example of a simple certificate filter is: uid=\${SubjectCN}.

You can also specify multiple properties and values as part of the certificate filter. Two examples of complex certificate filters are:

```
(&(cn=${IssuerCN}) (employeeNumber=${SerialNumber}))
```

```
(& (issuer=${IssuerDN}) (serial=${SerialNumber}) (subjectdn=${SubjectDN}))
```

The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. You can also use the **UniqueKey** certificate variable, which consists of the base64-encoding of the MD5 hash of the subject DN and issuer DN. The right side must begin with a dollar sign (\$) and open bracket ({} and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:

- \${UniqueKey}
- \${PublicKey}
- \${IssuerDN}
- \${Issuerxx} where xx is replaced by the characters that represent any valid component of the Issuer Distinguished Name. For example, you might use \${IssuerCN} for the Issuer Common Name.
- \${NotAfter}
- \${NotBefore}
- \${SerialNumber}
- \${SigAlgName}
- \${SigAlgOID}
- \${SigAlgParams}
- \${SubjectDN}
- \${Subjectxx} where xx is replaced by the characters that represent any valid component of the Subject Distinguished Name. For example, you might use \${SubjectCN} for the Subject Common Name.
- \${Version}

### *Require SSL communications:*

Specifies whether secure socket communication is enabled to the LDAP server.

When enabled, the Secure Sockets Layer (SSL) settings for LDAP are used, if specified.

### *Centrally managed:*

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations, rather than spreading them across the configuration documents.

**Default:** Enabled  
**Range:** Enabled or Disabled

*Use specific SSL alias:*

Specifies the SSL configuration alias to use for LDAP outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI platform.

***Migrating a stand-alone LDAP repository to a federated repositories LDAP repository configuration:***

When configuring the security for your application server, you might need to migrate a stand-alone LDAP registry to a federated repositories LDAP repository configuration.

**Before you begin**

- | Note the specifications of your stand-alone LDAP repository that you want to migrate, for reference when
- | configuring the LDAP repository in federated repositories. To access these fields, on the administrative
- | console, click **Security > Global security**. To access these fields in a multiple security domain
- | environment, click **Security > Security domains > DomainName**, and then, under Security Attributes,
- | expand User Realm, and click **Customize for this domain**. Select a Realm type. and then click
- | **Configure**.

The following table shows the administrative console panels and fields of the stand-alone LDAP repository configuration and their corresponding fields in a federated repositories LDAP repository configuration for mapping.

*Table 94. Mapping between a stand-alone LDAP repository configuration and a federated repositories LDAP repository configuration. This table illustrates the mapping between a stand-alone LDAP repository configuration and a federated repositories LDAP repository configuration.*

| <b>Stand-alone LDAP repository configuration</b>                                | <b>LDAP repository in a federated repositories configuration</b>                                                         |
|---------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Global security > Standalone LDAP registry                                      | Global security > Federated repositories                                                                                 |
| General properties – Primary administrative user name                           | General properties – Primary administrative user name                                                                    |
| Global security > Standalone LDAP registry<br>LDAP server – Type of LDAP server | Global security > Federated repositories > Manage repositories > <i>repository_ID</i><br>LDAP server – Directory Type    |
| Global security > Standalone LDAP registry<br>LDAP server – Host                | Global security > Federated repositories > Manage repositories > <i>repository_ID</i><br>LDAP server – Primary host name |
| Global security > Standalone LDAP registry<br>LDAP server – Port                | Global security > Federated repositories > Manage repositories > <i>repository_ID</i><br>LDAP server – Port              |

Table 94. Mapping between a stand-alone LDAP repository configuration and a federated repositories LDAP repository configuration (continued). This table illustrates the mapping between a stand-alone LDAP repository configuration and a federated repositories LDAP repository configuration.

| Stand-alone LDAP repository configuration                                                                                                                              | LDAP repository in a federated repositories configuration                                                                                                                                                                                                                                                             |

| Global security > Standalone LDAP registry > Advanced Lightweight Directory Access Protocol (LDAP) user registry settings<br>General properties – Certificate filter   | Global security > Federated repositories > Manage repositories > <i>repository_ID</i><br><br>Security – Certificate filter                                                                                                                                                                                            |

The Realm name field under General Properties on the federated repositories LDAP configuration panel is not listed in the previous table because it does not have a one-to-one correspondence with a field in the stand-alone LDAP configuration panel. The host name and the port number represent the realm name for

the standalone LDAP server in the WebSphere Application Server cell. For information on changing the realm name, see the topic Realm configuration settings.

The User Filter, Group Filter, User ID map, Group ID map, and Group member ID map fields also are not listed in the previous table as they do not have a one-to-one correspondence with fields in the federated repositories LDAP repository configuration panel. These LDAP attributes are set differently in the federated repositories LDAP repository configuration and involve multiple steps. These settings are explained in detail in the following sections and procedure.

### About this task

Migrating from a stand-alone LDAP repository configuration to a federated repositories LDAP repository configuration involves migrating the configuration parameters, most of which are straight forward as shown in Table 1 in the previous section. Migrating the search filters is an important part of migrating a stand-alone LDAP repository configuration to a federated repository LDAP configuration; therefore, the concept and migration of LDAP search filters is described here in detail.

Stand-alone LDAP registry search filters follow the LDAP filter syntax, where you specify the attribute on which the search is based and its value.

The user filter is used for searching the registry for users. It is used to authenticate a user by using the attribute specified in the filter.

The group filter is used for searching the registry for groups. It specifies the property by which to look up groups.

**Examples of commonly used LDAP user filters:** In the following examples of search filters, %v is replaced with the corresponding search pattern of the user or group at run time.

```
(&(uid=%v)(objectclass=ePerson))
```

Searches for users where the uid attribute matches the specified search pattern of the ePerson object class.

```
(&(cn=%v)(objectclass=user))
```

Searches for users where the cn attribute matches the specified search pattern of the user object class.

```
(&(sAMAccountName=%v)(objectcategory=user))
```

Searches for users where the sAMAccountName attribute matches the specified search pattern of the user object category.

```
(&(userPrincipalName=%v)(objectcategory=user))
```

Searches for users where the userPrincipalName attribute matches the specified search pattern of the user object category.

```
(&(mail=%v)(objectcategory=user))
```

Searches for users where the mail attribute matches the specified search pattern of the user object category.

```
(&(|(sAMAccountName=%v)(userPrincipalName=%v))(objectcategory=user))
```

Searches for users where the sAMAccountName or the userPrincipalName matches the specified search pattern of the user object category.

Examples of commonly used group filters:

```
(&cn=%v)(objectCategory=group)
```

Looks up groups based on their common names (cn).

```
(&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))
```

Looks up groups based on their common names (cn) and by using the object class of either groupOfNames or groupOfUniqueNames.

As shown in these examples, a stand-alone LDAP registry search filter consists of LDAP attributes and object classes, based on which the search or login is performed.

You can also specify the LDAP attributes and object classes in the LDAP adapter configuration of federated repositories, but they are configured differently and provide more flexibility. In federated repositories the user is represented as PersonAccount entity type and group as Group entity type. Each entity type can have its own RDN (Relative Distinguished Name) property (rdnProperties) and object class. For example, the default RDN property of PersonAccount is uid, and the default RDN property of Group is cn. The default object class mapping depends on the LDAP server type. For example, for Tivoli Directory Server, the object class for PersonAccount is inetOrgPerson and object class for Group is groupOfNames. PersonAccount can also have login properties. When a user logs in or a search is performed for a user in a user registry, these login properties are matched with the pattern. For example, if the login properties are uid and mail, then for the search pattern, a\*, all the users who match uid=a\* or mail=a\* are returned.

**gotcha:** You can specify the value of User ID Map property (userIdMap) of the stand-alone LDAP repository as the RDN property (rdnProperties) or the first login property (loginProperties) in federated repositories. Though you can set both the RDN property and the login property in federated repositories, it is sufficient if you set only the RDN property. The login property is optional and you need to set it only if the login property is different from RDN property or if there are more than one login properties. If both the RDN property and login property are set, the login property takes precedence over RDN property.

Migrating search filters involves one or more of the following steps: setting the correct login properties, mapping the attributes of the back-end repository to the federated repositories properties, setting the object class, setting the search filter by using object class or object category, and setting the member or membership attribute. This mapping and configuration for federated repositories is maintained in the wimconfig.xml file.

The stand-alone LDAP registry search filter can be split into two parts:

- User or group attributes filter
- User or group object class or object category filter

For example, in the search filter, (&(cn=%v)(objectclass=user)):

- The attribute filter is (cn=%v)
- The object class filter is (objectclass=user)

These two filters are mapped separately in a federated repositories configuration:

- The attribute filter is mapped to the RDN properties or login properties configuration for user and to RDN properties configuration for group.
- The object class filter is mapped to the entity type configuration of the LDAP adapter.

The default attribute and object class mapping is set based on the LDAP server type but additional steps might be required to migrate these two filters:

- attribute filter:
  - Setting either or both the RDN property and login properties (if applicable)
  - Mapping the federated repository property to the LDAP attribute (if applicable)
- object class filter:
  - Setting the object class for entity type (if applicable)
  - Setting the search filter of entity type (if applicable)

Some of the steps in the following procedure include two examples. In these steps:

- Example 1 is applicable to the scenario where you are migrating the search filter (&(cn=%v)(objectclass=ePerson)) from a stand-alone IBM Tivoli Directory Server LDAP repository to a federated repositories LDAP repository with the identifier LDAPTDS.
- Example 2 is applicable to the scenario where you are migrating the search filter (&(|(sAMAccountName=%v)(userPrincipalName=%v))(objectcategory=user)) from a stand-alone Microsoft Active Directory LDAP repository to a federated repositories LDAP repository with the identifier LDAPAD. sAMAccountName and userPrincipalName attributes are not defined in federated repositories, so these attributes must be mapped to federated repository properties.

## Procedure

1. Add the LDAP repository that you want to migrate to the federated repositories configuration.  
See Table 1 in the *Before you begin* section of this topic, and follow the steps described in the topic *Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories*. These steps include links to other procedures that you must complete such as:
  - Adding an external repository in a federated repository configuration.
  - Configuring supported entity types in a federated repository configuration.
  - Configuring Lightweight Directory Access Protocol in a federated repository configuration.

After you complete these steps, the LDAP repository that you want to migrate will be successfully configured in the federated repository configuration.

2. Set the login properties (if applicable).

Login properties are the property names that are used to log on to the WebSphere Application Server. You can specify multiple login properties by using the semicolon (;) as a delimiter. The federated repositories properties commonly used as login properties are uid, cn, sn, givenName, mail, and so on. To set login properties on the administrative console, follow the steps in the topic *Lightweight Directory Access Protocol repository configuration settings*, and apply the settings under the section, Login properties.

**Example 1:** In the **Login properties** field, enter cn.

**Example 2:** In the **Login properties** field, enter uid;cn.

Complete Step 3 to map these properties to LDAP attributes.

3. Map the federated repository property to the LDAP attribute (if applicable).  
If the LDAP attribute is not a federated repository property, then the login property that you defined must be mapped to the LDAP attribute.
  - a. In the administrative console, click **Global security > Federated repositories > Manage repositories > repository\_ID**, and then, under *Additional properties*, click the **LDAP attributes** link.
  - b. If the attribute mapping exists, you must first delete the existing mapping for the LDAP attribute, and then add a new mapping for the attribute. Select the checkbox next to the LDAP attribute name and click **Delete**.

- c. To add an attribute mapping, click **Add**, and select **Supported** from the drop-down menu. Enter the LDAP attribute name in the **Name** field, the federated repositories property name in the **Property name** field, and the entity type which applies the attribute mapping in the **Entity types** field.

**Example 1:** Because the federated repository property cn is implicitly mapped to the cn LDAP attribute, no additional mapping is required.

**Example 2:** Here the search filter includes two LDAP attributes, sAMAccountName and userPrincipalName.

- For the LDAP server type, Active Directory, the LDAP attribute sAMAccountName is mapped by default to the federated repositories property, uid, as shown in the list of attributes on LDAP attributes panel. Therefore, you do not have to execute the addIdMgrLDAPAttr command to add an attribute configuration for sAMAccountName.
- If an attribute mapping for the LDAP attribute userPrincipalName exists, then delete the existing attribute mapping before adding a new configuration.
  - a. Select the checkbox next to **userPrincalName** and click **Delete**.
  - b. Click **Add**, and select **Supported** from the drop-down menu.
  - c. In the **Name** field, enter userPrincipalName.
  - d. In the **Property name** field, enter cn.
  - e. In the **Entity types** field, enter PersonAccount.

4. Set the object class for an entity type (if applicable).

**gotcha:** Before executing this step, check the current mapping . If the object class mapping is already set, skip this step.

To set the object class for an entity type on the administrative console, follow the steps in the topic *Lightweight Directory Access Protocol entity types settings*, and apply the following settings under the section, Object classes:

- Specify PersonAccount as the entity type name for user filters
- Specify Group as the entity type name for group filters.

**Example 1:** In the **Entity type** field, enter PersonAccount.

In the **Object classes** field, enter ePerson.

**Example 2:** In the **Entity type** field, enter PersonAccount.

In the **Object classes** field, enter user.

5. Set the search filter for the entity type (if applicable).

Federated repositories performs the search based on the object class setting. To change this default setting and use object category as the filter, follow the steps in topic *Lightweight Directory Access Protocol entity types settings*, and apply the settings under the section, Search Filter.

**Example 1:** Because the search is based on object class, no additional configuration is required.

**Example 2:** In the **Search filter** field, enter (objectcategory=user).

6. To migrate group filters, you must also configure the group attribute definition settings.

The steps to configure the group attribute definition settings through the administrative console are specified in the topic *Locating user group memberships in a Lightweight Directory Access Protocol registry*, under the section, LDAP Registry within a Federated Repositories Registry. You can also use the wsadmin commands addIdMgrLDAPGroupDynamicMemberAttr or addIdMgrLDAPGroupMemberAttr that are described in the topic *IdMgrRepositoryConfig command group for the AdminTask object*.

7. Save your configuration changes

8. Restart the application server.

## Results

After completing these steps, your LDAP repository is configured for use within the federated repositories configuration.

### ***Adding an external repository in a federated repository configuration:***

Follow this task to add an external repository into a federated repository configuration.

## Procedure

1. If the Lightweight Directory Access Protocol (LDAP) repository that you want to add to your federated repository configuration is previously configured, select the corresponding Repository on the Repository reference panel. To access the Repository reference panel, complete the following steps:
  - a. Click **Security > Global security**.
  - b. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
  - c. Click **Add base entry to realm**.
2. Enter a distinguished name for the realm base entry in the Distinguished name that uniquely identifies... field. This base entry must uniquely identify the external repository in the realm. If multiple repositories are included in the realm, use this field to define an additional distinguished name (DN) that uniquely identifies this set of entries within the realm. For example, repositories LDAP1 and LDAP2 might both use o=ibm,c=us as the base entry in the repository. Use the DN in this field to uniquely identify this set of entries in the realm. For example: o=ibm,c=us for LDAP1 and o=ibm2,c=us for LDAP2. The specified DN in this field maps to the LDAP DN of the base entry within the repository.
3. Enter the LDAP DN of the base entry within the repository in the Distinguished name of a base entry... field. The base entry indicates the starting point for searches in this LDAP directory server. This entry and its descendents are mapped to the subtree that is identified by this unique base name entry field. For example, for a user with a DN of cn=John Doe, ou=Rochester, o=IBM, c=US, specify the LDAP base entry as any of the following options:  
ou=Rochester, o=IBM, c=us or o=IBM, c=us or c=us  
In most cases, this LDAP DN is the same as the distinguished name for the realm base entry.  
If this field is left blank, then the subtree defaults to the root of the LDAP repository. Consult your LDAP administrator to determine if your LDAP repository provides support to search from the root, or create users and groups under the root without defining a suffix beforehand.  
In WebSphere Application Server, the distinguished name is normalized according to the LDAP specification. Normalization consists of removing spaces in the base distinguished name before or after commas and equal symbols. An example of a non-normalized base distinguished name is o = ibm, c = us or o=ibm, c=us. An example of a normalized base distinguished name is o=ibm,c=us.
4. If the LDAP repository that you want to add to your realm is not previously configured, complete the following steps:
  - a. Click **Add Repository** on the Repository reference panel to configure the LDAP repository. See step 1 to access the Repository reference panel.
  - b. Configure LDAP on the LDAP configuration panel, as described in “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 1504.
  - c. Select the new Repository on the Repository reference panel.
5. Click **OK**.

## Results

You have added a new or previously configured external repository into your federated repository configuration.

### What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1543.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

### ***Configuring a property extension repository in a federated repository configuration:***

Follow this task to configure a property extension repository to store attributes that cannot be stored in your Lightweight Directory Access Protocol (LDAP) server.

### About this task

For security and business reasons, you might want to prohibit write operations to your repositories. However, applications calling the federated repository configuration might need to store additional properties for the entities. A federated repository configuration provides a *property extension repository*, which is a database regardless of the type of main profile repositories, for a propertylevel join configuration. For example, a company that uses an LDAP directory for its internal employees and a database for external customers and business partners might not allow write access to its LDAP and its database. The company can use the *property extension repository* in a federated repository configuration to store additional properties for the people in those repositories, excluding the user ID. When an application uses the federated repository configuration to retrieve an entry for a person, the federated repository configuration transparently joins the properties of the person that is retrieved from either the LDAP or the customer's database with the properties of the person that is retrieved from the property extension repository into a single logical person entry.

When you configure a property extension repository, you can supply a valid data source, a direct connection configuration, or both. The system first tries to connect by way of the data source. If the data source is not available, then the system uses the direct access configuration.

**Restriction:** You cannot configure a property extension repository in a mixed version deployment manager cell.

### Procedure

1. Configure the WebSphere Application Server data source. See “Configuring the WebSphere Application Server data source” on page 1539.
2. If you are adding new properties (including properties that are stored in the property extension repository) to the schema, you must do the following before you create the property extension repository.

- a. Open or create the wimxmlextension.xml file under the *profile\_root\config\cells\cell\_name\wim\model* directory.

**Attention:** Make sure the editor is on the deployment manager node.

- b. Add the schema definition of the new property. The following sample wimxmlextension.xml file adds a new property called `ibmotherEmail` to both the `Person` and `PersonAccount` entity types. This new property type is "String" and it is multivalued.

</wim:propertySchema>
</wim:schema>
</sdo:datagraph>

```

Available data types are defined in `com.ibm.websphere.wim.SchemaConstants`. For example:

```

/**
 * Instance Class: java.lang.String
 */
String DATA_TYPE_STRING = "String";
/**
 * Instance Class: int
 */
String DATA_TYPE_INT = "Int";
/**
 * Instance Class: java.lang.Object
 */
String DATA_TYPE_DATE = "Date";
/**
 * Instance Class: dojava.lang.Object
 */
String DATA_TYPE_ANY_SIMPLE_TYPE = "AnySimpleType";
/**
 * Instance Class: java.lang.String
 */
String DATA_TYPE_ANY_URI = "AnyURI";
/**
 * Instance Class: java.lang.boolean
 */
String DATA_TYPE_BOOLEAN = "Boolean";
/**

```

```

* Instance Class: long
*/
String DATA_TYPE_LONG = "Long";
/**
* Instance Class: double
*/
String DATA_TYPE_DOUBLE = "Double";
/**
* Instance Class: short
*/
String DATA_TYPE_SHORT = "Short";

```

- c. Follow the example inside this file to define the new property definitions. The schema file for wimlaproperties.xml is wimdbproperty.xsd and is in the same directory. It can be used for reference.
3. Run the setupIdMgrPropertyExtensionRepositoryTables command to create the property extension repository and to add the new properties.
4. Set up the property extension repository using wsadmin by following the procedure discussed in "Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands" on page 1523; ignore the "Before you begin" options.
5. Configure the property extension repository by completing the following steps:
  - a. In the administrative console, click **Security > Global security**.
  - b. Under User account repository, select **Federated repositories**, and click **Configure**.
  - c. Click **Property extension repository**.
  - d. Supply the name of the data source in the Data source name field.
  - e. Select the type of database that is used for the property extension repository.
  - f. Supply the name of the Java database connectivity (JDBC) driver in the JDBC driver field.

Values include:

**DB2** com.ibm.db2.jcc.DB2Driver

**Oracle**  
oracle.jdbc.driver.OracleDriver

**Informix**  
com.informix.jdbc.IfxDriver

**Microsoft SQL Server**  
com.microsoft.jdbc.sqlserver.SQLServerDriver

**Derby** org.apache.derby.jdbc.EmbeddedDriver

- g. Supply the database URL that is used to access the property extension repository with JDBC in the Database URL field. Use an alphanumeric text string that conforms to the standard JDBC URL syntax.

Values include:

**DB2** jdbc:db2://<hostname>:<port>/<DB2location>

**Oracle**  
jdbc:oracle:thin:@<hostname>:<port>:<dbname>

**Derby** jdbc:derby:c:\derby\wim

**Microsoft SQL Server**  
jdbc:microsoft:sqlserver://<hostname>:1433;databaseName=wim;selectmethod=cursor;

**Informix**  
jdbc:informixsql: //<hostname>:1526/wim:INFORMIXSERVER=<IFXServerName>;

- h. Supply the user name of the database administrator in the Database administrator user name field.
- i. Supply the password of the database administrator in the Password field.

- j. Specify the entity retrieval limit in the Entity retrieval limit field. The entity retrieval limit is the maximum number of entities that the system can retrieve from the property extension repository with a single database query. The default value is 200.
- k. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which includes a property extension repository, is configured.

## What to do next

1. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** on the Global security panel.
2. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

### *Property extension repository settings:*

Use this page to configure a property extension repository that is used to store attributes that cannot be stored in existing repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Property extension repository**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

### *Data source name:*

Specifies the Java Naming and Directory Interface (JNDI) name of the data source that is used to access the property extension repository.

**Default:** jdbc/wimDS

### *Database type:*

Specifies the type of database that is used for the property extension repository.

**Default:** DB2

### *JDBC driver:*

Specifies the Java Database Connectivity (JDBC) driver that is used to access the entry mapping repository.

Values include:

**DB2** COM.ibm.db2.jcc.DB2Driver

**Oracle**`oracle.jdbc.driver.OracleDriver`**Informix**`com.informix.jdbc.IfxDriver`**DataDirect Connect**`com.ddtek.jdbc.sqlserver.SQLServerDriver`**Derby**`org.apache.derby.jdbc.EmbeddedDriver`**Microsoft SQL Server**`com.microsoft.sqlserver.jdbc.SQLServerDriver`*Database URL:*

Specifies the web address for the property extension repository.

Values include:

**DB2** `jdbc:db2:wim`**DB2 for z/OS**`jdbc:db2://hostname:port/DB2location`**Informix**`jdbc:informix-sqli://host_name:port/wim:INFORMIXSERVER=IFXServerName;`**DataDirect Connect**`jdbc:datadirect:sqlserver://host_name:1433;databaseName=wim;selectMethod=cursor;`**Derby**`jdbc:derby:c:\derby\wim`**Oracle**`jdbc:oracle:thin:@host_name:port:dbname`**Microsoft SQL Server**`jdbc:sqlserver://host_name:1433;databaseName=wim;selectMethod=cursor;`*Database administrator user name:*

Specifies the user name of the database administrator that is used to access the property extension repository.

*Password:*

Specifies the password that is used to enable the database administrator to access the property extension repository.

*Entity retrieval limit:*

Specifies the maximum number of entities that the system can retrieve from the property extension repository with a single database query.

**Data type:**

Integer

**Default:**

200

*Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands:*

You can set up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands.

## Before you begin

If you are setting up an entry mapping repository, begin with the steps described in “Configuring an entry mapping repository in a federated repository configuration” on page 1539.

If you are setting up a property extension repository, begin with the steps described in “Configuring a property extension repository in a federated repository configuration” on page 1518.

## About this task

When you create a repository, use the appropriate wsadmin commands to define the database schema and to populate the database property definitions.

## Procedure

1. Create the database. You can use any relational database product. The following examples give you tips for specific vendors.

a. For **DB2**, open a DB2 command window or command center and enter the following:

```
db2 create database <name> using codeset UTF-8 territory US
```

Enter the following database tuning commands:

```
db2 update database configuration for <name> using applheapsz 1024
db2 update database configuration for <name> using stmtheap 4096
db2 update database configuration for <name> using app_ctl_heap_sz 2048
db2 update database configuration for <name> using locklist 1024
db2 update database configuration for <name> using indexrec RESTART
db2 update database configuration for <name> using logfilsiz 1000
db2 update database configuration for <name> using logprimary 12
db2 update database configuration for <name> using logsecond 10
db2 update database configuration for <name> using sortheap 2048
db2set DB2_RR_T0_RS=yes
```

b. Optional: For **Informix** databases using dbaccess, enter the following command:

```
CREATE DATABASE <name> WITH BUFFERED LOG
```

c. Optional: For **Oracle** databases, the database should already exist during Oracle installation (for example, orcl).

2. Run the `setupIdMgrEntryMappingRepositoryTables` command, the `setupIdMgrPropertyExtensionRepositoryTables` command, or the `setupIdMgrDBTables` command (for custom registry repositories) by doing the following:

a. Start WebSphere Application Server.

b. Open a command window and go to the `<WAS>/Profiles/<PROFILE_NAME>bin` directory.

c. Start wsadmin.

d. Type the necessary commands as described below.

## What to do next

Using these commands, you can:

- Specify the arguments on the command line.
- Specify the arguments in a file.

The `-file` option enables you to specify a file in which some or all of the parameters are specified. To use the `-file` argument on the command line, enter the full path to the file. Parameters in the file must be specified in `key=value` pairs and each must be on its own line. If a parameter is specified on both the command line and in the file, the value on the command line takes precedence.

Tips for diagnosing argument errors:

- If an argument is not properly specified on the command line or in the file, a message is returned which states that the argument was not properly specified. This might mean that the argument was not specified at all or was required for a given configuration but was not specified.
- If the argument was not specified at all, check that the parameter is specified on the command line or in the file, and that it is properly spelled and has matching case.
- If the argument was required for a given configuration but was not specified, it is possible that a value is not required solely by the command but is required for the type of database and configuration you are setting.

For example, if you set the `dn`, `wasAdminId`, or `wasAdminPassword` parameters, you must also specify the `dbDriver` parameter.

Additionally, if the `dn`, `wasAdminId` or `wasAdminPassword` parameters are specified, and the `databaseType` is not a Apache Derby v10.2 database, then the `dbAdminId` and `dbAdminPassword` parameters must also be specified.

**Important:** To use Apache Derby v10.2 for your repository, you must run the Apache Derby Network Server framework. This framework supports multiple concurrent JVM connections with the database, whereas the embedded framework works with only a single JVM, which cannot fulfill most workload-balancing requirements. Running the Network Server framework for Apache Derby v10.2 requires the Derby Client driver files and classes.

### The `setupIdMgrDBTables` command:

The `setupIdMgrDBTables` command creates, and populates the tables in the database that you previously created. Arguments are case-sensitive, both through the command line and the file.

*Parameters:*

**schemaLocation (String, Required)**

The location of the `<WAS>/etc/wim/setup` directory.

**dbPropXML (String)**

The location of database repository property definition XML file.

**databaseType (String, Required)**

The type of database. Supported databases are `db2`, `oracle`, `informix`, `derby`, `sqlserver`, `db2zos`, and `db2iseries`.

**dbURL (String, Required)**

The database URL for direct access mode. For example: `jdbc:db2:wim`.

**dbDriver (String)**

The name of the database driver. For example: `com.ibm.db2.jcc.DB2Driver`.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: `db2admin`.

**Note:** For a Apache Derby v10.2 embedded database, `dbAdminId` is not required.

**dbAdminPassword (String)**

The password associated with the `dbAdminId`.

**Note:** For a Apache Derby v10.2 embedded database, `dbAdminPassword` is not required.

**dn (String)**

The default organization `uniqueName` to replace. For example: `o=yourco`. If it is not set, `o=Default Organization` is used.

**wasAdminId (String)**

The WebSphere Application Server admin user ID. The ID should be a short name, not a uniqueName. For example: wasadmin. After creation, the uniqueName is uid=wasadmin, <defaultOrg>.

**wasAdminPassword (String)**

The WebSphere Application Server admin user password. If wasAdminId is set, then this parameter is mandatory.

**saltLength (Integer)**

The salt length of the randomly generated salt for password hashing.

**encryptionKey (String)**

The password encryption key. Set the password encryption key to match the encryption key in the wimconfig.xml file for the repository. If the encryption key is not set, the default is used.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**tablesBufferPool (String)**

The buffer pool variable of default tables in DB2 for z/OS. The default value is BP0.

**LOBtablesBufferPool (String)**

The buffer pool variable of auxiliary LOB tables in DB2 for z/OS. The default value is BP0.

**indextablesBufferPool (String)**

The buffer pool variable of unique index tables in DB2 for z/OS. The default value is BP0.

**dbSchema (String)**

The database schema where you want to create the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

**tablespacePrefix (String)**

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

**The deleteIdMgrDBTables command:**

The deleteIdMgrDBTables command deletes the tables in the database.

*Parameters:***schemaLocation (String, Required)**

The location of the <WAS>/etc/wim/setup directory.

**databaseType (String, Required)**

The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

**dbURL (String, Required)**

The database URL for direct access mode. For example: jdbc:db2:wim.

**dbDriver (String)**

The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: db2admin.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminId is not required.

**dbAdminPassword (String)**

The password associated with the dbAdminId.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**dbSchema (String)**

The database schema from which you want to delete the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

**tablespacePrefix (String)**

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

**The setupIdMgrPropertyExtensionRepositoryTables command:**

The setupIdMgrPropertyExtensionRepositoryTables command sets up the property extension repository. The default behavior includes creating and populating the tables in the database.

This command is available in connected or local mode.

*Parameters:***schemaLocation (String, Required)**

The location of the *app\_server\_root/etc/wim/setup* directory.

**laPropXML (String)**

The location of the property extension repository definition XML file.

**databaseType (String, Required)**

The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

**dbURL (String, Required)**

The database URL for direct access mode. For example: jdbc:db2:wim.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: db2admin.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminId is not required.

**dbAdminPassword (String)**

The password associated with the dbAdminId.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**skipDBCcreation (Boolean)**

Specifies whether to create the tables in the property extension repository.

If you set this parameter value to false or do not specify a value, then the command follows the default behavior of creating and populating the tables in the database.

If you set this parameter value to true, manually set up the property extension repository before running this command so that the tables get populated. For more information on this manual process, see the appropriate topic on manually setting up the property extension repository for your database.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**tablesBufferPool (String)**

The buffer pool variable of default tables in DB2 for z/OS. The default value is BP0.

**LOBtablesBufferPool (String)**

The buffer pool variable of auxiliary LOB tables in DB2 for z/OS. The default value is BP0.

**indextablesBufferPool (String)**

The buffer pool variable of unique index tables in DB2 for z/OS. The default value is BP0.

**dbSchema (String)**

The database schema where you want to create the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

**tablespacePrefix (String)**

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

**The deleteIdMgrPropertyExtensionRepositoryTables command:**

The deleteIdMgrPropertyExtensionRepositoryTables command deletes the tables in the property extension database.

This command is available in the connected or local mode.

*Parameters:***schemaLocation (String, Required)**

The location of the <WAS>/etc/wim/setup directory.

**databaseType (String, Required)**

The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

**dbURL (String, Required)**

The database URL for direct access mode. For example: jdbc:db2:wim.

**dbDriver (String)**

The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: db2admin.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminId is not required.

**dbAdminPassword (String)**

The password associated with the dbAdminId.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**dbSchema (String)**

The database schema from which you want to delete the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

**tablespacePrefix (String)**

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

**The setupIdMgrEntryMappingRepositoryTables command:**

The setupIdMgrEntryMappingRepositoryTables command sets up the entry mapping repository, which includes creating and populating the tables of the repository.

*Parameters:***schemaLocation (String, Required)**

The location of the <WAS>/etc/wim/setup directory.

**databaseType (String, Required)**

The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

**dbURL (String, Required)**

The database URL for direct access mode. For example: jdbc:db2:wim.

**dbDriver (String)**

The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: db2admin.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminId is not required.

**dbAdminPassword (String)**

The password associated with the dbAdminId.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**tablesBufferPool (String)**

The buffer pool variable of default tables in DB2 for z/OS. The default value is BP0.

**dbSchema (String)**

The database schema where you want to create the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

**tablespacePrefix (String)**

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

**The deleteIdMgrEntryMappingRepositoryTables command:**

The deleteIdMgrEntryMappingRepositoryTables command deletes the tables in the entry mapping repository.

*Parameters:***schemaLocation (String, Required)**

The location of the <WAS>/etc/wim/setup directory.

**databaseType (String, Required)**

The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

**dbURL (String, Required)**

The database URL for direct access mode. For example: jdbc:db2:wim.

**dbDriver (String)**

The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

**dbAdminId (String)**

The database administrator ID for direct access mode. For example: db2admin.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminId is not required.

**dbAdminPassword (String)**

The password associated with the dbAdminId.

**Note:** For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

**derbySystemHome (String)**

The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

**reportSqlError (String)**

Specifies whether to report SQL errors while setting up databases.

**file (String)**

The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

**dbSchema (String)**

The database schema from which you want to delete the federated repository tables. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

**tablespacePrefix (String)**

The tablespace prefix. The maximum length allowed for this string is 3 characters. The value of tablespacePrefix parameter is required when you use the dbSchema parameter. It is specific to DB2 for z/OS and will be ignored for any other database type.

**Sample command line usage:**

To set up a database using the command line, enter the following:

```
$AdminTask setupIdMgrDBTables {-schemaLocation "C:/WAS/etc/wim/setup" -dbPropXML
"C:/WAS/etc/wim/setup/wimdbproperties.xml" -databaseType db2
-dbURL jdbc:db2:wim -dbAdminId db2admin
-dbDriver com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd
-reportSqlError true}
```

To delete database tables using the command line, enter the following:

```
$AdminTask deleteIdMgrDBTables {-schemaLocation "C:/WAS/etc/wim/setup"
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin
-dbDriver com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd
-reportSqlError true}
```

To set up a property extension repository using the command line, enter the following:

```
$AdminTask setupIdMgrPropertyExtensionRepositoryTables {-schemaLocation
"C:/WAS/etc/wim/setup"
-laPropXML "C:/WAS/etc/wim/setup/wimlaproperties.xml" -databaseType db2
-dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver com.ibm.db2.jcc.DB2Driver
-dbAdminPassword db2adminPwd -reportSqlError true}
```

To delete a property extension repository using the command line, enter the following:

```
$AdminTask deleteIdMgrPropertyExtensionRepositoryTables {-schemaLocation "C:/WAS/etc/wim/setup "
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver
com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

To set up an entry mapping repository using the command line, enter the following:

```
$AdminTask setupIdMgrEntryMappingRepositoryTables {-schemaLocation "C:/WAS/etc/wim/setup"
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver
com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

To delete an entry mapping repository using the command line, enter the following:

```
$AdminTask deleteIdMgrEntryMappingRepositoryTables {-schemaLocation "C:/WAS/etc/wim/setup"
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver
com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

**Sample CLI Usage using -file option:**

To set up a database with the -file option using the example params.txt file below, enter the following:

```
$AdminTask setupIdMgrDBTables {-file C:/params.txt -dbPropXML
"C:/OverrideDBPropParam/wimdbproperties.xml"}
```

## Params.txt

```
schemaLocation=C:/WAS/etc/wim/setup
dbPropXML=C:/Program Files/IBM/WebSphere/AppServer/profiles/default
/config/cells/mycell1/wim/config/wimdbproperties.xml
laPropXML=C:/Program Files/IBM/WebSphere/AppServer/profiles/default
/config/cells/mycell1/wim/config/wimlaproperties.xml
databaseType=db2
dbURL=jdbc:db2:wim
dbDriver=com.ibm.db2.jcc.DB2Driver
reportSqlError=true
dn=o=db.com
dbAdminId=db2admin
dbAdminPassword=dbPassword
wasAdminId=wasadmin
wasAdminPassword=wasadmin1
```

To set up a database with the `-file` option using a file only, enter the following:

```
$AdminTask setupIdMgrDBTables {-file C:/params.txt}
```

**Note:** The use of a file only works if `-file` is the only parameter specified on the command line. If other parameters are specified then the file is completely ignored, and only the parameters on the command line are used to execute the command.

*Manually setting up the property extension repository for federated repositories:*

You can use the `createIdMgrPropExtDbTables` script to create tables in the property extension repository for federated repositories.

## Before you begin

The following databases are supported by the script when the database exists on a distributed operating system:

- IBM DB2
- Apache Derby
- IBM Informix Dynamic Server
- Oracle 11g
- Microsoft SQL Server

For a list of the supported database versions, see the IBM WebSphere Application Server detailed system requirements.

To use the IBM DB2 on z/OS or IBM DB2 on iSeries database, read about manually setting up the property extension repository in DB2.

If you do not have WebSphere Application Server installed on the same system on which you are setting up the database, you must copy the following files from a system where WebSphere Application Server is installed to the system on which you are setting up the database. Ensure that you replicate the same directory structure within the setup directory. The `db_type` variable represents one of the following directory names: `db2`, `oracle`, `informix`, `derby`, or `sqlserver`.

```
app_server_root\etc\wim\setup\bin\createIdMgrPropExtDbTables.sh
app_server_root\etc\wim\setup\bin\createIdMgrPropExtDbTables.bat
app_server_root\etc\wim\setup\lookaside\db_type\dbclean.sql
app_server_root\etc\wim\setup\lookaside\db_type\schema.sql
app_server_root\etc\wim\setup\lookaside\db_type\primarykeys.sql
app_server_root\etc\wim\setup\lookaside\db_type\indexes.sql
app_server_root\etc\wim\setup\lookaside\db_type\references.sql
app_server_root\etc\wim\setup\lookaside\keys.sql
app_server_root\etc\wim\setup\lookaside\bootstrap.sql
```

## Specifying the database schema:

You can specify the database schema where you want to create the federated repository tables when you are manually setting up the property extension repository.

If you want to use the default schema of the database, you must execute the following commands without specifying the DBSCHEMA parameter. Typically, the default schema is the namespace of the current database user.

Complete these steps to replace the schema variable in the SQL files with the actual database schema name. If WebSphere Application Server and the database are not on the same system, set the SCHEMA\_LOCATION value to the location where you copied the SQL files.

#### Windows operating systems:

1. Open a command window.
2. Change to the `app_server_root\etc\wim\setup` directory.
3. Enter the following commands:

```
set SCHEMA_LOCATION=app_server_root\etc\wim\setup\lookaside
set DBTYPE=<db_type>
set DBSCHEMA=dbschemaname
set SCHEMA_DEST_LOCATION=<location where the updated SQL files with replaced variables should be copied>
ws_ant.bat -f app_server_root\etc\wim\setup\filterbuild.xml
```

where the value of `<db_type>` is db2, derby, informix, oracle, or sqlserver.

**Note:** : If SCHEMA\_DEST\_LOCATION is not set, the updated SQL files are copied to a directory with the name as the value not substituted under the current directory. The output shows where the files are copied.

#### AIX, HP-UX, Linux, and Solaris operating systems:

1. Open a command window
2. Change to the `app_server_root/etc/wim/setup` directory.
3. Enter the following commands:

```
export SCHEMA_LOCATION=app_server_root/etc/wim/setup/lookaside
export DBTYPE=<db_type>
export DBSCHEMA=dbschemaname
export SCHEMA_DEST_LOCATION=<location where the updated SQL files with replaced variables should be copied>
ws_ant.sh -f app_server_root/etc/wim/setup/filterbuild.xml
```

where the value of `<db_type>` is db2, derby, informix, oracle, or sqlserver.

**Note:** If SCHEMA\_DEST\_LOCATION is not set, the updated SQL files are copied to a directory with the name as the value not substituted under the current directory. The output shows where the files are copied.

#### About this task

The following notes apply to specific databases:

- **Oracle 11g**

- If you did not create the default database when you installed Oracle product, you must manually create the database before you run the `createldMgrPropExtDbTables` script. The value of the `ORACLE_SID` variable is the same value as the name of the database.
- If you want to create the tables in the schema that you specified using DBSCHEMA (described in the previous section, Specifying the database schema) ensure that you create the specified schema in this database before you run the `createldMgrPropExtDbTables` script.
- On the AIX, HP-UX, Linux, and Solaris operating systems, run the `createldMgrPropExtDbTables` script either as an Oracle user or as a root user with database administrator (dba) rights and appropriate permissions to run SQL queries as a system database administrator (sysdba).

- **IBM DB2**

- On the Windows operating systems, you must initialize the DB2 environment before you run the `createIdMgrPropExtDbTables` script. At the Windows command prompt, enter `db2cmd` to open a new DB2 command window and run the `createIdMgrPropExtDbTables` batch file from this prompt.

- **Microsoft SQL Server**

- Open a command window, change to the `app_server_root\bin` directory, and enter the following commands to replace the variables in the SQL files. If WebSphere Application Server and the database are not on the same system, set the **SCHEMA\_LOCATION** value to the location where you copied the SQL files.

```
set SCHEMA_LOCATION=app_server_root\etc\wim\setup\lookaside
set DBTYPE=sqlserver
set SCHEMA_DEST_LOCATION=<location where the updated SQL files with replaced variables should be copied>
set DOWNER=dbo
ws_ant.bat -f app_server_root\etc\wim\setup\filterbuild.xml
```

**Note:** If `SCHEMA_DEST_LOCATION` is not set, the updated SQL files are copied to a directory with the name as the value not substituted under the current directory. The output shows where the files are copied.

The following default instance is created as a part of the database installation:

- DB2: `DB2`
- Informix: `demo_on`
- SQL Server: `%computername%`

The Informix database is created with the following environment:

```
CLIENT_LOCALE=EN_US.CP1252
DB_LOCALE=EN_US.8859-1
SERVER_LOCALE=EN_US.CP1252
DBLANG=EN_US.CP125
```

## Procedure

Run the `createIdMgrPropExtDbTables.sh` script or `createIdMgrPropExtDbTables.bat` script to create the tables in the property extension repository.

Run the script from the following location or from the directory to which you previously copied the script file:

### AIX, HP-UX, Linux, and Solaris operating systems

```
app_server_root/etc/wim/setup/bin/createIdMgrPropExtDbTables.sh
```

### Windows

```
app_server_root\etc\wim\setup\bin\createIdMgrPropExtDbTables.bat
```

Use the following parameters to specify the values that you require when you run the script:

- b** Use this parameter to specify the home directory of the database.  
This value is a string value that is required for all database types.
- d** Use this parameter to specify the schema of the database.  
The value of this parameter should be the same value that you specified for `DBSCHEMA` (described in the previous section, `Specifying the database schema`).  
This value is a string value that is optional for DB2, Derby, and SQL Server databases, if you want to specify the database schema where you want to create the federated repository tables. This value is not required for Oracle and Informix databases.
- h** Use this parameter to display the help information. (Optional)

- i** Use this parameter to specify the home directory of the database instance.  
This value is a string value that is required for a DB2 database only; do not specify a value for other database types.  
This parameter applies to the AIX, HP-UX, Linux, and Solaris operating systems.
- n** Use this parameter to specify the name of the database to which you are connecting.  
For an Oracle database, the value of the *ORACLE\_SID* variable is the same as the name of the database.  
This value is a string value that is required for all database types.
- p** Use this parameter to specify the password of the database administrator.  
This value is a string value that is required for DB2, Oracle, Informix, and SQL Server databases only; do not specify a value for a Derby database.
- s** On AIX, HP-UX, Linux, and Solaris operating systems, this parameter specifies the location of the *app\_server\_root/etc/wim/setup* directory, or the location to which the updated files are copied according to the steps in the previous section, Specifying the database schema.  
On Windows operating systems, this parameter specifies the location of the *app\_server\_root\etc\wim\setup* directory, or the location to which the updated files are copied according to the steps in the previous section, Specifying the database schema.  
This value is a string value that is required for all database types.
- t** Use this parameter to specify a database type.
  - On the AIX, HP-UX, Linux, and Solaris operating systems, specify one of the following valid values: *db2*, *oracle*, *informix*, *derby*.
  - On the Windows operating systems, specify one of the following valid values: *db2*, *oracle*, *informix*, *derby*, or *sqlserver*.
 This value is a string value that is required for all database types.
- u** Use this parameter to specify the user ID of the database administrator.  
This value is a string value that is required for DB2, Oracle, Informix, and SQL Server databases only; do not specify a value for a Derby database.

## Example

Run the appropriate script for your database and operating system to create tables in the property extension repository. Use the sample values to specify database parameters. If the database exists on a system where WebSphere Application Server is not installed, the following examples assume that your *PATH* variable includes an entry for the location to which you copied the script files. For the AIX, HP-UX, Linux, and Solaris operating systems, the entry might be the *app\_server\_root/etc/wim/setup/bin/* or the */setup/bin/* directory. For Windows operating systems, the entry might be the *app\_server\_root\etc\wim\setup\bin\* or the *\setup\bin\* directory.

The examples in the following section are organized into multiple lines for illustration purposes only.

On the AIX, HP-UX, Linux, and Solaris operating systems:

### Oracle databases

```
createIdMgrPropExtDbTables.sh
-b /space/oracle/product/10.2.0/Db_1/
-n orcl
-u system
-p manager
-s /opt/IBM/WebSphere/AppServer1/etc/wim/setup
-t oracle
```

### **Informix databases**

```
createIdMgrPropExtDbTables.sh
-b /opt/IBM/informix/
-n demo_on
-u informix
-p informix
-s /opt/IBM/WebSphere/AppServer/etc/wim/setup
-t informix
```

### **DB2 databases**

```
createIdMgrPropExtDbTables.sh
-b /opt/ibm/db2/V9.1/
-n db2inst1
-p db2inst1
-s /opt/IBM/WebSphere/AppServer/etc/wim/setup
-t DB2
-u db2inst1
-i /home/db2inst1/
```

### **Derby databases**

```
createIdMgrPropExtDbTables.sh
-b /opt/ibm/derby/
-n test11
-s /opt/IBM/WebSphere/AppServer/etc/wim/setup
-t derby
```

On the Windows operating systems:

### **Oracle databases**

```
createIdMgrPropExtDbTables.bat
-b "c:\oracle\product\10.2.0\Db_1"
-n orcl
-u system
-p manager
-s "c:\Program Files\IBM\WebSphere\AppServer1\etc\wim\setup"
-t oracle
```

### **Informix databases**

```
createIdMgrPropExtDbTables.bat
-b "c:\Program Files\IBM\informix"
-n demo_on
-u informix
-p informix
-s "c:\Program Files\IBM\WebSphere\AppServer\etc\wim\setup"
-t informix
```

### **DB2 databases**

```
createIdMgrPropExtDbTables.bat
-t db2
-u db2admin
-p sec001ret#
-n test23
-b "c:\Program Files\IBM\SQLLIB"
-s "c:\Program Files\IBM\WebSphere\AppServer1\etc\wim\setup"
```

### **Derby databases**

```
createIdMgrPropExtDbTables.bat
-t derby
-b "c:\Derby"
-n test11
-s "c:\Program Files\IBM\WebSphere\AppServer1\etc\wim\setup"
```

### **Microsoft SQL Server databases**

```
createIdMgrPropExtDbTables.bat
-t sqlserver
-u sa
-p sec001ret#
```

```
-n sqlsrv
-b "c:\Progra~1\Micros~1\90\Tools"
-s "C:\Progra~1\IBM\WebSphere\AppServer1\etc\wim\setup"
```

## What to do next

Run the `setupIdMgrPropertyExtensionRepositoryTables` command with the **skipDBCreation** parameter set to true to populate the tables that are created. For more information, read about setting up an entry mapping repository, a property extension repository, or a custom registry database repository using `wsadmin` commands.

*Manually setting up the property extension repository for DB2 for iSeries or DB2 for z/OS:*

Use this task to set up the property extension repository for DB2 for iSeries or DB2 for z/OS.

## Before you begin

The information in this topic applies in the following scenarios:

- The application server and the database both exist on the IBM i operating system.
- The application server and the database both exist on the z/OS operating system.
- The application server exists on a distributed operating system, but the database exists on either the IBM i or z/OS operating system.

If you do not have WebSphere Application Server installed in the system on which you are setting up the database, copy the following files from a system where WebSphere Application Server is installed to the system on which you are setting up the database:

### DB2 for iSeries

```
app_server_root/etc/wim/setup/lookaside/db2iseries/dbclean.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/schema.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/primarykeys.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/indexes.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/references.sql
app_server_root/etc/wim/setup/lookaside/keys.sql
app_server_root/etc/wim/setup/lookaside/bootstrap.sql
```

### DB2 for z/OS

```
app_server_root/etc/wim/setup/lookaside/db2zos/dbclean.sql
app_server_root/etc/wim/setup/lookaside/db2zos/schema.sql
app_server_root/etc/wim/setup/lookaside/db2zos/primarykeys.sql
app_server_root/etc/wim/setup/lookaside/db2zos/indexes.sql
app_server_root/etc/wim/setup/lookaside/db2zos/references.sql
app_server_root/etc/wim/setup/lookaside/keys.sql
app_server_root/etc/wim/setup/lookaside/bootstrap.sql
```

## About this task

For information about how to create a database and run SQL queries in DB2 for iSeries, see the DB2 Universal Database for iSeries in the IBM iSeries Information Center.

For information about how to create a database and run SQL queries in DB2 for z/OS, see the Information Management Software for z/OS Solutions Information Center.

## Procedure

1. Open a command window.
2. Change to the `app_server_root/bin` directory
3. Enter the following commands to replace the variables in the SQL files:
  - a. `export SCHEMA_LOCATION=app_server_root/etc/wim/setup/lookaside`

Set the SCHEMA\_LOCATION value to the location where you copied the SQL files if you do not have WebSphere Application Server installed on the same system on which you are setting up the database.

- b. `export DBTYPE=<db_type>`  
where the value of `<db_type>` is `db2iseries` or `db2zos`
- c. To specify the database schema where you want to create the federated repository tables use the DBSCHEMA command. If you want to use the default schema, which is typically the namespace of the current database user, do not specify the DBSCHEMA command.  
`export DBSCHEMA=dbschemaname`
- d. `export SCHEMA_DEST_LOCATION=<schema_dest_location>`  
where `<schema_dest_location>` is the location where the updated SQL files with replaced variables should be copied. If SCHEMA\_DEST\_LOCATION is not set, the updated SQL files are copied to a directory with the name as the unsubstituted value under the current directory. The output indicates where the files are copied to.
- e. Specify the buffer pool to use for creating the federated repository tables. The buffer pool value that you specify should exist in the database. The default buffer pool value in the database is BP0. Even if you want to use the default buffer pool value, you must still execute the following commands and specify the default value of BP0 explicitly:  
`export DEFAULT_TABLE=<buffer pool value for default tables>`  
`export LOB_TABLE=<buffer pool value for LOB tables>`  
`export INDEX_TABLE=<buffer pool value for unique index tables>`
- f. `export DBNAME=zos`
- g. `./ws_ant.sh -f app_server_root/etc/wim/setup/filterbuild.xml`

4. Start the DB2 server.
5. Create a database.
6. Run the SQL files, which were previously referenced, to create the tables for the property extension repository. If you are setting up the database on the same system on which the application server is installed, the files are located in the following locations:

#### DB2 for iSeries

```
app_server_root/etc/wim/setup/lookaside/db2iseries/dbclean.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/schema.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/primarykeys.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/indexes.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/references.sql
app_server_root/etc/wim/setup/lookaside/keys.sql
app_server_root/etc/wim/setup/lookaside/bootstrap.sql
```

#### DB2 for z/OS

```
app_server_root/etc/wim/setup/lookaside/db2zos/dbclean.sql
app_server_root/etc/wim/setup/lookaside/db2zos/schema.sql
app_server_root/etc/wim/setup/lookaside/db2zos/primarykeys.sql
app_server_root/etc/wim/setup/lookaside/db2zos/indexes.sql
app_server_root/etc/wim/setup/lookaside/db2zos/references.sql
app_server_root/etc/wim/setup/lookaside/keys.sql
app_server_root/etc/wim/setup/lookaside/bootstrap.sql
```

Otherwise, run the SQL files from the location to which you copied the files. If you executed the commands to substitute variables according to the steps in the previous section, Specifying the database schema, the SQL files are copied to the location you specified for SCHEMA\_DEST\_LOCATION. If SCHEMA\_DEST\_LOCATION is not set, the updated SQL files are copied to a directory with the name as the unsubstituted value under the current directory. The output shows where the files are copied.

## What to do next

Run the `setupIdMgrPropertyExtensionRepositoryTables` command with the **skipDBCcreation** parameter set to true to populate the tables that are created. For more information, read about setting up an entry mapping repository, a property extension repository, or a custom registry database repository using `wsadmin` commands.

### *Configuring the WebSphere Application Server data source:*

Installed applications use data sources as resources to obtain connection to relational databases. To create these connections between an application and a relational database, WebSphere Application Server uses the driver implementation classes that are encapsulated by the JDBC provider, which is an object that represents vendor-specific JDBC driver classes to WebSphere Application Server. For access to a relational databases, applications use the JDBC drivers and data sources that you configure for WebSphere Application Server.

### Procedure

1. Start the WebSphere Application Server administrative console.
2. Click **Security -> Global security**.
3. On the Configuration panel, expand Java Authentication and Authorization Service and click **J2C authentication data**.
4. Click **New** and enter the Alias, User ID and Password.
5. Click **Ok**.
6. On the WebSphere Application Server administrative console, expand **Resources**. Expand **JDBC** then click **JDBC Providers**.
7. In the Scope section, choose the **Node level** from the drop-down list.
8. Click **New** to create a new JDBC driver.
9. Select, in this order, the Database type, Provider type, Implementation type and Name. The Name automatically fills based on the implementation type you choose.
10. Click **Next** and configure the database class path. Click **Next**.
11. On the Summary page, click **Finish**.
12. Click **Save** to save your selections. The JDBC providers page then appears.
13. On the WebSphere Application Server administrative console, click **Data sources**.
14. Click **New** to create a new data source. Enter the Data source name and the JNDI name, and choose the authentication alias from the drop-down list in Component-managed authentication alias. The JNDI name should match the `datasourceName` value set in `wimconfig.xml`. By default, it is `jdbc/wimDS`.  
  
**Note:** For Apache Derby v10.2 embedded databases, leave the Component-managed authentication alias field set to NONE.
15. Click **Next**.
16. Enter the Database name and deselect the checkbox, **Use this data source in container managed persistence (CMP)**. Click **Next**.
17. On the Summary page, click **Finish**.
18. The Data sources page displays. Click **Save**, Then select the check box for the authentication alias previously created. Click **Test Connection**. The message should indicate that the connection is successful. Ignore any warnings, and then click **Next**.
19. Save the configurations, and restart WebSphere Application Server.

### *Configuring an entry mapping repository in a federated repository configuration:*

Follow this task to configure an entry mapping repository that is used to store data for managing profiles on multiple repositories.

### About this task

An *entry-level join* means that the federated repository configuration uses multiple repositories simultaneously and recognizes the entries in the different repositories as entries representing distinct entities. For example, a company might have a Lightweight Directory Access Protocol (LDAP) directory that contains entries for its employees and a database that contains entries for business partners and customers. By configuring an entry mapping repository, a federated repository configuration can use both the LDAP and the database at the same time. The federated repository configuration hierarchy and constraints for identifiers provide the aggregated namespace for both of those repositories and prevent identifiers from colliding.

When you configure an entry mapping repository, you can supply a valid data source, a direct connection configuration, or both. The system first tries to connect by way of the data source. If the data source is not available, then the system uses the direct access configuration.

**Restriction:** You cannot configure an entry mapping repository in a mixed-version deployment manager cell.

### Procedure

1. Configure the WebSphere Application Server data source. See “Configuring the WebSphere Application Server data source” on page 1539.
2. Set up the entry mapping repository using wsadmin. See “Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands” on page 1523; ignore the “Before you begin” options.
3. Configure the entry mapping repository into the federated repository by doing the following:
  - a. In the administrative console, click **Security > Global security**.
  - b. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
  - c. Click **Entry mapping repository**.
  - d. Supply the name of the data source in the Data source name field.
  - e. Select the type of database that is used for the property extension repository.
  - f. Supply the name of the Java database connectivity (JDBC) driver in the JDBC driver field.

Values include:

**DB2** com.ibm.db2.jcc.DB2Driver

**DB2 for z/OS**  
com.ibm.db2.jcc.DB2Driver

**Informix**  
com.informix.jdbc.IfxDriver

**DataDirect Connect**  
com.ddtek.jdbc.sqlserver.SQLServerDriver

**Derby** org.apache.derby.jdbc.EmbeddedDriver

**Microsoft SQL Server**  
com.microsoft.sqlserver.jdbc.SQLServerDriver

**Oracle**  
oracle.jdbc.driver.OracleDriver

- g. Supply the database URL that is used to access the property extension repository with JDBC in the Database URL field. Use an alphanumeric text string that conforms to the standard JDBC URL syntax.

Values include:

**DB2** jdbc:db2:wim

**Informix**

jdbc:informix-sqli://host\_name:1526/wim:INFORMIXSERVER=IFXServerName;

**DataDirect Connect**

jdbc:datadirect:sqlserver://host\_name:1433;databaseName=wim;selectMethod=cursor;

**Derby** jdbc:derby:c:\derby\wim

**Microsoft SQL Server**

jdbc:sqlserver://host\_name:1433;databaseName=wim;selectMethod=cursor;

**Oracle**

jdbc:oracle:thin:@host\_name:port:dbname

- h. Supply the user name of the database administrator in the Database administrator user name field.
- i. Supply the password of the database administrator in the Password field.
- j. Click **OK**.

## Results

After completing these steps, your federated repository configuration, which includes an entry mapping repository, is configured.

## What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

### *Entry mapping repository settings:*

Use this page to configure an entry mapping repository that is used to store data for managing profiles on multiple repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Entry mapping repository**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Data source name:*

Specifies the Java Naming and Directory Interface (JNDI) name of the data source that is used to access the entry mapping repository.

**Default:** jdbc/wimDS

*Database type:*

Specifies the type of database that is used to access the entry mapping repository.

**Default:** DB2

*JDBC driver:*

Specifies the Java Database Connectivity (JDBC) driver that is used to access the entry mapping repository.

Values include:

**DB2** com.ibm.db2.jcc.DB2Driver

**DB2 for z/OS**

com.ibm.db2.jcc.DB2Driver

**DataDirect Connect**

com.ddtek.jdbc.sqlserver.SQLServerDriver

**Informix**

com.informix.jdbc.IfxDriver

**Oracle**

oracle.jdbc.driver.OracleDriver

**Microsoft SQL Server**

com.microsoft.sqlserver.jdbc.SQLServerDriver

**Derby** org.apache.derby.jdbc.EmbeddedDriver

*Database URL:*

Specifies the web address for the entry mapping repository.

Values include:

**DB2** jdbc:db2:wim

**Derby** jdbc:derby:c:\derby\wim

**DataDirect Connect**

datadirect:sqlserver://:host\_name1433;databaseName=wim;selectMethod=cursor;

**Oracle**

jdbc:oracle:thin:@host\_name:port:dbname

**Microsoft SQL Server**

jdbc:sqlserver://host\_name:1433;databaseName=wim;selectMethod=cursor;

**Informix**

jdbc:informix-sqli://host\_name:port/wim:INFORMIXSERVER=IFXServerName;

*Database administrator user name:*

**1542** Administering WebSphere applications

Specifies the user name of the database administrator that is used to access the entry mapping repository.

*Password:*

Specifies the password that is used to enable the database administrator to access the entry mapping repository.

### ***Configuring supported entity types in a federated repository configuration:***

Follow this task to configure supported entity types for user and group management.

#### **About this task**

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The supported entity types are Group, OrgContainer, and PersonAccount. A Group entity represents a simple collection of entities that might not have any relational context. An OrgContainer entity represents an organization, such as a company or an enterprise, a subsidiary, or an organizational unit, such as a division, a location, or a department. A PersonAccount entity represents a human being. You cannot add or delete the supported entity types, because these types are predefined.

The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

**Note:** To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

**Note:** You must restart the server or dmgr if the federated repository has changed before using the Manage Users option. Otherwise, user or group changes made to the repository could be lost after restart.

#### **Procedure**

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Click **Supported entity types** to view a list of predefined entity types.
4. Click the name of a predefined entity type to change its configuration.
5. Supply the distinguished name of a base entry in the repository in the Base entry for the default parent field. This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.
6. Supply the relative distinguished name (RDN<sup>®</sup>) properties for the specified entity type in the Relative Distinguished Name properties field. Possible values are `cn` for Group, `uid` or `cn` for PersonAccount, and `o`, `ou`, `dc`, and `cn` for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

The following list outlines known requirements and limitations that apply to specific Lightweight Directory Access Protocol (LDAP) servers:

#### **Using Microsoft Active Directory as the LDAP server**

- Unless you modify the LDAP schema to use `uid`, you must specify `cn` in the Relative Distinguished Name (RDN) properties field for the PersonAccount entity type.
- Secure Sockets Layer communications must be enabled to create users with passwords. To select the **Require SSL communications** option, see the topic “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 1504.

- Typically the value of user is specified as the value in the Object classes field for the PersonAccount entity type and the value of group is specified as the value in the Object classes field for the Group entity type.

#### Using a Lotus Domino Enterprise Server as the LDAP server

- Typically, the value of cn is specified in the Relative Distinguished Name (RDN) properties field for the PersonAccount entity type. The value of uid is also acceptable.
- Typically, both inetOrgPerson and dominoPerson are used as values in the Object classes field for the PersonAccount entity type.

#### Using Sun ONE Directory Server as the LDAP server

- Typically, groupOfUniqueNames is specified as the value in the Object classes field for the Group entity type.

7. Click **OK**.

### Results

After completing these steps, your federated repository configuration, which uses supported entity types, is configured.

### What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** on the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

#### *Supported entity types collection:*

Use this page to list entity types that are supported by the member repositories or to select an entity type to view or change its configuration properties.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Supported entity types**.

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

#### *Entity type:*

Specifies the entity type name.

*Base entry for the default parent:*

Specifies the distinguished name of a base entry in the repository.

This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.

*Relative Distinguished Name properties:*

Specifies the relative distinguished name (RDN) properties for the specified entity type.

Possible values are `cn` for Group, `uid` or `cn` for PersonAccount, and `o`, `ou`, `dc`, and `cn` for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

*Supported entity types settings:*

Use this page to configure entity types that are supported by the member repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Supported entity types**.
4. Click the name of a configured entity type to view or change its configuration.

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Entity type:*

Specifies the name of the entity type.

*Base entry for the default parent:*

Specifies the distinguished name of a base entry in the repository.

This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.

*Relative Distinguished Name properties:*

Specifies the relative distinguished name (RDN) properties for the specified entity type.

Possible values are `cn` for Group, `uid` or `cn` for PersonAccount, and `o`, `ou`, `dc`, and `cn` for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

***Managing repositories in a federated repository configuration:***

Follow this topic to manage repositories in a federated repository configuration.

## Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**. Repositories that are configured in the system are listed in the collection panel. This list includes repositories that are configured using the federated repository functionality as well as repositories that are created using wsadmin commands described in the topic `IdMgrRepositoryConfig` command group for the AdminTask object.
4. Optional: Click **Add** to configure a new external repository. The Lightweight Directory Access Protocol (LDAP) repository configuration settings are described in detail in “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 1504.

**Restriction:** You cannot add a database repository using the administrative console. This repository configuration is supported by using wsadmin commands only.

5. Optional: Click **Delete** to delete a repository that you specified previously using the administrative console or wsadmin commands.

**Restriction:** You cannot delete the built-in, file-based repository from the collection panel.

6. Optional: Select one of the LDAP repository identifier entries to view or update an external repository that is configured in the system previously. The steps to configure LDAP settings are described in detail in “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 1504.

**Restriction:** While database repositories that are configured in the system are listed in the collection panel, you cannot update a database repository using the administrative console. Updates to a database repository are supported by using wsadmin commands only.

7. Click **OK**.

## Results

After completing these steps, the collection panel under Managing repositories reflects a current list of repositories that are configured in your system.

## What to do next

1. To add one or more external repositories that are listed on this collection panel into the realm, see “Managing the realm in a federated repository configuration” on page 1481.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

**Important:** Be aware of any changes made to built-in, file-based repositories that are part of the federated repositories configuration. You must replicate these changes to the managed nodes to ensure that your network deployment configuration is synchronized. See “Replicating changes to a built-in, file-based repository” on page 1547 for the steps needed to perform this replication.

*Replicating changes to a built-in, file-based repository:*

Changes to built-in, file-based repositories are not automatically replicated to managed nodes in a federated repositories configuration. You need to use the administrative console to replicate the changes you make to a built-in, file-based repository.

### **About this task**

The network deployment support in a federated repositories configuration only updates the in-memory state of the processes that are running on the managed nodes. Because WebSphere Application Server synchronizes the file systems, the network deployment support does not attempt to update the file systems of the managed nodes.

You must synchronize the node configuration to replicate the changes to the built-in, file-based repository.

### **Procedure**

1. In the administrative console, click **System Administration > Nodes**. to access the nodes panel.
2. On the Nodes panel, select all the relevant nodes for which the changes to the built-in, file-based repository need to be made.
3. Click **Full Resynchronize**. The resynchronize operation resolves conflicts among configuration files and can take several minutes to complete.

### **Results**

After completing these steps, your federated repository configuration of managed nodes reflects the changes to the built-in, file-based repository.

*Manage repositories collection:*

Use this page to list repositories that are configured in the system or to select a repository to view or change its configuration properties. You can add or delete external repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Repository identifier:*

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

*Repository type:*

Specifies the repository type, such as File or LDAP.

*Add:*

Select to add a new LDAP, custom or file repository.

*Repository reference settings:*

Use this page to configure a repository reference. A repository reference is a single repository that contains a set of identity entries that are referenced by a base entry into the directory information tree.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Click **Add base entry to realm**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Repository:*

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Expand the drop-down list to display a list of previously defined repository identifiers.

*Distinguished name that uniquely identifies this set of entries in the realm:*

Specifies the distinguished name (DN) that uniquely identifies this set of entries in the realm.

If multiple repositories are included in the realm, it is necessary to define an additional distinguished name that uniquely identifies this set of entries within the realm. Overlapping base entries are not supported. You should not define two base entries where one is `c=us`, and the other is `o=myorg,c=us` in the same realm; otherwise a search returns duplicate results.

*Distinguished name of a base entry in this repository:*

Specifies the Lightweight Directory Access Protocol (LDAP) distinguished name (DN) of the base entry within the repository. The entry and its descendents are mapped to the subtree that is identified by the unique base name entry field.

If this field is left blank, then the subtree defaults to the root of the LDAP repository.

### ***Increasing the performance of the federated repository configuration:***

Follow this page to manage the realm in a federated repository configuration.

### **Before you begin**

The settings that are available on the Performance panel are independent options that pertain specifically to the federated repositories functionality. These options do not affect your entire WebSphere Application Server configuration.

### **Procedure**

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories > repository\_name**.
4. Under Additional properties, click **Performance**.

5. Optional: Select the **Limit search time** option and enter the maximum number of milliseconds that the Application Server can use to search through your Lightweight Directory Access Protocol (LDAP) entries.
6. Optional: Select the **Limit search returns** option and enter the maximum number of entries to return that match the search criteria.
7. Optional: Select the **Use connection pooling** option to specify whether the Application Server can store separate connections to the LDAP server for reuse.
8. Optional: Select the **Enable context pool** option to specify whether multiple applications can use the same connection to the LDAP server. If you select the option, specify the initial, preferred, and maximum number of entries that can use the same connection. The **Enable context pool** option can be enabled either in conjunction with the **Use connection pool** option or separately. If this option is disabled, a new connection is created for each context. You can also select the **Context pool times out** option and specify the number of seconds after which the entries in the context pool expire.
9. Optional: Set the **Maximum size** value of the context pool to zero (0).
10. Optional: Select the **Cache the attributes** option and specify the maximum number of search attribute entries. This option enables WebSphere Application Server to save the LDAP entries so that it can search the entries locally rather than making multiple calls to the LDAP server. Click the **Cache times out** option that is associated with the **Cache the attributes** option to specify the maximum number of seconds that the Application Server can save these entries.
11. Optional: Select the **Cache the search results** option and specify the maximum number of search result entries. This option enables WebSphere Application Server to save the results of a search inquiry instead of making multiple calls to the LDAP server to search and retrieve the results of that search. Click the **Cache times out** option that is associated with the **Cache the search results** option to specify the maximum number of seconds that the Application Server can save the results.
12. Optional: Create the root DataObject object locally using the `com.ibm.websphere.wim.util.SDOHelper.createRootDataObject` method instead of the `com.ibm.websphere.wim.ServiceProvider.createRootDataObject` method.

## Results

These options are available to potentially increase the performance of your federated repositories configuration. However, the any increase in performance is dependant upon your specific configuration.

### *Lightweight Directory Access Protocol performance settings:*

Use this page to minimize impacts to performance by adding opened connections and contexts to internally maintained pools and reusing them. Also minimize performance impacts by maintaining internal caches of retrieved data.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Performance**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

### *Limit search time:*

Specifies the timeout value in milliseconds for a Lightweight Directory Access Protocol (LDAP) server to respond before stopping a request.

|                   |                                                                                      |
|-------------------|--------------------------------------------------------------------------------------|
| <b>Data type:</b> | Integer                                                                              |
| <b>Units:</b>     | Milliseconds                                                                         |
| <b>Default:</b>   | 0                                                                                    |
| <b>Range:</b>     | Equal to or greater than 0. A value of 0 specifies that no search time limit exists. |

*Limit search returns:*

Specifies the maximum number of entries that are returned in a search result.

|                   |                                                                                        |
|-------------------|----------------------------------------------------------------------------------------|
| <b>Data type:</b> | Integer                                                                                |
| <b>Units:</b>     | Entries                                                                                |
| <b>Default:</b>   | 0                                                                                      |
| <b>Range:</b>     | Equal to or greater than 0. A value of 0 specifies that no search return limit exists. |

*Use connection pooling:*

Specifies whether to utilize the connection pooling function, which is provided in the Software Development Kit (SDK).

Connection pooling is maintained by the Java run time. It is configured by system properties.

|                 |                     |
|-----------------|---------------------|
| <b>Default:</b> | Disabled            |
| <b>Range:</b>   | Enabled or Disabled |

*Enable context pool:*

Specifies whether context pooling is enabled to the LDAP server. To improve performance, use the context pool in combination with connection pooling.

|                 |                     |
|-----------------|---------------------|
| <b>Default:</b> | Enabled             |
| <b>Range:</b>   | Enabled or Disabled |

*Initial size:*

Specifies the number of context instances in the pool when the pool is initially created by the LDAP repository.

|                   |         |
|-------------------|---------|
| <b>Data type:</b> | Integer |
| <b>Default:</b>   | 1       |
| <b>Range:</b>     | 1 to 50 |

*Preferred size:*

Specifies the preferred number of context instances that the context pool maintains. Both in-use and idle context instances contribute to this number.

|                   |          |
|-------------------|----------|
| <b>Data type:</b> | Integer  |
| <b>Default:</b>   | 3        |
| <b>Range:</b>     | 0 to 100 |

*Maximum size:*

Specifies the maximum number of context instances that can be maintained concurrently by the context pool. Both in-use and idle context instances contribute to this number.

When the pool size reaches the maximum size, no new context instances can be created for a new request. The new request is blocked until a context instance is released or removed. The request periodically checks for context instances that are available in the pool. A request for a pooled context instance uses an existing pooled and idle context instance or a newly created pooled context instance.

A maximum pool size of 0 indicates that the context pool can maintain an infinite number of context instances.

**Data type:** Integer  
**Default:** 0

*Context pool times out:*

Specifies the number of seconds for the context pool to time out and remove idle context instances.

A timeout value of 0 indicates that the context pool does not time out context instances.

**Data type:** Integer  
**Default:** 0

*Distribution policy:*

Specifies the distribution policy for the cache in a clustered environment, which is one of the following:

**None** Sends out new entries, both ID and data, and updates to those entries.

**Push** Requests data from other servers in the cluster when that data is not locally present.

**Push and pull**

Sends out IDs for new entries and requests from other servers in the cluster entries for IDs that were previously broadcast. The dynamic cache always sends out cache entry invalidations.

*Cache the attributes:*

Specifies whether to cache the attributes that are returned from the LDAP server.

**Default:** Enabled  
**Range:** Enabled or Disabled

*Cache size:*

Specifies the maximum size of the cache.

**Data type:** Integer  
**Default:** 4000  
**Range:** Equal to or greater than 100

*Cache times out:*

Specifies the maximum number of seconds that the cached search results can stay in the cache.

A timeout value of 0 indicates that the cached search results stay in the cache until update operations are made.

|                   |                            |
|-------------------|----------------------------|
| <b>Data type:</b> | Integer                    |
| <b>Units:</b>     | Seconds                    |
| <b>Default:</b>   | 1200                       |
| <b>Range:</b>     | Equal to or greater than 0 |

#### *Cache the search results:*

Specifies whether to cache the search results that are returned from the LDAP server.

|                 |                     |
|-----------------|---------------------|
| <b>Default:</b> | Enabled             |
| <b>Range:</b>   | Enabled or Disabled |

#### *Cache size:*

Specifies the maximum size of the cache.

|                   |                              |
|-------------------|------------------------------|
| <b>Data type:</b> | Integer                      |
| <b>Default:</b>   | 2000                         |
| <b>Range:</b>     | Equal to or greater than 100 |

#### *Cache times out:*

Specifies the maximum number of seconds that the cached search results can stay in the cache.

A timeout value of 0 indicates that the cached search results stay in the cache until update operations are made.

|                   |                            |
|-------------------|----------------------------|
| <b>Data type:</b> | Integer                    |
| <b>Units:</b>     | Seconds                    |
| <b>Default:</b>   | 600                        |
| <b>Range:</b>     | Equal to or greater than 0 |

#### ***Using custom adapters for federated repositories:***

When the custom adapters for federated repositories are part of the default realm, the users and groups can be managed using wsadmin commands or the administrative console.

#### **About this task**

If custom adapters for federated repositories are part of the default realm, you use the administrative console to manage the users and groups in the realm.

**Note:** The default parent for PersonAccount and Group entities needs to be the same as the base entry of the custom adapter.

To view this administrative console page, complete the following steps:

- In the administrative console, click **Security > Global security**.

- Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
- Under Additional properties, click **Supported entity types**.

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

### Procedure

1. In the administrative console, click **Users and Groups** to access users and groups panel.
2. Click **Manage Groups** to test the basic functions of the custom adapter with respect to custom adapters for federated repositories.
3. Click **Manage Users** to test the basic functions of the custom adapter with respect to custom adapters for federated repositories.

**Note:** You must restart the server or dmgr if the federated repository has changed before using the Manage Users option. Otherwise, user or group changes made to the repository could be lost after restart.

### Results

After completing these steps, you will have ensured that the custom adapter is being used properly.

### What to do next

Adjustments to the custom adapter can be made by using the wsadmin tool to make configuration changes. See “Configuring custom adapters for federated repositories using wsadmin” on page 1555 for more details.

*Sample custom adapters for federated repositories examples:*

Out of the box adapters for federated repositories provide File, LDAP, and Database adapters for your use. These adapters implement the `com.ibm.wsspi.wim.Repository` software programming interface (SPI). A virtual member manager custom adapter needs to implement the same SPI.

### Developing custom adapters for federated repositories

Out of the box adapters for federated repositories provide File, LDAP and Database adapters for your use. All these adapters implement the `com.ibm.wsspi.wim.Repository` SPI. See the `com.ibm.wsspi.wim.Repository` SPI for more information. As you develop a virtual member manager custom adapter, you need to implement the same SPI.

Custom adapters for federated repositories must not depend on any WebSphere Application Server components, such as data sources and enterprise beans. These WebSphere Application Server components require that security is initialized and enabled prior to startup. If your implementation of custom adapters for federated repositories needs to use data sources to connect to a database, you need to use Java database connectivity (JDBC) to make the connection during server startup. Then, at a later time, switch to using the data sources when the data source is available.

There are examples of suggested behavior and requirements of custom adapters for federated repositories that you can find in the sample code.

### A sample custom adapter for federated repositories

A sample custom adapter implementation has been provided as an example. The custom adapter is based on file repository. The sample source code and class files are bundled in `vmmsampleadapter.jar`. The `vmmsampleadapter.jar` can be downloaded at this location: <http://www.ibm.com/developerworks/websphere/downloads/samples/vmmsampleadapter.html>.

Contents of the `vmmsampleadapter.jar` file are as follows:

- Class files for the sample adapter:
  - `com/ibm/ws/wim/adapter/sample/AbstractAdapterImpl.class`
  - `com/ibm/ws/wim/adapter/sample/SampleFileAdapter.class`
  - `com/ibm/ws/wim/adapter/sample/XPathHelper.class`
- Source code for the sample adapter:
  - `src/com/ibm/ws/wim/adapter/sample/AbstractAdapterImpl.java`
  - `src/com/ibm/ws/wim/adapter/sample/SampleFileAdapter.java`
  - `src/com/ibm/ws/wim/adapter/sample/XPathHelper.java`

**Note:** The sample files should not be used in the production environment. You should make a copy of these files, rename them, and update them based on your specific adapter implementation. Refer to the Javadoc in the source code for more information.

#### **`com/ibm/ws/wim/sample/adapter/AbstractAdapterImpl.java`**

Provides an abstract implementation class which handles most of the repository independent internal operations for the adapter and defines some simple abstract methods that should be implemented by the custom adapter. For most cases, you may not need to change this file.

#### **`com/ibm/ws/wim/sample/adapter/SampleFileAdapter.java`**

Extends from the `AbstractAdapterImpl` class and implements the abstracts method. This class implements the abstract methods using file as the repository. Adapter providers can use this class as a reference to implement these methods specific to their adapters.

#### **`com/ibm/ws/wim/sample/adapter/XPathHelper.java`**

Defines a helper class to parse the XPath search expression and build the search tree. This helper class also contains the method to evaluate the search expression. If your repository supports a search expression, then you need to convert XPath expression to an expression that your repository can process and let your repository evaluate the expression. This helper class evaluates the search expression based on the use of dataobjects. You can overwrite the `evaluate()` method to perform the evaluation using other objects, such as **`java.util.Map`**.

Some utility classes have been provided to help adapter providers. Most of these utility methods are used in the sample adapter. Refer to <http://publib.boulder.ibm.com/infocenter/wasinfo/v6r1/index.jsp?topic=/com.ibm.websphere.javadoc.doc/vmm/com/ibm/wsspi/wim/package-summary.html> for more details.

#### ***Establishing custom adapters for federated repositories:***

Out of the box adapters for federated repositories provide File, LDAP, and Database adapter for your use. These adapters implement the `com.ibm.wsspi.wim.Repository` software programming interface (SPI). Custom adapters for federated repositories need to implement the same SPI.

#### **Before you begin**

Refer to the Repository SPI implementation information in the related references for information about the custom adapters for federated repositories SPI.

Refer to the sample custom adapter code that is available in the `vmmsampleadapter.jar` file. The JAR file contains the sample customer adapter code in the `src/` directory. The `vmmsampleadapter.jar` can be downloaded at this location: <http://www.ibm.com/developerworks/websphere/library/samples/vmmsampleadapter.html>

**Note:**

- The sample that is provided is intended to familiarize you with the features of custom adapters for federated repositories and the handling of various types of dataobjects. Do not use this sample in an actual production environment.
- Copy the AbstractAdapterImpl class and rename it before making changes. Make sure that the new name is appropriate for your adapter.

Custom adapters for federated repositories must not depend on any WebSphere Application Server components, such as data sources and enterprise beans. These WebSphere Application Server components require that security is initialized and enabled prior to startup. If your implementation of the virtual member manager custom adapter needs to use data sources to connect to a database, you need to use Java database connectivity (JDBC) to make the connection during server startup. Then, at a later time, switch to using the data sources when the data source is available.

**Procedure**

1. Build your implementation.

**Note:** EMF JAR files contain version number in their names, such as v200607270021. Make sure to change the version number to reflect your installation.

To compile your code, you need the following JAR files in the classpath:

- *app\_server\_root*/plugins/com.ibm.ws.runtime\_6.1.0.jar
- *app\_server\_root*/plugins/org.eclipse.emf.commonj.sdo\_2.1.0.v200607270021.jar
- *app\_server\_root*/plugins/org.eclipse.emf.ecore\_2.2.1.v200607270021.jar
- *app\_server\_root*/plugins/org.eclipse.emf.common\_2.2.1.v200607270021.jar
- *app\_server\_root*/plugins/org.eclipse.emf.ecore.xmi\_2.2.0.v200607270021.jar
- *app\_server\_root*/plugins/org.eclipse.emf.ecore.sdo\_2.2.0.v200607270021.jar

Here is an example:

```
app_server_root/java/bin/javac -classpath
app_server_root/plugins/com.ibm.ws.runtime_6.1.0.jar;
app_server_root/plugins/org.eclipse.emf.commonj.sdo_2.1.0.
v200607270021.jar;app_server_root
/plugins/org.eclipse.emf.ecore_2.2.1.v200607270021.jar;
app_server_root/plugins/org.eclipse.emf.common_2.2.1.
v200607270021.jar;app_server_root/plugins/org.
eclipse.emf.ecore.xmi_2.2.0.v200607270021.jar;
app_server_root/plugins/org.eclipse.emf.ecore.sdo_2.2.0.v200607270021.jar
your_implementation_file.java
```

2. Copy the generated class files or the packaged JAR file to the product classpath. The preferred location is the *app\_server\_root/lib/ext* directory. This should be copied to the classpaths of all the product processes (cell and all NodeAgents).
3. Configure your custom adapter by following the steps in “Configuring custom adapters for federated repositories using wsadmin.”
4. Test your custom adapter by following the steps in “Using custom adapters for federated repositories” on page 1552

**What to do next**

“Configuring custom adapters for federated repositories using wsadmin” provides details about configuring your custom adapter with the wsadmin tool.

**Configuring custom adapters for federated repositories using wsadmin:**

You can use the Jython or Jacl scripting language with the wsadmin tool to define custom adapters in the federated repositories configuration file.

## Before you begin

Shut down the WebSphere Application Server and the wsadmin command window.

## About this task

The federated repositories configuration file, `wimconfig.xml`, is shipped with WebSphere Application Server 6.1.x and is located in the `app_server_root/profiles/profile_name/config/cells/cell_name/wim/config` directory.

**Note:** For additional information about the commands to use for this topic, see the `IdMgrRepositoryConfig` command group for the `AdminTask` object topic.

Use the following steps to add a custom adapter to any federated repositories configuration file and to any realm defined within the configuration file.

## Procedure

1. Open the `wimconfig.xml` file with a text editor.
2. Add a new `config:repositories` element to the file. This element should be placed before the `config:realmConfiguration` element.

The following example configures a custom repository to use the **`com.ibm.ws.wim.adapter.sample.SampleFileAdapter`** class and sets the **`SampleFileRepository`** repository as the identifier:

```
<config:repositories adapterClassName="com.ibm.ws.wim.adapter.sample.SampleFileAdapter" id="SampleFileRepository"/>
```

3. Save the `wimconfig.xml` file and close the text editor.
4. Copy the `vmmsampleadapter.jar` file that is provided to `app_server_root/lib`.
5. Enter the following command to start the wsadmin tool:

```
wsadmin -conntype none
```

6. Disable paging in the common repository configuration. Set the `supportPaging` parameter for the `updateIdMgrRepository` command to `false` to disable paging.

**Note:** You must perform this step because the sample adapter does not support paging.

The following examples use the **`SampleFileRepository`** repository as the identifier for the custom repository.

Using Jython:

```
AdminTask.updateIdMgrRepository('-id SampleFileRepository -supportPaging false')
```

Using Jacl:

```
$AdminTask updateIdMgrRepository {-id SampleFileRepository -supportPaging false}
```

**Note:** A warning will appear until the configuration of the sample repository is complete.

7. Add the necessary custom properties for the adapter. Use the `setIdMgrCustomProperty` command repeatedly to add multiple properties. Use this command once per property to add multiple properties to your configuration. You must use both the **`name`** and **`value`** parameters to add the custom property for the specified repository. For example, to add a custom property of **`fileName`**, enter the following command.

Using Jython:

```
AdminTask.setIdMgrCustomProperty('-id SampleFileRepository -name fileName -value "c:\sampleFileRegistry.xml"')
```

Using Jacl:

```
$AdminTask setIdMgrCustomProperty {-id SampleFileRepository -name fileName -value "c:\sampleFileRegistry.xml"}
```

8. Add a base entry to the adapter configuration. Use the `addIdMgrRepositoryBaseEntry` command to specify the name of the base entry for the specified repository. For example:

Using Jython:

```
AdminTask.addIdMgrRepositoryBaseEntry('-id SampleFileRepository -name
o=sampleFileRepository')
```

Using Jacl:

```
$AdminTask addIdMgrRepositoryBaseEntry {-id SampleFileRepository -name
o=sampleFileRepository}
```

9. Use the `addIdMgrRealmBaseEntry` command to add the base entry to the realm, which will link the realm with the repository:

Using Jython:

```
AdminTask.addIdMgrRealmBaseEntry('-name defaultWIMFileBasedRealm -baseEntry o=sampleFileRepository')
```

Using Jacl:

```
$AdminTask addIdMgrRealmBaseEntry {-name defaultWIMFileBasedRealm -baseEntry o=sampleFileRepository}
```

10. Save your configuration changes. Enter the following commands to save the new configuration and close the `wsadmin` tool.

Using Jython:

```
AdminConfig.save()
exit
```

Using Jacl:

```
$AdminConfig save
exit
```

The following example displays the complete text of the newly-revised `wimconfig.xml` file:

```

<config:groupSecurityNameMapping propertyForInput="cn" propertyForOutput="cn"/>
```

```
 <config:groupDisplayNameMapping propertyForInput="cn" propertyForOutput="cn"/>
 </config:realms>
</config:realmConfiguration>
</config:configurationProvider></sdo:datagraph>
```

11. Restart the application server.

### **Configuring the user registry bridge for federated repositories using wsadmin scripting:**

The user registry bridge is configured like other custom adapters. You can use the Jython or Jacl scripting language with the wsadmin scripting tool to define the user registry bridge in the federated repositories configuration.

#### **Before you begin**

Shut down WebSphere Application Server and the wsadmin command window.

**Important:** If you are migrating from the stand-alone user registry on the local operating system to federated repositories on the local operating system, you must first configure the current user registry under federated repositories. For more information, see *Managing the realm in a federated repository configuration*.

Authorization failures might occur if users or groups are mapped to roles before migration and you use those users or groups after migrating to user registry bridge. This situation occurs because the mapping contains registry-specific information. After migration, re-map the users or groups to avoid authorization failures.

#### **About this task**

For additional information about the commands to use for this topic, see *IdMgrRepositoryConfig* command group for the *AdminTask* object.

Use the following steps to add a user registry bridge to any federated repositories configuration and to any realm that is defined within the configuration.

#### **Procedure**

1. Start the wsadmin scripting tool. You can use the following command to start the wsadmin scripting tool:

```
wsadmin -conntype none
```

2. Use the *createIdMgrCustomRepository* command to add a new repository configuration for the user registry bridge.

The following example configures a custom repository to use the *com.ibm.ws.wim.adapter.urbridge.URBridge* class and sets *urbRACF* as the identifier:

#### **Using Jython:**

```
AdminTask.createIdMgrCustomRepository('-id urbRACF
-adapterClassName com.ibm.ws.wim.adapter.urbridge.URBridge')
```

#### **Using Jacl:**

```
$AdminTask createIdMgrCustomRepository {-id urbRACF
-adapterClassName com.ibm.ws.wim.adapter.urbridge.URBridge}
```

**gotcha:** The user registry bridge handles requests to one user registry only. Therefore, if you define multiple repositories, each user registry implementation must have a separate instance of the user registry bridge and you must define each implementation as a separate repository with a unique repository ID..

The Resource Access Control Facility (RACF) manages all the RACF attributes; therefore, you do not need to add any custom properties to use the user registry bridge adapter with RACF.

3. Add a base entry to the user registry bridge configuration. Use the `addIdMgrRepositoryBaseEntry` command to specify the name of the base entry for the specified repository. For example:

**Using Jython:**

```
AdminTask.addIdMgrRepositoryBaseEntry('-id urbRACF
-name o=local')
```

**Using Jacl:**

```
$AdminTask addIdMgrRepositoryBaseEntry {-id urbRACF
-name o=local}
```

4. Use the `addIdMgrRealmBaseEntry` command to add the base entry to the realm, which will link the realm with the repository.

**Note:** The default realm name is `defaultWIMFileBasedRealm`. If this realm name was previously renamed, use the new realm name instead of `defaultWIMFileBasedRealm`. For example, to ensure consistency, you can set the realm name of the federated repository configuration to be the same name as the local operating system user registry as specified in the `security.xml` file. For information about how to set the realm name, see Realm configuration settings.

Use the following command:

**Using Jython:**

```
AdminTask.addIdMgrRealmBaseEntry('-name defaultWIMFileBasedRealm
-baseEntry o=local')
```

**Using Jacl:**

```
$AdminTask addIdMgrRealmBaseEntry {-name defaultWIMFileBasedRealm
-baseEntry o=local}
```

5. Save your configuration changes. Enter the following commands to save the new configuration and close the `wsadmin` scripting tool:

**Using Jython:**

```
AdminConfig.save()
exit
```

**Using Jacl:**

```
$AdminConfig save
exit
```

6. Configure the System Authorization Facility (SAF) mapping module to ensure the property availability of SAF authorization.

For more information about how to configure a SAF mapping module, see *Installing and configuring a custom System Authorization Facility mapping module for WebSphere Application Server*, where a sample SAF mapping module is provided for you to install and use. If you want to customize the sample SAF mapping module for federated repositories, see *Configuring a custom System Authorization Facility (SAF) mapping module for federated repositories*.

**Note:** Some additional steps might be required if RACF is configured in a realm other than the `defaultWIMFileBasedRealm`. When a new realm is created, some properties take defaults that are not the same as those used by `defaultWIMFileBasedRealm` and are not appropriate for use with a federated RACF user registry. You must use the `setIdMgrRealmURAttrMapping` command to set the following values:

- The value of `userSecurityNameMapping` property, `propertyForOutput` parameter must be set to `principalName`.
- The value of `groupSecurityNameMapping` property, `propertyForOutput` parameter must be set to `cn`.

For more information on how to use the `setIdMgrRealmURAttrMapping` command, see `IdMgrRealmConfig` command group for the `AdminTask` object.

7. Restart the application server.

## Results

The following code is an example from a `wimconfig.xml` file configured for a user registry bridge accessing the local operating system registry using RACF:

```
<config:repositories xsi:type="config:FileRepositoryType"
 adapterClassName="com.ibm.ws.wim.adapter.file.was.FileAdapter"
 id="InternalFileRepository" supportPaging="false"
 messageDigestAlgorithm="SHA-1">
 <config:baseEntries name="o=defaultWIMFileBasedRealm"/>
</config:repositories>
<config:repositories adapterClassName="com.ibm.ws.wim.adapter.urbridge.URBridge"
 id="urbRACF" supportPaging="false">
 <config:baseEntries name="o=local"/>
</config:repositories>
<config:realmConfiguration defaultRealm="defaultWIMFileBasedRealm">
 <config:realms delimiter="/" name="defaultWIMFileBasedRealm" securityUse="active">
 <config:participatingBaseEntries name="o=defaultWIMFileBasedRealm"/>
 <config:participatingBaseEntries name="o=local"/>
 <config:uniqueUserIdMapping propertyForInput="uniqueName"
 propertyForOutput="uniqueName"/>
 <config:userSecurityNameMapping propertyForInput="principalName"
 propertyForOutput="principalName"/>
 <config:userDisplayNameMapping propertyForInput="principalName"
 propertyForOutput="principalName"/>
 <config:uniqueGroupIdMapping propertyForInput="uniqueName"
 propertyForOutput="uniqueName"/>
 <config:groupSecurityNameMapping propertyForInput="cn"
 propertyForOutput="cn"/>
 <config:groupDisplayNameMapping propertyForInput="cn" propertyForOutput="cn"/>
 </config:realms>
</config:realmConfiguration>
```

### *User registry bridge for federated repositories:*

The user registry bridge is a read-only adapter that provides an interface between federated repositories and an underlying user registry implementation, which can be either a local operating system user registry or a custom user registry implementation.

The user registry bridge enables IBM WebSphere Application Server applications to use your user registry implementation. It can work with any user registry that implements the `com.ibm.websphere.security.UserRegistry` interface, without knowing the details of its implementation. This capability makes the bridge versatile and allows it to connect to, and use, various registries.

The user registry bridge allows access to the same repository information without any platform-specific implementation. Thus, it eliminates the need to have a specialized user registry bridge for each operating system.

You can federate and configure the local operating system user registry, a custom user registry, or both, as a federated repository. The user registry bridge handles user registry-related requests from federated repositories, makes appropriate calls to the underlying user registry implementation, and returns data that is formatted according to the federated repositories specifications.

Therefore, to use the user registry bridge you must configure your user registry under federated repositories. This configuration can map the properties in the underlying user registry to the properties for the federated repository. You can also configure any user registry specific information, if required. For information about how to configure the user registry bridge, see [Configuring the user registry bridge for federated repositories using wsadmin scripting](#).

The following figure illustrates the difference between configuring a federated repository user registry with and without the user registry bridge.

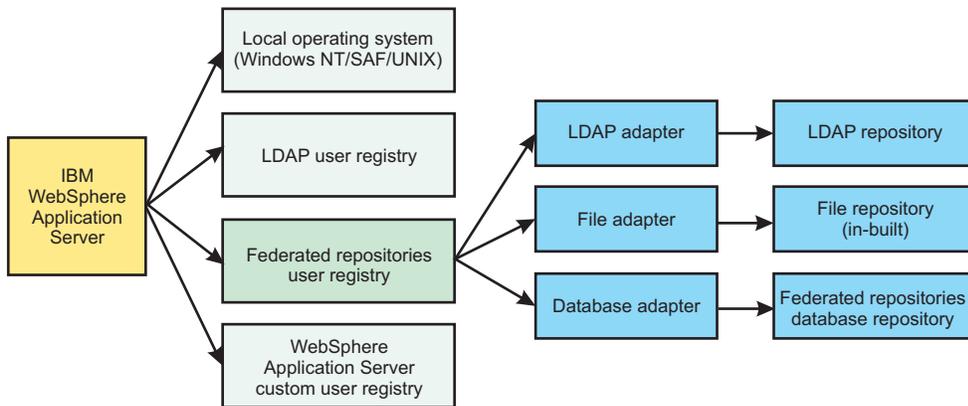

Figure 9. Configuring a federated repository user registry without the user registry bridge

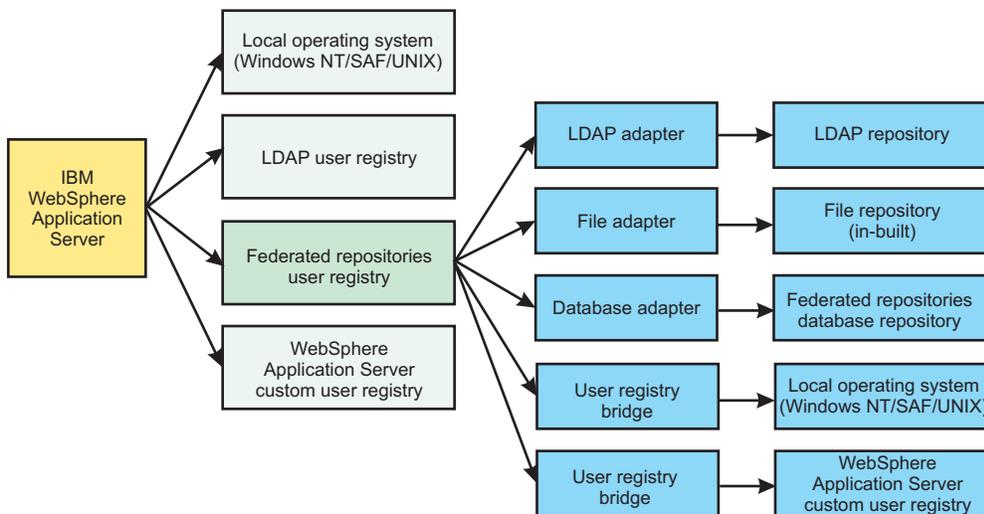

Figure 10. Configuring a federated repository user registry with the user registry bridge

As shown in the previous figure, using the same adapter, which is the user registry bridge, you can configure multiple user registries under federated repositories. For example, you can configure a local operating system user registry and one or more custom user registries.

## Limitations

The following limitations exist:

- You can use the user registry bridge only for read-only operations, such as authentication and search functions. You cannot perform write operations such as create, delete, or modify users and groups. An attempt to perform write operations results in an exception, which notifies the user that the operation is not supported by the bridge. This limitation exists because the user registry bridge does not have direct access to the repository. Instead, the bridge uses an underlying existing user registry implementation that is read-only; hence, it might not be able to fulfill requests for certain properties that exist in the federated repositories.
- The user registry bridge does not support a stand-alone Lightweight Directory Access Protocol (LDAP) user registry. LDAP repositories are supported as a standard federated repositories adapter with read and write capabilities.
- Some of the properties that are placed in control data objects are not relevant to the user registry bridge as they are not applicable in the underlying repository.

- The properties ignored for GroupMembershipControl and GroupMemberControl data objects are searchBases, timeLimit, treeView, expression, and level.
- The properties ignored for SearchControl data objects are searchBases and timeLimit. The property part of the expression, such as uid and mail, is ignored as you can search WebSphere Application Server user registry entities with security names only. The expression is parsed to get the entity type and the pattern with which the search must be performed.

## Supported user registries

WebSphere Application Server applications can access the user registry properties of the following user registry implementations as a read-only repository:

- Local operating system user registry
- Custom user registry

## **Configuring Lightweight Directory Access Protocol entity types in a federated repository configuration:**

Follow this task to configure Lightweight Directory Access Protocol (LDAP) entity types in a federated repository configuration.

### Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured. During LDAP configuration, based on the selected LDAP server type, some defaults and mappings are set in the configuration. When the selected LDAP server type is custom, no default is set, and you must set all of the mappings manually. To avoid setting all of the mappings manually, choose a non-custom LDAP server type (for example, IBM Directory Server or SunOne) which matches closely to your LDAP server.

### Note:

- If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.
- If you decide to use a custom LDAP server type, you must use the command-line interface to create the entity types. Read about IdMgrRepositoryConfig command group for the AdminTask object for more information.

After you create the entity types, you can use the administrative console to modify these entities. You cannot use the administrative console to create entity types for a custom LDAP server type.

5. Under Additional properties, click **LDAP entity types**.
6. View the entity types that are supported by the member repositories, or select an entity type to view or change its configuration properties.
7. Supply the object classes that are mapped to this entity type in the Object classes field. LDAP entries that contain one or more of the object classes belong to this entity type.
8. Supply the search bases that are used to search this entity type. The search bases specified must be subtrees of the base entry in the repository. For example, you can specify the following search bases, where `o=ibm,c=us` is the base entry in the repository:

```
o=ibm,c=us or cn=users,o=ibm,c=us or ou=austin,o=ibm,c=us
```

In the preceding example, you cannot specify search bases `c=us` or `o=ibm,c=uk`.

Delimit multiple search bases with a semicolon (;). For example:

ou=austin,o=ibm,c=us;ou=raleigh,o=ibm,c=us

9. Supply the LDAP search filter that is used to search this entity type.

For example, use `(objectclass=ePerson)` to search for users or

`(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames))` to search for groups in an external LDAP repository.

If a search filter is not specified, the object classes and the relative distinguished name (RDN) properties are used to generate the search filter. For information on RDN properties, see “Configuring supported entity types in a federated repository configuration” on page 1543.

## Results

After completing these steps, LDAP entity types are configured for your LDAP repository.

### What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

*Lightweight Directory Access Protocol entity types collection:*

Use this page to list Lightweight Directory Access Protocol (LDAP) entity types that are supported by the member repositories or to select an LDAP entity type to view or change its configuration properties.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **LDAP entity types**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Entity type:*

Specifies the entity type name.

*Object classes:*

Specifies the object classes that are mapped to this entity type. LDAP entries that contain one or more of the object classes belong to this entity type.

You cannot map multiple entity types to the same LDAP object class.

### *Lightweight Directory Access Protocol entity types settings:*

Use this page to configure Lightweight Directory Access Protocol (LDAP) entity types that are supported by the member repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **LDAP entity types**.
6. Select an entity type to view or change its configuration properties.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

#### *Entity type:*

Specifies the entity type.

#### *Object classes:*

Specifies the object classes that are mapped to this entity type. LDAP entries that contain one or more of the object classes belong to this entity type.

You cannot map multiple entity types to the same LDAP object class.

#### *Search bases:*

Specifies the search bases that are used to search this entity type.

The search bases specified must be subtrees of the base entry in the repository. For example, you can specify the following search bases, where `o=ibm,c=us` is the base entry in the repository:

```
o=ibm,c=us or cn=users,o=ibm,c=us or ou=austin,o=ibm,c=us
```

In the preceding example, you cannot specify search bases `c=us` or `o=ibm,c=uk`.

Delimit multiple search bases with a semicolon (;). For example:

```
ou=austin,o=ibm,c=us;ou=raleigh,o=ibm,c=us
```

#### *Search filter:*

Specifies the LDAP search filter that is used to search this entity type.

For example, use `(objectclass=ePerson)` to search for users or `(&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))` to search for groups in an external LDAP repository.

If a search filter is not specified, the object classes and the relative distinguished name (RDN) properties are used to generate the search filter.

### ***Configuring group attribute definition settings in a federated repository configuration:***

Follow this task to configure group definition settings in a federated repository configuration.

### Before you begin

Because group attribute definition settings apply only to a Lightweight Directory Access Protocol (LDAP) repository, you must first configure an LDAP repository. For more information, see “Managing repositories in a federated repository configuration” on page 1545.

### Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

**Note:** If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.

5. Under Additional properties, click **Group attribute definition**.
6. Supply the name of the group membership attribute in the Name of group membership attribute field. Only one membership attribute can be defined for each LDAP repository.

Every LDAP entry should have this attribute to indicate the groups to which this entry belongs. For example, `memberOf` is the name of the membership attribute that is used in Active Directory. The group membership attribute contains values that reference groups to which this entry belongs. If `UserA` belongs to `GroupA`, then the value of the `memberOf` attribute of `UserA` should contain the distinguished name of `GroupA`.

If your LDAP server does not support the group membership attribute, then do not specify this attribute. The LDAP repository can look up groups by searching the group member attributes, though the performance might be slower.

7. Select the scope of the group membership attribute. The default value is `Direct`.

**Direct** The membership attribute contains direct groups only. Direct groups are the groups that contain the member. For example, if `Group1` contains `Group2` and `Group2` contains `User1`, then `Group2` is a direct group of `User1`, but `Group1` is not a direct group of `User1`.

#### **Nested**

The membership attribute contains both direct groups and nested groups.

#### **All**

The membership attribute contains direct groups, nested groups, and dynamic members.

### Results

After completing these steps, group attribute definition settings are configured for your LDAP repository.

### What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that `Federated repositories` is identified in the Current realm definition field. If `Federated repositories` is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If `Federated repositories` is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.

3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

*Group attribute definition settings:*

Use this page to specify the name of the group membership attribute. Every Lightweight Directory Access Protocol (LDAP) entry includes this attribute to indicate the group to which this entry belongs.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Name of group membership attribute:*

Specifies the name of the group membership attribute. Only one membership attribute can be defined for each Lightweight Directory Access Protocol (LDAP) repository.

Every LDAP entry should have this attribute to indicate the groups to which this entry belongs. For example, memberOf is the name of the membership attribute that is used in Active Directory. The group membership attribute contains values that reference groups to which this entry belongs. If UserA belongs to GroupA, then the value of the memberOf attribute of UserA should contain the distinguished name of GroupA.

If your LDAP server does not support the group membership attribute, then do not specify this attribute. The LDAP repository can look up groups by searching the group member attributes, though the performance might be slower.

*Scope of group membership attribute:*

Specifies the scope of the group membership attribute.

|                 |                                                                                                                                                                                                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default:</b> | Direct                                                                                                                                                                                                                                                                         |
| <b>Range:</b>   | <b>Direct</b> The membership attribute contains direct groups only. Direct groups are the groups that contain the member. For example, if Group1 contains Group2 and Group2 contains User1, then Group2 is a direct group of User1, but Group1 is not a direct group of User1. |
|                 | <b>Nested</b> The membership attribute contains both direct groups and nested groups.                                                                                                                                                                                          |
|                 | <b>All</b> The membership attribute contains direct groups, nested groups, and dynamic members.                                                                                                                                                                                |

***Configuring member attributes in a federated repository configuration:***

Follow this task to configure member attributes in a federated repository configuration.

## Before you begin

Because member attributes apply only to a Lightweight Directory Access Protocol (LDAP) repository, you must first configure an LDAP repository. For more information, see “Managing repositories in a federated repository configuration” on page 1545.

## Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

**Note:** If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.

5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Member attributes**.
7. Click **New** to specify a new member attribute or **Delete** to remove a preconfigured member attribute.
8. Accept the default, or supply the name of the member attribute in the Name of member attribute field. For example, member and uniqueMember are two commonly used names of member attributes.  
The member attribute is used to store the values that reference members that the group contains. For example, a group type with an object class groupOfNames has a member attribute named member; group type with object class groupOfUniqueNames has a member attribute named uniqueMember. An LDAP repository supports multiple group types if multiple member attributes and their associated group object classes are specified.
9. Supply the object class of the group that uses this member attribute in the Object class field. If this field is not defined, this member attribute applies to all group object classes.
10. Select the scope of the member attribute. The default value is Direct.

**Direct** The member attribute contains direct members only. Direct members are members that are directly contained by the group. For example, if Group1 contains Group2 and Group2 contains User1, then User1 is a direct member of Group2, but User1 is not a direct member of Group1.

### Nested

The member attribute contains both direct members and nested members.

### All

The member attribute contains direct members, nested members, and dynamic members.

## Results

After completing these steps, member attributes are configured for your LDAP repository.

## What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.

3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

*Member attributes collection:*

Use this page to list Lightweight Directory Access Protocol (LDAP) member attributes or to select a member attribute to view or change its configuration properties.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Member attributes**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Name:*

Specifies the name of the member attribute in LDAP. For example, member and uniqueMember are two commonly used names of member attributes.

The member attribute is used to store the values that reference members that the group contains. For example, a group type with an object class groupOfNames has a member attribute named member; group type with object class groupOfUniqueNames has a member attribute named uniqueMember. An LDAP repository supports multiple group types if multiple member attributes and their associated group object classes are specified.

*Scope:*

Specifies the scope of the member attribute.

**Default:**

Direct

**Range:**

- Direct** The member attribute contains direct members only. Direct members are members that are directly contained by the group. For example, if Group1 contains Group2 and Group2 contains User1, then User1 is a direct member of Group2, but User1 is not a direct member of Group1.
- Nested** The member attribute contains both direct members and nested members.
- All** The member attribute contains direct members, nested members, and dynamic members.

*Object class:*

Specifies the object class of the group that uses this member attribute. If this field is not defined, this member attribute applies to all group object classes.

*Member attributes settings:*

Use this page to configure Lightweight Directory Access Protocol (LDAP) member attributes.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is pre-configured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Member attributes**.
7. Click **New** to specify a new member attribute.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Name of member attribute:*

Specifies the name of the member attribute in LDAP. For example, member and uniqueMember are two commonly used names of member attributes.

The member attribute is used to store the values that reference members that the group contains. For example, a group type with an object class groupOfNames has a member attribute named member; group type with object class groupOfUniqueNames has a member attribute named uniqueMember. An LDAP repository supports multiple group types if multiple member attributes and their associated group object classes are specified.

*Object class:*

Specifies the object class of the group that uses this member attribute. If this field is not defined, this member attribute applies to all group object classes.

*Scope:*

Specifies the scope of the member attribute.

**Default:**

Direct

**Range:**

- Direct** The member attribute contains direct members only. Direct members are members that are directly contained by the group. For example, if Group1 contains Group2 and Group2 contains User1, then User1 is a direct member of Group2, but User1 is not a direct member of Group1.
- Nested** The member attribute contains both direct members and nested members.
- All** The member attribute contains direct members, nested members, and dynamic members.

### ***Configuring dynamic member attributes in a federated repository configuration:***

Follow this task to configure dynamic member attributes in a federated repository configuration.

## Before you begin

Because dynamic member attributes apply only to a Lightweight Directory Access Protocol (LDAP) repository, you must first configure an LDAP repository. For more information, see “Managing repositories in a federated repository configuration” on page 1545.

### Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

**Note:** If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.

5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Dynamic member attributes**.
7. Click **New** to specify a new dynamic member attribute or **Delete** to remove a preconfigured dynamic member attribute.
8. Accept the default, or supply the name of the dynamic member attribute in the Name of dynamic member attribute field. The name of the dynamic member attribute defines the filter for dynamic group members in LDAP, for example, memberURL is the name of a commonly used dynamic member attribute.

If both member and dynamic member attributes are specified for the same group type, this group type is a hybrid group with both static and dynamic members.

A dynamic group defines its members differently than a static group. Instead of listing the members individually, the dynamic group defines its members using an LDAP search. The filter for the search is defined in a dynamic member attribute. For example, the dynamic group uses the structural objectclass groupOfURLs, or auxiliary objectclass ibm-dynamicGroup, and the attribute memberURL, to define the search using a simplified LDAP URL syntax:

```
ldap:///<base DN of search> ? ? <scope of search> ? <searchfilter>
```

The following is an example of the LDAP URL that defines all entries that are under o=Acme with the objectclass=person:

```
ldap:///o=Acme,c=US??sub?objectclass=person
```

9. Supply the object class of the group that contains the dynamic member attribute in the Dynamic object class field, for example, groupOfURLs. If this property is not defined, the dynamic member attribute applies to all group object classes.

### Results

After completing these steps, dynamic member attributes are configured for your LDAP repository.

### What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1325. As the final step, validate this setup by clicking **Apply** in the Global security panel.

3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

*Dynamic member attributes collection:*

Use this page to manage Lightweight Directory Access Protocol (LDAP) dynamic member attributes.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Dynamic member attributes**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Name:*

Specifies the name of the attribute that defines the filter for dynamic group members in LDAP. For example, memberURL is the name of a commonly used dynamic member attribute.

If both member and dynamic member attributes are specified for the same group type, this group type is a hybrid group with both static and dynamic members.

A dynamic group defines its members differently than a static group. Instead of listing the members individually, the dynamic group defines its members using an LDAP search. The filter for the search is defined in a dynamic member attribute. For example, the dynamic group uses the structural objectclass groupOfURLs, or auxiliary objectclass ibm-dynamicGroup, and the attribute memberURL, to define the search using a simplified LDAP URL syntax:

```
ldap:///<base DN of search>??<scope of search>?<searchfilter>
```

The following is an example of the LDAP URL that defines all entries that are under o=Acme with the objectclass=person:

```
ldap:///o=Acme,c=US??sub?objectclass=person
```

*Object class:*

Specifies the object class of the group that contains this dynamic member attribute, for example, groupOfURLs. If this property is not defined, the dynamic member attribute applies to all group object classes.

*Dynamic member attributes settings:*

Use this page to configure Lightweight Directory Access Protocol (LDAP) dynamic member attributes.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.

2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Dynamic member attributes**.
7. Click **New** to specify a new dynamic member attribute.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

*Name of dynamic member attribute:*

Specifies the name of the attribute that defines the filter for dynamic group members in LDAP. For example, memberURL is the name of a commonly used dynamic member attribute.

If both member and dynamic member attributes are specified for the same group type, this group type is a hybrid group with both static and dynamic members.

A dynamic group defines its members differently than a static group. Instead of listing the members individually, the dynamic group defines its members using an LDAP search. The filter for the search is defined in a dynamic member attribute. For example, the dynamic group uses the structural objectclass groupOfURLs, or auxiliary objectclass ibm-dynamicGroup, and the attribute memberURL, to define the search using a simplified LDAP URL syntax:

```
ldap:///<base DN of search>??<scope of search>?<searchfilter>
```

The following is an example of the LDAP URL that defines all entries that are under o=Acme with the objectclass=person:

```
ldap:///o=Acme,c=US??sub?objectclass=person
```

*Dynamic object class:*

Specifies the object class of the group that contains this dynamic member attribute, for example, groupOfURLs. If this property is not defined, the dynamic member attribute applies to all group object classes.

## **Standalone Lightweight Directory Access Protocol registries**

A Standalone Lightweight Directory Access Protocol (LDAP) registry performs authentication using an LDAP binding.

WebSphere Application Server security provides and supports the implementation of most major LDAP directory servers, which can act as the repository for user and group information. These LDAP servers are called by the product processes for authenticating a user and other security-related tasks. For example, the servers are used to retrieve user or group information. This support is provided by using different user and group filters to obtain the user and group information. These filters have default values that you can modify to fit your needs. The custom LDAP feature enables you to use any other LDAP server, which is not in the product-supported list of LDAP servers, for its user registry by using the appropriate filters.

**Note:** The initial profile creation configures WebSphere Application Server to use a federated repositories security registry option with the file-based registry. This security registry configuration can be changed to use other options, including the stand-alone LDAP registry. Instead of changing from the federated repositories option to the stand-alone LDAP registry option under the User account repository configuration, consider employing the federated repositories option, which provides for

LDAP configuration. Federated repositories provide a wide range of capabilities, including the ability to have one or multiple user registries. It supports federating one or more LDAPs in addition to file-based and custom registries. It also has improved failover capabilities, and a robust set of member (user and group) management capabilities. Federated repositories is required when you are using the new member management capabilities in WebSphere Portal 6.1 and above, and Process Server 6.1 and above. The use of federated repositories is required for following LDAP referrals, which is a common requirement in some LDAP server environments (such as Microsoft Active Directory).

It is recommended that you migrate from stand-alone LDAP registries to federated repositories. If you move to WebSphere Portal 6.1 and above, and or WebSphere Process Server 6.1 and above, you should migrate to federated repositories prior to these upgrades. For more information about federated repositories and its capabilities, read the Federated repositories topic. For more information about how to migrate to federated repositories, read the Migrating a stand-alone LDAP repository to a federated repositories LDAP repository configuration topic.

To use LDAP as the user registry, you need to know an administrative user name that is defined in the registry, the server host and port, the base distinguished name (DN) and, if necessary, the bind DN and the bind password. You can choose any valid user in the registry that is searchable and have administrative privileges. In some LDAP servers, the administrative users are not searchable and cannot be used, for example, `cn=root` in SecureWay. This user is referred to as WebSphere Application Server security server ID, server ID, or server user ID in the documentation. Being a server ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log into the administrative console after security is turned on. You can use other users to log in if those users are part of the administrative roles.

When security is enabled in the product, the primary administrative user name and password are authenticated with the registry during the product startup. If authentication fails, the server does not start. It is important to choose an ID and password that do not expire or change often. If the product server user ID or password need to change in the registry, make sure that the changes are performed when all the product servers are up and running.

When the changes are done in the registry, use the steps that are described in “Configuring Lightweight Directory Access Protocol user registries” on page 1423. Change the ID, password, and other configuration information, save, stop, and restart all the servers so that the new ID or password is used by the product. If any problems occur starting the product when security is enabled, disable security before the server can start up. To avoid these problems, make sure that any changes in this panel are validated in the Global security panel. When the server is up, you can change the ID, password, and other configuration information and then enable security.

You can use the custom Lightweight Directory Access Protocol (LDAP) feature to support any LDAP server by setting up the correct configuration. However, support is not extended to these custom LDAP servers because many configuration possibilities exist.

The users and groups and security role mapping information is used by the configured authorization engine to perform access control decisions.

If you are configuring an LDAP registry as the active registry, you can configure one of the following authorization mechanisms:

- System Authorization Facility (SAF) authorization using EJBROLE or GEJBROLE profiles. SAF overrides any other authorization mechanism.
- Tivoli Access Manager as a Java Contract for Containers (JACC) provider. For more information, see “Tivoli Access Manager integration as the JACC provider” on page 1792.
- User-to-role bindings, which are created by the application assembler or the WebSphere Application Server security administrator.

SAF authorization, which is the use of SAF EJBROLE profiles to assign SAF users and groups to roles, can be used as an authorization mechanism for all user registries. If SAF authorization is selected on the administrative console:

- SAF overrides any other authorization choice, such as Tivoli Access Manager.
- You must configure and install a Java Authentication and Authorization Service (JAAS) login mapping module that maps LDAP or a custom registry identity to a SAF user ID. For more information, see *Installing and configuring a custom System Authorization Facility mapping module for WebSphere Application Server*.

### ***Dynamic groups and nested group support for LDAP:***

Dynamic and nested groups simplify WebSphere Application Server security management and increase its effectiveness and flexibility.

Dynamic groups contain a group name and membership criteria:

- The group membership information is as current as the information on the user object.
- There is no need to manually maintain members on the group object.
- Dynamic groups are designed so an application does not need a large amount of information from the directory to find out if someone is a member of a group.

*Nested groups* enable the creation of hierarchical relationships that are used to define inherited group membership. A nested group is defined as a child group entry whose distinguished name (DN) is referenced by a parent group entry attribute.

You only need to assign a larger parent group if all nested groups share the same privilege. Assigning a role to a single parent group simplifies the run-time authorization table.

### **Dynamic groups and nested group support for the IBM Tivoli Directory Server**

WebSphere Application Server supports all Lightweight Directory Access Protocol (LDAP) dynamic and nested groups when using IBM Tivoli Directory Server. This function is enabled by default by taking advantage of a new feature in IBM Tivoli Directory Server. IBM Tivoli Directory Server uses the `ibm-allGroups` forward-reference group attribute that automatically calculates all the group memberships including dynamic and recursive memberships for a user. Security directly locates a user group membership from a user object rather than indirectly search all the groups to match group members.

For more information, see “Configuring dynamic and nested group support for the IBM Tivoli Directory Server” on page 1444.

### **Dynamic and nested group support for the SunONE or iPlanet Directory Server**

The SunONE or iPlanet Directory Server uses two grouping mechanisms:

#### **Groups**

Entries that name other entries as a list of members or as a filter for members.

**Roles** Entries that name other entries as a list of members or as a filter for members. Additional functionality is provided by generating the `nsrole` attribute on each role member.

Three types of roles are available:

#### **Filtered roles**

Depends upon the attributes that are contained in each entry. Entries are members, if they match a specified Lightweight Directory Access Protocol (LDAP) filter. This role is equivalent to a dynamic group.

### **Nested roles**

Creates roles that contain other roles. This role is equivalent to a nested group.

### **Managed roles**

Explicitly assigns a role to member entries. This role is equivalent to a static group.

Refer to “Configuring dynamic and nested group support for the SunONE or iPlanet Directory Server” on page 1444 for more information.

### ***Security failover among multiple LDAP servers:***

WebSphere Application Server security can be configured to attempt failovers between multiple Lightweight Directory Access Protocol (LDAP) hosts.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log`, `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

If the current active LDAP server is unavailable, WebSphere Application Server security attempts a failover to the first available LDAP host in the specified host list. The multiple LDAP servers can be replicas of the same master LDAP server, or they can be any LDAP host with the same schema, which contain data that is imported from the same LDAP Data Interchange Format (LDIF) file.

Whenever a failover occurs, WebSphere Application Server security always uses the first available LDAP server in the specified host list. For example, if there are four LDAP servers configured in the order of L1, L2, L3, and L4, L1 is treated as the primary LDAP server. The preference of connection is from L1 to L4. If, for example, WebSphere Application Server security is currently connected to L4, and failover or reconnection is necessary, WebSphere Application Server security first attempts to connect to L1, L2, and then L3 in that order until the connection is successful.

The current LDAP host name is logged in message CWSCJ0419I in the WebSphere Application Server log file, `SystemOut.log`. If you want to reconnect to the primary LDAP host, run the WebSphere Application Server MBean method, `resetLDAPBindInfo`, with `null,null` as the input.

To configure LDAP failover among multiple LDAP hosts, you must use `wsadmin` or `ConfigService` to include the backup LDAP host, which does not have a number limitation. The LDAP host that is displayed in the administrative console is the primary LDAP host, and is the first item listed in the LDAP host list in `security.xml`.

The WebSphere Application Server security realm name defaults to the primary LDAP host name that is displayed in the administrative console. It includes a trailing colon and a port number (if one exists). However, the custom property, `com.ibm.websphere.security ldap.logicRealm`, can be added to override the default security realm name. Use the `logicRealm` name to configure each cell to have its own LDAP host for interoperability and backward compatibility, and to provide flexibility for adding or removing the LDAP host dynamically. If migrating from a previous installation, the new `logicRealm` name does not take effect until administrative security is enabled again. To be compatible with a previous release that does not support logic realm, the `logicRealm` name has to be the same as that used by the previous installation (the LDAP host name, including a trailing colon and port number).

When LDAP failover is configured by associating a single hostname to multiple IP addresses through the use of a load balancer (which does that translation transparently to WebSphere Application Server), entering an invalid password can cause multiple LDAP bind retries. WebSphere Application Server retries and the load balancer routes requests to multiple replicas. With the default settings, the number of LDAP

bind retries is equal to one more than the number of associated IP addresses. This means a single invalid login attempt can cause the LDAP account to be locked. If the `com.ibm.websphere.security.ldap.retryBind` custom property is set to `false`, LDAP bind calls are not retried.

The following Jacl example shows how to use `wsadmin` to add a backup LDAP host for failover:

```
#-----
Main
This is a bi-modal script: it can be included in the wsadmin
command invocation like this:
wsadmin -f LDAPAdd.jacl ldapHost 800
#
or the script can be sourced from the wsadmin command line:
wsadmin> source LDAPAdd.jacl
wsadmin> LDAPAdd ldapHost 800
#
The script expects some parameters:
arg1 - LDAP Server host name
arg2 - LDAP Server port number
#-----
if { !($argc == 2) } {
 puts ""
 puts "LDAPAdd: This script requires 2 parameters: LDAP server host name and LDAP server port number"
 puts "For example: LDAPAdd ldapHost 389"
 puts ""
 return;
}
else {
 set ldapServer [lindex $argv 0]
 set ldapPort [lindex $argv 1]
 LDAPAdd $ldapServer $ldapPort
 return;
}
proc LDAPAdd {ldapServer ldapPort args} {
 global AdminConfig AdminControl ldapServer ldapPort
 set ldapServer lindex $args 0
 set ldapPort lindex $args 1
 global ldapUserRegistryId
 # Get the LDAP user registry object from the security configuration
 if { catch {$AdminConfig list LDAPUserRegistry} result } {
 puts stdout "\$AdminConfig list LDAPUserRegistry caught an exception $result\n"
 return
 }
 else {
 if {$result != {}} {
 set ldapUserRegistryId lindex $result 0
 }
 else {
 puts stdout "\$AdminConfig list LDAPUserRegistry caught an exception $result\n"
 return;
 }
 }
 # Set the host and port values in Attrs2
 set Attrs2 list list hosts list list list host
 $ldapServer
 list port $ldapPort

 # Modify the LDAP configuration host object
 $AdminConfig modify $ldapUserRegistryId $Attrs2
 $AdminConfig save
}
```

The following Jython example shows how to use `wsadmin` to add a backup LDAP host for failover:

```
#-----
Add ldap hostname and port
wsadmin -f LDAPAdd.py arg1 arg2
#
The script expects some parameters:
arg1 - LDAP Server hostname
arg2 - LDAP Server portnumber
#-----
import java

#-----
get the line separator and use to do the parsing
since the line separator on different platform are different
lineSeparator = java.lang.System.getProperty('line.separator')

#-----
add LDAP host
#-----
def LDAPAdd (ldapServer, ldapPort):
 global AdminConfig, lineSeparator, ldapUserRegistryId
 try:
 ldapObject = AdminConfig.list("LDAPUserRegistry")
 if len(ldapObject) == 0:
```

```

 print "LDAPUserRegistry ConfigId was not found\n"
 return

 ldapUserRegistryId = ldapObject.split(lineSeparator)[0]
 print "Got LDAPUserRegistry ConfigId is " + ldapUserRegistryId + "\n"
except:
 print "AdminConfig.list('LDAPUserRegistry') caught an exception\n"

try:
 secMbeans = AdminControl.queryNames('WebSphere:type=SecurityAdmin,*')

## Selecting an authentication mechanism

An *authentication mechanism* defines rules about security information, such as whether a credential is forwardable to another Java process, and the format of how security information is stored in both credentials and tokens. You can select and configure an authentication mechanism by using the administrative console.

### About this task

*Authentication* is the process of establishing whether a client is who or what it claims to be in a particular context. A client can be either an end user, a machine, or an application. An authentication mechanism in WebSphere Application Server typically collaborates closely with a *user registry*. The user registry is the user and groups account repository that the authentication mechanism consults with when performing authentication. The authentication mechanism is responsible for creating a *credential*, which is an internal product representation of a successfully authenticated client user. Not all credentials are created equally. The abilities of the credential are determined by the configured authentication mechanism.

WebSphere Application Server provides three authentication mechanisms: Lightweight Third Party Authentication (LTPA), Kerberos, and RSA token authentication mechanism.

Security support for Kerberos as the authentication mechanism has been added for this release of WebSphere Application Server. Kerberos (KRB5) is a mature, flexible, open, and very secure network authentication protocol. Kerberos includes authentication, mutual authentication, message integrity and confidentiality and delegation features. KRB5 is used for Kerberos in the administrative console and in the **sas.client.props**, **soap.client.props** and **ipc.client.props** files.

The RSA token authentication mechanism is new to this release of WebSphere Application Server. It aids the flexible management objective to preserve the base profiles configurations and isolate them from a security perspective. This mechanism permits the base profiles managed by an administrative agent to have different Lightweight Third-Party Authentication (LTPA) keys, different user registries, and different administrative users.

**Note:** Simple WebSphere Authentication Mechanism (SWAM) is deprecated in this release. SWAM does not provide authenticated communication between different servers.

Authentication is required for enterprise bean clients and web clients when they access protected resources. Enterprise bean clients, like a servlet or other enterprise beans or a pure client, send the authentication information to a web application server using one of the following protocols:

- Common Secure Interoperability Version 2 (CSIv2)
- z/OS Secure Authentication Service (z/SAS)

**Note:** z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Web clients use the HTTP or HTTPS protocol to send the authentication information.

The authentication information can be basic authentication (user ID and password), a credential token, or a client certificate. The web authentication is performed by the web authentication module.

You can configure web authentication for a web client by using the administrative console. Click **Security > Global security**. Under Authentication, expand **Web and SIP security** and click **General settings**. The following options exist for Web authentication:

#### **Authenticate only when the URI is protected**

Specifies that the web client can retrieve an authenticated identity only when it accesses a protected Uniform Resource Identifier (URI). WebSphere Application Server challenges the web client to provide authentication data when the web client accesses a URI that is protected by a J2EE role. This default option is also available in previous versions of WebSphere Application Server.

#### **Use available authentication data when an unprotected URI is accessed**

Specifies that the web client is authorized to call the `getRemoteUser`, `isUserInRole`, and `getUserPrincipal` methods; retrieves an authenticated identity from either a protected or an unprotected URI. Although the authentication data is not used when you access an unprotected URI, the authentication data is retained for future use. This option is available when you select the **Authenticate only when the URI is protected** check box.

#### **Authenticate when any URI is accessed**

Specifies that the web client must provide authentication data regardless of whether the URI is protected.

#### **Default to basic authentication when certificate authentication for the HTTPS client fails.**

Specifies that WebSphere Application Server challenges the web client for a user ID and password when the required HTTPS client certificate authentication fails.

The enterprise bean authentication is performed by the Enterprise JavaBeans (EJB) authentication module.

The EJB authentication module resides in the CSIv2 and z/SAS layer.

The authentication module is implemented using the Java Authentication and Authorization Service (JAAS) login module. The web authenticator and the EJB authenticator pass the authentication data to the login module, which can use the following mechanisms to authenticate the data:

- Kerberos
- LTPA
- RSA token
- Simple WebSphere Authentication Mechanism (SWAM)

**Note:** SWAM was deprecated in WebSphere Application Server Version 6.1 and will be removed in a future release.

The authentication module uses the registry that is configured on the system to perform the authentication. Four types of registries are supported:

- Federated repositories
- Local operating system
- Standalone Lightweight Directory Access Protocol (LDAP) registry
- Stand-alone custom registry

External registry implementation following the registry interface that is specified by IBM can replace either the local operating system or the LDAP registry.

The login module creates a JAAS subject after authentication and stores the credential that is derived from the authentication data in the public credentials list of the subject. The credential is returned to the web authenticator or to the enterprise beans authenticator.

The web authenticator and the enterprise beans authenticator store the received credentials for the authorization service to use in performing further access control checks.

You can configure authentication mechanisms in the administrative console by doing the following:

## Procedure

1. Click **Security > Global security**.
2. Under Authentication mechanisms and expiration, select an authentication mechanism to configure.

## Lightweight Third Party Authentication

Lightweight Third Party Authentication (LTPA) is intended for distributed, multiple application server and machine environments. LTPA supports forwardable credentials and single sign-on (SSO). LTPA can support security in a distributed environment through cryptography. This support permits LTPA to encrypt, digitally sign, and securely transmit authentication-related data, and later decrypt and verify the signature.

Application servers distributed in multiple nodes and cells can securely communicate using the LTPA protocol. It also provides the single sign-on (SSO) feature wherein a user is required to authenticate only once in a domain name system (DNS) domain and can access resources in other WebSphere Application Server cells without getting prompted. The realm names on each system in the DNS domain are case sensitive and must match identically.

For the Lightweight Directory Access Protocol (LDAP), the realm name is the `host:port` value of the LDAP server.

The LTPA protocol uses cryptographic keys to encrypt and decrypt user data that passes between the servers. These keys must be shared between the different cells for the resources in one cell to access resources in other cells, assuming that all the cells involved use the same LDAP or custom registry.

When using LTPA, a token is created with the user information and an expiration time and is signed by the keys. The LTPA token is time sensitive. All product servers that participate in a protection domain must have their time and date synchronized. If not, LTPA tokens appear prematurely expired and cause

authentication or validation failures. Coordinated Universal Time (UTC) is used by default, and all other machines must have the same UTC time. Consult your operating system documentation for information regarding how to ensure this.

This token passes to other servers, in the same cell or in a different cell through cookies, for web resources when SSO is enabled, or through the authentication protocol layer for enterprise beans.

If the receiving servers share the same keys as the originating server, the token can be decrypted to obtain the user information, which then is validated to make sure that it has not expired and that the user information in the token is valid in its registry. On successful validation, the resources in the receiving servers are accessible after the authorization check.

Each server must have valid credentials. When the credentials expire, the server is required to communicate to the user registry to authenticate. User registry outages can cause server processes to hang, requiring them to be restarted to recover. Extending the time the LTPA token remains cached reduces this risk, but does present a slightly increased security risk to be considered when defining your security policies.

All of the WebSphere Application Server processes in a cell (deployment manager, nodes, application servers) share the same set of keys. If key sharing is required between different cells, export them from one cell and import them to the other. For security purposes, the exported keys are encrypted with a random generated key and a user-defined password is used to protect the keys. This same password is needed when importing the keys into another cell. The password is only used to protect the keys and is not used to generate the keys.

WebSphere Application Server supports the LTPA and Kerberos protocols.

When security is enabled during profile creation time, LTPA is configured by default.

LTPA requires that the configured user registry be a centrally shared repository such as LDAP or a Windows domain-type registry so that users and groups are the same, regardless of the machine.

#### ***Lightweight Third Party Authentication key sets and key set groups:***

Key set groups contain lists of key sets and Lightweight Third Party Authentication (LTPA) key generation schedules. Each key set contains key references to keys in key stores.

**Note:** It is not recommended that you choose to generate new keys automatically. Keys should only be generated during off hours. Once keys are generated, you might need to export the keys and to import the keys to other WebSphere cells or IBM products in which the keys are required to be sync to communicate with each other.

The keys for some key configurations must be generated together. The LTPA key pair is referenced in one key set while the secret or private key is in a separate key set. When the key set group is created, the two key sets are added as members of the key set group. Key set group settings determine whether the keys for both key sets are generated together automatically or manually.

The key set group contains the following attributes:

- Member key sets
- Choice of either manual or automatic key generation in the member key sets
- Schedule for automatically generating keys

## Configuring LTPA and working with keys

You must configure Lightweight Third Party Authentication (LTPA) when you set up security for the first time. LTPA is the default authentication mechanism for WebSphere Application Server. After you have configured LTPA you can generate LTPA keys manually or automatically.

### Procedure

1. Configure LTPA and generate the first LTPA keys. Use the administrative console to configure LTPA or Kerberos when you set up security for the first time. The LTPA keys are generated automatically the first time. Read the Configuring the Lightweight Third Party Authentication mechanism article for more information.

Application servers distributed in multiple nodes and cells can securely communicate using the LTPA protocol. Key set groups contain lists of key sets and LTPA authentication key generation schedules. Each key set contains key references to keys in key stores. To generate keys automatically, each key set must be a member of a key set group.

Read the Lightweight Third Party Authentication key sets and key set groups article for more information.

The keys for some key configurations must be generated together. The LTPA key pair is referenced in one key set while the secret or private key is in a separate key set. When the key set group is created, the two key sets are added as members of the key set group. Key set group settings determine whether the keys for both key sets are generated together automatically or manually.

The key set group contains the following attributes:

- Member key sets
- Choice of either manual or automatic key generation in the member key sets
- Schedule for automatically generating keys

2. Generate keys manually or automatically, and control the number of active keys. WebSphere Application Server generates Lightweight Third Party Authentication (LTPA) keys automatically during the first server startup. You can generate additional keys as you need them in the Authentication mechanisms and expiration panel.

You can disable the automatic generation of new LTPA keys for key sets that are members of a key set group. Automatic generation creates new keys on a schedule that you specify when you configure a key set group, which manages one or more key sets. WebSphere Application Server uses key set groups to automatically generate cryptographic keys or multiple synchronized key sets.

Generating keys manually or enabling or disabling the generation of keys are tasks that require you to recycle the node agents and application servers to accept the new keys. If any of the node agents are down, run a manual file synchronization utility from the node agent machine to synchronize the security configuration from the deployment manager.

Key sets manage LTPA keys in a key store that is based on a key alias prefix. A key alias prefix is automatically generated when you generate a new key and store it in a key store. Key stores can contain multiple versions of keys for any given key alias prefix. You can specify a maximum number of active keys in the key set configuration.

Read the Generating Lightweight Third Party Authentication keys article for more information.

3. Import and export keys. To support single sign-on (SSO) in WebSphere® Application Server across multiple WebSphere Application Server domains or cells, you must share the LTPA keys and the password among the domains. You can import LTPA keys from other domains and export keys to other domains.

**Note:** You should disable automatic key generation if you import or export keys to or from another cell. This disabling causes the imported keys to get lost and the exported keys to no longer interoperate with this cell over time

You must recycle the node agents and application servers to accept the new keys. If any of the node agents are down, run a manual file synchronization utility from the node agent machine to synchronize the security configuration from the deployment manager.

Read the Importing Lightweight Third Party Authentication keys and Exporting Lightweight Third Party Authentication keys articles for more information.

4. Manage keys from multiple cells. You can specify the shared keys and configure the authentication mechanism that is used to exchange information between servers to import and export LTPA keys across multiple WebSphere® Application Server cells.

You must start the server again for any changes you make to become active.

Read the Managing LTPA keys from multiple WebSphere Application Server cells article for more information.

## **Kerberos (KRB5) authentication mechanism support for security**

The Kerberos authentication mechanism enables interoperability with other applications (such as .NET, DB2 and others) that support Kerberos authentication. It provides single sign on (SSO) end-to-end interoperable solutions and preserves the original requester identity.

**Note:** Security support for Kerberos as the authentication mechanism was added for WebSphere Application Server Version 7.0. Kerberos is a mature, flexible, open, and very secure network authentication protocol. Kerberos includes authentication, mutual authentication, message integrity and confidentiality and delegation features. You can enable Kerberos on the server side. Support is provided to enable the rich Java client to use the Kerberos token for authentication to the WebSphere Application Server.

The following sections describe Kerberos authentication in more detail:

- “What is Kerberos?”
- “The benefits of having Kerberos as an authentication mechanism” on page 1583
- “Kerberos authentication in a single Kerberos realm environment” on page 1583
- “Kerberos authentication in a cross or trusted Kerberos realm environment” on page 1584
- “Things to consider before setting up Kerberos as the authentication mechanism for WebSphere Application Server” on page 1588
- “Support information for Kerberos authentication” on page 1589
- “Setting up Kerberos as the authentication mechanism for WebSphere Application Server” on page 1590
- “Setting up Kerberos as the authentication mechanism for the pure Java client” on page 1590

## **What is Kerberos?**

Kerberos has withstood the test of time and is now at version 5.0. Kerberos enjoys wide spread platform support (for example, for Windows, Linux, Solaris, AIX, and z/OS) partly because the Kerberos source code is freely downloadable from the Massachusetts Institute of Technology (MIT) where it was originally created.

Kerberos is composed of three parts: a client, a server, and a trusted third party known as the Kerberos Key Distribution Center (KDC). The KDC provides authentication and ticket granting services.

The KDC maintains a database or repository of user accounts for all of the security principals in its realm. Many Kerberos distributions use file-based repositories for the Kerberos principal and policy DB and others use Lightweight Directory Access Protocol (LDAP) as the repository.

Kerberos does not support any notion of groups (that is, iKeys groups or groups of users or principals). The KDC maintains a long-term key for each principal in its accounts database. This long-term key is derived from the password of the principal. Only the KDC and the user that the principal represents should know what the long-term key or password is.

## The benefits of having Kerberos as an authentication mechanism

The benefits of having Kerberos as the authentication mechanism for WebSphere Application Server include the following:

- The Kerberos protocol is a standard. This enables interoperability with other applications (such as .NET, DB2 and others) that support Kerberos authentication. It provides single sign on (SSO) end-to-end interoperable solutions and preserves the original requester identity.
- When using Kerberos authentication, the user clear text password never leaves the user machine. The user authenticates and obtains a Kerberos ticket granting ticket (TGT) from a KDC by using a one-way hash value of the user password. The user also obtains a Kerberos service ticket from the KDC by using the TGT. The Kerberos service ticket that represents the client identity is sent to WebSphere Application Server for authentication.
- A Java client can participate in Kerberos SSO using the Kerberos credential cache to authenticate to WebSphere Application Server.
- J2EE, web service, .NET and web browser clients that use the HTTP protocol can use the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) token to authenticate to the WebSphere Application Server and participate in SSO by using SPNEGO web authentication. Support for SPNEGO as the web authentication service is new to this release of WebSphere Application Server.  
Read about “Single sign-on for HTTP requests using SPNEGO web authentication” on page 1610 for more information.
- WebSphere Application Server can support both Kerberos and Lightweight Third-Party Authentication (LTPA) authentication mechanisms at the same time.
- Server-to-server communication using Kerberos authentication is provided.

## Kerberos authentication in a single Kerberos realm environment

WebSphere Application Server supports Kerberos authentication in a single Kerberos realm environment as shown in the following figure:

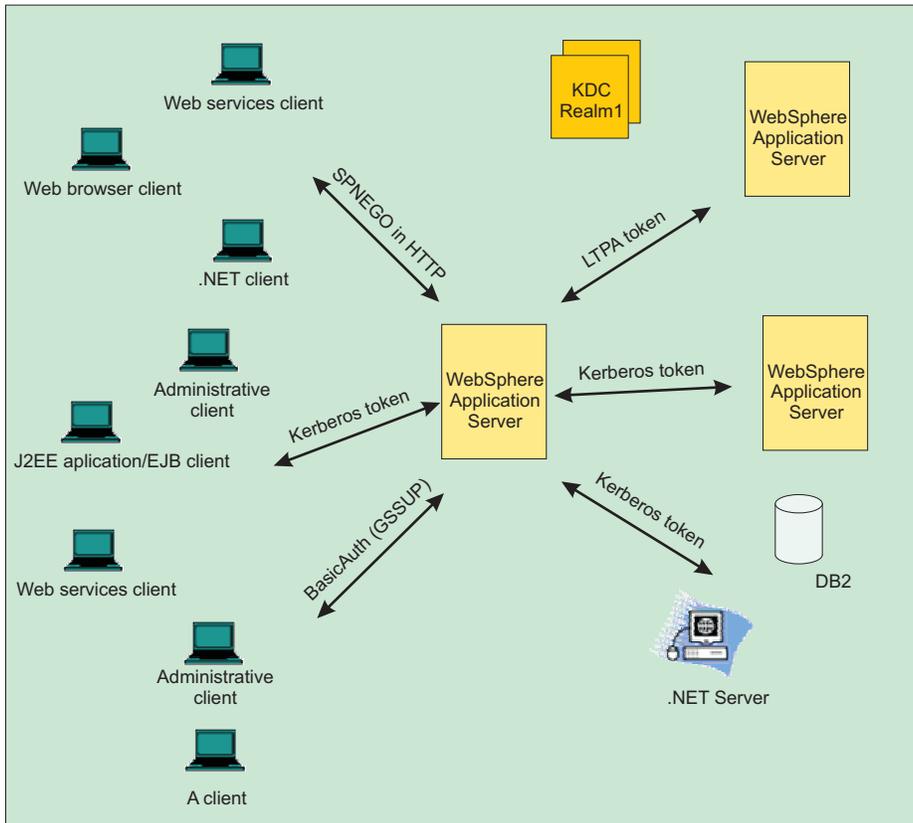

Figure 11. Kerberos authentication in a single Kerberos realm environment

When the WebSphere Application Server receives a Kerberos or SPNEGO token for authentication, it uses the Kerberos service principal (SPN) to establish a security context with a requestor. If a security context is established, the WebSphere Kerberos login module extracts a client GSS delegation credential, creates a Kerberos authentication token base on the Kerberos credential, and places them in the client subject with other tokens.

If the server must use a downstream server or back-end resources, it uses the client GSS delegation credential. If a downstream server does not support Kerberos authentication, the server uses the LTPA token instead of the Kerberos token. If a client does not include a GSS delegation credential in the request, the server uses the LTPA token for the downstream server . The Kerberos authentication token and principal are propagated to the downstream server as part of the security attributes propagation feature.

If the WebSphere Application Server and the KDC do not use the same user registry, then a JAAS custom login module might be required to map the Kerberos principal name to the WebSphere user name.

### Kerberos authentication in a cross or trusted Kerberos realm environment

WebSphere Application Server also supports Kerberos authentication in a cross or trusted Kerberos realm environment as shown in the following figure:

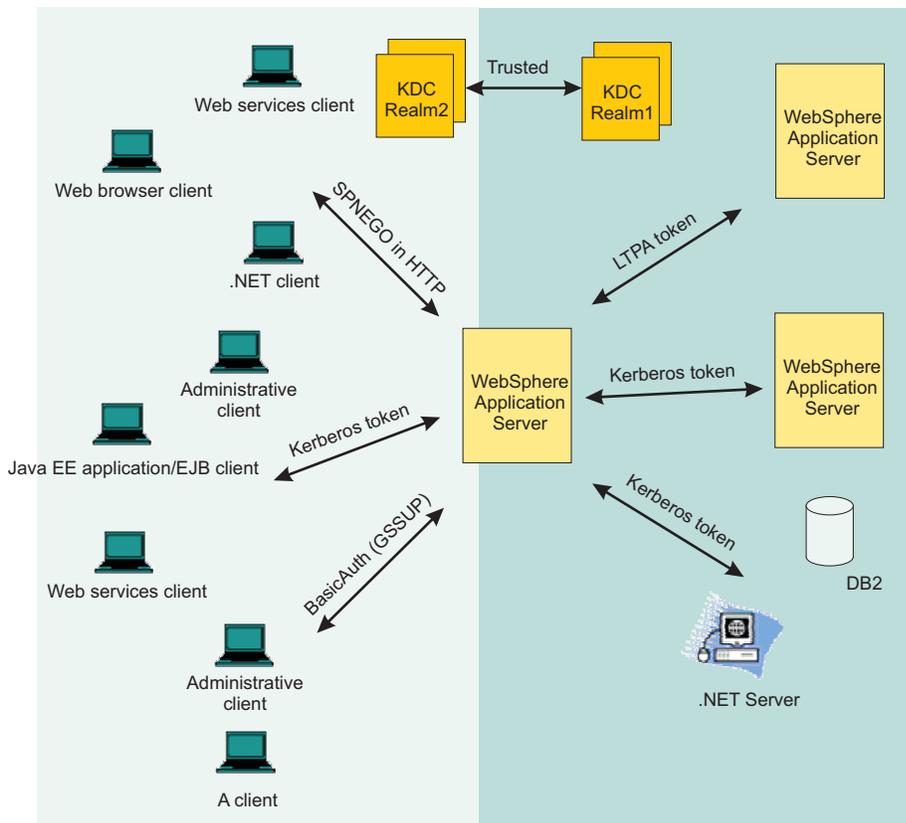

Figure 12. Kerberos authentication in a cross or trusted Kerberos realm environment

When the WebSphere Application Server receives a Kerberos or SPNEGO token for authentication, it uses the Kerberos service principal (SPN) to establish a security context with a requestor. If a security context is established, the WebSphere Kerberos login module always extracts a client GSS delegation credential and Kerberos ticket and places them in the client subject with other tokens.

If the server must use a downstream server or backend resources, it uses the client GSS delegation credential. If a downstream server does not support Kerberos authentication, the server uses the LTPA token instead of the Kerberos token. If a client does not include a GSS delegation credential in the request, the server uses the LTPA token for the downstream server. The Kerberos authentication token and principal are propagated to the downstream server as part of the security attributes propagation feature.

If the WebSphere Application Server and the KDC do not use the same user registry, then a JAAS custom login module might be required to map the Kerberos principal name to the WebSphere user name.

In this release of WebSphere Application Server, the new security multiple domains only support Kerberos at the cell level. All WebSphere Application Servers must be used by the same Kerberos realm. However, the clients and or backend resources (such as DB2, .NET server, and others) that support Kerberos authentication can have their own Kerberos realm. Only peer-to-peer and transitive trust cross-realm authentication are supported. The following steps must be performed for trusted Kerberos realms:

- The Kerberos trusted realm setup must be done on each of the Kerberos KDCs. See your Kerberos Administrator and User's guide for more information about how to set up a Kerberos trusted realm.
- The Kerberos configuration file might need to list the trusted realm.
- Add Kerberos trusted realms in the administrative console by clicking **Global security > CSiv2 outbound communications > Trusted authentication realms - outbound**.

The following figure shows a Java and administrative client that uses a Kerberos credential cache to authenticate to WebSphere Application Server with a Kerberos token in a trusted Kerberos realm:

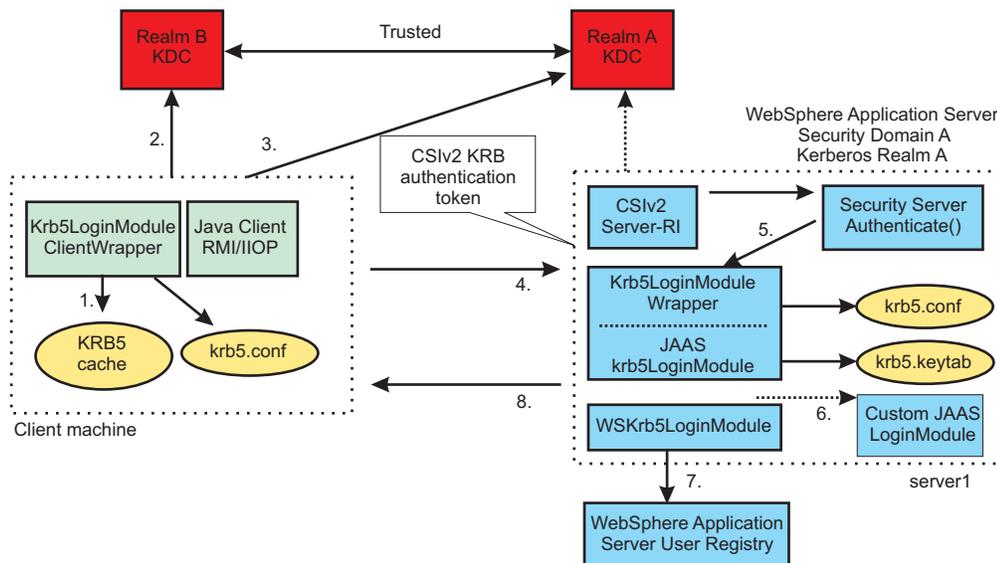

Figure 13. Using a Kerberos credential cache to authenticate to WebSphere Application Server with a Kerberos token in a trusted Kerberos realm

In the figure above, the following events occur:

1. The client uses the Kerberos credential cache if it exists.
2. The client requests a cross realm ticket (TGS\_REQ) for Realm A from the Realm B KDC using the Kerberos credential cache.
3. The client uses a cross realm ticket to request Kerberos service ticket for server1 (TGS\_REQ) from the Realm A KDC.
4. The Kerberos token returned from the KDC (TGS\_REP) is added to the CSIV2 message authentication token and sent to server1 for authentication.
5. The server calls Krb5LoginModuleWrapper to establish security context with the client using the server Kerberos Service Principal Name (SPN) and keys from the **krb5.keytab** file. If the server successfully establishes a security context with the client, it always extracts the client GSS delegation credential and tickets and places them in the client subject.
6. Optionally, a custom JAAS Login Module might be needed if the KDC and WebSphere Application Server do not use the same user registry.
7. The user is validated with the user registry for WebSphere Application Server.
8. The results (success or failure) are returned to the client.

The following figure shows a Java and administrative client that uses a Kerberos principal name and password to authenticate to WebSphere Application Server with a Kerberos token:

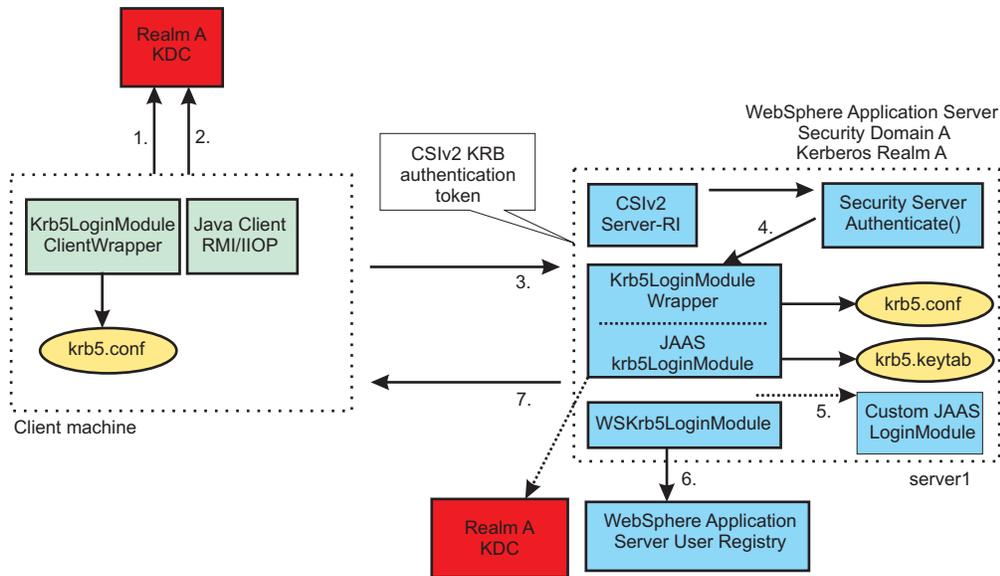

Figure 14. Using a Kerberos principal name and password to authenticate to WebSphere Application Server with a Kerberos token

In the figure above, the following events occur:

1. The client obtains the Kerberos granting ticket (TGT) from the KDC.
2. The client obtains a Kerberos service ticket for server1 (TGS\_REQ) using the TGT.
3. The Kerberos token returned from the KDC (TGS\_REP ) is added to the CSiv2 message authentication token and sent to server1 for authentication.
4. The server calls Krb5LoginModuleWrapper to establish security context with the client using the server Kerberos Service Principal Name (SPN) and keys from the **krb5.keytab** file. If the server successfully establishes a security context with the client, it always extracts the client GSS delegation credential and tickets and places them in the client subject.
5. Optionally, a custom JAAS Login Module might be needed if the KDC and WebSphere Application Server do not use the same user registry.
6. The user is validated with the user registry for WebSphere Application Server.
7. The results are returned to the client.

The following figure shows server-to-server communications:

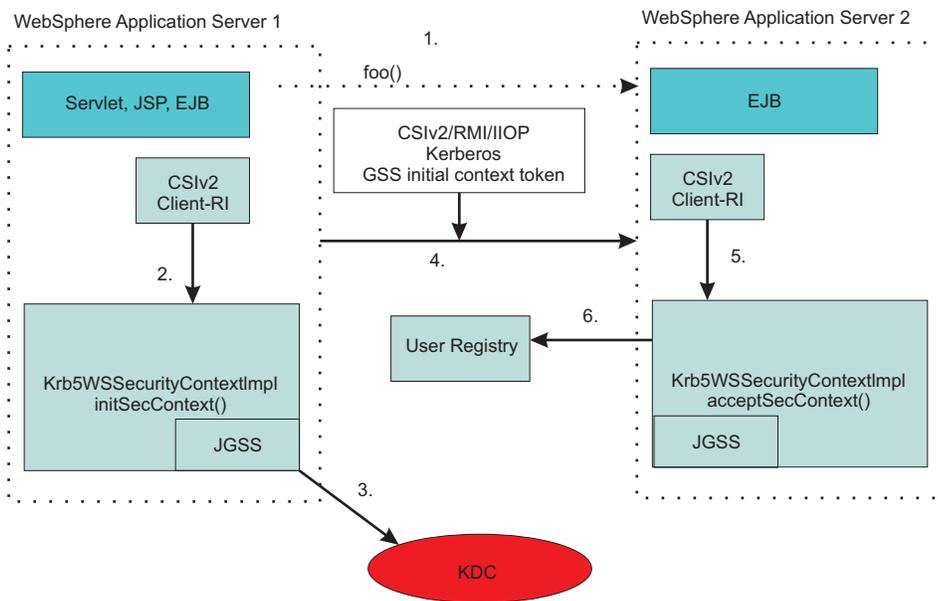

Figure 15. Server to server communications

When a WebSphere Application Server starts up, it uses the server ID and password to login to the KDC and then obtains the TGT. It then uses the TGT to request a service ticket to communicate with another server. If a WebSphere Application Server uses the internal server ID instead of the server ID and password, server-to-server communication is done using an LTPA token. In the figure above, the following events occur:

1. WebSphere Application Server 1 invokes a method, `foo()`, on an Enterprise JavaBeans (EJB) running in WebSphere Application Server 2.
2. Server1 obtains a Kerberos service ticket for Server2 (TGS\_REQ) using the Server1 TGT.
3. Same as step 2.
4. The Kerberos token returned from a KDC (TGS\_REP) is added to the CSiv2 message authentication token and sent to Server2 for authentication.
5. Server2 calls the `acceptSecContext()` method to establish security context with server1 using the server2 Kerberos Service Principal Name (SPN) and keys from the **krb5.keytab** file. If server2 successfully establishes a security context with server1, it always extracts the server1 GSS delegation credential and tickets and places them in the subject.
6. The server id is validated with the WebSphere user registry.

**Note:** If a Java client application and the application server exist on the same machine and they use different Kerberos realm names, the run time uses the default realm name from the Kerberos configuration file. Alternatively, you can specify the realm name during the login process.

### Things to consider before setting up Kerberos as the authentication mechanism for WebSphere Application Server

WebSphere Application Server now supports SPNEGO tokens in the HTTP header, Kerberos tokens, LTPA tokens and BasicAuth (GSSUP) for authentication.

To provide end-to-end Kerberos and end-to-end SPNEGO to Kerberos solutions, be aware of the following:

- The **Enabled delegation of Kerberos credentials** option must be selected. Read about Configuring Kerberos as the authentication mechanism using the administrative console for more information about this option.

- A client must obtain a ticket-granting ticket (TGT) with forwardable, address-less and renewable flags so that a target server can extract a client delegation Kerberos credential and use it for going to the downstream server.
- A client TGT that has an address can not be used for a downstream server, Data replication service (DRS) cache and cluster environments.
- See your Kerberos KDC platforms to make sure that it allows for client delegation Kerberos.
- For a long running application, a client should request a TGT with a renewable flag so that a target server can renew the delegation Kerberos.
- For a long-running application, ensure that the Kerberos ticket is valid for a period of time that is at least as long as the application runs. For example, if the application processes a transaction that takes 5 minutes, the Kerberos ticket must be valid for at least 5 minutes.
- Kerberos authentication and SPNEGO web authentication are both supported for Active Directory cross domain trusts within the same forest.
- In order for an administrative agent to use the Kerberos authentication mechanism, it must exchange an LTPA key with an administrative subsystem profile.  
The following security custom property should be set to true:  
com.ibm.websphere.security.krb.longLivedTicket.
- If you plan to use the client delegation Kerberos credential for downstream authentication, make sure the client can request a service ticket that is greater than 10 minutes. If the client delegation Kerberos credential lifetime is less than 10 minutes, then the server attempts to renew it.

**Note:** The client, WebSphere Application Server and KDC machines must keep the clock synchronized. The best practice is to use a time server to keep all of the systems synchronized.

For this release of WebSphere Application Server, be aware of the following:

- Complete end-to-end Kerberos support with Tivoli Access Manager is available using the following KDCs:
  - z/OS
  - Microsoft (single or multi-realm)
  - AIX
  - Linux
- You can now configure and enable Kerberos cross realms for WebSphere Application Server and the thin client.
- WebSphere Application Server administrative function with Kerberos is limited by the following:
  - The preferred authentication mechanism for flexible management activities is the Rivest Shamir Adleman (RSA) authentication mechanism (by default).
  - Job Manager configured with Kerberos as the administrative authentication does not support Cross-Kerberos realms. They must be in the same Kerberos realm as registered nodes, or have the administrative authentication set to RSA
  - While Kerberos authentication is supported for administrative clients (wsadmin or Java clients) you should use the same KDC realm as the WebSphere Application Server it administers. Otherwise, a user id and password are recommended.
  - Mixed cell Kerberos and LTPA configuration is not supported when some of the nodes are WebSphere Application Server Release 6.x nodes or earlier.

## Support information for Kerberos authentication

The following scenarios are supported:

- External domain trusts that are not on the same forests
- Domain trust within the same forest

- Kerberos realm trust

The following scenarios are not supported:

- Cross-forest trust
- Forest external trusts

## Setting up Kerberos as the authentication mechanism for WebSphere Application Server

You must perform the steps in order as listed in “Setting up Kerberos as the authentication mechanism for WebSphere Application Server” to set up Kerberos as the authentication mechanism for WebSphere Application Server.

**Note:** Kerberos authentication mechanism on the server side must be done by the system administrator and on the Java client side by end users. The Kerberos keytab file must to be protected.

## Setting up Kerberos as the authentication mechanism for the pure Java client

End users can optionally set up Kerberos authentication mechanism for the pure Java client. Read about Configuring a Java client for Kerberos authentication for more information.

## Setting up Kerberos as the authentication mechanism for WebSphere Application Server

You must perform steps in this article in order to set up Kerberos as the authentication mechanism for WebSphere Application Server.

### About this task

**Note:** Kerberos authentication mechanism on the server side must be done by the system administrator and on the Java client side by end users. The Kerberos keytab file must to be protected.

You must first ensure that the KDC is configured. See your Kerberos Administrator and User's guide for more information.

To configure a KDC on z/OS, you must activate the APPL class in RACF. This action has the effect of enabling the APPL class profile defined for WebSphere and might restrict the ability of authenticated users to access applications running on WebSphere. If your security configuration is using an SAF profile prefix, the profile name is the SAF profile prefix. Otherwise, the profile name is CBS390. To control whether the APPL profile is checked for WebSphere authorization, you can configure the checkbox labeled "Use APPL profile to restrict access to the server" on the SAF authorization panel in the administrative console. This setting can be configured at a WebSphere security domain level.

**gotcha:** When configuring the `envar` file for a z/OS KDC, order the encryption types from most secure to least secure for the `SKDC_TKT_ENCTYPES` environment variable. The z/OS KDC prefers to use the encryption types that are first in the list, from left to right.

You must perform the following steps in order to set up Kerberos as the authentication mechanism for WebSphere Application Server.

### Procedure

1. Create a Kerberos service principal name and keytab file You can create a Kerberos service principal name and keytab file using Microsoft Windows, iSeries, Linux, Solaris, Massachusetts Institute of Technology (MIT) and z/OS operating systems key distribution centers (KDCs).

Kerberos prefers servers and services to have a host-based service ID. The format of this ID is `<service name>/<fully qualified hostname>`. The default service name is `WAS`. For Kerberos authentication, the service name can be any strings that are allowed by the KDC. However, for

SPNEGO web authentication, the service name must be HTTP. An example of a WebSphere Application Server server ID is WAS/myhost.austin.ibm.com.

Each host must have a server ID unique to the hostname. All processes on the same node share the same host-based service ID.

A Kerberos administrator creates a Kerberos service principal name (SPN) for each node in the WebSphere cell. For example, for a cell with 3 nodes (such as server1.austin.ibm.com, server2.austin.ibm.com and server3.austin.ibm.com), the Kerberos administrator must create the following Kerberos service principals: WAS/server1.austin.ibm.com, WAS/server2.austin.ibm.com and WAS/server3.austin.ibm.com.

The Kerberos keytab file (**krb5.keytab**) contains all of the SPNs for the node and must be protected. This file can be placed in the `config/cells/<cell_name>` directory

Read the Creating a Kerberos principal and keytab article for more information.

2. Create a Kerberos configuration file The IBM implementation of the Java Generic Security Service (JGSS) and KRB5 require a Kerberos configuration file (**krb5.conf** or **krb5.ini**) on each node or Java virtual machine (JVM). In this release of WebSphere Application Server, this configuration file should be placed in the `config/cells/<cell_name>` directory so that all application servers can access this file. If you do not have a Kerberos configuration file, use a **wsadmin** command to create one.

Read the Creating a Kerberos configuration article for more information.

3. Configure Kerberos as the authentication mechanism for WebSphere Application Server using the administrative console Use the administrative console to configure Kerberos as the authentication mechanism for the application server. When you have entered and applied the required information to the configuration, the Kerberos service principal name is formed as `<service name>/<fully qualified hostname>@KerberosRealm`, and is used to verify incoming Kerberos token requests.

Read the Configuring Kerberos as the authentication mechanism using the administrative console article for more information.

4. Map a client Kerberos principal name to the WebSphere user registry ID You can map the Kerberos client principal name to the WebSphere user registry ID for both Simple and Protected GSS-API Negotiation (SPNEGO) web authentication and Kerberos authentication.

Read the Mapping of a client Kerberos principal name to the WebSphere user registry ID article for more information.

You can optionally map a Kerberos principal to a System Authorization Facility (SAF) identity on z/OS.

If you choose the **Use the KERB segment of an SAF user profile** radio button on the Kerberos panel of the WebSphere Application Server administrative console, you must have your Local OS users mapped to a specific Kerberos principal. Read Mapping a Kerberos principal to a System Authorization Facility (SAF) identity on z/OS for more information.

5. Set up Kerberos as the authentication mechanism for the pure Java client (optional) A Java client can authenticate with WebSphere Application Server with a Kerberos principal name and password or with the Kerberos credential cache (krb5Ccache).

Read the Configuring a Java client for Kerberos authentication article for more information.

## RSA token authentication mechanism

The Rivest Shamir Adleman (RSA) Authentication Mechanism is used to simplify the security environment for the Flexible Management Topology. It supports the ability to securely and easily register new servers to the Flexible Management topology. With the Flexible Management topology, you can submit and manage administrative jobs, locally or remotely, by using a job manager that manages applications, performs product maintenance, modifies configurations, and controls the application server runtime. The RSA authentication mechanism is only used for server-to-server administrative authentication, such as admin connector and file transfer requests. The RSA authentication mechanism does not replace LTPA or Kerberos for use by applications.

**Note:** The RSA token authentication mechanism aids the flexible management objective to preserve the base profiles configurations and isolate them from a security perspective. This mechanism permits

the base profiles managed by an administrative agent to have different Lightweight Third-Party Authentication (LTPA) keys, different user registries, and different administrative users.

**Important:** The RSA token is not related to the RSA SecureId token. Please note that the application server does not provide support for SecureId.

*Authentication* is the process of establishing whether a client is who or what it claims to be in a particular context. A client can be either an end user, a machine, or an application. An authentication mechanism in WebSphere Application Server typically collaborates closely with a *user registry*. The user registry is the user and groups account repository that the authentication mechanism consults with when performing authentication. The authentication mechanism is responsible for creating a *credential*, which is an internal product representation of a successfully authenticated client user. Not all credentials are created equally. The abilities of the credential are determined by the configured authentication mechanism.

## Authentication process

The RSA token authentication mechanism ensures that after the RSA root signer certificate (15 year lifetime) is exchanged between two administrative processes, there is no need to synchronize security information among disparate profiles for administrative requests. The RSA personal certificate (1 year lifetime) is used to perform the cryptographic operations on the RSA tokens and can be verified by the long-lived RSA root. RSA token authentication is different from LTPA where keys are shared and if one side changes, all sides need to change. Since RSA token authentication is based on a PKI infrastructure, it benefits from the scalability and manageability of this technology in a large topology.

An RSA token has more advanced security features than LTPA; this includes a nonce value that makes it a one-time use token, a short expiration period (since it's a one-time use token), and trust, which is established based on certificates in the target RSA trust store.

RSA token authentication does not use the same certificates as used by Secure Sockets Layer (SSL). This is the reason RSA has its own keystores. In order to isolate the trust established for RSA, the trust store, keystore, and root keystore, need to be different from the SSL configuration.

**Note:** SSL personal certificates given to pure clients are often signed by the same SSL root certificate used by servers, and this allows a pure client to send an RSA token to a server and act as an administrator. This should be avoided for the RSA token authentication mechanism. The RSA token authentication mechanism has its own root certificate which signs personal certificates that are used to encrypt and sign parts of the token.

The data stored in an RSA token is based on the identity of the client subject. The client subject can be based on LTPA or Kerberos, but the RSA token does not use this protection for administrative requests. The RSA token is easier to use while still maintaining a secure transportation of the identity. The data in an RSA token includes:

- Version
- Nonce
- Expiration
- Realm
- Principal
- Access ID
- Roles (not currently used)
- Groups
- Custom data

Custom data can be added to the WSCredential on the sending side (prior to going outbound) by creating a properties object, adding custom attributes, and adding this to the WSCredential in the following way.

```
import com.ibm.websphere.security.cred.WSCredential;

java.util.Properties props = new java.util.Properties();
props.setProperty("myAttribute", "myValue");
WSCredential.put ("customRSAProperties", props);
```

Once the Subject is created at the target process, you can get access to these attributes in the following way.

```
java.util.Properties props = (java.util.Properties) WSCredential.get("customRSAProperties");
```

This data is placed into a hash table at the target side and the hash table is used in a Java™ Authentication and Authorization Service (JAAS) login to obtain a subject at the target that contains the same attributes from the RSA token. With the target containing the same attributes from the RSA token, you can have a subject at the target side that is not from the same realm used by the target. For this authorization to succeed, a cross-realm mapping is required within the administrative authorization table unless the identity is a trusted server ID.

The figure (below) is an overview of the RSA token authentication mechanism and describes the process that takes place when a request is sent from a server-as-client to a target server. The server-as-client has an administrative subject on the thread that is used as input to create the RSA token. The other information needed is RSA public certificate of the target server. This certificate must be retrieved by making a “bootstrap” MBean request to the target process prior to sending any real requests. The target bootstrap request retrieves the public certificate from the target process. When creating an RSA token, the primary purpose of obtaining the target's public certificate is to encrypt the secret key. Only the target can decrypt the secret key, which is used to encrypt the user data.

The client's private key is used to sign both the secret key and the user data. The client's public key is embedded in the RSA token and validated at the target. If the client's public key is not trusted when calling the CertPath APIs at the target, the RSA token validation cannot continue. If the client's public key is trusted, it can be used to verify the secret key and user data signatures.

The basic goal is to convert the client subject into a subject at the target by securely propagating the required information. After the subject is generated at the target, the RSA authentication mechanism process is complete.

## Configuring the RSA token authentication mechanism

You use the WebSphere Application Server administrative console to configure the Rivest Shamir Adleman (RSA) token authentication mechanism. The RSA token authentication mechanism can only be used for administrative requests. As such, the authentication mechanism choices for administrative authentication are part of the Global Security panel of the administrative console.

### Before you begin

RSA token authentication mechanism is the default selection for the application server, administrative agent, and job manager profiles. LTPA is still the default for the deployment manager profile to preserve the same behavior for the existing topology.

### About this task

You configure Lightweight Third-Party Authentication (LTPA) and Kerberos on the main authentication mechanism panels of the administrative console as well as configure RSA token authentication. During registration of a base profile with the administrative agent, the trusted certificates on both sides are updated with the root signer for the other. The same process occurs during registration of an

administrative agent or deployment manager with a job manager. When removing the registration, the trusted signers are removed from both sides so that trust is no longer established.

By default, the RSA mechanism is set up correctly during the registration tasks, such as **registerNode** or **registerWithJobManager**. No further actions are necessary to establish trust within these environments. However, if you need to establish trust between two base servers or between two admin agents, for example, you can use the following steps to further configure the RSA token authentication mechanism:

## Procedure

1. Click **Security > Global security** . Under Administrative security click the link to **Administrative authentication**.
2. Select the RSA token radio button. Select a data encryption keystore from the drop-down list. The option is recommend for flexible systems administration.
3. Optional: To exchange the root signers between two base servers:
  - a. Select the root keystore from the Data encryption keystore drop-down list (such as NodeRSATokenRootStore).
  - b. Click **Extract Signer**.
  - c. Enter a fully-qualified name in the Certificate file name field.
  - d. Click **OK**.
4. Optional: Transfer the extracted root signer to the other server, and add it to that server's trusted signers keystore:
  - a. Select the trusted keystore from the drop-down list (such as NodeRSATokenTrustedStore).
  - b. Click **Add Signer**.
  - c. Enter a unique name for the Alias.
  - d. Enter a fully-qualified name for the signer key file.
  - e. Click **OK**.
5. Enter the nonce cache timeout value.
6. Enter token timeout value.
7. Click **Apply** and **Save**.

## Results

You have configured the RSA token authentication mechanism.

### ***RSA token authentication settings:***

Use this panel to configure RSA token authentication.

To view this administrative console page, click **Security > Global security**. Under Administrative security click **Administrative authentication**.

The administrative authentication method is used when an administrative process on this profile connects to another profile. If the primary authentication method is set to RSA token and that primary method fails, the system attempts to use the current application authentication method (which could be SWAM, Kerberos, or LTPA for example).

**Note:** SWAM is deprecated and will be removed in a future release.

### ***RSA token (recommended for flexible systems administration):***

RSA token is an authentication mechanism using certificates for signing and encryption portions of the security information being propagated.

**Default:** Enabled

*Data encryption keystore:*

This is the keystore that contains the personal certificate used to encrypt and sign RSA tokens.

**Data type:** text

*Personal certificate for encryption:*

This is the alias found in the Data encryption keystore that is used to encrypt and sign RSA tokens.

**Data type:** text

*Trusted signers keystore:*

This is the keystore used to contain signer certificates that can validate RSA tokens sent by other servers. The RSA token contains a sending certificate that needs to be validated by this trust store using a CertPath validation.

**Data type:** text

*Nonce cache timeout:*

Specifies the amount of time, in minutes, that the issued token is valid.

This field displays the maximum timeout, in minutes, for a token to be considered valid.

**Data type:** Integer  
**Default:** 20  
**Minimum:** 10  
**Maximum:** Integer.MAX\_VALUE

*Token timeout:*

Specifies the amount of time, in minutes, that the issued token is valid.

This field displays the maximum timeout, in minutes, for a token to be considered valid.

**Data type:** Integer  
**Default:** 10  
**Minimum:** 10  
**Maximum:** Integer.MAX\_VALUE

*Only use the active application authentication mechanism (currently LTPA):*

Select to encrypt authentication information so that the application server can send the data from one server to another in a secure manner.

The encryption of authentication information that is exchanged between servers involves the Lightweight Third-Party Authentication (LTPA) mechanism.

*Kerberos:*

Select to encrypt authentication information so that the application server can send the data from one server to another in a secure manner.

The encryption of authentication information that is exchanged between servers involves the Kerberos mechanism.

**Note:** Kerberos must be configured before this option can be selected.

### ***RSA token certificate use:***

The Rivest Shamir Adleman (RSA) token uses certificates in a similar way that Secure Sockets Layer (SSL) uses them. However, the trust established for SSL and RSA are different, and RSA certificates should not use SSL certificates and vice versa. The SSL certificates can be used by pure clients, and when used for the RSA mechanism would allow the client to send an RSA token to the server. The RSA token authentication mechanism is purely for server-to-server requests and should not be used by pure clients. The way to prevent this is to control the certificates used by RSA in such a way so they are never distributed to any clients. There is a different root certificate for RSA that prevents trust being established with clients who only need SSL certificates.

### **RSA root certificate**

For each profile there is a root certificate stored in the **rsatoken-root-key.p12** keystore. The sole purpose of this RSA root certificate is to sign the RSA personal certificate which is stored in the **rsatoken-key.p12** keystore. The RSA root certificate has a default lifetime of 15 years. The signer from the RSA root certificate is shared with other processes to establish trust.

The keytool utility is available using the QShell Interpreter. Using the keytool utility, you can list the contents of these keystores and display the keyEntry (personal certificate). The example below illustrated how this is accomplished for the **rsatoken-root-key.p12** (RSA root certificate) and **rsatoken-key.p12** (RSA personal certificate).

```
{profile_root}\config\cells\{cellname}\nodes\{nodename}> keytool -list -v -keystore rsatoken-root-key.p12 -storepass WebAS -storetype PKCS12
```

```

```

The purpose of the RSA personal certificate is to sign and encrypt information in the RSA token. The RSA personal certificate has a default lifetime of one year because it is used to sign and encrypt data that is transmitted over the wire. Refreshing the certificate is performed by the certificate expiration monitor, which is used for any other certificate in the system including SSL certificates.

RSA token trust is established when the **rsatoken-trust.p12** of the target process contains the signer of the root certificate of the client process that sends a token. Inside the RSA token is the public certificate of the client, which must be validated at the target before being used to decrypt data. The validation of the client's public certificate is performed using the CertPath APIs, which use the **rsatoken-trust.p12** as the source of certificates used during the validation.

The following example shows the use of the keytool utility to list the **rsatoken-trust.p12** keystore.

**Note:** This trust store contains three trustedCertEntry (public certificate) entries. The root public certificate from the administrative agent, a root public certificate from a job manager to which it is registered, and a root public certificate from a base profile to which it is registered.

```
 ${profile_root}\config\cells\${cellname}\nodes\${nodename}> keytool -list -v -keystore rsatoken-trust.p12
-storepass WebAS -storetype PKCS12

```

You can use the WebSphere Application Server certificate management tools to create a new personal certificate, and then replace the RSA personal certificate in the **rsa-key.p12** and the public key in the **rsa-trust.p12** with this newly created personal certificate. If you replace the RSA personal certificate prior to

federation to an administrative agent or job manager, the exchange of certificates is done for you. If you change the certificate after federation, you need to make sure the `rsa-trust.p12` on the administrative agent or job manager is updated with the signer for your new certificate to establish trust.

### Simple WebSphere authentication mechanism (deprecated)

The Simple WebSphere authentication mechanism (SWAM) defines rules about security information and the format of how security information is stored in both credentials and tokens. SWAM is intended for simple, non-distributed, single application server runtime environments.

**Note:** SWAM was deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

The single application server restriction is due to the fact that SWAM does not support *forwardable* credentials. If a servlet or enterprise bean in application server process 1, invokes a remote method on an enterprise bean living in another application server process 2, the identity of the caller identity in process 1 is not transmitted to server process 2. What is transmitted is an unauthenticated credential, which, depending on the security permissions configured on the EJB methods, can cause authorization failures.

Because SWAM is intended for a single application server process, single sign-on (SSO) is not supported.

The SWAM authentication mechanism is suitable for simple environments, software development environments, or other environments that do not require a distributed security solution.

### Message layer authentication

Defines the credential information and sends that information across the network so that a receiving server can interpret it.

When you send authentication information across the network using a token the transmission is considered message layer authentication because the data is sent with the message inside a service context.

A pure Java client uses Kerberos (KRB5) or basic authentication, or Generic Security Services Username Password (GSSUP), as the authentication mechanism to establish client identity.

However, a servlet can use either basic authentication (GSSUP) or the authentication mechanism of the server, Kerberos (KRB5) or Lightweight Third Party Authentication (LTPA), to send security information in the message layer. Use KRB5 or LTPA by authenticating or by mapping the basic authentication credentials to the security mechanism of the server.

The security token that is contained in a token-based credential is authentication mechanism-specific. The way that the token is interpreted is only known by the authentication mechanism. Therefore, each authentication mechanism has an object ID (OID) representing it. The OID and the client token are sent to the server, so that the server knows which mechanism to use when reading and validating the token. The following list contains the OIDs for each mechanism:

BasicAuth (GSSUP): oid:2.23.130.1.1.1  
KRB5: OID: 1.2.840.113554.1.2.2  
LTPA: oid:1.3.18.0.2.30.2  
SWAM: No OID because it is not forwardable

**Note:** SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

On the server, the authentication mechanisms can interpret the token and create a credential, or they can authenticate basic authentication data from the client, and create a credential. Either way, the created

credential is the *received* credential that the authorization check uses to determine if the user has access to invoke the method. You can specify the authentication mechanism by using the following property on the client side:

- `com.ibm.CORBA.authenticationTarget`

Basic authentication (BasicAuth) and KRB5 are currently the only valid values. You can configure the server through the administrative console.

**Note:** When **perform basic authentication** is enabled, if the client is not similarly configured (and does not pass a credential such as a user ID and password).

## Configuring authentication retries

Situations occur where you want a prompt to display again if you entered your user ID and password incorrectly or you want a method to retry when a particular error occurs back at the client. If you can correct the error by information at the client side, the system automatically performs a retry without the client seeing the failure, if the system is configured appropriately.

Some of these errors include:

- Entering a user ID and password that are not valid
- Having an expired credential on the server
- Failing to find the stateful session on the server

By default, authentication retries are enabled and perform three retries before returning the error to the client. Use the `com.ibm.CORBA.authenticationRetryEnabled` property (True or False) to enable or disable authentication retries. Use the `com.ibm.CORBA.authenticationRetryCount` property to specify the number of retry attempts.

## Immediate validating of a basic authentication login

In WebSphere Application Server Version 6.x, a behavior is defined during `request_login` for a BasicAuth login. In releases prior to Version 5, a BasicAuth login takes the user ID and password entered through the `loginSource` method and creates a BasicAuth credential. If either the user ID or the password is not valid, the client program does not find out until the first method request is attempted. When the user ID or password is specified during a prompt or programmatic login, the user ID and password are authenticated by default with the security server, with a True or False returned as the result. If False, an `org.omg.SecurityLevel2.LoginFailed` exception is returned to the client indicating that the user ID and password are not valid. If True, then the BasicAuth credential is returned to the caller of the `request_login`. To disable this feature on the pure client, specify `com.ibm.CORBA.validateBasicAuth=false`. By default, this feature is set to True. On the server side, specify this property in the security dynamic properties.

**Note:** Set `com.ibm.CORBA.validateBasicAuth=false` whenever connecting to a z/OS server. This function does not currently work from a distributed client to a z/OS server since the SecurityServer is located using the "UNAUTHENTICATED" principal, which is not accepted on a z/OS system.

## Integrating third-party HTTP reverse proxy servers

These steps are required to use a trust association interceptor with a reverse proxy security server.

### About this task

WebSphere Application Server enables you to use multiple trust association interceptors. The application server uses the first interceptor that can handle the request.

### Procedure

1. Access the administrative console.  
Type `http://fully_qualified_host_name:port_number/ibm/console` in a web browser.

Port 9060 is the default port number for accessing the administrative console. During installation, however, you might have specified a different port number. Use the appropriate port number.

2. Click **Security > Global security**.
3. Under Web and SIP security, click **Trust association**.
4. Select the **Enable trust association** option.
5. Under Additional properties, click **Interceptors**. The default value appears.
6. Verify that the appropriate trust association interceptors are listed.

## Results

Trust association is enabled.

## What to do next

1. If you are enabling security, make sure that you complete the remaining steps for enabling security.
2. Save, stop and restart all of the product servers (deployment managers, nodes and application servers) for the changes to take effect.

## Trust associations

*Trust association* enables the integration of IBM WebSphere Application Server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials that are passed by the proxy server.

Demand for such an integrated configuration has become more compelling, especially when a single product cannot meet all of the customer needs or when migration is not a viable solution. This article provides a conceptual background behind the approach.

In this setup, WebSphere Application Server is used as a back-end server to further exploit its fine-grained access control. The reverse proxy server passes the HTTP request to WebSphere Application Server that includes the credentials of the authenticated user. WebSphere Application Server then uses these credentials to authorize the request.

## Trust association model

The idea that WebSphere Application Server can support trust association implies that the product application security recognizes and processes HTTP requests that are received from a reverse proxy server. WebSphere Application Server and the proxy server engage in a contract in which the product gives its full trust to the proxy server and the proxy server applies its authentication policies on every web request that is dispatched to WebSphere Application Server. This trust is validated by the interceptors that reside in the product environment for every request received. The method of validation is agreed upon by the proxy server and the interceptor.

Running in trust association mode does not prohibit WebSphere Application Server from accepting requests that did not pass through the proxy server. In this case, no interceptor is needed for validating trust.

WebSphere Application Server supports the following trust association interceptor (TAI) interfaces:

### **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus**

This TAI interceptor implementation that implements the new WebSphere Application Server interface supports WebSphere Application Server Version 5.1.1 and later. The interface supports WebSEAL Version 5.1, but does not support WebSEAL Version 4.1. For an explanation of security attribute propagation, see “Security attribute propagation” on page 1700.

**Note:** The TAI interceptor implementation also supports WebSphere Application Server Version 5.1.0.2 for z/OS.

#### **com.ibm.ws.security.spnego.TrustAssociationInterceptorImpl**

This interceptor is new to this release. SPNEGO has replaced SPNEGO TAI as the web authenticator for WebSphere Application Server.

## **IBM WebSphere Application Server: WebSEAL Integration**

The integration of WebSEAL and WebSphere Application Server security is achieved by placing the WebSEAL server at the front-end as a reverse proxy server. From a WebSEAL management perspective, a junction is created with WebSEAL on one end, and the product web server on the other end. A junction is a logical connection that is created to establish a path from the WebSEAL server to another server.

In this setup, a request for web resources that are stored in a protected domain of the product is submitted to the WebSEAL server where it is authenticated against the WebSEAL security realm. If the requesting user has access to the junction, the request is transmitted to the WebSphere Application Server HTTP server through the junction, and then to the application server.

Meanwhile, WebSphere Application Server validates every request that comes through the junction to ensure that the source is a trusted party. This process is referenced as *validating the trust* and it is performed by a WebSEAL product-designated interceptor. If the validation is successful, WebSphere Application Server authorizes the request by checking whether the client user has the required permissions to access the web resource. If so, the web resource is delivered to the WebSEAL server through the web server, which then gives the resource to the client user.

### **WebSEAL server**

The policy director delegates all of the web requests to its web component, the WebSEAL server. One of the major functions of the server is to perform authentication of the requesting user. The WebSEAL server consults a Lightweight Directory Access Protocol (LDAP) directory. It can also map the original user ID to another user ID, such as when global single sign-on (GSO) is used.

For successful authentication, the server plays the role of a client to WebSphere Application Server when channeling the request. The server needs its own user ID and password to identify itself to WebSphere Application Server. This identity must be valid in the security realm of WebSphere Application Server. The WebSEAL server replaces the basic authentication information in the HTTP request with its own user ID and password. In addition, WebSphere Application Server must determine the credentials of the requesting client so that the application server has an identity to use as a basis for its authorization decisions. This information is transmitted through the HTTP request by creating a header called *iv-creds*, with the Tivoli Access Manager user credentials as its value.

### **HTTP server**

The junction that is created in the WebSEAL server must get to the HTTP server that serves as the product front end. However, the HTTP server is shielded from knowing that trust association is used. As far as it is concerned, the WebSEAL product is just another HTTP client, and as part of its normal routines, it sends the HTTP request to the product. The only requirement on the HTTP server is a Secure Sockets Layer (SSL) configuration using server authentication only. This requirement protects the requests that flow within the junction.

## Web collaborator

When trust association is enabled, the web collaborator manages the interceptors that are configured in the system. The web collaborator loads and initializes these interceptors when you restart your servers. When a request is passed to WebSphere Application Server by the Web server, the web collaborator eventually receives the request for a security check. Two actions must take place:

1. The request must be authenticated.
2. The request must be authorized.

The web authenticator is called to authenticate the request by passing the HTTP request. If successful, a good credential record is returned by the authenticator, which the web collaborator uses to base its authorization for the requested resource. If the authorization succeeds, the web collaborator indicates to WebSphere Application Server that the security check has succeeded and that the requested resource can be served.

## Web authenticator

The web authenticator is asked by the web collaborator to authenticate a given HTTP request. Knowing that trust association is enabled, the task of the web authenticator is to find the appropriate trust association interceptor to direct the request for processing. The web authenticator queries every available interceptor. If no target interceptor is found, the web authenticator processes the request as though trust association is not enabled.

### Note:

WebSphere Application Server Version 4 through WebSphere Application Server Version 6.x support the `com.ibm.websphere.security.TrustAssociationInterceptor.java` interface. WebSphere Application Server Version 7.0.x and later supports the `com.ibm.ws.security.spnego.TrustAssociationInterceptorImpl` interface.

## Trust association interceptor interface

The intent of the trust association interceptor interface is to have reverse proxy security servers (RPSS) exist as the exposed entry points to perform authentication and coarse-grained authorization, while WebSphere Application Server enforces further fine-grained access control. Trust associations improve security by reducing the scope and risk of exposure.

In a typical e-business infrastructure, the distributed environment of a company consists of web application servers, web servers, existing systems, and one or more RPSS, such as the Tivoli WebSEAL product. Such reverse proxy servers, front-end security servers, or security plug-ins registered within web servers, guard the HTTP access requests to the web servers and the web application servers. While protecting access to the Uniform Resource Identifiers (URIs), these RPSS perform authentication, coarse-grained authorization, and request routing to the target application server.

When a web server, such as an IBM HTTP Server, uses a TAI to communicate with WebSphere Application Server, sometimes it is essential for the TAI to know whether a request came through a web server or came directly to WebSphere Application Server. Therefore the WebSphere Application Server Web container uses three `HttpServletRequest` attributes to provide the TAI with the certificate information for a request:

- The `com.ibm.websphere.ssl.direct_connection_peer_certificates` attribute contains a `X509Certificate[]` object of the certificate for a direct peer.
- The `com.ibm.websphere.ssl.direct_connection_cipher_suite` attribute contains a string object of a direct cipher suite.

- The `com.ibm.websphere.webcontainer.is_direct_connection` attribute contains a boolean object that indicates whether the connection was made through a web server, or was made directly to WebSphere Application Server.

See the topic *Web container request attributes* for more information about these attributes.

## Trust association settings

Use this page to enable trust association, which integrates application server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials passed by the proxy server.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, expand Web security and click **Trust association**.

When security is enabled and any of these properties change, go to the Global security panel and click **Apply** to validate the changes.

### **Enable trust association:**

Specifies whether trust association is enabled.

|                   |                   |
|-------------------|-------------------|
| <b>Data type:</b> | Boolean           |
| <b>Default:</b>   | Disable           |
| <b>Range:</b>     | Enable or Disable |

## Trust association interceptor collection

Use this page to specify trust information for reverse security proxy servers.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, expand Web and SIP security and click **Trust association**.
3. Under Additional Properties, click **Interceptors**.

When security is enabled and any of these properties are changed, go to the Global security panel and click **Apply** to validate the changes.

### **Interceptor class name:**

Specifies the trust association interceptor class name.

|                  |        |
|------------------|--------|
| <b>Data type</b> | String |
|------------------|--------|

## Trust association interceptor settings

Use this page to specify trust information for reverse security proxy servers.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, click **Web and SIP security**.
3. Click **Trust association**.
4. Under Additional Properties, click **Interceptors > New**.

**Interceptor class name:**

Specifies the trust association interceptor class name.

**Data type**

String

## Single sign-on for authentication

With single sign-on (SSO) support, web users can authenticate once when accessing both WebSphere Application Server resources, such as HTML, JavaServer Pages (JSP) files, servlets, enterprise beans, and Lotus Domino resources, such as documents in a Domino database, or accessing resources in multiple WebSphere Application Server domains.

There are various ways to accomplish SSO, with the most common in WebSphere using LTPA cookies. LTPA cookies do not require any particular client and allow SSO across different cells provide the registry and LTPA keys are the same.

There are other flavors of SSO, including Simple and Protected GSS-API Negotiation (SPNEGO), which is a way to use the token from a Kerberos login (typically Windows) to authenticate to WebSphere Application Server. This prevents the user from having to type in their userid and passwords again.

**Note:** In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated in WebSphere Application Server 7.0. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

TAIs are also a form of single sign-on when used in combination with a Proxy server that does the front-end authentication. The TAI allows the credentials to flow to WebSphere from the Proxy server and to be used to login without the need to re-authenticate the user.

### Single sign-on for authentication using LTPA cookies

With single sign-on (SSO) support, web users can authenticate once when accessing both WebSphere Application Server resources, such as HTML, JavaServer Pages (JSP) files, servlets, enterprise beans, and Lotus Domino resources, such as documents in a Domino database, or accessing resources in multiple WebSphere Application Server domains.

Application servers distributed in multiple nodes and cells can securely communicate using the Lightweight Third Party Authentication (LTPA) protocol. LTPA is intended for distributed, multiple application server and machine environments. LTPA can support security in a distributed environment through cryptography. This support permits LTPA to encrypt, digitally sign, and securely transmit authentication-related data, and later decrypt and verify the signature.

LTPA also provides the SSO feature wherein a user is required to authenticate only once in a domain name system (DNS) domain and can access resources in other WebSphere Application Server cells without getting prompted. Web users can authenticate once to a WebSphere Application Server or to a Domino server. This authentication is accomplished by configuring WebSphere Application Servers and the Domino servers to share authentication information.

Without logging in again, web users can access other WebSphere Application Servers or Domino servers in the same DNS domain that are enabled for SSO. You can enable SSO among WebSphere Application Servers by configuring SSO for WebSphere Application Server. To enable SSO between WebSphere Application Servers and Domino servers, you must configure SSO for both WebSphere Application Server and for Domino.

## Prerequisites and conditions

To take advantage of support for SSO between WebSphere Application Servers or between WebSphere Application Server and a Domino server, applications must meet the following prerequisites and conditions:

- Verify that all servers are configured as part of the same DNS domain. The realm names on each system in the DNS domain are case sensitive and must match identically. For example, if the DNS domain is specified as `mycompany.com`, then SSO is effective with any Domino server or WebSphere Application Server on a host that is part of the `mycompany.com` domain, for example, `a.mycompany.com` and `b.mycompany.com`.
- Verify that all servers share the same registry. Domino servers do not support stand-alone custom registries, but you can use a Domino-supported registry as a stand-alone custom registry within WebSphere Application Server.

You can use a Domino directory that is configured for LDAP access or other LDAP directories for the registry. The LDAP directory product must have WebSphere Application Server support. Supported products include both Domino and LDAP servers, such as IBM Tivoli Directory Server. Regardless of the choice to use an LDAP or a stand-alone custom registry, the SSO configuration is the same. The difference is in the configuration of the registry.

- Define all users in a single LDAP directory. Using multiple Domino directory assistance documents to access multiple directories also is not supported.
- Enable HTTP cookies in browsers because the authentication information that is generated by the server is transported to the browser in a cookie. The cookie is used to propagate the authentication information for the user to other servers, exempting the user from entering the authentication information for every request to a different server.
- For a Domino server:
  - Domino Release 6.5.4 for iSeries and other platforms are supported.
  - A Lotus Notes® client Release 5.0.5 or later is required for configuring the Domino server for SSO.
  - You can share authentication information across multiple Domino domains.
- For WebSphere Application Server:
  - WebSphere Application Server Version 3.5 or later for all platforms are supported.
  - You can use any HTTP web server that is supported by WebSphere Application Server.
  - You can share authentication information across multiple product administrative domains.
  - Basic authentication (user ID and password) using the basic and form-login mechanisms is supported.

**Note:** Form-login mechanisms for web applications require that SSO is enabled.

- By default, WebSphere Application Server does a case-sensitive comparison for authorization. This comparison implies that a user who is authenticated by Domino matches the entry exactly (including the base distinguished name) in the WebSphere Application Server authorization table. If case sensitivity is not considered for the authorization, enable the **Ignore Case** property in the LDAP user registry settings.

## Using a WebSphere Application Server API to achieve downstream web single sign-on with an LtpaToken2 cookie

You can programmatically perform downstream Single Sign On (SSO) web propagation of a Lightweight Third Party Authentication (LTPA) cookie without the need for an application to store and send user credentials.

WebSphere Application Server provides API support to propagate an LtpaToken2 cookie to downstream web single sign-on applications.

### Note:

Web applications running in mid-tier WebSphere servers might need to propagate LtpaToken2 cookies on downstream web invocations. In this release of WebSphere Application Server, a new Application Programming Interface (API) is provided for application developers to programmatically perform downstream SSO without the need for an application to store and send user credentials.

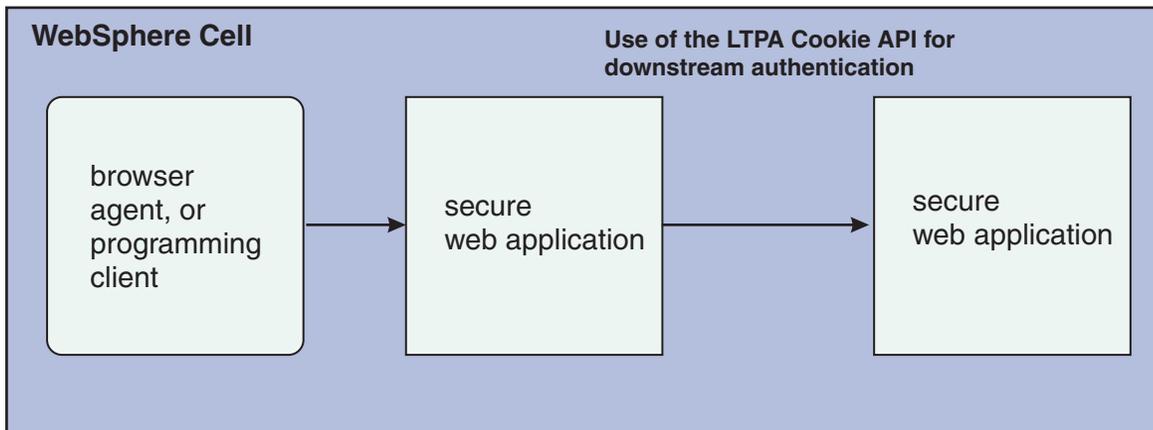

Figure 16. Use of the LTPA Cookie API for downstream authentication

This function is a public API in package `com.ibm.websphere.security.WSSecurityHelper`, and is defined as follows:

```

/**
 * Extracts an LTPA sso token from the subject of current
 * thread and builds a ltpa cookie out of it for use on
 * downstream web invocations.
 * When the returned value is not null use Cookie methods
 * getName() and getValue() to set the Cookie header
 * on an http request with header value of
 * Cookie.getName()=Cookie.getValue()
 *
 * @return an object of type javax.servlet.http.Cookie.
 */

```

The following is an example of how you can use the new `WSSecurityHelper` API:

```

import javax.servlet.http.Cookie;
import com.ibm.websphere.security.WSSecurityHelper;

Cookie ltpaCookie = WSSecurityHelper.getLTPACookieFromSSOToken()

```

Subsequently, the LTPA cookie can be set on an HTTP request header. In this case, the value of the cookie header is the string:

```
ltpaCookie.getName()=ltpaCookie.getValue()
```

For example, if you use `org.apache.commons.httpclient.HttpMethod` to build your HTTP request, the LTPA cookie can be set as follows:

```

HttpMethod method = .; // new your HttpMethod based on the
 // target URL for the web application
if (ltpaCookie != null)
 method.setRequestHeader("Cookie", ltpaCookie.getName()+"="+ltpaCookie.getValue());

```

**Note:** You should only send LTPA cookies over SSL connections.

**Note:** You must check whether the LTPA cookie that is returned from calling `WSSecurityHelper.getLTPACookieFromSSOToken()` in the example above is not null before you issue any getter methods. Also, to successfully retrieve a LTPA cookie object, and to ensure an SSO token on the thread of execution, make sure that the user has established a successful authentication with the mid-tier server.

**Note:** WebSphere Application Server does not ship supporting jars for HTTP programming, such as the Apache httpclient. You must provide your own supporting functions for HTTP programming.

## **Global single sign-on principal mapping for authentication**

You can use the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager to manage authentication to enterprise information systems (EIS) such as databases, transaction processing systems, and message queue systems that are located within the WebSphere Application Server security domain. Such authentication is achieved using the global single sign-on (GSO) principal mapper Java Authentication and Authorization Service (JAAS) login module for Java Platform, Enterprise Edition (Java EE) Connector Architecture resources.

With GSO principal mapping, a special-purpose JAAS login module inserts a credential into the subject header. This credential is used by the resource adapter to authenticate to the EIS. The JAAS login module used is configured on a per-connection factory basis. The default principal mapping module retrieves the user name and password information from XML configuration files. The JACC provider for Tivoli Access Manager bypasses the credential that is stored in the Extensible Markup Language (XML) configuration files and uses the Tivoli Access Manager global sign-on (GSO) database instead to provide the authentication information for the EIS security domain.

WebSphere Application Server provides a default principal mapping module that associates user credential information with EIS resources. The default mapping module is defined in the WebSphere Application Server administrative console on the Application login panel. To access the panel, click **Security > Global security**. Under Java Authentication and Authorization Service, click **Application logins**. The mapping module name is DefaultPrincipalMapping.

The EIS security domain user ID and password are defined under each connection factory by an authDataAlias attribute. The authDataAlias attribute does not contain the user name and password; this attribute contains an alias that refers to a user name and password pair that is defined elsewhere.

The Tivoli Access Manager principal mapping module uses the authDataAlias attribute to determine the GSO resource name and the user name that is required to perform the lookup on the Tivoli Access Manager GSO database. The Tivoli Access Manager Policy Server retrieves the GSO data from the user registry.

Tivoli Access Manager stores authentication information on the Tivoli Access Manager GSO database against a resource and user name pair.

## **GSO principal mapping architecture**

## **Implementing single sign-on to minimize web user authentications**

With single sign-on (SSO) support, web users can authenticate once when accessing web resources across multiple WebSphere Application Servers. Form login mechanisms for web applications require that SSO is enabled. Use this topic to configure single sign-on for the first time.

### **Before you begin**

SSO is supported when Lightweight Third Party Authentication (LTPA) is the authentication mechanism.

When SSO is enabled, a cookie is created containing the LTPA token and inserted into the HTTP response. When the user accesses other web resources in any other WebSphere Application Server process in the same domain name service (DNS) domain, the cookie is sent in the request. The LTPA token is then extracted from the cookie and validated. If the request is between different cells of

WebSphere Application Servers, you must share the LTPA keys and the user registry between the cells for SSO to work. The realm names on each system in the SSO domain are case sensitive and must match identically.

For the Lightweight Directory Access Protocol (LDAP) the realm name is the host:port realm name of the LDAP server. The LTPA authentication mechanism requires that you enable SSO if any of the web applications have form login as the authentication method.

Because single sign-on is a subset of LTPA, it is recommended that you read “Lightweight Third Party Authentication” on page 1579 for more information.

When you enable security attribute propagation, the following cookie is always added to the response:

### LtpaToken2

LtpaToken2 contains stronger encryption and enables you to add multiple attributes to the token. This token contains the authentication identity and additional information such as the attributes that are used for contacting the original login server and the unique cache key for looking up the Subject when considering more than just the identity in determining uniqueness.

**Note:** The following cookie is optionally added to the response when the **Interoperability mode** flag is enabled:

### LtpaToken

LtpaToken is used for inter-operating with previous releases of WebSphere Application Server. This token contains the authentication identity attribute only.

**Note:** LtpaToken is generated for releases prior to WebSphere Application Server Version 5.1.0.2. LtpaToken2 is generated for WebSphere Application Server Version 5.1.0.2 and beyond.

Table 95. LTPA token types. This table describes the LTPA token types.

| Token type               | Purpose                                                                                                                                                                                                                                                                                                       | How to specify                                                                                                                                                                                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LtpaToken2 only          | This is the default token type. It uses the AES-CBC-PKCS5 padding encryption strength (128-bit key size). This token is stronger than the older LtpaToken used prior to WebSphere Application Server Version 6.02. This is the recommended option when interoperability with older releases is not necessary. | Disable the <b>Interoperability mode</b> option in the SSO configuration panel within the administrative console. To access this panel, complete the following steps:<br>1. Click <b>Security &gt; Global security</b> .<br>2. Under Web security, click <b>Single sign-on (SSO)</b> . |
| LtpaToken and LtpaToken2 | Use to interoperate with releases prior to WebSphere Application Server Version 5.1.1. The older LtpaToken cookie is present along with the new LtpaToken2 cookie. Provided the LTPA keys are correctly shared, you should be able to interoperate with any version of WebSphere using this option.           | Enable the <b>Interoperability mode</b> option in the SSO configuration panel within the administrative console. To access this panel, complete the following steps:<br>1. Click <b>Security &gt; Global security</b> .<br>2. Under Web security, click <b>Single sign-on (SSO)</b> .  |

## About this task

The following steps are required to configure SSO for the first time.

### Procedure

1. Open the administrative console.  
Type `http://localhost:port_number/ibm/console` to access the administrative console in a web browser.  
Port 9060 is the default port number for accessing the administrative console. During installation, however, you might have specified a different port number. Use the appropriate port number.
2. Click **Security > Global security**.
3. Under Web security, click **Single sign-on (SSO)**.

4. Click the **Enabled** option if SSO is disabled. After you click the **Enabled** option, make sure that you complete the remaining steps to enable security.
5. Click **Requires SSL** if all of the requests are expected to use HTTPS.
6. Enter the fully qualified domain names in the **Domain name** field where SSO is effective. If you specify domain names, they must be fully qualified. If the domain name is not fully qualified, WebSphere Application Server does not set a domain name value for the LtpaToken cookie and SSO is valid only for the server that created the cookie.

When you specify multiple domains, you can use the following delimiters: a semicolon (;), a space ( ), a comma (,), or a pipe (|). WebSphere Application Server searches the specified domains in order from left to right. Each domain is compared with the host name of the HTTP request until the first match is located. For example, if you specify `ibm.com`; `austin.ibm.com` and a match is found in the `ibm.com` domain first, WebSphere Application Server does not continue to search for a match in the `austin.ibm.com` domain. However, if a match is not found in either the `ibm.com` or `austin.ibm.com` domains, then WebSphere Application Server does not set a domain for the LtpaToken cookie.

Table 96. Values to configure the Domain name field.

This table describes the values to configure the Domain name field.

| Domain name value type                     | Example                                                                                                           | Purpose                                                                                                                                                                |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Blank                                      |                                                                                                                   | The domain is not set. This causes the browser to set the domain to the request host name. The sign-on is valid on that single host only.                              |
| Single domain name                         | <code>austin.ibm.com</code>                                                                                       | If the request is to a host within the configured domain, the sign-on is valid for all hosts within that domain. Otherwise, it is valid on the request host name only. |
| UseDomainFromURL                           | UseDomainFromURL                                                                                                  | If the request is to a host within the configured domain, the sign-on is valid for all hosts within that domain. Otherwise, it is valid on the request host name only. |
| Multiple domain names                      | <code>austin.ibm.com;raleigh.ibm.com</code>                                                                       | The sign-on is valid for all hosts within the domain of the request host name.                                                                                         |
| Multiple domain names and UseDomainFromURL | <ul style="list-style-type: none"> <li>• <code>austin.ibm.com;raleigh.ibm.com; UseDomainFromURL</code></li> </ul> | The sign-on is valid for all hosts within the domain of the request host name.                                                                                         |

If you specify the `UseDomainFromURL`, WebSphere Application Server sets the SSO domain name value to the domain of the host that makes the request. For example, if an HTTP request comes from `server1.raleigh.ibm.com`, WebSphere Application Server sets the SSO domain name value to `raleigh.ibm.com`.

**Tip:** The value, `UseDomainFromURL`, is case insensitive. You can type `usedomainfromurl` to use this value.

For more information, see “Single sign-on settings” on page 1654.

7. Optional: Enable the **Interoperability mode** option if you want to support SSO connections in WebSphere Application Server version 5.1.1 or later to interoperate with previous versions of the application server.

This option sets the old-style LtpaToken token into the response so it can be sent to other servers that work only with this token type. Otherwise, only the LtpaToken2 token is added to the response.

If performance is a consideration, and you are only connecting to Version 6.1 or later servers that are not running products that depend on the LtpaToken, do not enable Interoperability mode. When Interoperability mode is not enabled, an LtpaToken is not returned in a response.

8. Optional: Enable the **Web inbound security attribute propagation** option if you want information added during the login at a specific front-end server to propagate to other front-end servers. The SSO token does not contain any sensitive attributes, but does understand where the original login server exists in cases where it needs to contact that server to retrieve serialized information. It also contains

the cache look-up value for finding the serialized information in DynaCache, if both front-end servers are configured in the same DRS replication domain. For more information, see “Security attribute propagation” on page 1700.

**Important:** If the following statements are true, it is recommended that you disable the **Web inbound security attribute propagation** option for performance reasons:

- You do not have any specific information added to the Subject during a login that cannot be obtained at a different front-end server.
- You did not add custom attributes to the PropagationToken token using WSSecurityHelper application programming interfaces (APIs).

If you find that you are missing custom information in the Subject, re-enable the **Web inbound security attribute propagation** option to see if the information is propagated successfully to other front-end application servers.

The following two custom properties might help to improve performance when security attribute propagation is enabled:

- **com.ibm.CSI.propagateFirstCallerOnly**  
The default value of this property is `true`. When this custom property is set to `true` the first caller in the propagation token that stays on the thread is logged when security attribute propagation is enabled. When this property is set to `false`, all of the caller switches are logged, which can affect performance.
- **com.ibm.CSI.disablePropagationCallerList**  
When this custom property is set to `true` the ability to add a caller or host list in the propagation token is completely disabled. This function is beneficial when the caller or host list in the propagation token is not needed in the environment.

9. Click **OK**.

## What to do next

For the changes to take effect, save, stop, and restart all the product deployment managers, nodes, and servers.

## Single sign-on for HTTP requests using SPNEGO web authentication

You can securely negotiate and authenticate HTTP requests for secured resources in WebSphere Application Server by using the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) as the web authentication service for WebSphere Application Server.

**Note:** In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated in WebSphere Application Server Version 7.0. SPNEGO web authentication has taken its place to provide the following enhancements:

- You can configure and enable SPNEGO web authentication and filters on WebSphere Application Server by using the administrative console.
- Dynamic reload of SPNEGO is provided without the need to stop and restart WebSphere Application Server.
- Fallback to an application login method is provided if the SPNEGO web authentication fails.
- SPNEGO can be customized at the WebSphere security domain level. Read about “Multiple security domains” on page 1380 for more information.

You can enable either SPNEGO TAI or SPNEGO Web Authentication but not both.

The following sections describe SPNEGO web authentication in more detail:

- “What is SPNEGO?”
- “The benefits of SPNEGO web authentication” on page 1612
- “SPNEGO web authentication in a single Kerberos realm” on page 1612
- “SPNEGO web authentication in a trusted Kerberos realm” on page 1613
- “Support information for SPNEGO web authentication with a Java client using the HTTP protocol” on page 1614
- “Support information for SPNEGO web authentication with a browser client” on page 1614
- “Setting up SPNEGO as the web authentication mechanism for WebSphere Application Server” on page 1614

## What is SPNEGO?

SPNEGO is a standard specification defined in The Simple and Protected GSS-API Negotiation Mechanism (IETF RFC 2478).

When WebSphere Application Server global and application security are enabled, and SPNEGO web authentication is enabled, SPNEGO is initialized when processing a first inbound HTTP request. The web authenticator component then interacts with SPNEGO, which is defined and enabled in the security configuration repository. When the filter criteria is met, SPNEGO is responsible for authenticating access to the secured resource that is identified in the HTTP request.

In addition to WebSphere Application Server security runtime services, some external components are required to enable the operation of SPNEGO. These external components include:

- A client application, for example, Microsoft .NET, or web service and J2EE client that supports the SPNEGO web authentication mechanism, as defined in IETF RFC 2478. Microsoft Internet Explorer Version 5.5 or later and Mozilla Firefox Version 1.0 are browser examples. Any browser must be configured to use the SPNEGO web authentication mechanism. For more information on performing this configuration, see *Configuring the client browser to use SPNEGO*.

The authentication of HTTP requests is triggered by the requestor (the client-side), which generates a SPNEGO token. WebSphere Application Server receives this token. Specifically, the SPNEGO web authentication decodes and retrieves the requester's identity from the SPNEGO token. The identity is used to establish a secure context between the requester and the application server.

SPNEGO web authentication is a server-side solution in WebSphere Application Server. Client-side applications are responsible for generating the SPNEGO token for use by SPNEGO web authentication. The requester's identity in the WebSphere Application Server security registry must be identical to the identity that the SPNEGO web authentication retrieves. An identical match does occur when Microsoft Windows Active Directory server is the Lightweight Directory Access Protocol (LDAP) server that is used in WebSphere Application Server. A custom login module is available as a plug-in to support custom mapping of the identity from the Active Directory to the WebSphere Application Server security registry.

WebSphere Application Server validates the identity against its security registry. If the validation is successful, the client Kerberos ticket and GSS delegation credential are retrieved and placed in the client subject, which then produces a Lightweight Third Party Authentication (LTPA) security token. It then places and returns a cookie to the requester in the HTTP response. Subsequent HTTP requests from this same requester to access additional secured resources in WebSphere Application Server use the LTPA security token previously created to avoid repeated login challenges.

The web administrator has access to the following SPNEGO security components and associated configuration data, as shown in the following figure:

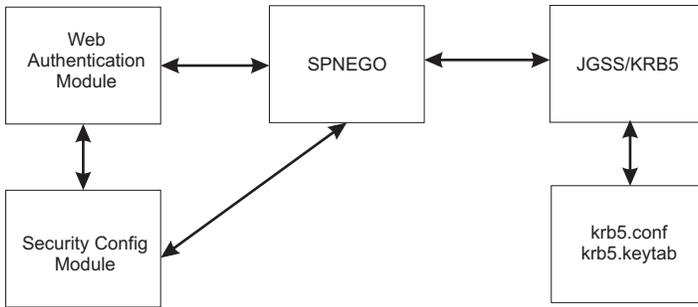

Figure 17. SPNEGO web authentication and security configuration elements

## The benefits of SPNEGO web authentication

The benefits of having WebSphere Application Server use SPNEGO as the web authentication service for WebSphere Application Server include the following:

- The cost of administering a large number of ids and passwords is reduced.
- A secure and mutually authenticated transmission of security credentials from the web browser or Microsoft .NET clients is established.
- Interoperability with web services and Microsoft .NET, or web service applications that use SPNEGO authentication at the transport level is achieved.
- With Kerberos authentication support, SPNEGO web authentication can provide an end-to-end SPNEGO to Kerberos solution and preserve the Kerberos credential from the client.

## SPNEGO web authentication in a single Kerberos realm

SPNEGO web authentication is supported in a single Kerberos realm. The challenge-response handshake process is shown in the following figure:

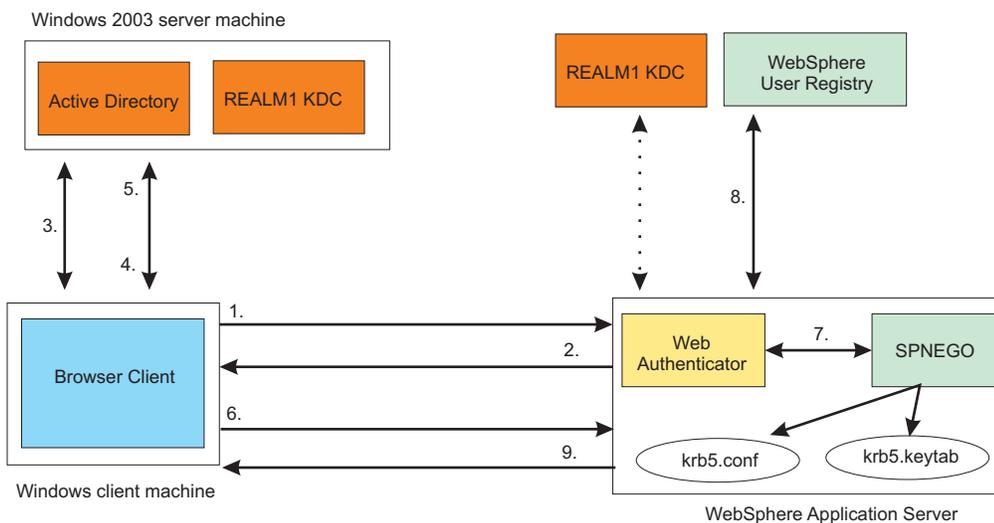

Figure 18. SPNEGO web authentication in a single Kerberos realm

In the figure above, the following events occur:

1. The client sends an HTTP/Post/Get/Web-Service request to WebSphere Application Server.
2. WebSphere Application Server returns HTTP 401 Authenticate/Negotiate.
3. The client obtains a Ticket Granting Ticket (TGT).

4. The client requests a Service Ticket (TGS\_REQ).
5. The client obtains a Service Ticket (TGS\_REP).
6. The client sends HTTP/Post/Get/Web-Service and an authorization SPNEGO token to WebSphere Application Server.
7. WebSphere Application Server validates the SPNEGO token. If the validation is successful, it retrieves the user ID and the GSS delegation credential from the SPNEGO token. Create a KRBAuthnToken with a client Kerberos credential.
8. WebSphere Application Server validates the user ID with the WebSphere user registry and creates an LTPA token.
9. WebSphere Application Server returns HTTP 200, content and the LTPA token to the client.

**Note:** Other clients (for example, web services, .NET and J2EE) that support SPNEGO do not have to follow the challenge-response handshake process as shown above. Those clients can obtain a ticket-granting ticket (TGT) and a Kerberos service ticket for the target server, create a SPNEGO token, insert it in the HTTP header, and then follow the normal process for creating an HTTP request.

### SPNEGO web authentication in a trusted Kerberos realm

SPNEGO web authentication is also supported in a trusted Kerberos realm. The challenge-response handshake process is shown in the following figure:

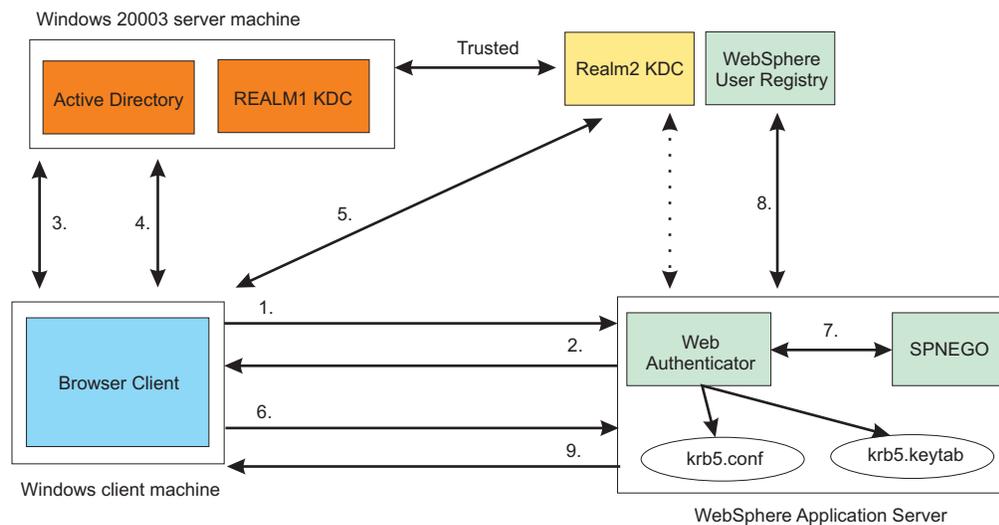

Figure 19. SPNEGO web authentication in a trusted Kerberos realm

In the figure above, the following events occur:

1. The client sends an HTTP/Post/Get/Web-Service request to WebSphere Application Server.
2. WebSphere Application Server returns HTTP 401 Authenticate/Negotiate
3. The client obtains a Ticket Granting Ticket (TGT).
4. The client requests a cross realm ticket (TGS\_REQ) for REALM2 from the REALM1 KDC.
5. The client uses the cross-realm ticket from step 4 to request a Service Ticket from the REALM2 KDC.
6. The client sends HTTP/Post/Get/Web-Service and an authorization SPNEGO token to WebSphere Application Server.

7. WebSphere Application Server validates the SPNEGO token. If the validation is successful, it retrieves the user ID and the GSS delegation credential from the SPNEGO token. Create a KRBAuthnToken with a client Kerberos credential.
8. WebSphere Application Server validates the user ID with the WebSphere user registry and creates an LTPA token.
9. WebSphere Application Server returns HTTP 200, content and the LTPA token to the client.

In the trusted Kerberos realms environment, be aware of the following:

- The Kerberos trusted realm setup must be done on each of the Kerberos KDCs. See your Kerberos Administrator and User's guide for more information about how to set up Kerberos trusted realms.
- The Kerberos client principal name from the SPNEGO token might not exist in the WebSphere user registry; the Kerberos principal mapping to the WebSphere user registry might require it.

### **Support information for SPNEGO web authentication with a Java client using the HTTP protocol**

The following scenarios are supported:

- Domain trust within the same forest
- External domain trust directly between domains within different forests.
- Kerberos realm trust

The following scenarios are not supported:

- Cross-forest trust
- Forest external trust

### **Support information for SPNEGO web authentication with a browser client**

The following scenarios are supported:

- Cross-forest trusts
- Domain trust within the same forest
- Kerberos realm trust

The following scenarios are not supported:

- Forest external trusts
- Domain external trusts

### **Setting up SPNEGO as the web authentication mechanism for WebSphere Application Server**

Before you set up SPNEGO web authentication in the administrative console or by using **wsadmin** commands, you must perform the steps as listed in “Creating a single sign-on for HTTP requests using SPNEGO Web authentication” to set up SPNEGO web authentication for WebSphere Application Server.

**Note:** SPNEGO web authentication on the server side must be done by the system administrator. The Kerberos keytab file must be protected.

### **Creating a single sign-on for HTTP requests using SPNEGO Web authentication**

Creating single sign-ons for HTTP requests using the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) web authentication for WebSphere Application Server requires the performance of several distinct, yet related functions that when completed, allow HTTP users to log in and authenticate to the Microsoft domain controller only once at their desktop and to receive automatic authentication from the WebSphere Application Server.

## Before you begin

### Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated in WebSphere Application Server Version 7.0. SPNEGO web authentication has taken its place to provide the following enhancements:

- You can configure and enable SPNEGO web authentication and filters on the WebSphere Application Server server side by using the administrative console.
- Dynamic reload of SPNEGO is provided without the need to stop and restart the WebSphere Application Server server.
- Fallback to an application login method is provided if the SPNEGO web authentication fails.

You can enable either SPNEGO TAI or SPNEGO Web Authentication but not both.

Read about “Single sign-on for HTTP requests using SPNEGO web authentication” on page 1610 for a better understanding of what SPNEGO Web Authentication is and how it is supported in this version of WebSphere Application Server.

Before starting this task, complete the following checklist:

- The domain member has users who can log on to the domain. Specifically, you need to have a functioning Microsoft Windows active directory domain that includes:
  - Domain controller
  - Client workstation
  - Users who can login to the client workstation
- A server platform with WebSphere Application Server running and application security enabled.
- Users on the active directory must be able to access WebSphere Application Server protected resources using a native WebSphere Application Server authentication mechanism.
- The domain controller and the host of WebSphere Application Server should have the same local time.
- Ensure the clock on clients, Microsoft Active Directory and WebSphere Application Server are synchronized to within five minutes.
- Be aware that client browsers must be SPNEGO enabled, which you perform on the client application machine (with details explained in procedure 4, "Configure the client application on the client application machine").

### About this task

The objective of this machine arrangement is to permit users to successfully access WebSphere Application Server resources without having to authenticate again and thus achieve Microsoft Windows desktop single sign-on capability.

Configuring the members of this environment to establish Microsoft Windows single sign-on involves specific activities that are performed on three distinct machines:

- A Microsoft Windows server running the Active Directory Domain Controller and associated Kerberos Key Distribution Center (KDC).
- A Microsoft Windows domain member (client application), such as a browser or Microsoft .NET client.
- A server platform with WebSphere Application Server running.

Continue with the following steps to create a single sign-on for HTTP requests using SPNEGO Web authentication:

## Procedure

1. Create a Kerberos service principal (SPN) and keytab file on your Microsoft domain controller machine  
You must configure your domain controller machine to create single sign-ons for HTTP requests using the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) web authentication for WebSphere® Application Server. Configure the Microsoft Windows Server running the Active Directory Domain Controller and associated Kerberos Key Distribution Center (KDC).  
Read the [Configuring your domain controller machine to create single sign-ons for HTTP requests using SPNEGO](#) article for more information.
2. Create a Kerberos configuration file  
The IBM implementation of the Java Generic Security Service (JGSS) and KRB5 require a Kerberos configuration file (**krb5.conf** or **krb5.ini**) on each node or Java virtual machine (JVM). In this release of WebSphere Application Server, this configuration file should be placed in the `config/cells/<cell_name>` directory so that all application servers can access this file. If you do not have a Kerberos configuration file, use a **wsadmin** command to create one.  
Read the [Creating a Kerberos configuration](#) article for more information.
3. Configure and enable SPNEGO web authentication using the administrative console on your WebSphere Application Server machine  
You can enable and configure the Simple and Protected GSS-API Negotiation (SPNEGO) as the web authenticator for the application server by using the administrative console on the WebSphere Application Server machine.  
Read the [Enabling and configuring SPNEGO web authentication using the administrative console](#) article for more information.
4. Configure the client application on the client application machine  
Client-side applications are responsible for generating the SPNEGO token. You begin this configuration process by configuring your web browser to use SPNEGO authentication.  
Read the [Configuring the client browser to use SPNEGO](#) article for more information.
5. Create SPNEGO tokens for J2EE, .NET, Java, web service clients for HTTP requests (optional)  
You can create a Simple and Protected GSS-API Negotiation (SPNEGO) token for your applications and insert this token into the HTTP headers to authenticate to the WebSphere Application Server.  
Read the [Creating SPNEGO tokens for J2EE, .NET, Java, web service clients for HTTP requests](#) article for more information.

## Creating a single sign-on for HTTP requests using the SPNEGO TAI (deprecated)

Creating single sign-ons for HTTP requests using the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server requires the performance of several distinct, yet related functions that when completed, allow HTTP users to log in and authenticate only once at their desktop and receive automatic authentication from the WebSphere Application Server.

## Before you begin

### Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Before starting this task, complete the following checklist:

- The domain member has users who can log on to the domain. Specifically, you need to have a functioning Microsoft Windows active directory domain that includes:
  - Domain controller
  - Client workstation
  - Users who can login to the client workstation

- A server platform with WebSphere Application Server running and application security enabled.
- Users on the active directory must be able to access WebSphere Application Server protected resources using a native WebSphere Application Server authentication mechanism.
- The domain controller and the host of WebSphere Application Server should have the same local time.
- Ensure the clock on clients, Microsoft Active Directory and WebSphere Application Server are synchronized to within five minutes.
- Be aware that client browsers have to be SPNEGO enabled, which you perform on the client application machine (with details explained in step 2 of this task).

## About this task

The objective of this machine arrangement is to permit users to successfully access WebSphere Application Server resources without having to reauthenticate and thus achieve Microsoft Windows desktop single sign-on capability.

Configuring the members of this environment to establish Microsoft Windows single sign-on involves specific activities that are performed on three distinct machines:

- Microsoft Windows Server running the Active Directory Domain Controller and associated Kerberos Key Distribution Center (KDC)
- A Microsoft Windows domain member (client application), such as a browser or Microsoft .NET client.
- A server platform with WebSphere Application Server running.

Perform the following steps on the indicated machines to create single sign-on for HTTP requests using SPNEGO

## Procedure

1. **Domain Controller Machine** - Configure the Microsoft Windows Server running the Active Directory Domain Controller and associated Kerberos Key Distribution Center (KDC) This configuration activity has the following steps:
  - Create a user account for the WebSphere Application Server in a Microsoft Active Directory. This account will be eventually mapped to the Kerberos service principal name (SPN).
  - On the Microsoft Active Directory machine where the Kerberos key distribution center (KDC) is active, map the user account to the Kerberos service principal name (SPN). This user account represents the WebSphere Application Server as being a Kerberize'd service with the KDC. Use the **setspn** command to map the Kerberos service principal name to a Microsoft user account. The topic, "Creating a Kerberos service principal and keytab file that is used by the WebSphere Application Server SPNEGO TAI (deprecated)" on page 1621 has more details about using the **setspn** command.
  - Create the Kerberos keytab file and make it available to WebSphere Application Server. Use the **ktpass** tool to create the Kerberos keytab file (krb5.keytab). The topic, "Creating a Kerberos service principal and keytab file that is used by the WebSphere Application Server SPNEGO TAI (deprecated)" on page 1621 has more details about using the **ktpass** command. to create the keytab file.

**Note:** You make the keytab file available to WebSphere Application Server by copying the krb5.keytab file from the Domain Controller (LDAP machine) to the WebSphere Application Server machine. See "Using the ktab command to manage the Kerberos keytab file" on page 1625 for more details.

**Important:** Your domain controller operations must lead to the following results:

- A user account is created in the Microsoft Active Directory and mapped to a Kerberos service principal name.

- A Kerberos keytab file (krb5.keytab) is created and made available to the WebSphere Application Server. The Kerberos keytab file contains the Kerberos service principal keys WebSphere Application Server uses to authenticate the user in the Microsoft Active Directory and the Kerberos account.
2. **Client Application Machine** - Configure the client application. Client-side applications are responsible for generating the SPNEGO token for use by the SPNEGO TAI. You begin this configuration process by configuring your web browser to use SPNEGO authentication. See “Configuring the client browser to use SPNEGO TAI (deprecated)” on page 1640 for the detailed steps required for your browser.
  3. **WebSphere Application Server Machine** - Configure and enable the Application Server and the associated SPNEGO TAI by performing the following tasks:
    - Ensure that LTPA is enabled. See Configuring the Lightweight Third Party Authentication mechanism for more details.
    - Enable the SPNEGO TAI. See “Configuring WebSphere Application Server and enabling the SPNEGO TAI (deprecated)” on page 1626 for more details.
    - Create SPNEGO TAI properties using either the wsadmin command task or the administrative console.
      - For using the wsadmin command task, see
        - SpnegoTAICommands group for the AdminTask object (deprecated)
      - For using the administrative console, see “Configuring WebSphere Application Server and enabling the SPNEGO TAI (deprecated)” on page 1626 for more details.
    - Configure JVM properties and enable the SPNEGO TAI in Application Server in which it is defined. See “Configuring JVM custom properties, filtering HTTP requests, and enabling SPNEGO TAI in WebSphere Application Server (deprecated)” on page 1641 or “Enabling the SPNEGO TAI as JVM custom property using scripting (deprecated)” on page 1642 for more details.
    - Install the Kerberos keytab file (created in step 1) on the WebSphere Application Server machine. “Creating a Kerberos service principal and keytab file that is used by the WebSphere Application Server SPNEGO TAI (deprecated)” on page 1621 provides the details.
    - Create a basic Kerberos configuration file (krb5.ini or krb5.conf). See The Kerberos configuration file for details.
    - Map the client Kerberos principal name to the WebSphere user registry ID, but only if the WebSphere Application Server does not use Microsoft Active Directory. See “Mapping Kerberos client principal name to WebSphere user registry ID for SPNEGO TAI (deprecated)” on page 1646 for more details.
  4. Optional: **Using a remote HTTP server** - To use a remote server, you must complete the following steps, which assume that you have already configured the JVM properties and enabled the SPNEGO TAI in the Application Server in which it is defined (as described in the previous three steps).
    - a. Complete the steps in “Creating a Kerberos service principal and keytab file that is used by the WebSphere Application Server SPNEGO TAI (deprecated)” on page 1621 for the remote proxy server.
    - b. Merge the previous keytab file created in step 1 with the keytab file created in step 4a. See “Using the ktab command to manage the Kerberos keytab file” on page 1625 for more information.
    - c. Create the SPN for the remote proxy server using the addSpnegoTAIProperties wsadmin command task. For more information, see SpnegoTAICommands group for the AdminTask object (deprecated).
    - d. Restart the WebSphere Application Server.

***Single sign-on for HTTP requests using SPNEGO TAI (deprecated):***

WebSphere Application Server provides a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources in WebSphere Application Server.

**Note:**

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Read about “Creating a single sign-on for HTTP requests using SPNEGO Web authentication” on page 1614 for more information.

SPNEGO is a standard specification defined in The Simple and Protected GSS-API Negotiation Mechanism (IETF RFC 2478).

When WebSphere Application Server administrative security is enabled, the SPNEGO TAI is initialized. While processing inbound HTTP requests, the web authenticator component interacts with the SPNEGO TAI, which is defined and enabled in the security configuration repository. One interceptor is selected and is responsible for authenticating access to the secured resource that is identified in the HTTP request.

**Important:** The use of TAIs is an optional feature. If no TAI is selected, the authentication process continues normally.

HTTP users log in and authenticate only once at their desktop and are subsequently authenticated (internally) with WebSphere Application Server. The SPNEGO TAI is invisible to the end-user of WebSphere applications. The SPNEGO TAI is only visible to the web administrator who is responsible for ensuring a proper configuration, capacity, and maintenance of the web environment.

In addition to WebSphere Application Server security runtime services, some external components are required to completely enable operation of the SPNEGO TAI. The external components include:

- A client application, for example, a browser or Microsoft .NET client, that supports the SPNEGO authentication mechanism, as defined in IETF RFC 2478. Microsoft Internet Explorer Version 5.5 or later and Mozilla Firefox Version 1.0 are browser examples. Any browser needs to be configured to use the SPNEGO mechanism. For more information on performing this configuration, see “Configuring the client browser to use SPNEGO TAI (deprecated)” on page 1640.

The authentication of HTTP requests is triggered by the requestor (the client-side), which generates a SPNEGO token. WebSphere Application Server receives this token and validates trust between the requestor and WebSphere Application Server. Specifically, the SPNEGO TAI decodes and retrieves the requestor's identity from the SPNEGO token. The identity is used to establish a secure context between the requestor and the application server.

**Remember:** The SPNEGO TAI is a server-side solution in WebSphere Application Server. Client-side applications are responsible for generating the SPNEGO token for use by the SPNEGO TAI. The requestor's identity in WebSphere Application Server security registry must be identical to that identity the SPNEGO TAI retrieves. An identical match does occur when Microsoft Windows Active Directory server is the Lightweight Directory Access Protocol (LDAP) server that is used in WebSphere Application Server. A custom login module is available as a plug-in to support custom mapping of the identity from the Active Directory to the WebSphere Application Server security registry. See “Mapping Kerberos client principal name to WebSphere user registry ID for SPNEGO TAI (deprecated)” on page 1646 for details on using this custom login module.

WebSphere Application Server validates the identity against its security registry and, if the validation is successful, produces a Lightweight Third Party Authentication (LTPA) security token and places and returns a cookie to the requestor in the HTTP response. Subsequent HTTP requests from this same

requester to access additional secured resources in WebSphere Application Server use the LTPA security token previously created, to avoid repeated login challenges.

The challenge-response handshake process is illustrated in the following graphic:

*Figure 20. HTTP request processing, WebSphere Application Server - SPNEGO TAI*

The SPNEGO TAI can be enabled for all or for selected WebSphere Application Servers in a WebSphere Application Server cell configuration. Also, the behavior of each SPNEGO TAI instance is controlled by custom configuration properties that are used to identify, for example, the criteria used to filter HTTP requests, such as the host name and security realm name used to construct the Kerberos Service Principal Name (SPN). For more information regarding establishing and setting the SPNEGO TAI custom configuration properties, see the following topics:

- Setting up the Kerberos configuration properties. See The Kerberos configuration file.
- Setting or adjusting the SPNEGO TAI custom properties. See “SPNEGO TAI custom properties configuration (deprecated)” on page 1636.
- Adjusting the SPNEGO TAI filter settings. See “Configuring JVM custom properties, filtering HTTP requests, and enabling SPNEGO TAI in WebSphere Application Server (deprecated)” on page 1641
- Using the custom login module to map the identity from the Active Directory to the WebSphere Application Server registry. See Mapping user Ids from client to server for SPNEGO.
- Setting the major and additional Java virtual machine (JVM) custom properties. See “SPNEGO TAI JVM configuration custom properties (deprecated)” on page 1644

The web administrator has access to the following SPNEGO TAI security components and associated configuration data, as illustrated in the following graphic.

*Figure 21. SPNEGO TAI security and configuration elements*

- The web authentication module and the Lightweight Third Party Authentication (LTPA) mechanism provide the plug-in runtime framework for trust association interceptors. See Configuring the Lightweight Third Party Authentication mechanism for more detail is configuring the LTPA mechanism for use with the SPNEGO TAI.
- The Java Generic Security Service (JGSS) provider is included in the Java SDK (`jre/lib/ibmjgssprovider.jar`) and used to obtain the Kerberos security context and credentials that are used for authentication. IBM JGSS 1.0 is a Java Generic Security Service Application Programming Interface (GSSAPI) framework with Kerberos V5 as the underlying default security mechanism. GSSAPI is a standardized abstract interface under which can be plugged different security mechanisms based on private-key, public-key and other security technologies. GSSAPI shields secure applications from the complexities and peculiarities of the different underlying security mechanisms. GSSAPI provides identity and message origin authentication, message integrity, and message confidentiality. For more information, see JGSS.
- The Kerberos configuration properties (`krb5.conf` or `krb5.ini`) and Kerberos encryption keys (stored in a Kerberos keytab file) are used to establish secure mutual authentication.

The Kerberos key table manager (Ktab), which is part of JGSS, allows you to manage the principal names and service keys stored in a local Kerberos keytab file. Principal name and key pairs listed in the Kerberos keytab file allow services running on a host to authenticate themselves to the Kerberos Key Distribution Center (KDC). Before a server can use Kerberos, a Kerberos keytab file must be initialized on the host that runs the server.

“Using the ktab command to manage the Kerberos keytab file” on page 1625 highlights the Kerberos configuration requirements for the SPNEGO TAI as well as the use of Ktab.

- The SPNEGO provider supplies the implementation of the SPNEGO authentication mechanism, located at `/$WAS_HOME/java/jre/lib/ext/ibmspnego.jar`.
- The custom configuration properties control the runtime behavior of the SPNEGO TAI. Configuration operations are performed with the administrative console or scripting facilities. Refer to “SPNEGO TAI custom properties configuration (deprecated)” on page 1636 for more information about these custom configuration properties.
- Java virtual machine (JVM) custom properties control diagnostic trace information for problem determination of the JGSS security provider and use of the property reload feature. “SPNEGO TAI JVM configuration custom properties (deprecated)” on page 1644 describes these JVM custom properties

The benefits of having WebSphere Application Server use the SPNEGO TAI include:

- The cost of administering a large number of ids and passwords is reduced.
- A secure and mutually authenticated transmission of security credentials from the web browser or Microsoft .NET clients is established.
- Interoperability with web services and Microsoft .NET applications that use SPNEGO authentication at the transport level is achieved.

Using the SPNEGO TAI in your WebSphere Application Server environment requires planning then implementation. See “Single sign-on capability with SPNEGO TAI - checklist (deprecated)” on page 1651 in planning for SPNEGO TAI. Implementing the use of the SPNEGO TAI is divided into the following areas of responsibility:

#### **End browser user**

The end user must configure the web browser or Microsoft .NET application to issue HTTP requests that are processed by the SPNEGO TAI.

#### **Web administrator**

The web administrator is responsible for configuring the SPNEGO TAI of WebSphere Application Server to respond to HTTP requests of the client.

#### **WebSphere Application Server administrator**

The WebSphere Application Server administrator is responsible for configuring WebSphere Application Server and the SPNEGO TAI for optimum installation performance.

See “Creating a single sign-on for HTTP requests using the SPNEGO TAI (deprecated)” on page 1616 for an explanation of the tasks required to use the SPNEGO TAI and how the responsible party performs these tasks.

#### ***Creating a Kerberos service principal and keytab file that is used by the WebSphere Application Server SPNEGO TAI (deprecated):***

You perform this configuration task on the Microsoft Active Directory domain controller machine. This task is a necessary part of preparing to process single sign on browser requests to WebSphere Application Server and the SPNEGO trust association interceptor (TAI).

#### **Before you begin**

You need to have a running domain controller and at least one client machine in that domain.

#### **Note:**

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application

Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

## About this task

**This task is performed on the active directory domain controller machine.** Complete the following steps to ensure that the Microsoft Windows Server that is running the active directory domain controller is configured properly to the associated key distribution center (KDC). For information on the supported Microsoft Windows Servers, see the System Requirements for WebSphere Application Server Version 8.0 on Windows.

## Procedure

1. Create a user account in the Microsoft Active Directory for the WebSphere Application Server.

Click **Start->Programs->Administrative Tools->Active Directory Users and Computers**

Use the name for the WebSphere Application Server. For example, if the Application Server you are running on the WebSphere Application Server machine is called myappserver.austin.ibm.com, create a new user in Active Directory called myappserver.

**Important:** Do not select "User must change password at next logon."

**Important:** Make sure that you do not have the computer name myappserver under Computers and Domain Controllers (You check for this condition as illustrated below.). If you already have a computer name myappserver, then you need to create a different user account name.

- Goto **Start -> Programs -> Administrative Tools -> Active Directory Users and Computers->Computers**
- Goto **Start -> Programs -> Administrative Tools -> Active Directory Users and Computers->Domain Controllers**

2. Use the **setspn** command to map the Kerberos service principal name, HTTP/<host name>, to a Microsoft user account. An example of **setspn** usage is as follows:

```
C:\Program Files\Support Tools>
setspn -A HTTP/myappserver.austin.ibm.com myappserver
```

**Note:** There may already be some SPNs related to the Microsoft Windows hosts that have been added to the domain. You can display those that exist by using the **setspn -L** command, but you still have to add an HTTP SPN for WebSphere Application Server. For example, **setspn -L myappserver** would list the SPNs.

**Important:** Make sure that you do not have the same SPNs mapping to more than one Microsoft user account. If you map the same SPN to more than one user account, the web browser client can send a NTLM instead of SPNEGO token to WebSphere Application Server.

More information about the **setspn** command can be found here, Windows 2003 Technical Reference (setspn command)

3. Create the Kerberos keytab file and make it available to WebSphere Application Server. Use the **ktpass** command to create the Kerberos keytab file (krb5.keytab).

Use the **ktpass** tool from the Windows Server toolkit to create the Kerberos keytab file for the service principal name (SPN). Use the latest version of the **ktpass** tool that matches the Windows server level that you are using. For example, use the Windows 2003 version of the tool for a Windows 2003 server.

To determine the appropriate parameter values for the **ktpass** tool, run the **ktpass -?** command from the command line. This command lists whether the **ktpass** tool, which corresponds to the particular operating system, uses the **-crypto RC4-HMAC** or **-crypto RC4-HMAC-NT** parameter value. To avoid warning messages from the toolkit, you must specify the **-ptype KRB5\_NT\_PRINCIPAL** parameter value.

The Windows 2003 server version of the **ktpass** tool supports the encryption type, RC4-HMAC, and Single data encryption standard (DES). For more information about the **ktpass** tool, see Windows 2003 Technical Reference (Kerberos keytab file and ktpass command).

The following code shows the functions that are available when you enter **ktpass -?** command on the command line. This information might be different depending on the version of the toolkit that you are using.

```
C:\Program Files\Support Tools>ktpass -?
Command line options:

-----most useful args
[- /] out : Keytab to produce
[- /] princ : Principal name (user@REALM)
[- /] pass : password to use
 use "*" to prompt for password.
[- +] rndPass : ... or use +rndPass to generate a random password
[- /] minPass : minimum length for random password (def:15)
[- /] maxPass : maximum length for random password (def:256)
-----less useful stuff
[- /] mapuser : map princ (above) to this user account (default:
don't)
[- /] mapOp : how to set the mapping attribute (default: add it)
[- /] mapOp : is one of:
[- /] mapOp : add : add value (default)
[- /] mapOp : set : set value
[- +] DesOnly : Set account for des-only encryption (default:don't)
[- /] in : Keytab to read/digest
-----options for key generation
[- /] crypto : Cryptosystem to use
[- /] crypto : is one of:
[- /] crypto : DES-CBC-CRC : for compatibility
[- /] crypto : DES-CBC-MD5 : for compatibiliity
[- /] crypto : RC4-HMAC-NT : default 128-bit encryption
[- /] ptype : principal type in question
[- /] ptype : is one of:
[- /] ptype : KRB5_NT_PRINCIPAL : The general ptype-- recommended
[- /] ptype : KRB5_NT_SRV_INST : user service instance
[- /] ptype : KRB5_NT_SRV_HST : host service instance
[- /] kvno : Override Key Version Number
 Default: query DC for kvno. Use /kvno 1 for Win2K
compat.
[- +] Answer : +Answer answers YES to prompts. -Answer answers
NO.
[- /] Target : Which DC to use. Default:detect
-----options for trust attributes (Windows Server 2003
Sp1 Only
[- /] MitRealmName : MIT Realm which we want to enable RC4 trust on.
[- /] TrustEncryp : Trust Encryption to use; DES is default
[- /] TrustEncryp : is one of:
[- /] TrustEncryp : RC4 : RC4 Realm Trusts (default)
[- /] TrustEncryp : DES : go back to DES
```

**Important:** Do not use the **-pass** switch on the **ktpass** command to reset a password for a Microsoft Windows server account.

See Windows 2003 Technical Reference (Kerberos keytab file and ktpass command) for more information. You must use the **-mapUser** option with **ktpass** command to enable the KDC to create an encryption key. Otherwise, when the SPENGO token is received, it fails the validation process and the application server challenges the user for a user name and password.

Depending on the encryption type, you use the **ktpass** tool in one of the following ways to create the Kerberos keytab file. The following section shows the different types of encryption that are used by the **ktpass** tool. It is important that you run the **ktpass -?** command to determine which **-crypto** parameter value is expected by the particular toolkit in your Microsoft Windows environment.

- For a single DES encryption type

From a command prompt, run the **ktpass** command:

```
ktpass -out c:\temp\myappserver.keytab
-princ HTTP/myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
-mapUser myappserv
```

```

-mapOp set
-pass was1edu
-crypto DES-CBC-MD5
-pType KRB5_NT_PRINCIPAL
+DesOnly

```

Table 97. Using *ktpass* for a single DES encryption type.

This table describes how to use *ktpass* for a single DES encryption type.

| Option                                                      | Explanation                                                                                                         |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| -out c:\temp\myappserver.keytab                             | The key is written to this output file.                                                                             |
| -princ HTTP/myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM | The concatenation of the user logon name, and the realm must be in uppercase.                                       |
| -mapUser                                                    | The key is mapped to the user, myappserver.                                                                         |
| -mapOp                                                      | This option sets the mapping.                                                                                       |
| -pass was1edu                                               | This option is the password for the user ID.                                                                        |
| -crypto DES-CBC-MD5                                         | This option uses the single DES encryption type.                                                                    |
| -pType KRB5_NT_PRINCIPAL                                    | This option specifies the KRB5_NT_PRINCIPAL principal value. Specify this option to avoid toolkit warning messages. |
| +DesOnly                                                    | This option generates only DES encryptions.                                                                         |

- For the RC4-HMAC encryption type

**Important:** RC4-HMAC encryption is only supported when using a Windows 2003 Server as KDC. From a command prompt, run the **ktpass** command.

```

ktpass -out c:\temp\myappserver.keytab
-princ HTTP/myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
-mapUser myappserver
-mapOp set
-pass was1edu
-crypto RC4-HMAC
-pType KRB5_NT_PRINCIPAL

```

Table 98. Using *ktpass* for the RC4-HMAC encryption type.

This table identifies and describes the *ktpass* options for RC4-HMAC encryption

| Option                                                      | Explanation                                                                                                         |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| -out c:\temp\myappserver.keytab                             | The key is written to this output file.                                                                             |
| -princ HTTP/myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM | The concatenation of the user logon name, and the realm must be in uppercase.                                       |
| -mapUser                                                    | The key is mapped to the user, myappserver.                                                                         |
| -mapOp                                                      | This option sets the mapping.                                                                                       |
| -pass was1edu                                               | This option is the password for the user ID.                                                                        |
| -crypto RC4-HMAC                                            | This option chooses the RC4-HMAC encryption type.                                                                   |
| -pType KRB5_NT_PRINCIPAL                                    | This option specifies the KRB5_NT_PRINCIPAL principal value. Specify this option to avoid toolkit warning messages. |

- For the RC4-HMAC-NT encryption type

From a command prompt, run the **ktpass** command.

```

ktpass -out c:\temp\myappserver.keytab
-princ HTTP/myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
-mapUser myappserver
-mapOp set
-pass was1edu
-crypto RC4-HMAC-NT
-pType KRB5_NT_PRINCIPAL

```

Table 99. Using *ktpass* for the RC4-HMAC encryption type. This table describes the use of *ktpass* for RC4-HMAC encryption types.

| Option                          | Explanation                             |
|---------------------------------|-----------------------------------------|
| -out c:\temp\myappserver.keytab | The key is written to this output file. |

Table 99. Using ktpass for the RC4-HMAC encryption type (continued). This table describes the use of ktpass for RC4-HMAC encryption types.

| Option                                                          | Explanation                                                                                                         |
|-----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| -princ HTTP/<br>myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM | The concatenation of the user logon name, and the realm must be in uppercase.                                       |
| -mapUser                                                        | The key is mapped to the user, myappserver.                                                                         |
| -mapOp                                                          | This option sets the mapping.                                                                                       |
| -pass wasledu                                                   | This option is the password for the user ID.                                                                        |
| -crypto RC4-HMAC-NT                                             | This option chooses the RC4-HMAC-NT encryption type.                                                                |
| -pType KRB5_NT_PRINCIPAL                                        | This option specifies the KRB5_NT_PRINCIPAL principal value. Specify this option to avoid toolkit warning messages. |

The Kerberos keytab file is created for use with the SPNEGO TAI.

**Note:** A Kerberos keytab configuration file contains a list of keys that are analogous to user passwords. It is important for hosts to protect their Kerberos keytab files by storing them on the local disk, which makes them readable only by authorized users.

You make the keytab file available to WebSphere Application Server by copying the krb5.keytab file from the Domain Controller (LDAP machine) to the WebSphere Application Server machine.

```
ftp> bin
ftp> put c:\temp\KRB5_NT_SEV_HST\krb5.keytab
```

## Results

Your active directory domain controller is properly configured to process single sign on requests to WebSphere Application Server and the SPNEGO TAI

*Using the ktab command to manage the Kerberos keytab file:*

The Kerberos key table manager command (Ktab) allows the product administrator to manage the Kerberos service principal names and keys stored in a local Kerberos keytab file. With the IBM Software Development Kit (SDK) or Sun Java Development Kit (JDK) 1.6 or later, you can use the ktab command to merge two Kerberos keytab files.

Kerberos service principal (SPN) name and keys listed in the Kerberos keytab file allow services running on the host to validate the incoming Kerberos or SPNEGO token request. Before configuring Kerberos or SPNEGO web authentication, the WebSphere Application Server administrator must setup a Kerberos keytab file on the host that is running WebSphere Application Server.

## Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server Version 7.0, this function is now deprecated.

SPNEGO web authentication has taken its place to provide the following enhancements:

- Configure and enable SPNEGO Web Authentication and filters on the WebSphere Application Server side by using the administrative console.
- Provide dynamic reload of SPNEGO without having to stop and restart the WebSphere Application Server.
- Provide fallback to an application login method if the SPNEGO web authentication fails.

## Important:

- It is important to protect the keytab files and make them readable only by authorized product users.
- Any updates to the Kerberos keytab file using Ktab do not affect the Kerberos database. If you change the keys in the Kerberos keytab file, you must also make the corresponding changes to the Kerberos database.

The syntax of Ktab is illustrated below by using Ktab with the `-help` operand.

```
$ ktab -help
```

```
Usage: java com.ibm.security.krb5.internal.tools.Ktab [options]
```

```
Available options:
```

```
-l list the keytab name and entries
-a <principal_name> [password] add an entry to the keytab
-d <principal_name> delete an entry from the keytab
-k <keytab_name> specify keytab name and path with FILE: prefix
-m <source_keytab_name> <destination_keytab_name> specify merging source keytab file name and destination keytab file name
```

Below is an example of how Ktab is used to merge the `krb5Host1.keytab` file to the `krb5.keytab` file:

```
[root@wssecjibe bin]# ./ktab -m /etc/krb5Host1.keytab /etc/krb5.keytab
Merging keytab files: source=krb5Host1.keytab destination=krb5.keytab
Done!
[root@wssecjibe bin]# ls /etc/krb5.*
/etc/krb5Host1.keytab/etc/krb5.keytab
/etc/krb5.keytab
```

Below is an example of how Ktab is used on a LINUX platform to add new principal names to the Kerberos keytab file, where `ot56prod` is the password for the Kerberos principal name:

```
[root@wssecjibe bin]# ./ktab -a
HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM ot56prod -k /etc/krb5.keytab
Done!
Service key for principal HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM saved
```

Below is an example of how Ktab is used on a Linux platform to list Kerberos keytab file content.

```
[root@wssecjibe bin]# ./ktab

 KVNO Principal
 ---- -
 1 HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM

[root@wssecjibe bin]# ls /etc/krb5.*
/etc/krb5.conf
/etc/krb5.keytab
```

**Tip:** You can run the `ktab` command from the `install_root/java/J5.0/bin` or `install_root/java64/J5.0_64/bin` directory.

### **Configuring WebSphere Application Server and enabling the SPNEGO TAI (deprecated):**

Performing this task helps you, as web administrator, to ensure that WebSphere Application Server is properly configured to enable the operation of the Simple and Protected GSS-API Negotiation (SPNEGO) trust association interceptor (TAI).

#### **Before you begin**

You need to know how to use the WebSphere Application Server administrative console to manage the security configuration and have the proper authority to modify the security configuration of the application server.

#### **Note:**

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

### About this task

Complete the following steps to enable the operation of the SPNEGO TAI.

### Procedure

1. Log on to the WebSphere Application Server administrative console.
2. Click **Security > Global security**.
3. Expand **Web security** and click **Trust association**.
4. Under the General Properties heading, select the **Enable trust association** check box, then click **Interceptors**.
5. Select the SPNEGO TAI in the list of interceptors.
6. Then click **Custom properties**.
7. Click **New** and then fill in the **Name** and **Value** fields. Click **OK**. Repeat this step for each custom property that you want to apply to the SPNEGO TAI. See “SPNEGO TAI custom properties configuration (deprecated)” on page 1636 for a complete list of SPNEGO TAI custom properties.

**Note:** It is recommended that you use the **wsadmin** utility to manage the SPNEGO TAI properties. You can add, modify, and delete SPNEGO TAI properties as well as display them using **wsadmin**. See “Adding SPNEGO TAI properties using the **wsadmin** utility (deprecated)” on page 1629 to add, “Modifying SPNEGO TAI properties using the **wsadmin** utility (deprecated)” on page 1631 to modify, and “Deleting SPNEGO TAI properties using the **wsadmin** utility (deprecated)” on page 1633 to delete SPNEGO TAI properties.

8. After you finish defining your custom properties, click **Save** to store the updated SPNEGO TAI configuration.
9. Optional: If an alias for a connecting host name is added dynamically after the application server is started, you need to configure the alias. Refer to the “Using an alias host name for SPNEGO TAI or SPENGO web authentication using the administrative console (deprecated)” topic.

### Results

Your SPNEGO TAI configuration is now configured for WebSphere Application Server.

*Using an alias host name for SPNEGO TAI or SPENGO web authentication using the administrative console (deprecated):*

When you use the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for authentication, and you would like to use alias host name as the host name for the application server, you must configure a custom property to resolve the alias host name to the actual hostname for SPNEGO single sign-on. Then, you can dynamically add or modify an alias name in the DNS without changing the application server’s configuration. If you enable this custom property you will no longer need to set alias host names through the SPNEGO configuration.

### Before you begin

You must have completed the steps as described in “Creating a single sign-on for HTTP requests using the SPNEGO TAI (deprecated)” on page 1616 and “Configuring WebSphere Application Server and enabling the SPNEGO TAI (deprecated)” on page 1626 before these settings will have an effect. This

configuration requires a working SPNEGO-TAI single sign-on environment.

## About this task

The application server will perform a DNS lookup as an HTTP request comes in, and if the alias host name is resolved as a host name that is already configured for SPNEGO single sign-on, the application server will continue to process it. It is usually not required to add alias hostname to a SPNEGO account.

## Procedure

1. Define the actual host name for the `com.ibm.ws.security.spnego.SPNx.hostName` variable.
  - a. From administration console, click **Global security > Web and SIP security > Trust association > Interceptors > com.ibm.ws.security.spnego.TrustAssociationInterceptorImpl > Custom Properties**
  - b. Add or modify the `com.ibm.ws.security.spnego.SPNx.hostName` variable. For example:

**Name** `com.ibm.ws.security.spnego.SPNx.hostName`

**Value** `real_host_name`

This custom property specifies the actual host name to which the application server can resolve an alias host name for SPNEGO single sign-on. You can then dynamically add or modify an alias name in the DNS without changing the configuration for the application server.

You can optionally define the alias host name, but you are only required to define the real host name. The application server resolves the alias host name to real host name as the HTTP request is received.

2. Turn on the Canonical support flag.
  - a. From administration console, click **Global security > Custom properties**
  - b. Add or modify the `com.ibm.websphere.security.krb.canonical_host` variable and set it to "true".

**Name** `com.ibm.websphere.security.krb.canonical_host`

**Value** `true`

This custom property specifies whether the application server uses the canonical form of the URL/HTTP host name in authenticating a client. If you set this custom property to `false`, a Kerberos ticket can contain a host name that differs from the HTTP host name header and the application server might issue the following message:

CWSPN0011E: An invalid SPNEGO token has been encountered while authenticating a HttpServletRequest

If you set this custom property to `true`, you can avoid this error message and allow the application server to authenticate using the canonical form of the URL/HTTP host name.

3. Configure the browser. On the browser for the client machine, the alias host name needs to be configured as a trusted host.
  - For Internet Explorer:
    - a. Select **Tools > Internet options**.
    - b. Select the Security tab.
    - c. Click **Local intranet > Sites > Advanced**
    - d. Add the alias host name in this panel.
  - For Mozilla Firefox:
    - a. Type **About:config** in the address bar and press ENTER to access configuration options.
    - b. Locate the **network.negotiate-auth.trusted-uris** preference name, right-click on the preference, and select **Modify**. If you do not have this preference, right-click within the panel, and select **New > string**.
    - c. Add alias host names in the text box, separating host names with a comma.
4. Ensure that the real host name is added to the keytab file.

**config:** You can configure the keytab file in two ways:

- If `com.ibm.websphere.security.krb.canonical_host` is set to "true", the application server expects the real host name to be in the keytab files. Aliases are not necessary.
- If `com.ibm.websphere.security.krb.canonical_host` is set to false and aliases are defined, aliases need to be present in the keytab file.

*Adding SPNEGO TAI properties using the wsadmin utility (deprecated):*

You use the `wsadmin` utility to add properties for the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) in the security configuration for WebSphere Application Server.

### About this task

#### Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Verify that end-user desktop browsers are configured to support SPNEGO authentication, that the SPNEGO TAI is enabled, that the Java virtual machine (JVM) property is set and, that WebSphere Application Server is configured to enable the operation of the SPNEGO TAI.

Use the `wsadmin` utility to configure the SPNEGO TAI for WebSphere Application Server:

#### Procedure

1. Start WebSphere Application Server.
2. Start the command-line utility by running the **wsadmin** command from the `app_server_root/bin` directory.
3. At the **wsadmin** prompt, enter the following command:  
`$AdminTask addSpnegoTAIProperties`

You can use the following parameters with this command:

| Option                      | Description                                                                                                                                                                                                       |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;spnId&gt;</code>  | This parameter is optional. It is the SPN identifier for the group of custom properties that are to be defined with this command. If you do not specify this parameter, an unused SPN identifier is assigned.     |
| <code>&lt;host&gt;</code>   | This parameter is required. It specifies the host name portion in the SPN used by the SPNEGO TAI to establish a Kerberos secure context.                                                                          |
| <code>&lt;filter&gt;</code> | This parameter is optional. It defines the filtering criteria used by the class specified with the above attribute. If you do not specify this parameter, all HTTP requests are subject to SPNEGO authentication. |

| Option          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <filterClass>   | This parameter is optional. It specifies the name of the Java class used by the SPNEGO TAI to select which HTTP requests will be subject to SPNEGO authentication. If you do not specify this parameter, the default filter class, com.ibm.ws.security.spnego.HTTPHeaderFilter, is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <noSpnegoPage>  | <p>This parameter is optional. It specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application if it does not support SPNEGO authentication.</p> <p>If you do not specify the noSpnegoPage parameter then the default is used:</p> <pre data-bbox="800 617 1182 772">&lt;html&gt;&lt;head&gt;&lt;title&gt;SPNEGO authentication is not supported.&lt;/title&gt;&lt;/head&gt;" + "&lt;body&gt;SPNEGO authentication is not supported on this client.&lt;/body&gt;&lt;/html&gt;";</pre>                                                                                                                                                                                                                                |
| <ntlmTokenPage> | <p>This parameter is optional. It specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response that is to be displayed by the (browser) client application when the SPNEGO token received by the interceptor (after the challenge-response handshake) contains a NT LAN manager (NTLM) token instead of the expected SPNEGO token.</p> <p>If you do not specify the ntlmTokenPage parameter then the default is used:</p> <pre data-bbox="800 1083 1243 1289">&lt;html&gt;&lt;head&gt;&lt;title&gt;An NTLM Token was received.&lt;/title&gt;&lt;/head&gt;" + "&lt;body&gt;Your browser configuration is correct, but you have not logged into a supported Windows Domain." + "&lt;p&gt;Please login to the application using the normal login page.&lt;/html&gt;";</pre> |
| <trimUserName>  | This parameter is optional. It specifies whether or not the SPNEGO TAI is to remove the suffix of the principal user name, starting from the "@" that precedes the Kerberos realm name. If this parameter is set to true, the suffix of the principal user name is removed. If this parameter is set to false, the suffix of the principal name is retained. The default value used is true.                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Results

SPNEGO TAI properties have been added for this WebSphere Application Server.

## Example

### Example 1

The following example configures the SPNEGO TAI to intercept HTTP requests that contain IE 6 in the user agent request header. The SPNEGO TAI uses the SPN of HTTP/myhost.ibm.com@<default\_realm> to authenticate the request originator.

```
$AdminTask addSpnegoTAIProperties -host myhost.ibm.com -filter user-agent%=IE 6
```

## Example 2

The following is an example of adding SPNEGOTAIProperties for SPN1 to use the default filterClass and to intercept all requests for the host, central01.austin.ibm.com.

```
wsadmin>$AdminTask addSpnegoTAIProperties -interactive
Add SPNEGO TAI properties

Add SPNEGO TAI configuration properties.

*Host name in Service Principal Name (host): central01.austin.ibm.com
Service Principal Name identifier (spnId): 1
HTTP header filter rule (filter):
Name of class used to filter HTTP requests (filterClass):
SPNEGO not supported browser response (noSpnegoPage):
NTLM Token received browser response (ntlmTokenPage):
Trim User Name browser response (trimUserName):

Add SPNEGO TAI properties

F (Finish)
C (Cancel)

Select [F, C]: [F] f
WASX7278I: Generated command line: $AdminTask addSpnegoTAIProperties {-host central01.austin.ibm.com}
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
wsadmin>
```

### *Modifying SPNEGO TAI properties using the wsadmin utility (deprecated):*

You use the wsadmin utility to modify the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

### About this task

#### Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Verify that end-user desktop browsers are configured to support SPNEGO authentication, that the SPNEGO TAI is enabled, that the Java virtual machine (JVM) property is set and, that WebSphere Application Server is configured to enable the operation of the SPNEGO TAI.

You use the wsadmin utility to configure the SPNEGO TAI for WebSphere Application Server:

#### Procedure

1. Start WebSphere Application Server.
2. Start the command-line utility by running the **wsadmin** command from the `app_server_root/bin` directory.
3. At the **wsadmin** prompt, enter the following command:  
`$AdminTask modifySpnegoTAIProperties`

You can use the following parameters with this command:

| Option                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&lt;spnId&gt;</b>         | This parameter is required. It is the SPN identifier for the group of custom properties that are to be defined with this command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>&lt;host&gt;</b>          | This parameter is optional. It specifies the host name portion in the SPN used by the SPNEGO TAI to establish a Kerberos secure context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>&lt;filter&gt;</b>        | This parameter is optional. It defines the filtering criteria used by the class specified with the above attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>&lt;filterClass&gt;</b>   | This parameter is optional. It specifies the name of the Java class used by the SPNEGO TAI to select which HTTP requests will be subject to SPNEGO authentication. If no class is specified, all HTTP requests will be subject to SPNEGO authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>&lt;noSpnegoPage&gt;</b>  | <p>This parameter is optional. It specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application if it does not support SPNEGO authentication.</p> <p>If you do not specify the noSpnegoPage attribute then the default is used:</p> <pre>"&lt;html&gt;&lt;head&gt;&lt;title&gt;SPNEGO authentication is not supported. &lt;/title&gt;&lt;/head&gt;" + "&lt;body&gt;SPNEGO authentication is not supported on this client. &lt;/body&gt;&lt;/html&gt;";</pre>                                                                                                                                                                                                                                                                                      |
| <b>&lt;ntlmTokenPage&gt;</b> | <p>This parameter is optional. The ntlmTokenPage parameter specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response, which will be displayed by the (browser) client application. The (browser) client application displays this HTTP response when the browser client sends a NT LAN manager (NTLM) token instead of the expected SPNEGO token during the challenge-response handshake.</p> <p>If you do not specify the ntlmTokenPage attribute then the default is used:</p> <pre>"&lt;html&gt;&lt;head&gt;&lt;title&gt;An NTLM Token was received.&lt;/title&gt;&lt;/head&gt;" + "&lt;body&gt;Your browser configuration is correct, but you have not logged into a supported Windows Domain." + "&lt;p&gt;Please login to the application using the normal login page.&lt;/html&gt;";</pre> |
| <b>&lt;trimUserName&gt;</b>  | This parameter is optional. It specifies whether (true) or not (false) the SPNEGO TAI is to remove the suffix of the principal user name, starting from the "@" that precedes the Kerberos realm name. If this attribute is set to true, the suffix of the principal user name is removed. If this attribute is set to false, the suffix of the principal name is retained. The default value used is true.                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Results

SPNEGO TAI properties are modified for this WebSphere Application Server.

### Example

#### Example 1

The following example configures the SPNEGO TAI to intercept HTTP requests that contain IE 6 in the user agent request header. The SPNEGO TAI uses the SPN of HTTP/myhost.ibm.com@<default\_realm> to authenticate the request originator. Then the example modifies the value of the filter custom property that was defined and changes it from user-agent%=IE 6 to host==myhost.company.com.

```
$AdminTask addSpnegoTAIProperties -host myhost.ibm.com -filter user-agent%=IE 6
$AdminTask modifySpnegoTAIProperties -spnId 1 -filter host==myhost.company.com
```

#### Example 2

This is an example of modifying the SPNEGO TAI for SPN1 properties to add a filter for host central01.austin.ibm.com.

```
wsadmin>$AdminTask modifySpnegoTAIProperties -interactive
Modify SPNEGO TAI properties
```

Modify SPNEGO TAI configuration properties

```
*Service Principal Name identifier (spnId): 1
Host name in Service Principal Name (host): central01.austin.ibm.com
HTTP header filter rule (filter): request-url!=noSPNEGO;request-url%=snoop
Name of class used to filter HTTP requests (filterClass):
SPNEGO not supported browser response (noSpnegoPage):
NTLM Token received browser response (ntlmTokenPage):
Trim User Name browser response (trimUserName):
```

Modify SPNEGO TAI properties

```
F (Finish)
C (Cancel)
```

```
Select [F, C]: [F] f
WASX7278I: Generated command line: $AdminTask modifySpnegoTAIProperties {-spnId
1 -host w2003secdev.austin.ibm.com -filter request-url!=noSPNEGO;request-url%=sn
oop}
com.ibm.ws.security.spnego.SPN1.filter=request-url!=noSPNEGO;request-url%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
wsadmin>
```

*Deleting SPNEGO TAI properties using the wsadmin utility (deprecated):*

You use the wsadmin utility to delete properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

### About this task

#### Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Verify that end-user desktop browsers are configured to support SPNEGO authentication, that the SPNEGO TAI is enabled, that the Java virtual machine (JVM) property is set and, that WebSphere Application Server is configured to enable the operation of the SPNEGO TAI.

You use the `wsadmin` utility to configure the SPNEGO TAI for WebSphere Application Server:

### Procedure

1. Start WebSphere Application Server.
2. Start the command-line utility by running the `wsadmin` command from the `app_server_root/bin` directory.
3. At the `wsadmin` prompt, enter the following command:  
`$AdminTask deleteSpnegoTAIProperties`

You can use the following parameters with this command:

| Option  | Description                                                                                                                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <spnId> | This is an optional parameter. It is the SPN identifier for the group of custom properties that are to be deleted with this command. If you do not specify this parameter, all SPNEGO TAI custom properties are deleted. |

### Results

SPNEGO TAI properties are deleted for this WebSphere Application Server.

### Example

#### Example 1

The following example deletes all the SPNEGO TAI properties for SPN2

```
wsadmin>$AdminTask deleteSpnegoTAIProperties {-spnId 2}
```

#### Example 2

The following example deletes all SPNEGO TAI properties

```
wsadmin>$AdminTask deleteSpnegoTAIProperties
com.ibm.ws.security.spnego.SPN1.filter=request-ur!!=noSPNEGO;request-ur!%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
com.ibm.ws.security.spnego.SPN2.hostName=wssecpd.austin.ibm.com
wsadmin>
```

*Displaying SPNEGO TAI properties using the wsadmin utility (deprecated):*

You use the `wsadmin` utility to display the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

### About this task

#### Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Verify that end-user desktop browsers are configured to support SPNEGO authentication, that the SPNEGO TAI is enabled, that the Java virtual machine (JVM) property is set and, that WebSphere Application Server is configured to enable the operation of the SPNEGO TAI.

You use the `wsadmin` utility to configure the SPNEGO TAI for WebSphere Application Server:

### Procedure

1. Start WebSphere Application Server.
2. Start the command-line utility by running the `wsadmin` command from the `app_server_root/bin` directory.
3. At the `wsadmin` prompt, enter the following command:  
`$AdminTask showSpnegoTAIProperties`

You can use the following parameters with this command:

| Option                     | Description                                                                                                                                                                                                                                           |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;spnId&gt;</code> | This is an optional parameter. It is the service principal name (SPN) identifier for the group of custom properties that are to be displayed with this command. If you do not specify this parameter, all SPNEGO TAI custom properties are displayed. |

### Results

SPNEGO TAI properties are displayed for this WebSphere Application Server.

### Example

#### Example 1

The following example displays all SPNEGO TAI properties.

```
wsadmin>$AdminTask showSpnegoTAIProperties
com.ibm.ws.security.spnego.SPN1.filter=request-url!=noSPNEGO;request-url%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
com.ibm.ws.security.spnego.SPN2.hostName=wssecpd.austin.ibm.com
wsadmin>
```

#### Example 2

The following example displays SPNEGO TAI properties for SPN1 and host, central01.austin.ibm.com.

```
wsadmin>$AdminTask showSpnegoTAIProperties -interactive
Show SPNEGO TAI configuration properties.
```

Display SPNEGO TAI configuration properties.

Service Principal Name identifier (spnId): 1

Show SPNEGO TAI configuration properties.

F (Finish)  
C (Cancel)

Select [F, C]: [F]

WASX7278I: Generated command line: `$AdminTask showSpnegoTAIProperties {-spnId 1}`

```
com.ibm.ws.security.spnego.SPN1.filter=request-url!=noSPNEGO;request-url%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
com.ibm.ws.security.spnego.SPN1.trimUserName=true
wsadmin>
```

### *SPNEGO TAI custom properties configuration (deprecated):*

The Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) custom configuration properties control different operational aspects of the SPNEGO TAI. You can specify different property values for each application server.

#### **Note:**

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Each of the properties defined in the following table is specified in the Custom Properties panel for the SPNEGO TAI using the administrative console facility. For convenience, you can optionally place these properties in a properties file. In this case, the SPNEGO TAI loads the configuration properties from the file instead of the Custom Properties panel definition. Refer to `com.ibm.ws.security.spnego.propertyReloadFile` property as defined in “SPNEGO TAI JVM configuration custom properties (deprecated)” on page 1644.

To assign unique property names that identify each possible SPN, an `SPN<id>` is embedded in the property name and used to group the properties that are associated with each SPN. The `SPN<id>`s are numbered sequentially for each property group.

*Table 100. SPNEGO TAI custom properties.*

*This table lists the SPNEGO TAI custom properties.*

| Property Name                                                                             | Required | Default Value                     |
|-------------------------------------------------------------------------------------------|----------|-----------------------------------|
| <code>com.ibm.ws.security.spnego.SPN&lt;id&gt;.enableCredDelegate</code>                  | No       | false                             |
| <code>com.ibm.ws.security.spnego.SPN&lt;id&gt;.filter</code> on page 1637                 | No       | See the description that follows. |
| <code>com.ibm.ws.security.spnego.SPN&lt;id&gt;.filterClass</code> on page 1638            | No       | See the description that follows. |
| <code>com.ibm.ws.security.spnego.SPN&lt;id&gt;.hostName</code> on page 1638               | Yes      | None                              |
| <code>com.ibm.ws.security.spnego.SPN&lt;id&gt;.NTLMTokenReceivedPage</code> on page 1638  | No       | See the description that follows. |
| <code>com.ibm.ws.security.spnego.SPN&lt;id&gt;.spnegoNotSupportedPage</code> on page 1639 | No       | See the description that follows. |
| <code>com.ibm.ws.security.spnego.SPN&lt;id&gt;.trimUserName</code> on page 1639           | No       | true                              |

**Note:** The following commands tasks can be used to operate on these SPNEGO TAI properties:

- “Adding SPNEGO TAI properties using the `wsadmin` utility (deprecated)” on page 1629
- “Deleting SPNEGO TAI properties using the `wsadmin` utility (deprecated)” on page 1633
- “Modifying SPNEGO TAI properties using the `wsadmin` utility (deprecated)” on page 1631
- “Displaying SPNEGO TAI properties using the `wsadmin` utility (deprecated)” on page 1634

#### *`com.ibm.ws.security.spnego.SPN<id>.enableCredDelegate:`*

This property is optional. It indicates whether or not the Kerberos delegated credentials are stored by the SPNEGO TAI. This property enables the capability for an application to retrieve the stored credentials and propagate them to other applications downstream for additional SPNEGO authentication.

This property requires use of the advanced Kerberos credential delegation feature and requires development of custom logic by the application developer. The developer must interact directly with the Kerberos Ticket Granting Service (TGS) to obtain a Ticket Granting Ticket (TGT) using the delegated Kerberos credentials on behalf of the end-user who originated the request. The developer must also construct the appropriate Kerberos SPNEGO token and include it in the HTTP request to continue the downstream SPNEGO authentication process, including handling additional SPNEGO challenge-response exchange, if necessary.

*com.ibm.ws.security.spnego.SPN<id>.filter:*

This property is optional. It defines the filtering criteria that is used by the specified class with the `com.ibm.ws.security.spnego.SPN<id>.filterClass` property. It defines arbitrary criteria that is meaningful to the implementation class used.

The `com.ibm.ws.security.spnego.HTTPHeaderFilter` default implementation class uses this property to define a list of selection rules that represent conditions that are matched against the HTTP request headers to determine whether or not the HTTP request is selected for SPNEGO authentication.

Each condition is specified with a key-value pair, separated from each other by a semicolon. The conditions are evaluated from left to right, as they display in the specified property. If all conditions are met, the HTTP request is selected for SPNEGO authentication.

The key and value in the key-value pair are separated by an operator that defines which condition is checked. The key identifies an HTTP request header to extract from the request and its value is compared with the value that is specified in the key-value pair according to the operator specification. If the header that is identified by the key is not present in the HTTP request, the condition is treated as not being met.

Any of the standard HTTP request headers can be used as the key in the key-value pairs. Refer to the HTTP specification for the list of valid headers. In addition, two keys are defined to extract information from the request, also useful as a selection criterion, which is not available through standard HTTP request headers. The `remote-address` key is used as a pseudo header to retrieve the remote TCP/IP address of the client application that sent the HTTP request. The `request-URL` key is used as a pseudo header to retrieve the URL that is used by the client application to make the request. The interceptor uses the result of the `getRequestURL` operation in the `javax.servlet.http.HttpServletRequest` interface to construct the web address. If a query string is present, the result of the `getQueryString` operation in the same interface is also used. In this case, the complete URL is constructed as follows:

```
String url = request.getRequestURL() + '?' + request.getQueryString();
```

The following operators and conditions are defined:

*Table 101. Filter conditions and operations.*

*This table defines the conditions and operators used in filtering and gives examples.*

| Condition                  | Operator                                                       | Example                  |
|----------------------------|----------------------------------------------------------------|--------------------------|
| Match exactly              | = =<br>Arguments are compared as equal.                        | host=host.my.company.com |
| Match partially (includes) | %=<br>Arguments are compared with a partial match being valid. | user-agent%=IE 6         |

Table 101. Filter conditions and operations (continued).

This table defines the conditions and operators used in filtering and gives examples.

| Condition                              | Operator                                                                                           | Example                              |
|----------------------------------------|----------------------------------------------------------------------------------------------------|--------------------------------------|
| Match partially (includes one of many) | ^=<br>Arguments are compared with a partial match being valid for one of many arguments specified. | request-url^=webApp1 webApp2 webApp3 |
| Does not match                         | !=<br>Arguments are compared as not equal.                                                         | request-url!=noSPNEGO                |
| Greater than                           | ><br>Arguments are compared lexogaphically as greater than.                                        | remote-address>192.168.255.130       |
| Less than                              | <<br>Arguments are compared lexographically as less than.                                          | remote-address<192.168.255.135       |

*com.ibm.ws.security.spnego.SPN<id>.filterClass:*

This property is optional. It specifies the name of the Java class that is used by the SPNEGO TAI to select which HTTP requests are subject to SPNEGO authentication.

If no class is specified, the default `com.ibm.ws.security.spnego.HTTPHeaderFilter` implementation class is used. The Java class that is specified must implement the `com.ibm.wsspi.security.spnego.SpnegoFilter` interface. A default implementation of this interface is provided. Specify the `com.ibm.ws.security.spnego.HTTPHeaderFilter` class to use the default implementation. This class uses the selection rules specified with the `com.ibm.ws.security.spnego.SPN<id>.filter` property.

*com.ibm.ws.security.spnego.SPN<id>.hostName:*

This property is required. It specifies the hostname in the SPN used by the SPNEGO TAI to establish a Kerberos secure context. It has no default value.

**Note:** The hostname is the long form of hostname. For example, `myHostName.austin.ibm.com`. The Kerberos SPN is a string of the form `HTTP/hostname@realm`. The complete SPN is used with the Java Generic Security Service (JGSS) by the SPNEGO provider to obtain the security credential and security context that are used in the authentication process.

*com.ibm.ws.security.spnego.SPN<id>.NTLMTokenReceivedPage:*

This property is optional. It specifies the web address of a resource that contains the content that the SPNEGO TAI includes in the HTTP response that the (browser) client application displays when the SPNEGO token is received by the interceptor when the challenge-response handshake contains a NT LAN Manager (NTLM) token instead of the expected SPNEGO token.

It can specify a web (`http://`) or a file (`file://`) resource. If this property is not specified or the interceptor cannot find the specified resource, the following content is used:

```
<html><head><title>An NTLM Token was received.</title></head>
<body>Your browser configuration is correct, but you have not logged into a supported
Microsoft(R) Windows(R) Domain.
<p>Please login to the application using the normal login page.</html>
```

*com.ibm.ws.security.spnego.SPN<id>.spnegoNotSupportedPage:*

This property is optional. It specifies the web address of a resource that contains the content that the SPNEGO TAI includes in the HTTP response that the (browser) client application displays if it does not support SPNEGO authentication. It can specify a Web (http://) or a file (file://) resource.

If this property is not specified or the interceptor cannot find the specified resource, the following content is used:

```
<html><head><title>SPNEGO authentication is not supported</title></head>
<body>SPNEGO authentication is not supported on this client</body></html>;
```

*com.ibm.ws.security.spnego.SPN<id>.trimUserName:*

This property is optional. It specifies whether (true) or not (false) the SPNEGO TAI is to remove the suffix of the principal user name, starting from the "@" that precedes the Kerberos realm name.

If this property is set to true, the suffix of the principal user name is removed. If this property is set to false, the suffix of the principal name is retained. The default value used is true. For example,

When *com.ibm.ws.security.spnego.SPN<id>.trimUserName = true*

`bobsmith@myKerberosRealm` becomes `bobsmith`

When *com.ibm.ws.security.spnego.SPN<id>.trimUserName = false*

`bobsmith@myKerberosRealm` remains `bobsmith@myKerberosRealm`

*SPNEGO TAI configuration requirements (deprecated):*

The configuration that is used by the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) on each selected application server is governed by various system requirements.

**Note:**

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, the SPNEGO TAI was deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

The following list of configuration requirements highlights those attributes, properties, qualities, restrictions, exclusions, inclusions, and dependencies that you need to be aware of when planning a WebSphere Application Server configuration that incorporates the use of the SPNEGO TAI.

*Table 102. SPNEGO TAI requirements.*

*This table lists the SPNEGO TAI configuration requirements.*

Function item	Description
SPNEGO TAI	The SPNEGO TAI is a server side solution in WebSphere Application Server. Client-side applications are responsible for generating the SPNEGO token for use by the SPNEGO TAI.
Microsoft Windows	Microsoft Windows Servers with Active Directory domain and its associated Kerberos key distribution center (KDC) is required. For information on the supported Microsoft Windows Servers, see the System Requirements for WebSphere Application Server Version 8.0 on Windows.

Table 102. SPNEGO TAI requirements (continued).

This table lists the SPNEGO TAI configuration requirements.

Function item	Description
Client application (browser or .NET client)	A browser (client application) or .NET client that supports the SPNEGO authentication mechanism, as defined in IETF RFC 2478 is required.
Simple and Protected GSS-API Negotiation Mechanism (SPNEGO)	SPNEGO authentication, as defined in IETF RFC 2478 is used.
Internet browsers	<ul style="list-style-type: none"> <li>• Use Microsoft Internet Explorer version 5.5 or higher</li> <li>• Use Mozilla Firefox version 1.0</li> </ul>
Kerberos Level	Kerberos version 5 is required.
WebSphere Application Server	Version 7.0 is required.
Java SDK level	Java 6.0 SDK is required.
Encryption Types	RC4-HMAC encryption is only supported when using a Windows 2003 Server as Kerberos key distribution center (KDC).
J2EE client	Client application (browser or .NET client) A browser (client application) or .NET client that supports the SPNEGO authentication mechanism, as defined in IETF RFC 2478 is required.

### **Configuring the client browser to use SPNEGO TAI (deprecated):**

You can configure your browser to utilize the Simple and Protected GSS-API Negotiation (SPNEGO) mechanism. Authentication of your browser requests are processed by the SPNEGO trust association interceptor (TAI) in the WebSphere Application Server.

### **Before you begin**

You need to know how to display and set options in the Microsoft Internet Explorer browser or any other browser (such as Firefox). You must have a browser installed that supports SPNEGO authentication.

### **Note:**

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

### **About this task**

Complete the following steps to ensure that your Microsoft Internet Explorer browser is enabled to perform SPNEGO authentication.

### **Procedure**

1. At the desktop, log in to the windows active directory domain.
2. Activate Internet Explorer.
3. In the Internet Explorer window, click **Tools > Internet Options > Security** tab.
4. Select the **Local intranet** icon and click **Sites**.
5. In the Local intranet window, ensure that the "check box" to include all local (intranet) not listed in other zones is selected, then click **Advanced**.

6. In the **Local intranet** window, fill in the Add this web site to the zone field with the web address of the host name so that the single sign-on (SSO) can be enabled for the list of websites shown in the websites field. Your site information technology staff provides this information. Click **OK** to complete this step and close the Local intranet window.
7. On the **Internet Options** window, click the **Advanced** tab and scroll to **Security settings**. Ensure that the **Enable Integrated Windows Authentication (requires restart)** box is selected.
8. Click **OK**. Restart your Microsoft Internet Explorer to activate this configuration.

## Results

Complete the following steps to ensure that your Firefox browser is enabled to perform SPNEGO authentication.

1. At the desktop, log in to the windows active directory domain.
2. Activate Firefox.
3. At the address field, type **about:config**.
4. In the Filter, type **network.n**
5. Double click on **network.negotiate-auth.trusted-uris**. This preference lists the sites that are permitted to engage in SPNEGO Authentication with the browser. Enter a comma-delimited list of trusted domains or URLs.

**Note:** You must set the value for **network.negotiate-auth.trusted-uris**.

6. If the deployed SPNEGO solution is using the advanced Kerberos feature of Credential Delegation double click on **network.negotiate-auth.delegation-uris**. This preference lists the sites for which the browser may delegate user authorization to the server. Enter a comma-delimited list of trusted domains or URLs.
7. Click **OK**. The configuration appears as updated.
8. Restart your Firefox browser to activate this configuration.

Your Internet browser is properly configured for SPNEGO authentication. You can use applications that are deployed in WebSphere Application Server that use secured resources without being repeatedly requested for an ID and password.

### ***Configuring JVM custom properties, filtering HTTP requests, and enabling SPNEGO TAI in WebSphere Application Server (deprecated):***

Performing this task helps you, as web administrator, to ensure that WebSphere Application Server is configured to enable the operation of the Simple and Protected GSS-API Negotiation mechanism (SPNEGO) trust association interceptor (TAI) with the required Java virtual machine (JVM) property and with the appropriate filtering of HTTP requests.

### **Before you begin**

You need to know how to use the WebSphere Application Server administrative console to manage the security configuration and have the proper authority to modify the security configuration of the application server.

### **Note:**

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

## About this task

Verify the configuration of your SPNEGO TAI. The deployment of the SPNEGO TAI can vary from a single WebSphere Application Server system on which a single application is running to a large multinode WebSphere Application Server, Network Deployment (ND) cell, with dozens of application servers, hosting many applications. Every SPNEGO TAI is installed at the cell level. You must be aware of your particular SPNEGO TAI configuration.

The default behavior of the SPNEGO TAI is to not intercept HTTP requests. This default behavior ensures that the SPNEGO TAI can be installed into an existing cell, configured for a single application server and not change any other application servers in the cell. Other WebSphere Application Servers can run exactly as before within a given configuration.

Decide whether or not to use the sample `SPN<id>.filterClass` and determine the exact filter properties to use.

**Note:** The default behavior of the SPNEGO TAI is to use the `com.ibm.ws.security.spnego.SPN<id>.filterClass` and intercept all requests.

If the default behavior is not appropriate, you can use a customer provided class, or extend or modify the sample class as required. The system programmer interface, `com.ibm.ws.security.spnego.SpnegoFilter` allows you to implement a custom filter to determine whether or not to intercept a particular HTTP request. With the default implementation, you can set filter rules for coarse as well as fine-grained criteria in selecting which HTTP requests to intercept.

**Note:** For an alternative to the steps below for enabling the SPNEGO TAI, you can use scripting to perform the operation. See “Enabling the SPNEGO TAI as JVM custom property using scripting (deprecated)” for the details.

Complete the following steps to enable the operation of the SPNEGO TAI with your selected filtering and with the JVM required property.

### Procedure

1. Log on to WebSphere Application Server administrative console.
2. Click **Servers > Application servers**.
3. Select the appropriate server. Under Server Infrastructure, expand **Java and process management > Process Definition**. Select **Servant**.
4. Click **Java virtual machine**. Under Additional Properties, click **Custom Properties**. Create a new custom property, if required, by clicking **New**, then code `com.ibm.ws.security.spnego.isEnabled` in the name field and `true` in the value field.
5. Click **Apply > OK** to save the configuration
6. Repeat step 3, but Select **Control**. Then repeat steps 4 and 5.
7. Identify when the SPNEGO TAI intercepts a given request. A set of filter properties is provided, but you must determine what is appropriate and modify the `com.ibm.ws.security.spnego.SPN<id>.filterClass` accordingly.

### Results

The application server is configured and ready to provide a single sign-on environment for end users who have successfully authenticated in a Microsoft Active Directory domain. You must restart each application server that is configured for SPNEGO web authentication. Then your SPNEGO TAI is set to filter HTTP request when it is operating.

*Enabling the SPNEGO TAI as JVM custom property using scripting (deprecated):*

You use the wsadmin utility to enable the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

## Before you begin

Before starting this task, the wsadmin tool must be running. See the information about starting the wsadmin scripting client using wsadmin scripting.

### Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

## About this task

Perform the following steps to enable the SPNEGO TAI:

### Procedure

1. Identify the server and assign it to the server1 variable:

- Using Jacl:

```
set server1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
```

- Using Jython:

```
server1 = AdminConfig.getid("/Cell:mycell/Node:mynode/Server:server1/")
print server1
```

Example output:

```
server1(cells/mycell/nodes/mynode|servers/seerver1|server.xml#Server_1)
```

2. Identify the Java virtual machine (JVM) belonging to this server and assign it to the jvm variable:

- Using Jacl:

```
set jvm [$AdminConfig list JavaVirtualMachine $server1]
```

- Using Jython:

```
jvm = AdminConfig.list('JavaVirtualMachine',server1)
```

Example output:

```
(cells/mycell/nodes/mynode/servers/server1:server.xml#JavaVirtualMachine_1)
(cells/mycell/nodes/mynode/servers/server1:server.xml#JavaVirtualMachine_2)
```

3. Identify the controller JVM of the server:

- Using Jacl:

```
set cjvm [lindex $jvm 0]
```

- Using Jython:

```
get line separator
import java
lineSeparator = java.lang.System.getProperty('line.separator')
arrayJVMs = jvm.split(lineSeparator)
cjvm = arrayJVMs[0]
```

4. Modify the generic JVM arguments to enable SPNEGO TAI:

- Using Jacl:

```
set attr_name [list name com.ibm.ws.security.spnego.isEnabled]
set attr_value [list value true]
set attr_required [list required false]
set attr_description [list description "Enabled SPNEGO TAI"]
```

```
set attrs [list $attr_name $attr_value $attr_required $attr_description]
```

```
$AdminConfig create Property $cjvm $attrs
```

- Using Jython:

```
attr_name = ['name', "com.ibm.ws.security.spnego.isEnabled"]
attr_value = ['value', "true"]
attr_required = ['required', "false"]
attr_description = ['description', "Enabled SPNEGO TAI"]
attr_list = [attr_name, attr_value, attr_required, attr_description]
property=['systemProperties',[attr_list]]
AdminConfig.modify(cjvm, [property])
```

5. Save the configuration changes.

6. In a network deployment environment only, synchronize the node.

*SPNEGO TAI JVM configuration custom properties (deprecated):*

Java virtual machine (JVM) custom properties control the operation of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI).

**Note:**

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

The following JVM custom properties control operation of the SPNEGO TAI. Different custom property values can be specified for each application server.

*Table 103. JVM configuration custom properties.*

*This table lists the SPNEGO JVM configuration custom properties.*

Custom Property Name	Required	Value Type	Default Value	Recommended Value
com.ibm.ws.security.spnego.isEnabled	No	Boolean	False	True
com.ibm.ws.security.spnego.propertyReloadFile	No	String	None	For Windows C:\temp\TAI.props  For UNIX /tmp/TestTAI.Properties
com.ibm.ws.security.spnego.propertyReloadTimeout	No	Integer	None	120

**com.ibm.ws.security.spnego.isEnabled**

Use this custom property to enable or disable operation of the SPNEGO TAI in a given application server. When set to false, the SPNEGO TAI is disabled and not used by the web authentication module for authenticating any web requests. When set to true, the SPNEGO TAI is enabled and used by the web authentication module for authenticating any web requests.

**com.ibm.ws.security.spnego.propertyReloadFile**

Use this custom property to identify the file that contains configuration properties for the SPNEGO TAI, when it is not convenient to stop and restart the application server. The properties contained in this file can be reloaded to configure the SPNEGO TAI.

**Important:** The properties that are defined in the specified file override any properties defined using the administrative console.

A sample of this reload file follows:

```

Template properties files for SPNEGO TAI

Where possible defaults have been provided.

#-----
Hostname
#-----
#com.ibm.ws.spnego.SPN1.HostName=wsecurity.austin.ibm.com

#-----
(Optional) SpnegoNotSupportedPage
#-----
#com.ibm.ws.spnego.SPN1.SpnegoNotSupportedPage=

#-----
(Optional) NTLMTokenReceivedPage
#-----
#com.ibm.ws.spnego.SPN1.NTLMTokenReceivedPage=

#-----
(Optional) FilterClass
#-----
#com.ibm.ws.spnego.SPN1.FilterClass=com.ibm.ws.spnego.HTTPHeaderFilter

#-----
(Optional) Filter
#-----
#com.ibm.ws.spnego.SPN1.Filter=
```

**Important:** If `com.ibm.ws.security.spnego.propertyReloadFile` custom property is set, but the `com.ibm.ws.security.spnego.propertyReloadTimeout` custom property is not, then the SPNEGO TAI is not initialized.

#### **com.ibm.ws.security.spnego.propertyReloadTimeout**

Use this custom property to specify a time interval in seconds that elapses after which the SPNEGO TAI reloads the configuration properties. Also, the SPNEGO TAI reloads the configuration properties if the file that is identified by the `com.ibm.ws.security.spnego.propertyReloadFile` custom property changed since the last time the configuration custom properties were retrieved. This time interval in seconds must be specified as a positive integer.

#### **Important:**

- If the `com.ibm.ws.security.spnego.propertyReloadFile` custom property and the `com.ibm.ws.security.spnego.propertyReloadTimeout` custom property are not set, then the SPNEGO TAI properties are only loaded once from the SPNEGO TAI custom properties defined in the WebSphere Application Server configuration data. This one time loading occurs when the JVM is initialized.
- If `com.ibm.ws.security.spnego.propertyReloadTimeout` custom property is set, but the `com.ibm.ws.security.spnego.propertyReloadFile` custom property is not, then the SPNEGO TAI is not initialized. “Configuring JVM custom properties, filtering HTTP requests, and enabling SPNEGO TAI in WebSphere Application Server (deprecated)” on page 1641 or how to configure the JVM custom properties for SPNEGO TAI.

**Remember:** You can also use the `wsadmin` command for the `AdminConfig` scripting object to interactively set the `com.ibm.ws.security.spnego.isEnabled` custom property. See “Enabling the SPNEGO TAI as JVM custom property using scripting (deprecated)” on page 1642 for more information.

The following custom properties are not used directly by the SPNEGO TAI; however, they affect the operation of the core security runtime and can also be used for problem determination.

Table 104. JVM configuration custom properties.

This table describes the JVM configuration custom properties

Custom Property Name	Required	Value Type	Default Value	Recommended Value
<code>com.ibm.security.jgss.debug</code>	No	String	None	"off" or "all"
<code>com.ibm.security.krb5.Krb5Debug</code>	No	String	None	"off" or "all"
<code>java.security.properties</code>	No	String	None	
<code>javax.security.auth.useSubjectCredsOnly</code>	Yes	Boolean	True	False

#### **`com.ibm.security.jgss.debug`**

This custom property is optional. It can be used to collect diagnostic trace information for problem determination in the Java Generic Security Service (JGSS) application programmer interface (API) implementation. The value can be set to `all` or `off` to enable or disable tracing, respectively. See Java Generic Security Service User's Guide for specific JGSS API information.

#### **`com.ibm.security.krb5.Krb5Debug`**

This custom property is optional. It can be used to collect additional diagnostic trace information for problem determination in the JGSS implementation. The value can be set to `all` or `off` to enable or disable tracing, respectively.

#### **`java.security.properties`**

This property is optional. It can be used when different application servers in a cell have different security requirements and it is not convenient to modify the global `java.security` file for the entire cell. In such situations, the `java.security.properties` custom property is used to specify the location of the `java.security` file used by the JVM for each application server.

#### **`javax.security.auth.useSubjectCredsOnly`**

JGSS includes an optional Java Authentication and Authorization Service (JAAS) login facility that saves `Principal` credentials and secret keys in the `Subject` of the application's JAAS login context. JGSS retrieves credentials and secret keys from the `Subject` by default. This feature can be disabled by setting the Java property `javax.security.auth.useSubjectCredsOnly` to `false`.

**Attention:** The SPNEGO TAI does not use the optional JAAS login module. The `javax.security.auth.useSubjectCredsOnly` property must be set to `false`.

### ***Mapping Kerberos client principal name to WebSphere user registry ID for SPNEGO TAI (deprecated):***

You can use a system programming interface to customize the behavior of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) by implementing arbitrary mappings of the end-user's identity, which is retrieved from Microsoft Active Directory to the identity that is used in the WebSphere Application Server security registry.

#### **Before you begin**

You need to perform some administrative tasks in the WebSphere Application Server environment to use SPNEGO TAI and to ensure that the requester's identity matches the identity in the WebSphere Application Server user registry.

**Note:**

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

**Note:** Make sure the following tasks have been performed successfully:

1. Configuring the web browser to use SPNEGO. See “Configuring the client browser to use SPNEGO TAI (deprecated)” on page 1640
2. Configuring Java virtual machine (JVM) properties, custom SPNEGO TAI properties, and enabling the SPNEGO TAI. See “Configuring JVM custom properties, filtering HTTP requests, and enabling SPNEGO TAI in WebSphere Application Server (deprecated)” on page 1641

**About this task**

In the simplest deployment of the SPNEGO TAI, it is assumed that the requester's identity in the WebSphere Application Server user registry is identical to the identity retrieved. This is the case when Microsoft Windows Active Directory server is the lightweight directory access protocol (LDAP) server used in WebSphere Application Server. This is default behavior of the SPNEGO TAI.

You do not need to use this simple deployment of the SPNEGO TAI. WebSphere Application Server can use a different registry, such as a local OS, LDAP, or custom registry instead of the Microsoft Active Directory. If WebSphere Application Server uses a different registry than the Microsoft Active Directory, then a mapping from the Microsoft Windows user Id to a WebSphere Application Server user Id is necessary.

**Procedure**

Use the JAAS custom login module to perform any custom mapping of a client Kerberos principal name from the Microsoft Active Directory to the WebSphere user registry identity. The JAAS custom login module is a plug-in mechanism that is defined for authenticating incoming and outgoing requests in WebSphere Application Server and is inserted before the `ltpaLoginModule`. The JAAS custom login module retrieves a client Kerberos principal name in the `javax.security.auth.Subject` using `subject.getPrincipals(KerberosPrincipal.class)` method, maps the client Kerberos principal name to the WebSphere user registry identity, and inserts the mapping identity in the hash table property `com.ibm.wsspi.security.cred.userId`. The `ltpaLoginModule` then uses the mapped identity to create a `WSCredential`.

**Note:** The custom login module can also supply the full set of security properties in the `javax.security.auth.Subject` in the `com.ibm.wsspi.security.tai.TAIResult` to fully assert the mapped identity. When the identity is fully asserted, the `wsMapDefaultInboundLoginModule` maps those security properties to a `WSCredential`.

A sample of the custom login module follows:

```
package com.ibm.ws.security.server.lm;

import java.util.Map;
import java.lang.reflect.Array;
import javax.security.auth.Subject;
import javax.security.auth.callback.*;
import javax.security.auth.login.LoginException;
import javax.security.auth.spi.LoginModule;
import javax.security.auth.kerberos.*;
import com.ibm.websphere.security.auth.WSLoginFailedException;
import com.ibm.wsspi.security.token.AttributeNameConstants;
```

```

/**

protected boolean debug = false;
}

```

## Results

Using the custom login module, Microsoft Active Directory identities are mapped to the WebSphere Application Server's security registry and the behavior of the SPNEGO TAI is customized.

### ***Single sign-on capability with SPNEGO TAI - checklist (deprecated):***

WebSphere Application Server provides a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources in WebSphere Application Server. To deploy and use the SPNEGO TAI you need to examine your installation and decide on how best to configure the SPNEGO TAI.

### **Note:**

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Lightweight Third Party Authentication (LTPA) is the default authentication mechanism for WebSphere Application Server. However, you may need to configure LTPA prior to configuring the SPNEGO TAI. LTPA is the required authentication mechanism for all trust association interceptors. You can configure LTPA by clicking **Security > Global security > Authentication mechanisms and expiration**.

**Note:** Enabling web security single sign-on (SSO) is optional when you configure the SPNEGO TAI. For more information, see "Implementing single sign-on to minimize web user authentications" on page 1607.

Answer the following questions to establish how the SPNEGO TAI is deployed.

#### 1. What is your criteria for intercepting HTTP requests?

You must decide if the SPNEGO TAI deployment will use the HTTPHeaderFilter class as the default. If you do use this class, then you must specify the exact filter properties for this class. The default behavior of the SPNEGO TAI is to use the com.ibm.ws.spnego.HTTPHeaderFilter class to intercept all requests.

If you do not use the sample com.ibm.ws.spnego.HTTPHeaderFilter class, then you must define a new class that implements the com.ibm.wsspi.security.spnego.SpnegoTAIFilter interface.

You can decide to further control what HTTP requests are intercepted using the Service Provider Programming Interface (SPI), “Filtering HTTP requests for SPNEGO TAI (deprecated)” on page 1653 See “SPNEGO TAI custom properties configuration (deprecated)” on page 1636 for descriptions of

- `com.ibm.ws.security.spnego.SPN<id>.filterClass`
- `com.ibm.ws.security.spnego.SPN<id>.filter`

2. Is user Id mapping to be used? If not, why not?

WebSphere Application Server enables you to define or develop a custom login module to map user IDs. See “Mapping Kerberos client principal name to WebSphere user registry ID for SPNEGO TAI (deprecated)” on page 1646 for more detail about performing this mapping.

You must decide, before deploying the TAI, whether or not to use this custom login module to perform the SPNEGO TAI identity mapping

3. What type of encryption is to be used to process the SPNEGO tokens?

Microsoft Windows Active Directory supports two different Kerberos encryption types: RC4-HMAC and DES-CBC-MD5. The IBM Java Generic Security Service (JGSS) library (and SPNEGO library) support both of these encryption types.

**Restriction:** RC4-HMAC encryption is only supported with a Windows 2003 Server key distribution center (KDC).

4. How will you handle credential delegation?

Kerberos supports the delegation of credentials. A server that receives Kerberos credentials from a client can impersonate that client to other servers by using delegated credentials. Since SPNEGO TAI tokens are a wrapping of a Kerberos credential, a server that receives Kerberos credentials within an SPNEGO token can use those Kerberos credentials to impersonate the original user. That server can interact using SPNEGO over HTTP as a SPNEGO client to other SPNEGO servers by composing an appropriate HTTP Authorization header.

5. Will the SPNEGO TAI be deployed in a single or multiple domain name service (DNS) domain environment?

Web browsers running on Windows are sensitive to DNS domains. They only send a SPNEGO token when the target host name identifies a host name defined in the DNS domain of the client machine. You can use HTTP redirection to support this configuration with the creation of a pseudo Kerberos service principal name (SPN) in each DNS domain. All SPNs that WebSphere Application Server supports must have their secret keys available in Kerberos keytab files. To enable single sign-on across multiple DNS domains, a separate Kerberos keytab file is generated for each SPN per domain. These individual Kerberos keytab files must be merged before they can be used by WebSphere Application Server.

6. How frequently will application servers reload the SPNEGO TAI properties?

The SPNEGO TAI has an optional property reload feature that allows the reloading of the TAI properties without restarting the Java virtual machine (JVM). This reload feature is controlled by the system properties `com.ibm.ws.security.spnego.propertyReloadFile` and `com.ibm.ws.security.spnego.propertyReloadTimeout`. These properties taken together enable the SPNEGO TAI internal properties to be reloaded from a file on the file system after a certain time period. If the `com.ibm.ws.security.spnego.propertyReloadTimeout` attribute is set to a valid integer value, and the `com.ibm.ws.security.spnego.propertyReloadFile` attribute points to a file on the file system, then each JVM reloads the SPNEGO TAI properties from the file after the timeout period expires. Also, the SPNEGO TAI properties are reloaded only if the date on the file has changed. If these reload properties are not set, then the SPNEGO TAI properties are only loaded once, at JVM initialization, from the SPNEGO TAI custom properties that are defined in WebSphere Application Server configuration data. See “SPNEGO TAI JVM configuration custom properties (deprecated)” on page 1644 for more information about these reload properties.

The Windows Active Directory (Web) administrator, the WebSphere Application Server administrator, and the application team review and answer these questions to determine the best deployment and configuration settings for the SPNEGO TAI.

### ***Filtering HTTP requests for SPNEGO TAI (deprecated):***

You can use a system programming interface to customize the behavior of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) by specifying whether or not a particular HTTP request should be intercepted.

### **Before you begin**

Before you begin, you need to understand the deployment of the SPNEGO TAI in your installation.

### **Note:**

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

### **About this task**

Verify the configuration of your SPNEGO TAI. The deployment of the SPNEGO TAI can vary from a single WebSphere Application Server system on which a single application is running to a large multinode WebSphere Application Server, Network Deployment (ND) cell, with dozens of application servers, hosting many applications. Every SPNEGO TAI is installed at the cell level. You must be aware of your particular SPNEGO TAI configuration.

The default behavior of the SPNEGO TAI is to not intercept HTTP requests. This default behavior ensures that the SPNEGO TAI can be installed into an existing cell, configured for a single application server and not change any other application servers in the cell. Other WebSphere Application Servers can run exactly as before within a given configuration.

Then decide whether or not to use the sample `SPN<id>.filter` class and determine the exact filter properties to use.

**Note:** The default behavior of the SPNEGO TAI is to use the `com.ibm.ws.security.spnego.SPN<id>.filter` class and intercept all requests.

If the default behavior is not appropriate, you can use a customer provided class, or extend or modify the sample class as required. The system programmer interface, `com.ibm.ws.security.spnego.SpnegoFilter` allows you to implement a custom filter to determine whether or not to intercept a particular HTTP request. With the default implementation, you can set filter rules for coarse as well as fine-grained criteria in selecting which HTTP requests to intercept.

### **Procedure**

1. Set the `com.ibm.ws.security.spnego.isEnabled` Java virtual machine (JVM) custom property to true to enable the SPNEGO TAI on any JVM.
2. Identify when the SPNEGO TAI intercepts a given request. A set of filter properties is provided, but you must determine what is appropriate and modify the `com.ibm.ws.security.spnego.SPN<id>.filter` class accordingly.

## Results

Your SPNEGO TAI is set to filter HTTP requests when it is operating.

## Configuring single sign-on capability with Tivoli Access Manager or WebSEAL

Use the following information to enable single sign-on to WebSphere Application Server using either WebSEAL or the plug-in for web servers.

### About this task

Either Tivoli Access Manager WebSEAL or Tivoli Access Manager plug-in for web servers can be used as reverse proxy servers to provide access management and single sign-on (SSO) capability to WebSphere Application Server resources. With such an architecture, either WebSEAL or the plug-in authenticates users and forwards the collected credentials to WebSphere Application Server in the form of an IV Header. Two types of single sign-on are available, the TAI interface and the TAI++ interface, so named as both use WebSphere Application Server trust association interceptors (TAI). With the TAI, the end-user name is extracted from the HTTP header and forwarded to embedded Tivoli Access Manager where the end-user name is used to construct the client credential information and authorize the user. With the TAI++, all of the user credential information is available in the HTTP header and not just the user name. The TAI++ is the more efficient of the two solutions because a Lightweight Directory Access Protocol (LDAP) call is not required. TAI functionality is retained for backwards compatibility.

Complete the following tasks to enable single sign-on to WebSphere Application Server using either WebSEAL or the plug-in for web servers. These tasks assume that embedded Tivoli Access Manager is configured for use.

### Procedure

1. Create a trusted user account for Tivoli Access Manager in the shared Lightweight Directory Access Protocol (LDAP) user registry. For more information, see “Creating a trusted user account in Tivoli Access Manager” on page 1660.
2. Configure either WebSEAL or the Tivoli Access Manager plug-in for Web servers to work with WebSphere Application Server. For more information, see either of the following articles:
  - “Configuring WebSEAL for use with WebSphere Application Server” on page 1661
  - “Configuring Tivoli Access Manager plug-in for web servers for use with WebSphere Application Server” on page 1662
3. Configure single sign-on using either the TAI or TAI++ interface. For more information, see either of the following articles:
  - “Configuring single sign-on using trust association” on page 1663
  - “Configuring single sign-on using trust association interceptor ++” on page 1663

### *Single sign-on settings:*

Use this page to set the configuration values for single sign-on (SSO).

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, click **Web and SIP security > Single sign-on (SSO)**.

**Note:** The Set security cookies as HTTPOnly to resist cross-site scripting attacks check box has been added to the Single sign-on settings page for this release. The HttpOnly attribute is a browser attribute created to prevent client side applications (such as Java scripts) from accessing cookies to prevent some cross-site scripting vulnerabilities. The attribute specifies that LTPA and WASReqURL cookies include the HTTPOnly field.

*Enabled:*

Specifies that the single sign-on function is enabled.

Web applications that use J2EE FormLogin style login pages, such as the administrative console, require single sign-on (SSO) enablement. Only disable SSO for certain advanced configurations where LTPA SSO-type cookies are not required.

<b>Data type:</b>	Boolean
<b>Default:</b>	Enabled
<b>Range:</b>	Enabled or Disabled

*Requires SSL:*

Specifies that the single sign-on function is enabled only when requests are made over HTTPS Secure Sockets Layer (SSL) connections.

<b>Data type:</b>	Boolean
<b>Default:</b>	Disable
<b>Range:</b>	Enable or Disable

*Domain name:*

Specifies the domain name (.ibm.com, for example) for all single sign-on hosts.

The application server uses all the information after the first period, from left to right, for the domain names. If this field is not defined, the web browser defaults the domain name to the host name where the web application is running. Also, single sign-on is then restricted to the application server host name and does not work with other application server host names in the domain.

You can specify multiple domains separated by a semicolon (;), a space ( ), a comma (,), or a pipe (|). Each domain is compared with the host name of the HTTP request until the first match is located. For example, if you specify `ibm.com;austin.ibm.com` and a match is found in the `ibm.com` domain first, the application server does not match the `austin.ibm.com` domain. However, if a match is not found in either `ibm.com` or `austin.ibm.com`, then the application server does not set a domain for the `LtpaToken` cookie.

If you specify the `UseDomainFromURL` value, the application server sets the SSO domain name value to the domain of the host that is used in the web address. For example, if an HTTP request comes from `server1.raleigh.ibm.com`, the application server sets the SSO domain name value to `raleigh.ibm.com`.

**Tip:** The `UseDomainFromURL` value is case insensitive. You can type `usedomainfromurl` to use this value.

<b>Data type:</b>	String
-------------------	--------

*Interoperability mode:*

Specifies that an interoperable cookie is sent to the browser to support back-level servers.

In WebSphere Application Server, Version 6 and later, a new cookie format is needed by the security attribute propagation functionality. When the interoperability mode flag is enabled, the server can send a maximum of two single sign-on (SSO) cookies back to the browser. In some cases, the server just sends the interoperable SSO cookie.

*Web inbound security attribute propagation:*

When web inbound security attribute propagation is enabled, security attributes are propagated to front-end application servers. When this option is disabled, the single sign-on (SSO) token is used to log in and recreate the Subject from the user registry.

If the application server is a member of a cluster and the cluster is configured with a data replication service (DRS) domain, then propagation occurs. If DRS is not configured, then the SSO token contains the originating server information.

With this information, the receiving server can contact the originating server using an MBean call to get the original serialized security attributes.

*Set security cookies as HTTPOnly to resist cross-site scripting attacks:*

The HttpOnly attribute is a browser attribute created to prevent client side applications (such as Java scripts) from accessing cookies to prevent some cross-site scripting vulnerabilities. The attribute specifies that LTPA and WASReqURL cookies include the HTTPOnly field.

For session cookies, see the session settings for servers, applications, and web modules.

<b>Data type:</b>	boolean
<b>Default:</b>	enabled
<b>Range:</b>	enabled or disabled

### ***com.tivoli.pd.jcfg.PDJrteCfg utility for Tivoli Access Manager single sign-on:***

The com.tivoli.pd.jcfg.PDJrteCfg utility configures the Java Runtime Environment component for Tivoli Access Manager. This utility enables Java applications to use the Tivoli Access Manager policy and authorization servers.

### **Purpose**

**Important:** If you are using the WebSphere Application Server, Network Deployment product, run the pdjrtecfg utility first on the deployment manager. Then, run the script on the other nodes in the cell.

### **Syntax**

```
java com.tivoli.pd.jcfg.PDJrteCfg -action {config | unconfig} -cfgfiles_path
configuration_file_path -host policy_server_host -was -java_home jre_path
```

### **Parameters**

**-action {config|unconfig}**

Specifies the action to be performed. Actions include:

**config** Use to configure the Access Manager Java Runtime Environment component.

**unconfig**

Use to reconfigure the Access Manager Java Runtime Environment component.

**-cfgfiles\_path**

Specifies where the generated configuration files will be placed.

**Note:** This parameter is required.

**-host policy\_server\_host**

Specifies the policy server host name.

Valid values for *policy\_server\_host* include any valid IP host name.

Examples include:

```
host = libra
host = libra.dallas.ibm.com
```

**-was**

Notifies Tivoli Access Manager Runtime for Java that the WebSphere Application Server version is being configured so it is not necessary to perform certain steps such as copying the Java security jar files and PD.jar file since they were already placed in the appropriate directory by the WebSphere Application Server installer.

**-java\_home *jre\_path***

Specifies the fully qualified path to the Java runtime (such as the directory ending in jre). If this parameter is not specified, the home directory for the jre in the PATH statement is used. If the home directory for the jre is not in the PATH statement, this utility can create an incorrect parameter in the output files.

**Comments**

This command copies Tivoli Access Manager Java libraries to a library extensions directory that exists for a Java runtime that has already been installed on the system.

You can install more than one Java Runtime Environment (JRE) on a given machine. The pdjrtecfg command can be used to configure the Tivoli Access Manager Java Runtime Environment component independently for each of the JRE configurations.

```
${JAVA_HOME}/bin/java
-Dfile.encoding=ISO8859-1 \
-Dws.output.encoding=CP1047 \
-Xnoargsconversion \
-Dpd.home=${WAS_HOME}/java/jre/PolicyDirector \
-cp ${WAS_HOME}/java/jre/lib/ext/PD.jar \
 com.tivoli.pd.jcfg.PDJrteCfg \
-action config \
 -cfgfiles_path ${WAS_HOME}/java/jre \
 -host gary.us.ibm.com \
 -java_home ${JAVA_HOME}
```

where:

**-Dws.output.encoding**

Is used to enable z/OS to display all of its messages and errors in a readable format.

**-Dpd.home**

Indicates where Tivoli Access Manager Runtime for Java has been installed. For WebSphere Application Server, this is java.home/PolicyDirector

***com.tivoli.pd.jcfg.SvrSslCfg utility for Tivoli Access Manager single sign-on:***

The utility is used to configure and remove the configuration information associated with WebSphere Application Server and the Tivoli Access Manager server.

**Purpose**

Run the svrsslcfg script first on the deployment manager and then on the other nodes in the cell.

## Syntax

```
java com.tivoli.pd.jcfg.SvrSslCfg
-action {config | unconfig} -admin_id admin_user_ID
-admin_pwd admin_password -appsvr_id application_server_name
-appsvr_pwd application_server_password -mode{local|remote}
-host host_name_of_application_server
-policysvr policy_server_name:port:rank [...]
-authzsvr authorization_server_name:port:rank [...]
-cfg_file fully_qualified_name_of_configuration_file
-domain Tivoli_Access_Manager_domain
-key_file fully_qualified_name_of_keystore_file
-cfg_action {create|replace}
```

## Parameters

### **-action {config | unconfig}**

Specifies the configuration action that is performed by the script. The following options apply:

#### **-action config**

Configuring a server creates user and server information in the user registry and creates local configuration and key store files on the application server. Use the `-action unconfig` option to reverse this operation.

If this action is specified, the following options are required: `-admin_id`, `-admin_pwd`, `-appsvr_id`, `-port`, `-mode`, `-policysvr`, `-authzsvr`, and `-key_file`.

#### **-action unconfig**

Reconfigures an application server to complete the following actions:

- Remove the user and server information from the user registry
- Delete the local key store file
- Remove information for this application from the configuration file without deleting the file

The reconfiguration operation fails only if the caller is unauthorized or the policy server cannot be contacted.

This action can succeed when a configuration file does not exist. When the configuration file does not exist, it is created and used as a temporary file to hold configuration information during the operation, and then the file is deleted completely.

If this action is specified, the following options are required: `-admin_id`, `-admin_pwd`, `-appsvr_id`, and `-policysvr`.

### **-admin\_id *admin\_user\_ID***

Specifies the Tivoli Access Manager administrator name. If this option is not specified, `sec_master` is the default.

A valid administrative ID is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the administrative ID.

For example, for U.S. English the valid characters are the letters a-Z, the numbers 0-9, a period (.), an underscore (\_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (\*). The minimum and maximum lengths of the administrative ID, if there are limits, are imposed by the underlying registry.

### **-admin\_password *admin\_password***

Specifies the password of the Tivoli Access Manager administrator user that is associated with the `-admin_id` parameter. The password restrictions depend upon the password policy for your Tivoli Access Manager configuration.

### **-appsvr\_id *application\_server\_name***

Specifies the name of the application server. The name is combined with the host name to create unique names for Tivoli Access Manager objects created for your application. The following names are reserved for Tivoli Access Manager applications: `ivacld`, `secmgrd`, `ivnet`, and `ivweb`.

**-appsrvr\_pwd** *application\_server\_password*

Specifies the password of the application server. This option is required. A password is created by the system and the configuration file is updated with the password created by the system.

If this option is not specified, the server password will be read from standard input.

**-authzsvr** *authorization\_server\_name*

Specifies the name of the Tivoli Access Manager authorization server with which the application server communicates. The server is specified by fully qualified host name, the SSL port number, and the rank. The default SSL port number is 7136. For example: `myauth.mycompany.com:7136:1`. You can specify multiple servers if the entries are separated by a comma (,).

**-cfg\_action** {**create** | **replace**}

Specifies the action to take when creating the configuration and key files. Valid values are **create** or **replace**. Use the **create** option to initially create the configuration and keystore files. Use the **replace** option if these files already exist. If you use the **create** option and the configuration or keystore files already exist, an exception is created.

Options are as follows:

**create** Specifies to create the configuration and key store files during server configuration. Configuration fails if either of these files already exists.

**replace**

Specifies to replace the configuration and key store files during server configuration. Configuration deletes any existing files and replaces them with new ones.

**-cfg\_file** *fully\_qualified\_name\_of\_configuration\_file*

Specifies the configuration file path and name.

A file name should be an absolute file name (fully qualified file name) to be valid.

**-domain** *Tivoli\_Access\_Manager\_domain*

Specifies the Tivoli Access Manager domain name to which the administrator is authenticated. This domain must exist and an administrator ID and password must be valid for this domain. The application server is specified in this domain.

If not specified, the local domain that was specified during Tivoli Access Manager runtime configuration will be used. The local domain value will be retrieved from the configuration file.

A valid domain name is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the domain name.

For example, for U.S. English the valid characters for domain names are the letters a-Z, the numbers 0-9, a period (.), an underscore (\_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (\*). The minimum and maximum lengths of the domain name, if there are limits, are imposed by the underlying registry.

**-host** *host\_name\_of\_application\_server*

Specifies the TCP host name used by the Tivoli Access Manager policy server to contact this server. This name is saved in the configuration file using the `azn-app-host` key.

The default is the local host name returned by the operating system. Valid values for `host_name` include any valid IP host name.

Examples:

```
host = libra
host = libra.dallas.ibm.com
```

**-key\_file** *fully\_qualified\_name\_of\_keystore\_file*

Specifies the directory that is to contain the key files for the server. A valid directory name is determined by the operating system. Use a fully qualified file name that contains the application server certificate and key file.

Make sure that server user (for example, `ivmgr`) or all users have permission to access the `.kdb` file and the folder that contains the `.kdb` file.

This option is required.

**-mode** *server\_mode*

Specifies the mode in which the application operates. This value must be either `local` or `remote`.

**-policysvr** *policy\_server\_name*

Specifies the name of the policy server.

## Comments

After the successful configuration of a Tivoli Access Manager Java application server, `SvrSslCfg` creates a user account and server entries representing the Java application server in the Tivoli Access Manager user registry. In addition, `SvrSslCfg` creates a configuration file and a Java key store file, which securely stores a client certificate, locally on the application server. This client certificate permits callers to make authenticated use of Tivoli Access Manager services. Conversely, reconfiguration removes the user and server entries from the user registry and cleans up the local configuration and keystore files.

The contents of an existing configuration file can be modified by using the `SvrSslCfg` utility. The configuration file and the key store file must already exist when calling `SvrSslCfg` with all options other than `-action config` or `-action unconfig`.

The following options are parsed and processed into the configuration file, but are otherwise ignored in this version of Tivoli Access Manager:

The host name is used to build a unique name (identity) for the application. The `pdadmin` user list command displays the application identity name in the following format:

*server\_name/host\_name*

Note that the `pdadmin` `server list` command displays the server name in a slightly different format:

*server\_name-host\_name*

```
CLASSPATH=${WAS_HOME}/java/jre/lib/ext/PD.jar:${WAS_CLASSPATH}
java \
-cp ${CLASSPATH} \
-Dpd.cfg.home= ${WAS_HOME}/java/jre \
-Dfile.encoding=ISO8859-1 \
-Dws.output.encoding=CP1047 \
-Xnoargsconversion \
 com.tivoli.pd.jcfg.SvrSslCfg \
-action config \
-admin_id sec_master \
-admin_pwd $TAM_PASSWORD \
-appsvr_id $APPSVR_ID \
-policysvr ${TAM_HOST}:7135:1 \
-port 7135 \
-authzsvr ${TAM_HOST}:7136:1 \
-mode remote \
-cfg_file ${CFG_FILE} \
-key_file ${KEY_FILE} \
-cfg_action create
```

## **Creating a trusted user account in Tivoli Access Manager:**

Tivoli Access Manager trust association interceptors require the creation of a trusted user account in the shared LDAP user registry.

### About this task

This account includes the ID and password that WebSEAL uses to identify itself to WebSphere Application Server. To prevent potential vulnerabilities, do not use the `sec_master` ID as the trusted user account and ensure that the password you use is unique and generated randomly. Use the trusted user account for the TAI or TAI++ only.

### Procedure

1. Use either the Tivoli Access Manager `pdadmin` command-line utility or Web Portal Manager to create the trusted user. For example, from the **pdadmin** command line.
2. Reference the code listed below as an example for creating a trusted user account.
3. Reference the following additional resources for more information:
  - a. “Configuring WebSEAL for use with WebSphere Application Server”
  - b. “Configuring Tivoli Access Manager plug-in for web servers for use with WebSphere Application Server” on page 1662

### Example

```
pdadmin> user create webseal_userid webseal_userid_DN firstname
 surname password

pdadmin> user modify webseal_userid account-valid yes
```

### Configuring WebSEAL for use with WebSphere Application Server:

Use this topic to set the SSO password in WebSEAL for single sign-on to WebSphere Application Server.

### About this task

A junction must be created between WebSEAL and WebSphere Application Server. This junction carries the `iv-credentials` (for TAI++) or `iv-user` (for TAI) and the HTTP basic authentication headers with the request. You can configure WebSEAL to pass the end user identity in other ways, the `iv-credentials` header is the only one supported by the TAI++ and the `iv-user` is the only one supported by TAI.

Communications over the junction should use Secure Sockets Layer (SSL) for increased security. Setting up SSL across this junction requires that you configure the HTTP Server used by WebSphere Application Server, and WebSphere Application Server itself, to accept inbound SSL traffic and route it correctly to WebSphere Application Server. This activity requires importing the necessary signing certificates into the WebSEAL certificate keystore, and possibly also the HTTP Server certificate keystore.

Create the junction between WebSEAL and WebSphere Application Server using the **-c iv\_creds** option for TAI++ and **-c iv\_user** for TAI. Enter either of the following commands as one line using the variables that are appropriate for your environment:

#### TAI++

```
server task webseald-server create -t ssl -b supply -c iv_creds
-h host_name -p websphere_app_port_number junction_name
```

#### TAI

```
server task webseald-server create -t ssl -b supply -c iv_user
-h host_name -p websphere_app_port_number junction_name
```

### Notes:

1. If warning messages are displayed about the incorrect setup of certificates and key databases, delete the junction, correct problems with the key databases, and recreate the junction.
2. The junction can be created as `-t tcp` or `-t ssl`, depending on your requirements.

For single sign-on (SSO) to WebSphere Application Server the SSO password must be set in WebSEAL. To set the password, complete the following steps:

### Procedure

1. Edit the WebSEAL configuration file `webseal_install_directory/etc/webseald-default.conf`. Set the following parameter: `basicauth-dummy-passwd=webseal_userid_passwd` where `webseal_userid_passwd` is the SSO password for the trusted user account set in “Creating a trusted user account in Tivoli Access Manager” on page 1660.
2. Restart WebSEAL.

### What to do next

For more details and options about how to configure junctions between WebSEAL and WebSphere Application Server, including other options for specifying the WebSEAL server identity, refer to the *Tivoli Access Manager WebSEAL Administration Guide* as well as to the documentation for the HTTP Server you are using with your WebSphere Application Server. Tivoli Access Manager documentation is available at <http://publib.boulder.ibm.com/tividd/td/tdprodlst.html>.

### **Configuring Tivoli Access Manager plug-in for web servers for use with WebSphere Application Server:**

Tivoli Access Manager plug-in for web servers can be used as a security gateway for your protected WebSphere Application Server resources.

### About this task

With such an arrangement the plug-in authorizes all user requests before passing the credentials of the authorized user to WebSphere Application Server in the form of an `iv-creds` header. Trust between the plug-in and WebSphere Application Server is established through use of basic authentication headers containing the single sign-on (SSO) user password.

### Procedure

1. The Tivoli Access Manager plug-in for web servers configuration shows IV headers configured for post-authorization processing, and basic authentication that is configured as the authentication mechanism and for post-authorization processing, as shown in the example below.
2. After a request is authorized, the basic authentication header is removed from the request (`strip-hdr=always`) and a new one is added (`add-hdr=supply`).
3. Included in this new header is the password that is set when the SSO user is created in “Creating a trusted user account in Tivoli Access Manager” on page 1660.
4. Specify this password in the **supply-password** parameter and it is passed in the newly created header. This basic authentication header enables trust between WebSphere Application Server and the plug-in.
5. An `iv-creds` header is also added (`generate=iv-creds`), which contains the credential information of the user passed onto WebSphere Application Server. Session cookies are used to maintain session state.

### Example

```
[common-modules]
authentication = BA
session = session-cookie
post-authzn = BA
post-authzn = iv-headers
```

```
[iv-headers]
accept = all
generate = iv-creds

[BA]
strip-hdr = always
add-hdr = supply
supply-password = sso_user_password
```

## What to do next

“Configuring single sign-on using trust association” or “Configuring single sign-on using trust association interceptor ++”

### ***Configuring single sign-on using trust association:***

This task is performed to enable single sign-on using trust association. Trust association is used to connect reversed proxy servers to the application server.

### **Before you begin**

**Note:** Use of TAIs for Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) authentication is deprecated in this release. The SPNEGO web authentication panels provide a much easier and less error-prone way to configure SPNEGO.

To establish the trust association for the single sign-on, perform the following steps:

### **Procedure**

1. From the administrative console for WebSphere Application Server, click **Security > Global security**.
2. From Authentication mechanisms, click **Web and SIP security > Trust association**.
3. Select the **Enable trust association** option.
4. Under Additional properties, click the **Interceptors** link.
5. Click **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus** to use a WebSEAL interceptor, or **com.ibm.ws.security.spnego.TrustAssociationInterceptorImpl** to use a SPNEGO interceptor.
6. Under Custom properties, select a custom property to edit or click **New** to create a new one. Enter the property name and value pairs.
7. Click **OK**.
8. Save the configuration and log out.
9. Restart WebSphere Application Server.

### ***Configuring single sign-on using trust association interceptor ++:***

Perform this task to enable single sign-on using trust association interceptor ++. The steps involve setting up trust association and creating the interceptor properties.

### **Before you begin**

Although you can use Simple WebSphere Authentication Mechanism (SWAM) by selecting the **Use SWAM-no authenticated communication between servers** option on the Authentication mechanisms and expiration panel, single sign-on (SSO) requires LTPA as the configured authentication mechanism.

Lightweight Third Party Authentication (LTPA) is the default authentication mechanism for WebSphere Application Server. You can configure LTPA prior to configuring single sign-on (SSO) by clicking **Security > Global security > Authentication mechanisms and expiration**.

To establish the trust association for the single sign-on, perform the following steps:

## Procedure

1. From the administrative console for WebSphere Application Server, click **Security > Global security**.
2. Under Web security, click **Trust association**.
3. Click **Enable Trust Association**.
4. Click **Interceptors**.
5. Click **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus** to use a WebSEAL interceptor. This interceptor is one of two WebSEAL interceptors that are supplied for your use. You choose to use this interceptor by supplying properties as described in the next step.  
**Attention:** WebSphere Application Server attempts to initialize both of these interceptors even if you only supplied properties for the **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus** interceptor. As a result, messages AWXRB0008E and SECJ0384E can appear during initialization to indicate that the interceptor you did not choose has failed to initialize. This is normal processing and does not affect the initialization of the interceptor you did select. To inhibit the display of messages AWXRB0008E and SECJ0384E, you can delete the interceptor you do not want to use prior to beginning the initialization. You can add that interceptor back later if your environment changes.
6. Click **Custom Properties**.
7. Click **New** to enter the property name and value pairs. Ensure that the following parameters are set:

Table 105. Custom properties.

This table describes the TAI custom properties.

Option	Description
com.ibm.websphere.security.webseal.checkViaHeader	You can configure TAI so that the via header can be ignored when validating trust for a request. Set this property to <i>false</i> if none of the hosts in the via header need to be trusted. When set to <i>false</i> you do not need to set the trusted host names and host ports properties. The only mandatory property to check when via header is <i>false</i> is com.ibm.websphere.security.webseal.loginId.  The default value of the check via header property is <i>false</i> . When using Tivoli Access Manager plug-in for web servers, set this property to <i>false</i> . <b>Note:</b> The via header is part of the standard HTTP header that records the server names the request that passed through.
com.ibm.websphere.security.webseal.loginId	The WebSEAL trusted user as created in "Creating a trusted user account in Tivoli Access Manager" on page 1660 The format of the username is the short name representation. This property is mandatory. If it is not set in WebSphere Application Server, the TAI initialization fails.
com.ibm.websphere.security.webseal.id	A comma-separated list of headers that exists in the request. If all of the configured headers do not exist in the request, trust cannot be established. The default value for the ID property is <i>iv-creds</i> . Any other values set in WebSphere Application Server are added to the list along with <i>iv-creds</i> , separated by commas.
com.ibm.websphere.security.webseal.hostnames	Do not set this property if using Tivoli Access Manager Plug-in for Web Servers. The property specifies the host names (case sensitive) that are trusted and expected in the request header. Requests arriving from un-listed hosts might not be trusted. If the checkViaHeader property is not set or is set to <i>false</i> then the trusted host names property has no influence. If the checkViaHeader property is set to <i>true</i> , and the trusted host names property is not set, TAI initialization fails.
com.ibm.websphere.security.webseal.ports	Do not set this property if using Tivoli Access Manager plug-in for web servers. This property is a comma-separated list of trusted host ports. Requests that arrive from unlisted ports might not be trusted. If the checkViaHeader property is not set, or is set to <i>false</i> this property has no influence. If the checkViaHeader property is set to <i>true</i> , and the trusted host ports property is not set in WebSphere Application Server, the TAI initialization fails.

Table 105. Custom properties (continued).

This table describes the TAI custom properties.

Option	Description
com.ibm.websphere.security.webseal.viaDepth	<p>A positive integer that specifies the number of source hosts in the via header to check for trust. By default, every host in the via header is checked, and if any host is not trusted, trust cannot be established. The via depth property is used when only some of the hosts in the via header have to be trusted. The setting indicates the number of hosts that are required to be trusted.</p> <p>As an example, consider the following header: Via: HTTP/1.1 webseal1:7002, 1.1 webseal2:7001</p> <p>If the viaDepth property is not set, is set to 2 or is set to 0, and a request with the previous via header is received then both webseal1:7002 and webseal2:7001 need to be trusted. The following configuration applies: com.ibm.websphere.security.webseal.hostnames = webseal1,webseal2 com.ibm.websphere.security.webseal.ports = 7002,7001</p> <p>If the via depth property is set to 1, and the previous request is received, then only the last host in the via header needs to be trusted. The following configuration applies: com.ibm.websphere.security.webseal.hostnames = webseal2 com.ibm.websphere.security.webseal.ports = 7001</p> <p>The viaDepth property is set to 0 by default, which means all of the hosts in the via header are checked for trust.</p>
com.ibm.websphere.security.webseal.ssoPwdExpiry	<p>After trust is established for a request, the single sign-on user password is cached, eliminating the need to have the TAI re-authenticate the single sign-on user with Tivoli Access Manager for every request. You can modify the cache timeout period by setting the single sign-on password expiry property to the required time in seconds. If the password expiry property is set to 0, the cached password never expires. The default value for the password expiry property is 600.</p>
com.ibm.websphere.security.webseal.ignoreProxy	<p>This property can be used to tell the TAI to ignore proxies as trusted hosts. If set to true the comments field of the hosts entry in the via header is checked to determine if a host is a proxy. Remember that not all proxies insert comments in the via header indicating that they are proxies. The default value of the ignoreProxy property is false. If the checkViaHeader property is set to false then the ignoreProxy property has no influence in establishing trust.</p>
com.ibm.websphere.security.webseal.configURL	<p>For the TAI to establish trust for a request, it requires that the SvrSslCfg run for the Java Virtual Machine on the Application Server and result in the creation of a properties file. If this properties file is not at the default URL, which is file://java.home/PdPerm.properties, the correct URL of the properties file must be set in the configuration URL property. If this property is not set, and the SvrSslCfg-generated properties file is not in the default location, the TAI initialization fails. The default value for the config URL property is file://{WAS_INSTALL_ROOT}/java/jre/PdPerm.properties.</p>

8. Click **OK**.
9. Save the configuration and log out.
10. Restart WebSphere Application Server.

### Configuring global sign-on principal mapping:

You can create a new application login that uses the Tivoli Access Manager GSO database to store the login credentials.

#### Procedure

1. Click **Security > Global security**.
2. Under Authentication, click **Java Authentication and Authorization Service > Application logins**.
3. Click **New** to create a new Java Authentication and Authorization Service (JAAS) login configuration.
4. Enter the alias name of the new application login. Click **Apply**.
5. Under Additional properties, click **JAAS login modules** to define the JAAS Login Modules.
6. Click **New** and enter the following information:

**Module class name:** com.tivoli.pdwas.gso.AMPrincipalMapper  
**Use Login Module Proxy:** enable  
**Authentication strategy:** REQUIRED

7. Click **Apply**
8. Under Additional Properties section, click **Custom Properties** to define login module-specific values that are passed directly to the underlying login modules.
9. Click **New**.

The Tivoli Access Manager principal mapping module uses the `authDataAlias` configuration string to retrieve the correct user name and password from the security configuration.

The `authDataAlias` attribute that is passed to the module is configured for the J2C connection factory. Because the `authDataAlias` attribute is an arbitrary string that is entered at configuration time, the following scenarios are possible:

- The `authDataAlias` attribute contains both the global sign-on (GSO) resource name and the user name. The format of this string is "Resource/User".
- The `authDataAlias` attribute contains the GSO Resource name only. The user name is determined by using the Subject of the current session.

The scenario to use is determined by a JAAS configuration option, as shown here:

**Name:** `com.tivoli.pd.as.gso.AliasContainsUserName`

**Value:** True, if the alias contains the user name; false, if the user name must be retrieved from the security context

When entering `authDataAlias` attributes through the WebSphere Application Server administrative console, the node name is automatically pre-pended to the alias. The JAAS configuration entry determines whether this node name is removed or included as part of the resource name, as shown here:

**Name:** `com.tivoli.pd.as.gso.AliasContainsNodeName`

**Value:** True, if the alias contains the node name

**Note:** If the `PdPerm.properties` configuration file is not located in the `JAVA_HOME/PdPerm.properties` default location, then you also need to add the following property:

**Name:** `com.tivoli.pd.as.gso.AMCfgURL`

**Value:** `file:///path to PdPerm.properties`

Enter each new parameter using the following scenario information as a guide, then click **Apply**.

#### **Scenario 1**

**Auth Data Alias** - BackendEIS/eisUser

**Resource** - BackEndEIS

**User** - eisUser

#### **Principal Mapping Parameters**

Table 106. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
<code>delegate</code>	<code>com.tivoli.pdwas.gso.AMPrincipalMapper</code>
<code>com.tivoli.pd.as.gso.AliasContainsUserName</code>	<code>true</code>
<code>com.tivoli.pd.as.gso.AliasContainsNodeName</code>	<code>false</code>
<code>com.tivoli.pd.as.gso.AMLoggingURL</code>	<code>file:///log_props_path</code>
<code>debug</code>	<code>false</code>

#### **Scenario 2**

**Auth Data Alias** - BackendEIS

**Resource** - BackEndEIS

**User** - Currently authenticated WebSphere Application Server user

#### **Principal Mapping Parameters**

Table 107. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///jlog_props_path
debug	false

### Scenario 3

**Auth Data Alias** - nodename/BackendEIS/eisUser

**Resource** - BackEndEIS

**User** - eisUser

### Principal Mapping Parameters

Table 108. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	true
com.tivoli.pd.as.gso.AliasContainsNodeName	true
com.tivoli.pd.as.gso.AMLoggingURL	file:///jlog_props_path
debug	false

### Scenario 4

**Auth Data Alias** - nodename/BackendEIS/eisUser

**Resource** - nodename/BackEndEIS (notice that node name is not removed)

**User** - eisUser

### Principal Mapping Parameters

Table 109. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	true
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///jlog_props_path
debug	false

### Scenario 5

**Auth Data Alias** - BackendEIS/eisUser

**Resource** - BackEndEIS

**User** - eisUser

### Principal Mapping Parameters

Table 110. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false

Table 110. Principal Mapping Parameters (continued).

This table lists the principal mapping parameters.

com.tivoli.pd.as.gso.AliasContainsNodeName	true
com.tivoli.pd.as.gso.AMLoggingURL	file:///jlog_props_path
debug	false

### Scenario 6

**Auth Data Alias** - nodename/BackendEIS/eisUser

**Resource** - nodename/BackendEIS/eisUser

(notice that the resource is the same as Auth Data Alias).

**User** - Currently authenticated WebSphere Application Server user

### Principal Mapping Parameters

Table 111. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///jlog_props_path
debug	false

10. Create the Java 2 Connector (J2C) authentication aliases. The user name and password that are assigned to these alias entries are irrelevant because Tivoli Access Manager is responsible for providing user names and passwords. However, the user name and password that are assigned to the J2C authentication aliases need to exist so that they can be selected for the J2C connection factory in the administrative console.

To create the J2C authentication aliases, from the WebSphere Application Server administrative console, click **Security > Global security**. Under Authentication, click **Java Authentication and Authorization Service > J2C authentication data**, and then click **New** for each new entry. Refer to the previous table for scenario inputs.

The connection factories for each resource adapter that need to use the GSO database must be configured to use the Tivoli Access Manager Principal mapping module:

- a. From the WebSphere Application Server administrative console, click **Applications > Enterprise Applications > application\_name > Resourcer references**. Note that J2C connection factories must be already configured for the selected application. To configure a new J2C connection factory, see the Configuring Java EE Connector connection factories in the administrative console article.
- b. Under Additional properties, click **Resource Adapter**.  
The resource adapter can be stand-alone and does not need to be packaged with the application. The resource adapter is configured from **Resources > Resource Adapters** for stand-alone scenarios.
- c. Under Additional properties, click **J2C Connection Factories**.
- d. Click **New** and enter the connection factory properties.
- e. When finished, click **Apply > Save**.

### Attention:

Custom mapping configuration for the connection factory is deprecated in WebSphere Application Server Version 6. To configure the GSO credential mapping, use the Map Resource References to Resources panel on the administrative console. For more information, see the J2EE connector security article.

## Configuring administrative authentication

An authentication mechanism defines rules about security information, such as whether a credential is forwardable to another Java process, and the format of how security information is stored in both credentials and tokens. The Rivest Shamir Adleman (RSA) token authentication mechanism simplifies the security environment for flexible management topology, that is, the topology where you can locally or remotely submit and manage administrative jobs through a job manager that manages applications, perform product maintenance, modify configurations, and control the application server runtime. You use the administrative console to configure administrative authentication, which involves the configuring of the Rivest Shamir Adleman (RSA) token authentication mechanism.

### Before you begin

The following keystore, truststore, and rootstore descriptions give you an idea of where certificates are stored and how trust is configured between processes.

The **NodeRSATokenKeyStore** contains the Rivest Shamir Adleman (RSA) token personal certificate used for this process. Not only is the public/private key from this certificate used to create RSA tokens, but the public key is used by other processes to create tokens. The RSA personal certificate is signed by an RSA root certificate.

The **NodeRSATokenTrustStore** contains all RSA signer certificates from other processes that are trusted to send RSA tokens to this process. The signers in this trust store are placed there automatically during the registration process. However, this task allows an administrator to configure trust between to processes not normally involved in the same administrative domain. There may be requirements where two base servers are communicating administratively. When using the RSA token authentication mechanism, the base servers need to share RSA signers if administrative communications is operating in both directions.

The **NodeRSATokenRootStore** contains the root personal certificate that is used to create new RSA personal certificates. Do not use the root certificate to create RSA tokens because this usage compromises the long-lived keys. Only use the root certificate to sign other certificates.

No manual steps are required with these keystores, and this allows uncommon trust establishment among processes not in the same administrative domain. You can also replace the RSA personal certificate with a personal certificate obtained from a certificate authority (CA) if desired. In this case, make sure the CA root certificate is placed in all RSA trust stores in the same administrative domain.

### Procedure

1. Click **Security > SSL certificate and key management**.
2. Under **Related Items**, click **Key stores and certificates**.
3. Under **Keystore usages**, select **RSA token keystores**.
4. Select the RSA token key store you want to administer.
5. Modify the description if required.
6. Modify the path if required.
7. Select **read only**, **initialize at setup**, or both if required.
8. Enter the correct password to make these modifications
9. Click **Apply** and **Save**.

### Results

You configured administrative authentication.

## What to do next

In cases where the process is back-level or a target RSA certificate cannot be obtained, the fallback mechanism is Lightweight Third-Party Authentication (LTPA) which is supported in all previous releases for administrative communications. The fallback occurs automatically. If the LTPA keys are not shared and a fallback occurs, LTPA will fail as well. However, this situation is typically an error case in the RSA mechanism and should occur infrequently.

## Job manager security

When performing a job manager registration process there are a number of WebSphere Application Server security impacts to consider.

**Note:** In WebSphere Application Server Version 7.0, a new style of system management called *flexible management* was introduced. It differs from the existing style of synchronous invocation and response calls through wsadmin or Java APIs by offering an asynchronous job queuing mechanism for administration purposes. At the core of flexible management is a new administrative process called the *job manager*. You can make both application servers registered to administrative agents and deployment manager servers known to the job manager through a registration process. After you register the servers, you can queue administrative jobs directed at the application servers or deployment managers through the job manager. You can submit these jobs to a large number of servers over a geographically dispersed area. There are a number of security considerations you must keep in mind both during and after the job manager registration process.

Consider the following:

- Security configuration requirements should be kept to a minimum prior to registration.
- Allow an agent or a deployment manager (dmgr) to be federated to the job manager with almost any security configuration. Some exceptions include:
  - The administrative agent or deployment manager must have the same administrative security state (either enabled or disabled).
  - To enable security after federation, you must enable all administrative agent and deployment manager processes within the same administrative domain, then restart all of the processes at the same time.
- Leverage the creation of a chained certificate to exchange only the long-lived root certificates between an administrative agent, deployment manager and job manager. When a personal certificate expires in either the administrative agent, deployment manager or the job manager, it does not affect trust that was established during federation.
- Use the Rivest Shamir Adleman (RSA) certificate administrative-specific authentication mechanism, which does not rely on shared keys and is the default administrative authentication mechanism for the job manager. The RSA token authentication mechanism is also new to this release of WebSphere Application Server. Read about “RSA token authentication mechanism” on page 1591 for more information.
- Add a profile Universal Unique Identifier (UUID) to all certificates generated in WebSphere Application Server Version 8.0. This profile UUID is used to authorize requests to extract jobs from the job manager queue.
- Job Manager jobs can be associated with caller credentials: either Lightweight Third-Party Authentication (LTPA) or with specified credentials using a user ID and password. Both are stored with the job. The password is obfuscated using the standard utilities and can be encrypted when the password encryption plug point is enabled. LTPA is refreshed as long as the authentication mechanism allows it to be refreshed.
- With this service release, Job Manager jobs can be associated with caller credentials: either Lightweight Third-Party Authentication (LTPA) or Kerberos, or with specified credentials using a user ID and password). Both are stored with the job. The password is obfuscated using the standard utilities and

can be encrypted when the password encryption plug point is enabled. LTPA and Kerberos are refreshed as long as the authentication mechanism allows them to be refreshed.

- Administrative agent or deployment manager access to `FileTransferServlet` is performed by sending a valid RSA certificate that is trusted by the job manager and is validated by `CertPath`.

The required administrative roles for executing flexible management jobs are defined by the underlying administrative commands used by those jobs. For example, the required role for starting and stopping servers is the operator role. The operator role is also required for execution of the flexible management jobs that start and stop servers. The general rules for assigning required administrative roles are:

- Viewing data requires the monitor role.
- Updating data requires the configurator role.
- Managing jobs requires the operator role.
- Registering or un-registering managed nodes requires the administrator role.

## Java Authentication and Authorization Service

The standard Java 2 security application programming interface (API) helps enforce access control based on the location of the code source or the author or packager of the code that signed the jar file. The current principal of the running thread is not considered in the Java 2 security authorization. Instances where authorization is based on the principal, as opposed to the code base, and the user exist. The Java Authentication and Authorization Service is a standard Java API that supports the Java 2 security authorization to extend the code base on the principal as well as the code base and users.

The Java Authentication and Authorization Service (JAAS) Version 1.0 extends the Java 2 security architecture of the Java 2 platform with additional support to authenticate and enforce access control with principals and users. JAAS implements a Java version of the standard Pluggable Authentication Module (PAM) framework, and extends the access control architecture of the Java 2 platform in a compatible fashion to support user-based authorization or principal-based authorization. WebSphere Application Server fully supports the JAAS architecture. JAAS extends the access control architecture to support role-based authorization for Java Platform, Enterprise Edition (Java EE) resources including servlets, JavaServer Pages (JSP) files, and Enterprise JavaBeans (EJB) components.

Refer to “Java 2 security” on page 1315 for more information.

The following sections cover the JAAS implementation and programming model:

- Login configuration for Java Authentication and Authorization Service
- Programmatic login for JAAS
- “Java Authentication and Authorization Service authorization”

The JAAS documentation can be found at <http://www.ibm.com/developerworks/java/jdk/security>. Scroll down to find the JAAS documentation for your platform.

### Java Authentication and Authorization Service authorization

Java 2 security architecture uses a security policy to specify which access rights are granted to running code. This architecture is *code-centric*. The permissions are granted based on code characteristics including where the code is coming from, whether it is digitally signed, and by whom. Authorization of the Java Authentication and Authorization Service (JAAS) augments the existing code-centric access controls with new user-centric access controls. Permissions are granted based on what code is running and who is running it.

When using JAAS authentication to authenticate a user, a *subject* is created to represent the authenticated user. A subject is comprised of a set of principals, where each principal represents an identity for that user. You can grant permissions in the policy to specific principals. After the user is authenticated, the application can associate the subject with the current access control context. For each subsequent security-checked operation, the Java runtime automatically determines whether the policy grants the

required permission to a specific principal only. If so, the operation is supported if the subject that is associated with the access control context contains the designated principal only.

Associate a subject with the current access control context by calling the static `doAs` method from the subject class, passing it an authenticated subject and the `java.security.PrivilegedAction` or `java.security.PrivilegedExceptionAction` method. The `doAs` method associates the provided subject with the current access control context and then invokes the `run` method from the action. The `run` method implementation contains all the code that ran as the specified subject. The action runs as the specified subject.

In the Java 2 Platform, Enterprise Edition (J2EE) programming model, when invoking the Enterprise JavaBeans (EJB) method from an enterprise bean or servlet, the method runs under the user identity that is determined by the `run-as` setting. The J2EE Version 1.4 Specification does not indicate which user identity to use when invoking an enterprise bean from a `Subject.doAs` action block within either the EJB code or the servlet code. A logical extension is to use the proper identity that is specified in the subject when invoking the EJB method within the `Subject.doAs` action block.

Letting the `Subject.doAs` action overwrite the `run-as` identity setting is an ideal way to integrate the JAAS programming model with the J2EE run-time environment. However, JAAS introduced an issue into the Software Development Kit (SDK), Java Technology Edition Versions 1.3 or later when integrating the JAAS Version 1.0 or later implementation with the Java 2 security architecture. A subject, which is associated with the access control context is cut off by a `doPrivileged` call when a `doPrivileged` call occurs within the `Subject.doAs` action block. Until this problem is corrected, no reliable and run-time efficient way is available to guarantee the correct behavior of `Subject.doAs` action in a J2EE run-time environment.

The problem can be explained better with the following example:

```
Subject.doAs(subject, new java.security.PrivilegedAction() {
 Public Object run() {
 // Subject is associated with the current thread context
 java.security.AccessController.doPrivileged(new
 java.security.PrivilegedAction() {
 public Object run() {
 // Subject was cut off from the current
 // thread context

 }
 }
);
 return null;
 }
});
// Subject is associated with the current thread context
return null;
}
```

In the previous code example, the `Subject` object is associated with the context of the current thread. Within the `run` method of a `doPrivileged` action block, the `Subject` object is removed from the thread context. After leaving the `doPrivileged` block, the `Subject` object is restored to the current thread context. Because `doPrivileged` blocks can be placed anywhere along the running path and instrumented quite often in a server environment, the run-time behavior of a `doAs` action block becomes difficult to manage.

To resolve this difficulty, WebSphere Application Server provides a `WSSubject` helper class to extend the JAAS authorization to a J2EE EJB method invocation, as described previously. The `WSSubject` class provides static `doAs` and `doAsPrivileged` methods that have identical signatures to the subject class. The `WSSubject.doAs` method associates the `Subject` to the currently running thread. The `WSSubject.doAs` and `WSSubject.doAsPrivileged` methods then invoke the corresponding `Subject.doAs` and `Subject.doAsPrivileged` methods. The original credential is restored and associated with the running thread upon leaving the `WSSubject.doAs` and `WSSubject.doAsPrivileged` methods.

The WSSubject class is not a replacement of the subject object, but rather a helper class to ensure consistent run-time behavior as long as an EJB method invocation is a concern.

The following example illustrates the run-time behavior of the WSSubject.doAs method:

```
WSSubject.doAs(subject, new java.security.PrivilegedAction() {
 Public Object run() {
 // Subject is associated with the current thread context
 java.security.AccessController.doPrivileged(new
 java.security.PrivilegedAction() {
 public Object run() {
 // Subject was cut off from the current thread
 // context.

 return null;
 }
 });
 // Subject is associated with the current thread context
 return null;
 }
});
```

The Subject.doAs and Subject.doAsPrivileged methods are not integrated with the J2EE run-time environment. EJB methods that are invoked within the Subject.doAs and Subject.doAsPrivileged action blocks run under the identity that is specified by the run-as setting and not by the subject identity.

- The Subject object that is generated by the WSLoginModuleImpl instance and the WSCliientLoginModuleImpl instance contains a principal that implements the WSPrincipal interface. Using the getCredential method for a WSPrincipal object returns an object that implements the WSCredential interface. You can also find the WSCredential object instance in the PublicCredentials list of the subject instance. Retrieve the WSCredential object from the PublicCredentials list instead of using the getCredential method.
- The getCallerPrincipal method for the WSSubject class returns a string that represents the caller security identity. The return type differs from the getCallerPrincipal method of the java.security.Principal EJBContext interface.
- The Subject object that is generated by the Java 2 Connector (J2C) DefaultPrincipalMapping module contains a resource principal and a PasswordCredentials list. The resource principal represents the RunAs identity.

For more information, see J2EE connector security.

## Using the Java Authentication and Authorization Service programming model for web authentication

WebSphere Application Server supports the Java Platform, Enterprise Edition (Java EE) declarative security model. You can define the authentication and access control policy using the Java EE deployment descriptor. You can further stack custom login modules to customize the WebSphere Application Server authentication mechanism.

### Before you begin

A custom login module can perform principal and credential mapping, custom security token and custom credential-processing, and error-handling among other possibilities. Typically, you do not need to use application code to perform authentication function. Use the programming techniques that are described in this section if you have to perform authentication function in application code. For example, if you have applications that programmed to the SSOAuthenticator helper function, you can use the following programming interface. The SSOAuthenticator helper function was deprecated starting with WebSphere Application Server Version 4.0. Use declarative security as a rule; use the techniques that are described in this section as a last resort.

## About this task

When the Lightweight Third-Party Authentication (LTPA) mechanism single sign-on (SSO) option is enabled, the web client login session is tracked by an LTPA SSO token cookie after successful login. At logout, this token is deleted to terminate the login session, but the server-side subject is not deleted. When you use the declarative security model, the WebSphere Application Server web container performs client authentication and login session management automatically. You can perform authentication in application code by setting a login page without a Java EE security constraint and by directing client requests to your login page first. Your login page can use the Java Authentication and Authorization Service (JAAS) programming model to perform authentication. To enable WebSphere Application Server web login modules to generate SSO cookies, use the following steps.

## Procedure

1. Create a new system login JAAS configuration. To access the panel, click **Security > Global security**. Under Java Authentication and Authorization Service, click **System logins**.
2. Manually clone the WEB\_INBOUND login configuration, and give it a new alias. To clone the login configuration, click **New**, enter a name for the configuration, click **Apply**, then click **JAAS login modules** under Additional properties. Click **New** and configure the JAAS login module. For more information, see Login module settings for Java Authentication and Authorization Service. WebSphere Application Server web container uses the WEB\_INBOUND login configuration to authenticate web clients. Changing the WEB\_INBOUND login configuration affects all web applications in the cell. You should create your own login configuration by cloning the contents of the WEB\_INBOUND login configuration.
3. Select the `wsMapDefaultInboundLoginModule` login module and click **Custom properties**. There are two login modules defined in your login configuration: `ltpaLoginModule` and `wsMapDefaultInboundLoginModule`.
4. Add a login property name `cookie` with a value of **true**. The two login modules are enabled to generate LTPA SSO cookies. Do not add the cookie login option to the original WEB\_INBOUND login configuration.
5. Stack your custom LoginModule(s) in the new login configuration (optional).
6. Use your login page for programmatic login by perform a JAAS `LoginContext.login` using your newly defined login configuration. After a successful login, either the `ltpaLoginModule` or the `wsMapDefaultInboundLoginModule` generates an LTPA SSO cookie upon a successful authentication. Exactly which LoginModule generates the SSO cookie depends on many factors, including system authentication configuration and runtime condition (which is beyond the scope of this section).
7. Call the modified `WSSubject.setRunAsSubject` method to add the subject to the authentication cache. The subject must be a WebSphere Application Server JAAS subject created by LoginModule. Adding the subject to the authentication cache recreates a subject from SSO token.
8. Use your programmatic logout page to revoke SSO cookies by invoking the `revokeSSOCookies` method from the `WSSecurityHelper` class. The term cookies is used because WebSphere Application Server Release 5.1.1 (and later) release supports a new LTPA SSO token with a different encryption algorithm, but can be configured to generate the original LTPA SSO token for backward compatibility. Note that the subject is still in the authentication cache and only the SSO cookies are revoked.

## Example

Use the following code sample to perform authentication.

**gotcha:** If you set the password for the `WSCallbackHandlerFactoryset` factory class for getting handlers to `null`, as is done in the following example, you allow identity assertion without a password.

Suppose you wrote a `LoginServlet.java`:

```
import com.ibm.wsspi.security.auth.callback.WSCallbackHandlerFactory;
import com.ibm.websphere.security.auth.WSSubject;

public Object login(HttpServletRequest req, HttpServletResponse res)
```

```

throws ServletException {

PrintWriter out = null;
try {
 out = res.getWriter();
 res.setContentType("text/html");
} catch (java.io.IOException e){
 // Error handling
}

Subject subject = null;
try {
 LoginContext lc = new LoginContext("system.Your_login_configuration",
WSCallbackHandlerFactory.getInstance().getCallbackHandler(
userid, null, password, req, res, null));
 lc.login();
 subject = lc.getSubject();
 WSSubject.setRunAsSubject(subject);
} catch(Exception e) {
 // catch all possible exceptions if you want or handle them separately
 out.println("Exception in LoginContext login + Exception = " +
e.getMessage());
 throw new ServletException(e.getMessage());
}
}

```

The following is sample code to revoke the SSO cookies upon a programming logout:

The LogoutServlet.java:

```

public void logout(HttpServletRequest req, HttpServletResponse res,
Object retCreds) throws ServletException {
 PrintWriter out =null;
 try {
 out = res.getWriter();
 res.setContentType("text/html");
 } catch (java.io.IOException e){
 // Error Handling
 }
 try {
 WSSecurityHelper.revokeSSOCookies(req, res);
 } catch(Exception e) {
 // catch all possible exceptions if you want or handle them separately
 out.println("JAASLogoutServlet: logout Exception = " + e.getMessage());
 throw new ServletException(e);
 }
}
}

```

## What to do next

For more information on JAAS authentication, refer to [Developing programmatic logins with the Java Authentication and Authorization Service](#). For more information on the `AuthenLoginModule` login module, refer to [Example: Customizing a server-side Java Authentication and Authorization Service authentication and login configuration](#).

## Developing custom login modules for a system login configuration for JAAS

For WebSphere Application Server, multiple Java Authentication and Authorization Service (JAAS) plug-in points exist for configuring system logins. WebSphere Application Server uses system login configurations to authenticate incoming requests, outgoing requests, and internal server logins.

### About this task

Application login configurations are called by Java Platform, Enterprise Edition (Java EE) applications for obtaining a Subject that is based on specific authentication information. This login configuration enables the application to associate the Subject with a specific protected remote action. The Subject is picked up on the outbound request processing. The following list identifies the main system plug-in points. If you write a login module that adds information to the Subject of a system login, these are the main login configurations to plug in:

- WEB\_INBOUND
- RMI\_OUTBOUND
- RMI\_INBOUND
- DEFAULT

## Procedure

- Authenticate web requests with the WEB\_INBOUND login configuration.

The WEB\_INBOUND login configuration authenticates web requests.

For more detailed information on the WEB\_INBOUND configuration including its associated callbacks, see "RMI\_INBOUND, WEB\_INBOUND, DEFAULT" in System login configuration entry settings for Java Authentication and Authorization Service. Figure 1 shows an example of a configuration using a trust association interceptor (TAI) that creates a Subject with the initial information that is passed into the WEB\_INBOUND login configuration. If the trust association interceptor is not configured, the authentication process goes directly to the WEB\_INBOUND system login configuration, which consists of all the login modules combined in Figure 1. Figure 1 shows where you can plug in custom login modules and where the ltpaLoginModule and the wsMapDefaultInboundLoginModule login modules are required.

### Figure 1

- Handle outbound requests with the RMI\_OUTBOUND login configuration.

The RMI\_OUTBOUND login configuration is a plug point for handling outbound requests. WebSphere Application Server uses this plug point to create the serialized information that is sent downstream based on the invocation Subject passed in and other security context information such as propagation tokens. A custom login module can use this plug point to change the identity. For more information, see "Configuring outbound identity mapping to a different target realm" on page 1695. Figure 2 shows where you can plug in custom login modules and shows where the wsMapCSlv2OutboundLoginModule login module is required.

### Figure 2

For more information on the RMI\_OUTBOUND login configuration, including its associated callbacks, see "RMI\_OUTBOUND" in System login configuration entry settings for Java Authentication and Authorization Service.

- Handle inbound authentication for enterprise bean requests with the RMI\_INBOUND login configuration. The RMI\_INBOUND login configuration is a plug point that handles inbound authentication for enterprise bean requests. WebSphere Application Server uses this plug point for either an initial login or a propagation login. For more information about these two login types, see "Security attribute propagation" on page 1700. During a propagation login, this plug point is used to deserialize the information that is received from an upstream server. A custom login module can use this plug point to change the identity, handle custom tokens, add custom objects into the Subject, and so on. For more information on changing the identity using a Hashtable object, which is referenced in figure 3, see "Configuring inbound identity mapping" on page 1688. Figure 3 shows where you can plug in custom login modules and shows that the ltpaLoginModule and the wsMapDefaultInboundLoginModule login modules are required.

### Figure 3

For more information on the RMI\_INBOUND login configuration, including its associated callbacks, see "RMI\_INBOUND, WEB\_INBOUND, DEFAULT" in System login configuration entry settings for Java Authentication and Authorization Service.

- Handle all other types of authentication requests with the DEFAULT login configuration. **DEFAULT login configuration**

The DEFAULT login configuration is a plug point that handles all of the other types of authentication requests, including administrative SOAP requests and internal authentication of the server ID. Propagation logins typically do not occur at this plug point.

For more information on the DEFAULT login configuration including its associated callbacks, see "RMI\_INBOUND, WEB\_INBOUND, DEFAULT" in System login configuration entry settings for Java Authentication and Authorization Service.

- Develop login configuration logic to know when specific information is present and how to use the information. **Writing a login module**

When you write a login module that plugs into a WebSphere Application Server application login or system login configuration, read the JAAS programming model, which is located at:

<http://java.sun.com/products/jaas>. The JAAS programming model provides basic information about JAAS. However, before writing a login module for the WebSphere Application Server environment, read the following sections in this article:

- Useable callbacks
- Shared state variables
- Initial versus propagation logins
- Sample custom login module

### **Useable Callbacks**

Each login configuration must document the callbacks that are recognized by the login configuration. However, the callbacks are not always passed data. The login configuration must contain logic to know when specific information is present and how to use the information. For example, if you write a custom login module that can plug into all four of the pre-configured system login configurations mentioned previously, three sets of callbacks might be presented to authenticate a request. Other callbacks might be present for other reasons, including propagation and making other information available to the login configuration.

Login information can be presented in the following combinations:

#### **User name (NameCallback) and password (PasswordCallback)**

This information is a typical authentication combination.

#### **User name only (NameCallback)**

This information is used for identity assertion, trust association interceptor (TAI) logins, and certificate logins.

#### **Token (WSCredTokenCallbackImpl)**

This information is for Lightweight Third Party Authentication (LTPA) token validation.

#### **Propagation token list (WSTokenHolderCallback)**

This information is used for a propagation login.

The first three combinations are used for typical authentication. However, when the WSTokenHolderCallback callback is present in addition to one of the first three information combinations, the login is called a *propagation login*. A propagation login means that some security attributes are propagated to this server from another server. The servers can reuse these security attributes if the authentication information validates successfully. In some cases, a WSTokenHolderCallback callback might not have sufficient attributes for a full login. Check the requiresLogin method on the WSTokenHolderCallback callback to determine if a new login is required. You can always ignore the information returned by the requiresLogin method, but, as a result, you might duplicate information. The following list contains the callbacks that might be present in the system login configurations. The list includes the callback name and a description of their responsibility.

**callbacks[0] = new javax.security.auth.callback.NameCallback("Username: ");**

This callback handler collects the user name for the login. The result can be the user name for a basic authentication login (user name and password) or a user name for an identity assertion login.

**callbacks[1] = new javax.security.auth.callback.PasswordCallback("Password: ", false);**

This callback handler collects the password for the login.

**callbacks[2] = new com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl("Credential Token: ");**

This callback handler collects the Lightweight Third Party Authentication (LTPA) token or other token type for the login. This callback handler is typically present when a user name and password are not present.

**callbacks[3] = new com.ibm.wsspi.security.auth.callback.WSTokenHolderCallback("Authz Token List: ");**

This callback handler collects the ArrayList of TokenHolder objects that are returned from a call to the WSOpaqueTokenHelper.createTokenHolderListFromOpaqueToken API using the Common Secure Interoperability Version 2 (CSlv2) authorization token as input.

**callbacks[4] = new com.ibm.websphere.security.auth.callback.WSServletRequestCallback("HttpServletRequest: ");**

This callback handler collects the HTTP servlet request object, if present. This callback handler enables login modules to get information from the HTTP request for use in the login, and is presented from the WEB\_INBOUND login configuration only.

**callbacks[5] = new com.ibm.websphere.security.auth.callback.WSServletResponseCallback("HttpServletResponse: ");**

This callback handler collects the HTTP servlet response object, if present. This callback handler enables login modules to put information into the HTTP response as a result of the login. An example of this situation might be adding the SingleSignonCookie cookie to the response. This callback handler is presented from the WEB\_INBOUND login configuration only.

**callbacks[6] = new com.ibm.websphere.security.auth.callback.WSAppContextCallback("ApplicationContextCallback: ");**

This callback handler collects the web application context that is used during the login. This callback handler consists of a HashMap object, which contains the application name and the redirect web address, if present. The callback handler is presented from the WEB\_INBOUND login configuration only.

**callbacks[7] = new WSRealmNameCallbackImpl("Realm Name: ", default\_realm);**

This callback handler collects the realm name for the login information. The realm information might not always be provided. If the realm information is not provided, assume that it is the current realm.

**callbacks[8] = new WSX509CertificateChainCallback("X509Certificate[]: ");**

This callback handler contains the certificate that was validated by Secure Sockets Layer (SSL) if the login source is an X509Certificate from SSL client authentication. The ItpaLoginModule calls the same mapping functions as WebSphere Application Server releases prior to version 6.1. However, having it passed into the login gives a custom login module the opportunity to map the certificate in a custom way. Then, it performs a Hashtable login. See "Configuring inbound identity mapping" on page 1688 for more information on a Hashtable login.

- Use shared state variables to share information between login modules during the login phase.

If you want to access the objects that WebSphere Application Server creates during a login, refer to the following shared state variables. The variables are set in the following login modules: ItpaLoginModule, swamLoginModule, and wsMapDefaultInboundLoginModule.

#### **Shared state variable**

com.ibm.wsspi.security.auth.callback.Constants.WSPRINCIPAL\_KEY

#### **Purpose**

Specifies the com.ibm.websphere.security.auth.WSPPrincipal object. See the WebSphere Application Server API documentation for application programming interface (API) usage. This shared state variable is for read-only purposes. Do not set this variable in the shared state for custom login modules.

#### **The login module in which variables are set**

ItpaLoginModule, swamLoginModule, and wsMapDefaultInboundLoginModule

#### **Shared state variable**

com.ibm.wsspi.security.auth.callback.Constants.WSCREDENTIAL\_KEY

#### **Purpose**

Specifies the com.ibm.websphere.security.cred.WSCredential object. See the WebSphere

Application Server API documentation for API usage. This shared state variable is for read-only purposes. Do not set this variable in the shared state for custom login modules.

### Login module in which variables are set

wsMapDefaultInboundLoginModule

### Shared state variable

com.ibm.wsspi.security.auth.callback.Constants.WSAUTHZTOKEN\_KEY

### Purpose

Specifies the default com.ibm.wsspi.security.token.AuthorizationToken object. Login modules can use this object to set custom attributes plugged in after the wsMapDefaultInboundLoginModule login module. The information set here is propagated downstream and is available to the application. See the WebSphere Application Server API documentation for API usage.

### Initial versus propagation logins

As mentioned previously, some logins are considered initial logins because of the following reasons:

- It is the first time authentication information is presented to WebSphere Application Server.
- The login information is received from a server that does not propagate security attributes so this information must be gathered from a user registry.

Other logins are considered propagation logins when a WSTokenHolderCallback callback is present and contains sufficient information from a sending server to recreate all the required objects needed by WebSphere Application Server runtime. In cases where there is sufficient information for the WebSphere Application Server runtime, the information you might add to the Subject is likely to exist from the previous login. To verify if your object is present, you can get access to the ArrayList object that is present in the WSTokenHolderCallback callback, and search through this list looking at each TokenHolder getName method. This search is used to determine if WebSphere Application Server is deserializing your custom object during this login. Check the class name returned from the getName method using the String startsWith method because the runtime might add additional information at the end of the name to know which Subject is set to add the custom object after deserialization.

- Code your login() method to determine when sufficient information is present.

The following code snippet can be used in your login() method to determine when sufficient information is present. For another example, see “Configuring inbound identity mapping” on page 1688.

```
// This is a hint provided by WebSphere Application Server that
// sufficient propagation information does not exist and, therefore,
// a login is required to provide the sufficient information. In this
// situation, a Hashtable login might be used.
boolean requiresLogin = ((com.ibm.wsspi.security.auth.callback.
WSTokenHolderCallback) callbacks[1]).requiresLogin();

if (requiresLogin)
{
 // Check to see if your object exists in the TokenHolder list,
 // if not, add it.
 java.util.ArrayList authzTokenList = ((WSTokenHolderCallback) callbacks[6]).
 getTokenHolderList();boolean found = false;

 if (authzTokenList != null)
 {
 Iterator tokenListIterator = authzTokenList.iterator();

 while (tokenListIterator.hasNext())
 {
 com.ibm.wsspi.security.token.TokenHolder th = (com.ibm.wsspi.security.token.
 TokenHolder) tokenListIterator.next();

 if (th != null && th.getName().startsWith("com.acme.myCustomClass"))
 {
 found=true;
 break;
 }
 }
 if (!found)
 {
 // go ahead and add your custom object.
 }
 }
}
else
```

```

{
// This code indicates that sufficient propagation information is present.
// User registry calls are not needed by WebSphere Application Server to
// create a valid Subject. This code might be a no-op in your login module.
}

```

## Sample custom login module

You can use the following sample to get ideas on how to use some of the callbacks and shared state variables.

```

{
// Defines your login module variables
com.ibm.wsspi.security.token.AuthenticationToken customAuthzToken = null;
com.ibm.wsspi.security.token.AuthenticationToken defaultAuthzToken = null;
com.ibm.websphere.security.cred.WSCredential credential = null;
com.ibm.websphere.security.auth.WSPrincipal principal = null;
private javax.security.auth.Subject _subject;
private javax.security.auth.callback.CallbackHandler _callbackHandler;
private java.util.Map _sharedState;
private java.util.Map _options;

public void initialize(Subject subject, CallbackHandler callbackHandler,
 Map sharedState, Map options)
{
 _subject = subject;
 _callbackHandler = callbackHandler;
 _sharedState = sharedState;
 _options = options;
}

public boolean login() throws LoginException
{
 boolean succeeded = true;

 // Gets the CALLBACK information
 javax.security.auth.callback.Callback callbacks[] = new javax.security.
 auth.callback.Callback[7];
 callbacks[0] = new javax.security.auth.callback.NameCallback(
 "Username: ");
 callbacks[1] = new javax.security.auth.callback.PasswordCallback(
 "Password: ", false);
 callbacks[2] = new com.ibm.websphere.security.auth.callback.
 WSCredTokenCallbackImpl ("Credential Token: ");
 callbacks[3] = new com.ibm.wsspi.security.auth.callback.
 WSServletRequestCallback ("HttpServletRequest: ");
 callbacks[4] = new com.ibm.wsspi.security.auth.callback.
 WSServletResponseCallback ("HttpServletResponse: ");
 callbacks[5] = new com.ibm.wsspi.security.auth.callback.
 WSApplContextCallback ("ApplicationContextCallback: ");
 callbacks[6] = new com.ibm.wsspi.security.auth.callback.
 WSTokenHolderCallback ("Authz Token List: ");

 try
 {
 callbackHandler.handle(callbacks);
 }
 catch (Exception e)
 {
 // Handles exceptions
 throw new WSLoginFailedException (e.getMessage(), e);
 }

 // Sees which callbacks contain information
 uid = ((NameCallback) callbacks[0]).getName();
 char password[] = ((PasswordCallback) callbacks[1]).getPassword();
 byte[] credToken = ((WSCredTokenCallbackImpl) callbacks[2]).getCredToken();
 javax.servlet.http.HttpServletRequest request = ((WSServletRequestCallback)
 callbacks[3]).getHttpServletRequest();
 javax.servlet.http.HttpServletResponse response = ((WSServletResponseCallback)
 callbacks[4]).getHttpServletResponse();
 java.util.Map appContext = ((WSApplContextCallback)
 callbacks[5]).getContext();
 java.util.List authzTokenList = ((WSTokenHolderCallback)
 callbacks[6]).getTokenHolderList();

 // Gets the SHARED STATE information
 principal = (WSPrincipal) _sharedState.get(com.ibm.wsspi.security.
 auth.callback.Constants.WSPRINCIPAL_KEY);
 credential = (WSCredential) _sharedState.get(com.ibm.wsspi.security.
 auth.callback.Constants.WSCREDENTIAL_KEY);
 defaultAuthzToken = (AuthorizationToken) _sharedState.get(com.ibm.
 wsspi.security.auth.callback.Constants.WSAUTHZTOKEN_KEY);

 // What you tend to do with this information depends upon the scenario
 // that you are trying to accomplish. This example demonstrates how to
 // access various different information:
 // - Determine if a login is initial versus propagation
 // - Deserialize a custom authorization token (For more information, see
 // "Security attribute propagation" on page 1700

```

```

 // - Add a new custom authorization token (For more information, see
 // "Security attribute propagation" on page 1700
 // - Look for a WSCredential and read attributes, if found.
 // - Look for a WSPincipal and read attributes, if found.
 // - Look for a default AuthorizationToken and add attributes, if found.
 // - Read the header attributes from the HttpServletRequest, if found.
 // - Add an attribute to the HttpServletResponse, if found.
 // - Get the web application name from the appContext, if found.

 // - Determines if a login is initial versus propagation. This is most
 // useful when login module is first.
boolean requiresLogin = ((WSTokenHolderCallback) callbacks[6]).requiresLogin();

// initial login - asserts privilege attributes based on user identity
if (requiresLogin)
{
 // If you are validating a token from another server, there is an
 // application programming interface (API) to get the uniqueID from it.
 if (credToken != null && uid == null)
 {
 try
 {
 String uniqueID = WSSecurityPropagationHelper.
 validateLTPAToken(credToken);
 String realm = WSSecurityPropagationHelper.getRealmFromUniqueID
 (uniqueID);
 // Now set it to the UID so you can use that to either map or
 // login with.
 uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);
 }
 catch (Exception e)
 {
 // handle exception
 }
 }
 // Adds a Hashtable to shared state.
 // Note: You can perform custom mapping on the NameCallback value returned
 // to change the identity based upon your own mapping rules.
 uid = mapUser (uid);

 // Gets the default InitialContext for this server.
 javax.naming.InitialContext ctx = new javax.naming.InitialContext();

 // Gets the local UserRegistry object.
 com.ibm.websphere.security.UserRegistry reg = (com.ibm.websphere.security.
 UserRegistry) ctx.lookup("UserRegistry");

 // Gets the user registry uniqueID based on the uid specified in the
 // NameCallback.
 String uniqueid = reg.getUniqueUserId(uid);
 uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);

 // Gets the display name from the user registry based on the uniqueID.
 String securityName = reg.getUserSecurityName(uid);

 // Gets the groups associated with this uniqueID.
 java.util.List grouplist = reg.getUniqueGroupIds(uid);

 // Creates the java.util.Hashtable with the information you gathered from
 // the UserRegistry.
 java.util.Hashtable hashtable = new java.util.Hashtable();
 hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_UNIQUEID, uniqueid);
 hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_SECURITYNAME, securityName);
 hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_GROUPS, grouplist);

 // Adds a cache key that is used as part of the lookup mechanism for
 // the created Subject. The cache key can be an Object, but should
 // implement the toString() method. Make sure the cacheKey contains
 // enough information to scope it to the user and any additional
 // attributes that you use. If you do not specify this property the
 // Subject is scoped to the WSCREDENTIAL_UNIQUEID returned, by default.
 hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_CACHE_KEY,
 "myCustomAttribute" + uniqueid);

 // Adds the hashtable to the sharedState of the Subject.
 _sharedState.put(com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_PROPERTIES_KEY,hashtable);
}
// propagation login - process propagated tokens
else
{
 // - Deserializes a custom authorization token. For more information, see
 // "Security attribute propagation" on page 1700.
 // This can be done at any login module plug in point (first,
 // middle, or last).

```

```

if (authzTokenList != null)
{
 // Iterates through the list looking for your custom token
 for (int i=0; i<authzTokenList.size(); i++)
 {
 TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

 // Looks for the name and version of your custom AuthorizationToken
 // implementation
 if (tokenHolder.getName().equals("com.ibm.websphere.security.token.
 CustomAuthorizationTokenImpl") && tokenHolder.getVersion() == 1)

- Configure the system login for your custom login module.

After developing your custom login module for a system login configuration, you can configure the system login using either the administrative console or using the wsadmin utility. To configure the system login using the administrative console, click **Security > Global security**. Under Java Authentication and Authorization Service, click **System logins**. For more information on using the wsadmin utility for system login configuration, see Customizing a server-side Java Authentication and Authorization Service authentication and login configuration. Also refer to that article for information on system login modules and to determine whether to add additional login modules.

### ***Customizing application login with Java Authentication and Authorization Service:***

Using Java Authentication and Authorization Service (JAAS), you can customize your application login.

#### **About this task**

Java Authentication and Authorization Service (JAAS) is an API that enables applications to access authentication and access control services without being tied to those services. The following topics explaining customizing your application with JAAS are covered in this section:

#### **Procedure**

1. Develop programmatic logins with JAAS.

You can develop programmatic logins with JAAS, which represents the strategic application programming interfaces (API) for authentication.

2. Configure programmatic logins with JAAS.

A new JAAS login configuration can be added and modified using the administrative console. The changes are saved in the cell-level security document and are available to all managed application servers.

3. Customize an application login to perform an identity assertion using JAAS.

Using the JAAS login framework, you can create a JAAS login configuration that can be used to perform login to an identity assertion.

4. Configure a server-side JAAS authentication and login configuration.

WebSphere Application Server supports plugging in a custom JAAS login module before or after the WebSphere Application Server system login module. However, WebSphere Application Server does not support the replacement of the WebSphere Application Server system login modules, which are used to create the WSCredential credential and WSPincipal principal in the Subject. By using a custom login module, you can either make additional authentication decisions or add information to the Subject to make additional, potentially finer-grained, authorization decisions inside a Java Platform, Enterprise Edition (Java EE) application.

#### ***Enabling identity assertion with trust validation using JAAS:***

By enabling identity assertion with trust validation, an application can use the JAAS login configuration to perform a programmatic identity assertion.

## About this task

To enable an identity assertion with trust validation, follow these steps:

### Procedure

1. Create a custom login module to perform a trust validation. The login module must set trust and identity information in the shared state, which is then passed on to the `IdentityAssertionLoginModule`. The trust and identity information is stored in a map in the shared state under the key, `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state`. If this key is missing from the shared state, a `WSLoginFailedException` error is thrown by the `IdentityAssertionLoginModule` module. The custom login module should include the following:
  - A trust key named `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trust`. If the trust key is set to `true`, trust is established. If the trust key is set to `false`, the `IdentityAssertionLoginModule` module creates a `WSLoginFailedException` error.
  - The identity of the `java.security.Principal` type set in the `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal` key.
  - The identity in the form of a `java.security.cert.X509Certificate[]` certificate set in the `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates` key.

**Note:** If both a principal and a certificate are supplied, the principal is used, and a warning is issued.

2. Create a new Java Authentication and Authorization Service (JAAS) configuration for application logins. It contains the user-implemented trust validation custom login module and the `IdentityAssertionLoginModule` module. To configure an application login configuration from the administrative console, complete the following steps:
  - a. Click **Security > Global security**.
  - b. Under Java Authentication and Authorization Service, click **Application logins > New**.
  - c. Supply the JAAS configuration with an alias, and then click **Apply**.
  - d. Under Additional properties, click **JAAS Login Modules > New**.
  - e. Enter the module class name of the user-implemented trust validation custom login module, and then click **Apply**.
  - f. Enter the `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule` module class name.
  - g. Make sure that the module class name classes are in the correct order. The user-implemented trust validation login module must be the first class in the list, and the `IdentityAssertionLoginModule` module must be the second class.
  - h. Click **Save**. The new JAAS configuration is used by the application to perform an identity assertion.

### What to do next

An application can now use the JAAS login configuration to perform a programmatic identity assertion. The application can create a login context for the JAAS configuration created in step 2, then login to that login context with the identity it asserts to. If the login is successful, that identity can be set in the current running process, as in the following example:

```
MyCallbackHandler handler = new MyCallbackHandler(new MyPrincipal("Joe"));
LoginContext lc = new LoginContext("MyAppLoginConfig", handler);
lc.login(); //assume successful
Subject s = lc.getSubject();
WSSubject.setRunAsSubject(s);
// From here on, the runas identity is "Joe"
```

## Performing identity mapping for authorization across servers in different realms

Identity mapping is a one-to-one mapping of a user identity between two servers so that the proper authorization decisions are made by downstream servers. Identity mapping is necessary when the integration of servers is needed, but the user registries are different and not shared between the systems.

### About this task

In most cases, requests flow downstream between two servers that are part of the same security domain. In WebSphere Application Server, two servers that are members of the same cell are also members of the same security domain. In the same cell, the two servers have the same user registry and the same Lightweight Third Party Authentication (LTPA) keys for token encryption. These two commonalities ensure that the LTPA token, among other user attributes, which flows between the two servers, not only can be decrypted and validated, but also the user identity in the token can be mapped to attributes that are recognized by the authorization engine.

The most reliable and recommended configuration involves two servers within the same cell. However, sometimes you need to integrate multiple systems that cannot use the same user registry. When the user registries are different between two servers, the security domain or realm of the target server does not match the security domain of the sending server.

WebSphere Application Server enables mapping to occur either before sending the request outbound or before enabling the existing security credentials to flow to the target server. The credentials are mapped inbound with the specification that the target realm is trusted.

An alternative to mapping is to send the user identity without the token or the password to a target server without actually mapping the identity. The use of the user identity is based on trust between the two servers. Use Common Secure Interoperability Version 2 (CSIv2) identity assertion. When enabled, the server sends just the X.509 certificate, principal name, or distinguished name (DN) based upon what was used by the original client to perform the initial authentication. During CSIv2 identity assertion, trust is established between WebSphere Application Servers.

The user identity must exist in the target user registry for identity assertion to work. This process can also enable interoperability between other Java 2 Platform, Enterprise Edition (J2EE) Version 1.4 and higher compliant application servers. If both the sending server and target servers have identity assertion configured, WebSphere Application Server always uses this method of authentication, even when both servers are in the same security domain. For more information on CSIv2 identity assertion, see “Identity assertion to the downstream server” on page 1752.

When the user identity is not present in the user registry of the target server, identity mapping must occur either before the request is sent outbound or when the request comes inbound. This decision depends upon your environment and requirements. However, it is typically easier to map the user identity before the request is sent outbound for the following reasons:

- You know the user identity of the existing credential as it comes from the user registry of the sending server.
- You do not have to worry about sharing Lightweight Third Party Authentication (LTPA) keys with the other target realm because you are not mapping the identity to LTPA credentials. Typically, you are mapping the identity to a user ID and password that are present in the user registry of the target realm.

When you do perform outbound mapping, in most cases, it is recommended that you use Secure Sockets Layer (SSL) to protect the integrity and confidentiality of the security information sent across the network. If LTPA keys are not shared between servers, an LTPA token cannot be validated at the inbound server. In this case, outbound mapping is necessary because the user identity cannot be determined at the inbound server to do inbound mapping. For more information, see “Configuring outbound identity mapping to a different target realm” on page 1695.

When you need inbound mapping, potentially due to the mapping capabilities of the inbound server, you must ensure that both servers have the same LTPA keys so that you can get access to the user identity. Typically, in secure communications between servers, an LTPA token is passed into the WSCredTokenCallback callback of the inbound JAAS login configuration for the purposes of client authentication. A method is available that enables you to open the LTPA token, if valid, and get access to the user unique ID so that mapping can be performed. For more information, see “Configuring inbound identity mapping.” In other cases, such as identity assertion, you might receive a user name in the NameCallback callback of the inbound login configuration that enables you to map the identity.

The following topics are covered in this section:

## Procedure

- **Configuring inbound identity mapping** For inbound identity mapping, you can write a custom login module and configure WebSphere Application Server to run the login module first within the system login configurations. Consider the following steps when you write your custom login module: “Configuring inbound identity mapping.”
- **Configuring outbound identity mapping to a different target realm** By default, when WebSphere Application Server makes an outbound request from one server to another server in a different security realm, the request is rejected. This topic details alternatives for enabling one server to send outbound requests to a target server in a different realm. For more information, see “Configuring outbound identity mapping to a different target realm” on page 1695

## Configuring inbound identity mapping

For inbound identity mapping, write a custom login module and configure WebSphere Application Server to run the login module first within the system login configurations. Consider the following steps when you write your custom login module.

## Procedure

1. Get the inbound user identity from the callbacks and map the identity, if necessary This step occurs in the login method of the login module. A valid authentication has either or both NameCallback and the WSCredTokenCallback callbacks present. The following code sample shows you how to determine the user identity:

```
javax.security.auth.callback.Callback callbacks[] =
 new javax.security.auth.callback.Callback[3];
callbacks[0] = new javax.security.auth.callback.NameCallback("");
callbacks[1] = new javax.security.auth.callback.PasswordCallback
 ("Password: ", false);
callbacks[2] = new com.ibm.websphere.security.auth.callback.
 WSCredTokenCallbackImpl("");
callbacks[3] = new com.ibm.wsspi.security.auth.callback.
 WSTokenHolderCallback("");

try
{
 callbackHandler.handle(callbacks);
}
catch (Exception e)
{
 // Handles exceptions
 throw new WSLoginFailedException (e.getMessage(), e);
}

// Shows which callbacks contain information
boolean identitySwitched = false;
String uid = ((NameCallback) callbacks[0]).getName();
char password[] = ((PasswordCallback) callbacks[1]).getPassword();
byte[] credToken = ((WSCredTokenCallbackImpl) callbacks[2]).getCredToken();
java.util.List authzTokenList = ((WSTokenHolderCallback)
 callbacks[3]).getTokenHolderList();
```

```

if (credToken != null)
{
 try
 {
 String uniqueID = WSSecurityPropagationHelper.validateLTPAToken(credToken);
 String realm = WSSecurityPropagationHelper.getRealmFromUniqueID (uniqueID);
 // Now set the string to the UID so that you can use the result for either
 // mapping or logging in.
 uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);
 }
 catch (Exception e)
 {
 // Handles the exception
 }
}
else if (uid == null)
{
 // Throws an exception if authentication data is not valid.
 // You must have either UID or CredToken
 throw new WSLoginFailedException("invalid authentication data.");
}
else if (uid != null && password != null)
{
 // This is a typical authentication. You can choose to map this ID to
 // another ID or you can skip it and allow WebSphere Application Server
 // to log in for you. When passwords are presented, be very careful to not
 // validate the password because this is the initial authentication.

 return true;
}

// If desired, map this uid to something else and set the identitySwitched
// boolean. If the identity was changed, clear the propagated attributes
// below so they are not used incorrectly.
uid = myCustomMappingRoutine (uid);

// Clear the propagated attributes because they are no longer applicable
// to the new identity
if (identitySwitched)
{
 ((WSTokenHolderCallback) callbacks[3]).setTokenHolderList(null);
}

```

2. Check to see if attribute propagation occurred and if the attributes for the user are already present when the identity remains the same. Check to see if the user attributes are already present from the sending server to avoid duplicate calls to the user registry lookup. To check for the user attributes, use a method on the WSTokenHolderCallback callback that analyzes the information present in the callback to determine if the information is sufficient for WebSphere Application Server to create a Subject. The following code sample checks for the user attributes:

```

boolean requiresLogin =
((com.ibm.wsspi.security.auth.callback.WSTokenHolderCallback)
callbacks[2]).getrequiresLogin();

```

If sufficient attributes are not present to form the WSCredential and the WSPincipal objects that are needed to perform authorization, the previous code sample returns a true result. When the result is false, you can choose to discontinue processing as the necessary information exists to create the Subject without performing additional remote user registry calls.

3. Optional: Look up the required attributes from the user registry, put the attributes in a hashtable, and add the hashtable to the shared state. If the identity is switched in this login module, you must complete the following steps:
  - a. Create the hashtable of attributes, as shown in the following example.
  - b. Add the hashtable to the shared state.

If the identity is not switched, but the value of the `requiresLogin` code sample shown previously is true, you can create the hashtable of attributes. However, you are not required to create a hashtable in this situation as WebSphere Application Server handles the login for you. However, you might consider creating a hashtable to gather attributes in special cases where you are using your own special user registry. Creating a `UserRegistry` implementation, using a hashtable, and letting WebSphere Application Server gather the user attributes for you might be the easiest solution. The following table shows how to create a hashtable of user attributes:

```

if (requiresLogin || identitySwitched)
{
 // Retrieves the default InitialContext for this server.
 javax.naming.InitialContext ctx = new javax.naming.InitialContext();

 // Retrieves the local UserRegistry implementation.
 com.ibm.websphere.security.UserRegistry reg = (com.ibm.websphere.
 security.UserRegistry)
 ctx.lookup("UserRegistry");

 // Retrieves the user registry uniqueID based on the uid specified
 // in the NameCallback.
 String uniqueid = reg.getUniqueUserId(uid);
 uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueid);

 // Retrieves the display name from the user registry based on the uniqueID.
 String securityName = reg.getUserSecurityName(uid);

 // Retrieves the groups associated with the uniqueID.
 java.util.List groupList = reg.getUniqueGroupIds(uid);

 // Creates the java.util.Hashtable with the information that you gathered
 // from the UserRegistry implementation.
 java.util.Hashtable hashtable = new java.util.Hashtable();
 hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_UNIQUEID, uniqueid);
 hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_SECURITYNAME, securityName);
 hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_GROUPS, groupList);

 // Adds a cache key that is used as part of the lookup mechanism for
 // the created Subject. The cache key can be an object, but should have
 // an implemented toString method. Make sure that the cacheKey contains
 // enough information to scope it to the user and any additional attributes
 // that you are using. If you do not specify this property the Subject is
 // scoped to the returned WSCREDENTIAL_UNIQUEID, by default.
 hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_CACHE_KEY, "myCustomAttribute" + uniqueid);
 // Adds the hashtable to the sharedState of the Subject.
 _sharedState.put(com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_PROPERTIES_KEY, hashtable);
}

```

The following rules define in more detail how a hashtable login is performed. You must use a `java.util.Hashtable` object in either the Subject (public or private credential set) or the shared-state `HashMap`. The `com.ibm.wsspi.security.token.AttributeNameConstants` class defines the keys that contain the user information. If the `Hashtable` object is put into the shared state of the login context using a custom login module that is listed prior to the Lightweight Third Party Authentication (LTPA) login module, the value of the `java.util.Hashtable` object is searched using the following key within the shared-state `HashMap`:

#### Property

`com.ibm.wsspi.security.cred.propertiesObject`

#### Reference to the property

`AttributeNameConstants.WSCREDENTIAL_PROPERTIES_KEY`

**Explanation**

This key searches for the Hashtable object that contains the required properties in the shared state of the login context.

**Expected result**

A java.util.Hashtable object.

If a java.util.Hashtable object is found either inside the Subject or within the shared state area, verify that the following properties are present in the hashtable:

**Property**

com.ibm.wsspi.security.cred.uniqueId

**Reference to the property**

AttributeNameConstants.WSCREDENTIAL\_UNIQUEID

**Returns**

java.util.String

**Explanation**

The value of the property must be a unique representation of the user. For the WebSphere Application Server default implementation, this property represents the information that is stored in the application authorization table. The information is located in the application deployment descriptor after it is deployed and user-to-role mapping is performed. See the expected format examples if the user to role mapping is performed using a lookup to a WebSphere Application Server user registry implementation.

If a third-party authorization provider overrides the user-to-role mapping, then the third-party authorization provider defines the format. To ensure compatibility with the WebSphere Application Server default implementation for the unique ID value, call the WebSphere Application Server public String getUniqueUserId(String userSecurityName) UserRegistry method.

**Expected format examples**

Table 112. Format examples.

This table gives some format examples when configuring inbound identity mapping.

Realm	Format (uniqueUserId)
Lightweight Directory Access Protocol (LDAP)	ldaphost.austin.ibm.com:389/cn=user,o=ibm,c=us
Windows	MYWINHOST/S-1-5-21-963918322-163748893-4247568029-500
UNIX	MYUNIXHOST/32

The com.ibm.wsspi.security.cred.uniqueId property is required.

**Property**

com.ibm.wsspi.security.cred.securityName

**Reference to the property**

AttributeNameConstants.WSCREDENTIAL\_SECURITYNAME

**Returns**

java.util.String

**Explanation**

This property searches for the securityName of the authentication user. This name is commonly called the *display name* or *short name*. WebSphere Application Server uses the securityName attribute for the getRemoteUser, getUserPrincipal and getCallerPrincipal application programming interfaces (APIs). To ensure compatibility with the WebSphere Application Server default implementation for the securityName value, call the WebSphere Application Server public String getUserSecurityName(String uniqueUserId) UserRegistry method.

## Expected format examples

Table 113. Format examples. This table gives expected format examples.

Realm	Format (uniqueUserId)
LDAP	user (LDAP UID)
Windows	user (Windows username)
UNIX	user (UNIX username)

The com.ibm.wsspi.security.cred.securityName property is required.

### Property

com.ibm.wsspi.security.cred.groups

### Reference to the property

AttributeNameConstants.WSCREDENTIAL\_GROUPS

### Returns

java.util.ArrayList

### Explanation

This key searches for the array list of groups to which the user belongs. The groups are specified in the *realm\_name/user\_name* format. The format of these groups is important as the groups are used by the WebSphere Application Server authorization engine for group-to-role mappings in the deployment descriptor. The format that is provided must match the format expected by the WebSphere Application Server default implementation. When you use a third-party authorization provider, you must use the format that is expected by the third-party provider. To ensure compatibility with the WebSphere Application Server default implementation for the unique group IDs value, call the WebSphere Application Server public List getUniqueGroupIds(String uniqueUserId) UserRegistry method.

## Expected format examples for each group in the array list

Table 114. Format examples. This table gives expected format examples for each group in the array list.

Realm	Format
LDAP	ldapl.austin.ibm.com:389/cn=group1,o=ibm,c=us
Windows	MYWINREALM/S-1-5-32-544
UNIX	MY/S-1-5-32-544

The com.ibm.wsspi.security.cred.groups property is not required. A user is not required to have associated groups.

### Property

com.ibm.wsspi.security.cred.cacheKey

### Reference to the property

AttributeNameConstants.WSCREDENTIAL\_CACHE\_KEY

### Returns

java.lang.Object

### Explanation

This key property can specify an object that represents the unique properties of the login, including the user-specific information and the user dynamic attributes that might affect uniqueness. For example, when the user logs in from location A, which might affect their access control, the cache key needs to include location A so that the Subject that is received is the correct Subject for the current location.

This com.ibm.wsspi.security.cred.cacheKey property is not required. When this property is not specified, the cache lookup is the value that is specified for WSCREDENTIAL\_UNIQUEID. When this information is found in the java.util.Hashtable object, WebSphere Application Server creates a Subject

similar to the Subject that goes through the normal login process at least for LTPA. The new Subject contains a WSCredential object and a WSPincipal object that is fully populated with the information found in the Hashtable object.

4. Add your custom login module into the RMI\_INBOUND, WEB\_INBOUND, and DEFAULT Java Authentication and Authorization Service (JAAS) system login configurations. Configure the RMI\_INBOUND login configuration so that WebSphere Application Server loads your new custom login module first.
  - a. Click **Security > Global security > Java Authentication and Authorization Service > System logins > RMI\_INBOUND**
  - b. Under Additional Properties, click **JAAS login modules > New** to add your login module to the RMI\_INBOUND configuration.
  - c. Return to the JAAS login modules panel for RMI\_INBOUND.
  - d. Click **Set order** to change the order that the login modules are loaded so that WebSphere Application Server loads your custom login module first. Use the **Move Up** or **Move Down** buttons to arrange the order of the login modules.
  - e. Repeat the previous three steps for the WEB\_INBOUND and DEFAULT login configurations.

## Results

This process configures identity mapping for an inbound request.

## Example

The “Example: Custom login module for inbound mapping” topic shows a custom login module that creates a java.util.Hashtable hashtable that is based on the specified NameCallback callback. The java.util.Hashtable hashtable is added to the sharedState java.util.Map map so that the WebSphere Application Server login modules can locate the information in the hashtable.

### *Example: Custom login module for inbound mapping:*

This sample shows a custom login module that creates a java.util.Hashtable hashtable that is based on the specified NameCallback callback. The java.util.Hashtable hashtable is added to the sharedState java.util.Map map so that the WebSphere Application Server login modules can locate the information in the Hashtable.

```
public customLoginModule()
{

public void initialize(Subject subject, CallbackHandler callbackHandler,
 Map sharedState, Map options)
{
 // (For more information on initialization, see
 // "Developing custom login modules for a system login configuration for JAAS" on page 1675.)
 _sharedState = sharedState;
}

public boolean login() throws LoginException
{
 // (For more information on what to do during login, see
 // "Developing custom login modules for a system login configuration for JAAS" on page 1675.)

 // Handles the WSTokenHolderCallback to see if this is an initial or
 // propagation login.
 javax.security.auth.callback.Callback callbacks[] =
 new javax.security.auth.callback.Callback[3];
 callbacks[0] = new javax.security.auth.callback.NameCallback("");
 callbacks[1] = new javax.security.auth.callback.PasswordCallback(
 "Password: ", false);
 callbacks[2] = new com.ibm.websphere.security.auth.callback.
 WSCredTokenCallbackImpl("");
 callbacks[3] = new com.ibm.wsspi.security.auth.callback.
 WSTokenHolderCallback("");

 try
 {
 callbackHandler.handle(callbacks);
 }
 catch (Exception e)
```

```

{
// Handles the exception
}

// Determines which callbacks contain information
boolean identitySwitched = false;
String uid = ((NameCallback) callbacks[0]).getName();
char password[] = ((PasswordCallback) callbacks[1]).getPassword();
byte[] credToken = ((WSCredTokenCallbackImpl) callbacks[2]).getCredToken();
java.util.List authzTokenList = ((WSTokenHolderCallback) callbacks[3]).
 getTokenHolderList();

if (credToken != null)
{
try
{
String uniqueID = WSSecurityPropagationHelper.validateLTPAToken(credToken);
String realm = WSSecurityPropagationHelper.getRealmFromUniqueID (uniqueID);
// Set the string to the UID so you can use the information to either
// map or login.
uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueid);
}
catch (Exception e)
{
// handle exception
}
}
else if (uid == null)
{
// The authentication data is not valid. You must have either UID
// or CredToken
throw new WLoginFailedException("invalid authentication data.");
}
else if (uid != null && password != null)
{
// This is a typical authentication. You can choose to map this ID to
// another ID or you can skip it and allow WebSphere Application Server
// to log in for you. When passwords are presented, be very careful not
// to validate the password because this is the initial authentication.

return true;
}

// You can map this uid to something else and set the identitySwitched
// boolean. If the identity is changed, clear the following propagated
// attributes so they are not used incorrectly.

## Configuring outbound identity mapping to a different target realm

By default, when WebSphere Application Server makes an outbound request from one server to another server in a different security realm, the request is rejected. This topic details alternatives for enabling one server to send outbound requests to a target server in a different realm.

### About this task

This outbound request is rejected to protect against a rogue server reading potentially sensitive information if successfully impersonating the home of the object. Select one of the following alternative procedures so that one server can send outbound requests to a target server in a different realm. When you are finished with a procedure on the administrative console, click **Apply**.

### Procedure

- Do not perform mapping. Instead, allow the existing security information to flow to a trusted target server, even if the target server resides in a different realm. Complete the following steps in the administrative console:
  1. Click **Security > Global security**.
  2. Under RMI/IIOP security, click **CSlv2 outbound authentication**.
  3. Specify the target realms in the **Trusted target realms** field. You can specify each trusted target realm that is separated by a pipe (|) character. For example, specify *server\_name.domain:port\_number* for a Lightweight Directory Access Protocol (LDAP) server or the machine name for local operating system. If you want to propagate security attributes to a different target realm, you must specify that target realm in the **Trusted target realms** field.
- Use the Java Authentication and Authorization Service (JAAS) WSLogin application login configuration to create a basic authentication Subject that contains the credentials of the new target realm. This configuration enables you to log in with a realm, user ID, and password that are specific to the user registry of the target realm. You can provide the login information from within the Java Platform,

Enterprise Edition (Java EE) application that is making the outbound request or from within the RMI\_OUTBOUND system login configuration. These two login options are described in the following information:

1. Use the WLogin application login configuration from within the Java EE application to log in and get a Subject that contains the user ID and the password of the target realm. The application can wrap the remote call with a WSSubject.doAs call. For an example, see “Example: Using the WLogin configuration to create a basic authentication subject” on page 1697.
2. Use the code sample in “Example: Using the WLogin configuration to create a basic authentication subject” on page 1697 from this plug point within the RMI\_OUTBOUND login configuration. Every outbound Remote Method Invocation (RMI) request passes through this login configuration when it is enabled. Complete the following steps to enable and plug in this login configuration:
  - a. Click **Security > Global security**.
  - b. Under RMI/IIOP security, click **CSiv2 outbound authentication**.
  - c. Select the **Custom outbound mapping** option. If the **Security Attribute Propagation** option is selected, then WebSphere Application Server is already using this login configuration and you do not need to enable custom outbound mapping.
  - d. Write a custom login module. For more information, see “Developing custom login modules for a system login configuration for JAAS” on page 1675.

The “Example: Sample login configuration for RMI\_OUTBOUND” on page 1697 shows a custom login module that determines whether the realm names match. In this example, the realm names do not match so the WLoginmodule is used to create a basic authentication Subject based on custom mapping rules. The custom mapping rules are specific to the customer environment and must be implemented using a realm to user ID and password mapping utility.

- e. Configure the RMI\_OUTBOUND login configuration so that your new custom login module is first in the list.
    - 1) Click **Security > Global security**.
    - 2) Under Java Authentication and Authorization Service, click **System logins > RMI\_OUTBOUND**
    - 3) Under Additional Properties, click **JAAS login modules > New** to add your login module to the RMI\_OUTBOUND configuration.
    - 4) Return to the JAAS login modules panel for RMI\_OUTBOUND.
    - 5) Click **Set order** to change the order that the login modules are loaded so that your custom login is loaded first.
- Add the use\_realm\_callback and use\_appcontext\_callback options to the outbound mapping module for WLogin. To add these options, complete the following steps:
    1. Click **Security > Global security**.
    2. Under Java Authentication and Authorization Service, click **Application logins > WLogin**.
    3. Under Additional properties, click **JAAS login modules > com.ibm.ws.security.common.auth.module.WLoginModuleImpl**.
    4. Under Additional properties, click **Custom Properties > New**.
    5. On the Custom properties panel, enter use\_realm\_callback in the **Name** field and true in the **Value** field.
    6. Click **OK**.
    7. Click **New** to enter the second custom property.
    8. On the Custom properties panel, enter use\_appcontext\_callback in the **Name** field and true in the **Value** field.

The following changes are made to the security.xml file:

```
<entries xmi:id="JAASConfigurationEntry_2" alias="WLogin">
<loginModules xmi:id="JAASLoginModule_2"
 moduleClassName="com.ibm.ws.security.common.auth.module.proxy.WLoginModuleProxy"
 authenticationStrategy="REQUIRED">
```

```

<options xmi:id="Property_2" name="delegate"
 value="com.ibm.ws.security.common.auth.module.WSLoginModuleImpl"/>
<options xmi:id="Property_3" name="use_realm_callback" value="true"/>
<options xmi:id="Property_4" name="use_appcontext_callback" value="true"/>
</loginModules>
</entries>

```

### **Example: Using the WSLogin configuration to create a basic authentication subject:**

This example shows how to use the WSLogin application login configuration from within a Java 2 Platform, Enterprise Edition (J2EE) application to log in and get a Subject that contains the user ID and the password of the target realm.

```

javax.security.auth.Subject subject = null;

try
{
 // Create a login context using the WSLogin login configuration and specify a
 // user ID, target realm, and password. Note: If the target_realm_name is the
 // same as the current realm, an authenticated Subject is created. However, if
 // the target_realm_name is different from the current realm, a basic
 // authentication Subject is created that is not validated. This unvalidated
 // Subject is created so that you can send a request to the different target
 // realm with valid security credentials for that realm.
 javax.security.auth.login.LoginContext ctx = new LoginContext("WSLogin",
 new WSCallbackHandlerImpl("userid", "target_realm_name", "password"));

 // Note: The following code is an alternative that validates the user ID and
 // password specified against the target realm. The code performs a remote call
 // to the target server and will return true if the user ID and password are
 // valid and false if the user ID and password are not valid. If false is
 // returned, a WSLoginFailedException exception is created. You can catch
 // that exception and perform a retry or stop the request from flowing by
 // allowing that exception to surface out of this login.

 // ALTERNATIVE LOGIN CONTEXT THAT VALIDATES THE USER ID AND PASSWORD TO THE
 // TARGET REALM

 /**** currently remarked out ****
 java.util.Map appContext = new java.util.HashMap();
 appContext.put(javax.naming.Context.INITIAL_CONTEXT_FACTORY,
 "com.ibm.websphere.naming.WsnInitialContextFactory");
 appContext.put(javax.naming.Context.PROVIDER_URL,
 "corbaloc:iiop:target_host:2809");

 javax.security.auth.login.LoginContext ctx = new LoginContext("WSLogin",
 new WSCallbackHandlerImpl("userid", "target_realm_name", "password", appContext));
 **** currently remarked out ****/

 // Starts the login
 ctx.login();

 // Gets the Subject from the context
 subject = ctx.getSubject();
}
catch (javax.security.auth.login.LoginException e)
{
 throw new com.ibm.websphere.security.auth.WSLoginFailedException (e.getMessage(), e);
}

if (subject != null)
{
 // Defines a privileged action that encapsulates your remote request.
 java.security.PrivilegedAction myAction = java.security.PrivilegedAction()
 {
 public Object run()
 {
 // Assumes a proxy is already defined. This example method returns a String
 return proxy.remoteRequest();
 }
 };

 // Starts this action using the basic authentication Subject needed for
 // the target realm security requirements.
 String myResult = (String) com.ibm.websphere.security.auth.WSSubject.doAs
 (subject, myAction);
}

```

### **Example: Sample login configuration for RMI\_OUTBOUND:**

This example shows a sample login configuration for RMI\_OUTBOUND that determines whether the realm names match between two servers.

```

public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
 Map sharedState, Map options)
 {
 // (For more information on what to do during initialization, see
 // "Developing custom login modules for a system login configuration for JAAS" on page 1675.)
 }

 public boolean login() throws LoginException
 {
 // (For more information on what to do during login, see
 // "Developing custom login modules for a system login configuration for JAAS" on page 1675.)

 // Gets the WSPolicyCallback object

 // Removes everything from the current Subject and adds everything from the
 // basic_auth_subject
 try
 {
 public final Subject basic_auth_subject_priv = basic_auth_subject;
 // Do this in a doPrivileged code block so that application code
 // does not need to add additional permissions
 java.security.AccessController.doPrivileged(new java.security.
 PrivilegedExceptionAction()
 {
 public Object run() throws WSLoginFailedException
 {
 // Removes everything user-specific from the current outbound
 // Subject. This a temporary Subject for this specific invocation
 }
 });
 }
 }
 }
}

```

```

 // so you are not affecting the Subject set on the thread. You may
 // keep any custom objects that you want to propagate in the Subject.
 // This example removes everything and adds just the new information
 // back in.
 try
 {
 subject.getPublicCredentials().clear();
 subject.getPrivateCredentials().clear();
 subject.getPrincipals().clear();
 }
 catch (Exception e)
 {
 throw new WSLoginFailedException (e.getMessage(), e);
 }

 // Adds everything from basic_auth_subject into the login subject.
 // This completes the mapping to the new user.
 try
 {
 subject.getPublicCredentials().addAll(basic_auth_subject.
 getPublicCredentials());
 subject.getPrivateCredentials().addAll(basic_auth_subject.
 getPrivateCredentials());
 subject.getPrincipals().addAll(basic_auth_subject.
 getPrincipals());
 }
 catch (Exception e)

 e.getException());
}
}
}

// Defines your login module variables
com.ibm.wsspi.security.csiv2.CSiv2PerformPolicy csiv2PerformPolicy = null;
javax.security.auth.Subject basic_auth_subject = null;
}

```

## Updating system login configurations to perform a System Authorization Facility identity user mapping

Use this task to modify configurations to perform System Authorization Facility (SAF) identity mapping.

### Before you begin

**Note:** If you are using the SAF distributed identity mapping feature, you do not need to configure a mapping module.

### About this task

A mapping module must be placed in the Java Authentication and Authorization Service (JAAS) configuration to provide the mapping from a non-local operating system registry to a SAF user ID. The `com.ibm.ws.security.common.auth.module.MapPlatformSubject` login module follows this mapping module in the configuration. You can do this using either the Simple WebSphere Authentication Mechanism (SWAM) or the Lightweight Third Party Authentication (LTPA) authentication mechanism.

Refer to [Selecting an authentication mechanism](#) for more information. Refer to [Java Authentication and Authorization Service](#) for more information.

**Note:** SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

Application login configurations do not require changes to modify configurations to perform SAF identity mapping. The WebSphere application login configuration entry `WSLogin`, calls a system login module that is configured as the default, which performs the mapping if SAF authorization is required.

To modify configurations to perform System Authorization Facility (SAF) identity mapping and if WebSphere Application Server is configured, you must take the following steps.

## Procedure

- Use the WebSphere Application Server administrative console or the scripting tools to update the required system login configurations.
- If required, update the appropriate user registry panel to enable SAF authorization.
- If you are migrating an existing WebSphere Application Server, Network Deployment installation, you must update all the nodes to the service level that supports SAF identity mapping before enabling SAF authorization for a non-local operating system registry.

## Results

### What to do next

When LTPA is configured, if you are mapping the WebSphere Application Server registry to a SAF user ID, the following system login configuration entries must be configured to provide the user mapping:

#### WEB\_INBOUND

The WEB\_INBOUND login configuration handles logins for web application requests, including servlets and JavaServer pages (JSP). This login configuration interacts with the output object that is generated from a trust association interceptor (TAI) if configured. The Subject that is passed into the WEB\_INBOUND login configuration can contain objects that are generated by the TAI.

WebSphere Application Server administrative console requests and a subset of administrative functions, including file transfer, authenticate using this login configuration entry.

#### RMI\_INBOUND

The RMI\_INBOUND login configuration handles logins for inbound RMI requests. Typically, these logins are requests for authenticated access to Enterprise JavaBeans (EJB) files, and can be performed as Java Management Extensions (JMX) requests when using the RMI connector.

#### DEFAULT

The DEFAULT login configuration handles the logins for inbound requests made by most other protocols and internal authentications, such as communication between a z/OS controller and servant processes after an initial authentication request is performed.

When SWAM is configured and you are mapping the WebSphere Application Server user registry to a SAF identity, configure the following system login configuration entry to provide the user mapping:

**Note:** SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

#### SWAM

This entry is used for all authentication when SWAM is selected.

## Security attribute propagation

With *Security attribute propagation*, WebSphere Application Server can transport security attributes (authenticated Subject contents and security context information) from one server to another in your configuration. WebSphere Application Server might obtain these security attributes from either an enterprise user registry, which queries static attributes, or a custom login module, which can query static or dynamic attributes. Dynamic security attributes, which are custom in nature, might include the authentication strength that is used for the connection, the identity of the original caller, the location of the original caller, the IP address of the original caller, and so on.

Security attribute propagation provides propagation services using Java serialization for any objects that are contained in the Subject. However, Java code must be able to serialize and deserialize these objects.

The Java programming language specifies the rules for how Java code can serialize an object. Because problems can occur when dealing with different platforms and versions of software, WebSphere Application Server also offers a token framework that enables custom serialization functionality. The token framework has other benefits that include the ability to identify the uniqueness of the token. This uniqueness determines how the Subject gets cached and the purpose of the token. The token framework defines four marker token interfaces that enable the WebSphere Application Server runtime to determine how to propagate the token.

**Important:** Any custom tokens that are used in this framework are not used by WebSphere Application Server for authorization or authentication. The framework serves as a way to notify WebSphere Application Server that you want these tokens propagated in a particular way. WebSphere Application Server handles the propagation details, but does not handle serialization or deserialization of custom tokens. Serialization and deserialization of these custom tokens are carried out by the implementation and handled by a custom login module.

With WebSphere Application Server Version 6.0 and later, a custom Java Authorization Contract for Container (JACC) provider can be configured to enforce access control for Java Platform, Enterprise Edition (Java EE) applications. A custom JACC provider can explore the custom security attributes in the caller JAAS subject in making access control decisions.

When a request is being authenticated, a determination is made by the login modules whether this request is an *initial login* or a *propagation login*. An initial login is the process of authenticating the user information, typically a user ID and password, and then calling the application programming interfaces (APIs) for the remote user registry to look up secure attributes that represent the user access rights. A propagation login is the process of validating the user information, typically a Lightweight Third Party Authentication (LTPA) token, and then deserializing a series of tokens that constitute both custom objects and token framework objects known to WebSphere Application Server.

The following marker tokens are introduced in the framework:

#### **Authorization token**

The authorization token contains most of the authorization-related security attributes that are propagated. The default authorization token is used by the WebSphere Application Server authorization engine to make Java Platform, Enterprise Edition (Java EE) authorization decisions. Service providers can use custom authorization token implementations to isolate their data in a different token, perform custom serialization and de-serialization, and make custom authorization decisions using the information in their token at the appropriate time. For information on how to use and implement this token type, see “Using the default propagation token to propagate security attributes” on page 1711 and Implementing a custom propagation token for security attribute propagation.

#### **Single sign-on (SSO) token**

A custom SingleSignonToken token that is added to the Subject is automatically added to the response as an HTTP cookie and contains the attributes sent back to web browsers. The token interface getName method with the getVersion method defines the cookie name. WebSphere Application Server defines a default SingleSignonToken token with the LtpaToken name and Version 2. The cookie name added is LtpaToken2. Do not add sensitive information, confidential information, or unencrypted data to the response cookie.

It is also recommended that any time that you use cookies, use the Secure Sockets Layer (SSL) protocol to protect the request. Using an SSO token, web users can authenticate once when accessing web resources across multiple WebSphere Application Servers. A custom SSO token extends this functionality by adding custom processing to the single sign-on scenario. For more information on SSO tokens, see “Implementing single sign-on to minimize web user authentications” on page 1607. For information on how to use and implement this token type, see

“Using the default single sign-on token with default or custom token factory to propagate security attributes” on page 1716 and Implementing a custom single sign-on token for security attribute propagation.

### **Propagation token**

The propagation token is not associated with the authenticated user so it is not stored in the Subject. Instead, the propagation token is stored on the thread and follows the invocation wherever it goes. When a request is sent outbound to another server, the propagation tokens on that thread are sent with the request and the tokens are run by the target server. The attributes that are stored on the thread are propagated regardless of the Java Platform, Enterprise Edition (Java EE) RunAs user switches.

The default propagation token monitors and logs all user switches and host switches. You can add additional information to the default propagation token using the WSSecurityHelper application programming interfaces (APIs). To retrieve and set custom implementations of a propagation token, you can use the WSSecurityPropagationHelper class. For information on how to use and implement this token type, see “Using the default propagation token to propagate security attributes” on page 1711 and Implementing a custom propagation token for security attribute propagation.

### **Authentication token**

The authentication token flows to downstream servers and contains the identity of the user. This token type serves the same function as the Lightweight Third Party Authentication (LTPA) token in previous versions. Although this token type is typically reserved for internal WebSphere Application Server purposes, you can add this token to the Subject and the token is propagated using the getBytes method of the token interface.

A custom authentication token is used solely for the purpose of the service provider that adds it to the Subject. WebSphere Application Server does not use it for authentication purposes because a default authentication token exists that is used for WebSphere Application Server authentication. This token type is available for the service provider to identify how the custom data uses the token to perform custom authentication decisions. For information on how to use and implement this token type, see “Default authentication token” on page 1704 and Implementing a custom authentication token for security attribute propagation .

### **Kerberos authentication token**

The Kerberos authentication token contains Kerberos credentials such as the Kerberos principal name, GSSCredential and Kerberos delegation credential. This token is propagated to the downstream server. Although this token type is typically reserved for internal WebSphere Application Server purposes, if it contains the GSSCredential you can use the getGSSCredential method to extract the GSSCredential. You can then place it in the subject and it can be used for your application. This token is created when you authenticate to WebSphere Application Server with either SPNEGO web or Kerberos authentication.

## **Horizontal propagation versus downstream propagation**

In WebSphere Application Server, both horizontal propagation, which uses single sign-on for web requests, and downstream propagation, which uses Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) to access enterprise beans, are available.

### **Horizontal propagation**

In horizontal propagation, security attributes are propagated among front-end servers. The serialized security attributes, which are the Subject contents and the propagation tokens, can contain both static and dynamic attributes. The single sign-on (SSO) token stores additional system-specific information that is needed for horizontal propagation. The information contained in the SSO token tells the receiving server where the originating server is located and how to communicate with that server. Additionally, the SSO token also contains the key to look up the serialized attributes. To enable horizontal propagation, you must

configure the single sign-on token and the web inbound security attribute propagation features. You can configure both of these features using the administrative console.

When front-end servers are configured and in the same data replication service (DRS) replication domain, the application server automatically propagates the serialized information to all of the servers within the same domain. In figure 1, application 1 is deployed on server 1 and server 2, and both servers are members of the same DRS replication domain. If a request originates from application 1 on server 1 and then gets redirected to application 1 on server 2, the original login attributes are found on server 2 without additional remote requests.

However, if the request originates from application 1 on either server 1 or server 2, but the request is redirected to application 2 on either server 1 or server 2, the serialized information is not found in the DRS cache because the servers are not configured in the same replication domain. As a result, a remote Java Management Extensions (JMX) request is sent back to the originating server that hosts application 1 to obtain the serialized information so that original login information is available to the application. By getting the serialized information using a single JMX remote call back to the originating server, the following benefits are realized:

- You gain the function of retrieving login information from the original server.
- You do not need to perform any remote user registry calls because the application server can regenerate the Subject from the serialized information. Without this ability, the application server might make five to six separate remote calls.

#### Figure 1

## Performance implications for horizontal propagation

The performance implications of either the DRS or JMX remote call depends upon your environment. The DRS or JMX remote call is used for obtaining the original login attributes. Horizontal propagation reduces many of the remote user registry calls in cases where these calls cause the most performance problems for an application. However, the de-serialization of these objects also might cause performance degradation, but this degradation might be less than the remote user registry calls. It is recommended that you test your environment with horizontal propagation enabled and disabled. In cases where you must use horizontal propagation for preserving original login attributes, test whether DRS or JMX provides better performance in your environment. Typically, it is recommended that you configure DRS both for failover and performance reasons. However, because DRS propagates the information to all of the servers in the same replication domain (whether the servers are accessed or not), there might be a performance degradation if too many servers are in the same replication domain. In this case, either reduce the number of servers in the replication domain or do not configure the servers in a DRS replication domain. The later suggestion causes a JMX remote call to retrieve the attributes, when needed, which might be quicker overall.

## Downstream propagation

In *downstream propagation*, a Subject is generated at the web front-end server, either by a propagation login or a user registry login. WebSphere Application Server propagates the security information downstream for enterprise bean invocations when both Remote Method Invocation (RMI) outbound and inbound propagation are enabled.

## Benefits of propagating security attributes

The security attribute propagation feature of WebSphere Application Server has the following benefits:

- Enables WebSphere Application Server to use the security attribute information for authentication and authorization purposes. The propagation of security attributes can eliminate the need for user registry

calls at each remote hop along an invocation. Previous versions of WebSphere Application Server propagated only the user name of the authenticated user, but ignored other security attribute information that needed to be regenerated downstream using remote user registry calls. To accentuate the benefits of this new functionality, consider the following example:

In previous releases, you might use a reverse proxy server (RPSS), such as WebSEAL, to authenticate the user, gather group information, and gather other security attributes. As stated previously, WebSphere Application Server accepted the identity of the authenticated user, but disregarded the additional security attribute information. To create a Java Authentication and Authorization Service (JAAS) Subject containing the needed WSCredential and WSPincipal objects, WebSphere Application Server made 5 to 6 calls to the user registry. The WSCredential object contains various security information that is required to authorize a Java EE resource. The WSPincipal object contains the realm name and the user that represents the principal for the Subject.

In the current release of the Application Server, information that is obtained from the reverse proxy server can be used by WebSphere Application Server and propagated downstream to other server resources without additional calls to the user registry. The retaining of the security attribute information enables you to protect server resources properly by making appropriate authorization and trust-based decisions. User switches that occur because of Java EE RunAs configurations do not cause the application server to lose the original caller information. This information is stored in the PropagationToken located on the running thread.

- Enables third-party providers to plug in custom tokens. The token interface contains a getBytes method that enables the token implementation to define custom serialization, encryption methods, or both.
- Provides the ability to have multiple tokens of the same type within a Subject created by different providers. WebSphere Application Server can handle multiple tokens for the same purpose. For example, you might have multiple authorization tokens in the Subject and each token might have distinct authorization attributes that are generated by different providers.
- Provides the ability to have a unique ID for each token type that is used to formulate a more unique subject identifier than just the user name in cases where dynamic attributes might change the context of a user login. The token type has a getUniqueld() method that is used for returning a unique string for caching purposes. For example, you might need to propagate a location ID, which indicates the location from which the user logs into the system. This location ID can be generated during the original login using either an reverse proxy server or the WEB\_INBOUND login configuration and added to the Subject prior to serialization. Other attributes might be added to the Subject as well and use a unique ID. All of the unique IDs must be considered for the uniqueness of the entire Subject. WebSphere Application Server has the ability to specify what is unique about the information in the Subject, which might affect how the user accesses the Subject later.

### **Default authentication token**

Do not use the default authentication token in service provider code. This default token is used by the WebSphere Application Server run-time code only and is authentication mechanism specific.

Any modifications to this token by service provider code can potentially cause interoperability problems. If you need to create an authentication token for custom usage, see Implementing a custom authentication token for security attribute propagation for more information.

### **Changing the token factory that is associated with the default authentication token**

When WebSphere Application Server generates a default authentication token, the application server utilizes the TokenFactory class that is specified using the com.ibm.wsspi.security.token.authenticationTokenFactory property. To modify this property using the administrative console, complete the following steps:

1. Click **Security > Global security**.
2. Under Additional properties, click **Custom properties**.

The `com.ibm.ws.security.ltpa.LTPATokenFactory` token factory is the default for this property. The `LTPATokenFactory` token factory uses the `DESede/ECB/PKCS5Padding` cipher. This token factory creates an interoperable Lightweight Third Party Authentication (LTPA) token.

If you associate the `com.ibm.ws.security.ltpa.LTPAToken2Factory` token factory with the `com.ibm.wsspi.security.token.authenticationTokenFactory` property, the token is Advanced Encryption Standard (AES) encrypted. However, you need to weigh the performance against your security needs. You might add additional attributes to the authentication token in the Subject during a login that are available downstream.

If you need to perform your own signing and encryption of the default authentication token, you must implement the following classes:

- `com.ibm.wsspi.security.ltpa.Token`
- `com.ibm.wsspi.security.ltpa.TokenFactory`

Your token factory implementation instantiates (`createToken`) and validates (`validateTokenBytes`) your token implementation. You can use the LTPA keys that are passed into the `initialize` method of the token factory or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API documentation, available through a link on the front page of the information center, for more information on implementing your own custom token factory. To associate your token factory with the default authentication token using the administrative console, complete the following steps:

1. Click **Security > Global security**.
2. Under Additional properties, click **Custom properties**.
3. Locate the `com.ibm.wsspi.security.token.authenticationTokenFactory` property and verify that the value of this property matches your custom token factory implementation.
4. Verify that your implementation classes are put into the `install_dir/classes` directory so that the WebSphere Application Server class loader can load the classes.

## Propagating security attributes among application servers

Use the security attribute propagation feature of WebSphere Application Server to send security attribute information regarding the original login to other servers using a token. This topic will help to configure WebSphere Application Server to propagate security attributes to other servers.

### About this task

To fully enable security attribute propagation, you must configure the single sign-on (SSO), Common Secure Interoperability Version 2 (CSIv2) inbound, and CSIv2 outbound panels in the WebSphere Application Server administrative console. You can enable just the portions of security attribute propagation relevant to your configuration. For example, you can enable web propagation, which is propagation amongst front-end application servers, using either the push technique (DynaCache) or the pull technique (remote method to originating server).

You also can choose whether to enable Remote Method Invocation (RMI) outbound and inbound propagation, which is commonly called downstream propagation. Typically both types of propagation are enabled for any given cell. In some cases, you might want to choose a different option for a specific application server using the server security panel within the specific application server settings.

**Restriction:** To prevent propagating the same security attributes among application servers multiple times, WebSphere Application Server verifies that a Lightweight Third Party Authentication (LTPA) token does not exist. Two cases can occur. Absence of the LTPA token tells the Application Server that propagation can proceed. Presence of the LTPA token indicates that propagation has occurred if the LTPA token has been generated within the cluster. However,

in the second case, if the LTPA token is present, but has been generated by a server outside the cluster, such as by Tivoli Access Manager, Lotus Domino or a different Application Server cluster, security attributes are not propagated.

To access the server security panel in the administrative console, click **Servers > Application Servers > *server\_name***. Under Security, click **Server security**.

Complete the following steps to configure WebSphere Application Server for security attribute propagation:

## Procedure

1. Access the WebSphere Application Server administrative console by typing `http://server_name:port_number/ibm/console`. The administrative console address might differ if you have previously changed the port number.
2. Click **Security > Global security**.
3. Under Web security, click **Single sign-on (SSO)**.
4. Optional: Select the **Interoperability Mode** option if you need to interoperate with servers that do not support security attribute propagation. Servers that do not support security attribute propagation receive the Lightweight Third Party Authentication (LTPA) token and the Propagation token, but ignore the security attribute information that they do not understand.
5. Select the **Web inbound security attribute propagation** option. The Web inbound security attribute propagation option enables horizontal propagation, which allows the receiving SSO token to retrieve the login information from the original login server. If you do not enable this option, downstream propagation can occur if you enable the Security Attribute Propagation option on both the CSiv2 Inbound authentication and CSiv2 outbound authentication panels.

Typically, you enable the web inbound security attribute propagation option if you need to gather dynamic security attributes set at the original login server that cannot be regenerated at the new front-end server. These attributes include any custom attributes that might be set in the PropagationToken token using the `com.ibm.websphere.security.WSSecurityHelper` application programming interfaces (APIs). You must determine whether enabling this option improves or degrades the performance of your system. While the option prevents some remote user registry calls, the deserialization and decryption of some tokens might impact performance. In some cases propagation is faster, especially if your user registry is the bottleneck of your topology. It is recommended that you measure the performance of your environment both using and not using this option. When you test the performance, it is recommended that you test in the operating environment of the typical production environment with the typical number of unique users accessing the system simultaneously.

6. Click **Security > Global security**. Under RMI/IIOP security, click **CSiv2 inbound authentication**. The Login configuration field specifies `RMI_INBOUND` as the system login configuration that is used for inbound requests. To add custom Java Authentication and Authorization Service (JAAS) login modules, complete the following steps:
  - a. Click **Security > Global security**. Under Java Authentication and Authorization Service, click **System logins**. A list of the system login configurations is displayed. WebSphere Application Server provides the following pre-configured system login configurations: `DEFAULT`, `LTPA`, `LTPA_WEB`, `RMI_INBOUND`, `RMI_OUTBOUND`, `SWAM`, `WEB_INBOUND`, `wssecurity.IDAssertion`, and `wssecurity.Signature`. Do not delete these predefined configurations.

**Note:** SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.
  - b. Click the name of the login configuration that you want to modify.
  - c. Under Additional Properties, click **JAAS Login Modules**. The JAAS Login Modules panel is displayed, which lists all of the login modules that are processed in the login configuration. Do not

delete the required JAAS login modules. Instead, you can add custom login modules before or after the required login modules. If you add custom login modules, do not begin their names with `com.ibm.ws.security.server`.

You can specify the order in which the login modules are processed by clicking **Set Order**.

7. Select the **Security attribute propagation** option on the CSiv2 inbound authentication panel. When you select **Security Attribute Propagation**, the server advertises to other application servers that it can receive propagated security attributes from another server in the same realm over the Common Secure Interoperability version 2 (CSiv2) protocol.
8. Click **Security > Global security**. Under RMI/IIOP security, click **CSiv2 Outbound authentication**. The CSiv2 outbound authentication panel is displayed. The **Login configuration** field specifies `RMI_OUTBOUND` as the JAAS login configuration that is used for outbound configuration. You cannot change this login configuration. Instead, you can customize this login configuration by completing the substeps that are listed previously for CSiv2 Inbound authentication.
9. Optional: Verify that the **Security Attribute Propagation** option is selected if you want to enable outbound Subject and security context token propagation for the Remote Method Invocation (RMI) protocol. When you select this option, WebSphere Application Server serializes the Subject contents and the PropagationToken contents. After the contents are serialized, the server uses the CSiv2 protocol to send the Subject and PropagationToken token to the target servers that support security attribute propagation. If the receiving server does not support security attribute tokens, WebSphere Application Server sends the Lightweight Third Party Authentication (LTPA) token only.

**Important:** WebSphere Application Server propagates only the objects within the Subject that it can serialize. The server propagates custom objects on a best-effort basis.

When **Security Attribute Propagation** is enabled, WebSphere Application Server adds marker tokens to the Subject to enable the target server to add additional attributes during the inbound login. During the commit phase of the login, the marker tokens and the Subject are marked as read-only and cannot be modified thereafter.

**Important:** When using security attribute propagation, use the same LTPA keys in all cell configurations.

10. Optional: Select the **Custom Outbound Mapping** option if you clear the **Security Attribute Propagation** option and you want to use the `RMI_OUTBOUND` login configuration. If neither the **Custom Outbound Mapping** option nor the **Security Attribute Propagation** option is selected, WebSphere Application Server does not call the `RMI_OUTBOUND` login configuration. If you need to plug in a credential mapping login module, you must select the **Custom Outbound Mapping** option.
11. Optional: Specify trusted target realm names in the **Trusted Target Realms** field. By specifying these realm names, information can be sent to servers that reside outside the realm of the sending server to support inbound mapping that is at these downstream servers. To perform outbound mapping to a realm different from the current realm, you must specify the realm in this field so that you can get to this point without having the request rejected because of a realm mismatch. If you need WebSphere Application Server to propagate security attributes to another realm when a request is sent, you must specify the realm name in the **Trusted Target Realms** field. Otherwise, the security attributes are not propagated to the unspecified realm. You can add multiple target realms by adding a pipe (|) delimiter between each entry.
12. Optional: Enable propagation for a pure client. For a pure client to propagate attributes added to the invocation Subject, you must add the following property to the `sas.client.props` file:  
`com.ibm.CSI.rmiOutboundPropagationEnabled=true`

**Note:** The `sas.client.props` file is located at `<WAS-HOME>/profiles/<ProfileName>/properties`.

## Results

After completing these steps, you have configured WebSphere Application Server to propagate security attributes to other servers.

## What to do next

If you need to disable security attribute propagation, determine whether you need to disable it for either the server level or the cell level.

**Attention:** Changes to the server-level settings override the cell settings.

To disable security attribute propagation on the server level, complete the following steps:

1. Click **Server > Application Servers > *server\_name***.
2. Under Security, click **Server security**.
3. Select the **RMI/IIOP security for this server overrides cell settings** option.
4. Disable security attribute propagation for inbound requests by clicking **CSI inbound authentication** under Additional Properties and clearing the **Security attribute propagation** option.
5. Disable security attribute propagation for outbound requests by clicking **CSI outbound authentication** under Additional Properties and clearing the **Security attribute propagation** option.

To disable security attribute propagation on the cell level, undo each of the steps that you completed to enable security attribute propagation in this task.

## Using the default authorization token to propagate security attributes

This topic explains how WebSphere Application Server uses the default authorization token. Consider using the default authorization token when you are looking for a place to add string attributes that get propagated downstream.

### About this task

However, make sure that the attributes you add to the authorization token are specific to the user that is associated with the authenticated Subject. If they are not specific to a user, the attributes probably belong in the propagation token, which is also propagated with the request. For more information on the propagation token, see “Using the default propagation token to propagate security attributes” on page 1711. To add attributes into the authorization token, you must plug in a custom login module into the various system login modules that are configured. Any login module configuration that has the `com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule` implementation configured can receive propagated information and can generate propagation information that can be sent outbound to another server.

If propagated attributes are not presented to the login configuration during an initial login, a default authorization token is created in the `wsMapDefaultInboundLoginModule` login module after the login occurs in the `ltpaLoginModule` login module. You can obtain a reference to the default authorization token from the login method using the `sharedState` hashmap. You must plug in the custom login module after the `wsMapDefaultInboundLoginModule` implementation for WebSphere Application Server to see the default authorization token.

For more information on the Java Authentication and Authorization Service (JAAS) programming model, see the [Security: Resources for learning](#) article.

### Procedure

- Obtain a reference to the default authorization token from the login method.
- Add attributes to the token.
- Read existing attributes used for authorization.
- Ensure that your custom login module code is trusted. Whenever you plug a custom login module into the WebSphere Application Server login infrastructure, you must ensure that the code is trusted. When you add the login module into the `app_server_root/classes` directory, it has Java 2 Security AllPermissions permissions. It is recommended that you add your login module and other infrastructure

classes into a private directory. However, if you use a private directory, modify the `$(WAS_INSTALL_ROOT)/properties/server.policy` file so that the private directory, Java archive (JAR) file, or both have the permissions that are needed to run the application programming interfaces (API) that are called from the login module. Because the login module might run after the application code on the call stack, you might consider adding a `doPrivileged` code block so that you do not need to add additional permissions to your applications.

- Modify the authorization token factory to use a token factory other than the default token factory.

When WebSphere Application Server generates a default authorization token, the application server utilizes the `TokenFactory` class that is specified using the `com.ibm.wsspi.security.token.authorizationTokenFactory` property.

The `com.ibm.ws.security.ltpa.AuthzPropTokenFactory` token factory is the default. This token factory encodes the data, but does not encrypt the data in the authorization token. Because the authorization token typically flows over Common Secure Interoperability Version 2 (CSIv2) using Secure Sockets Layer (SSL), encrypting the token is not necessary. However, if you need additional security for the authorization token, you can associate a different token factory implementation with this property to get encryption. For example, if you associate the `com.ibm.ws.security.ltpa.LTPAToken2Factory` token factory with this property, the token uses Advanced Encryption Standard (AES) encryption. However, you need to weigh the performance impacts against your security needs. Adding sensitive information to the authorization token is one reason to change the token factory implementation to something that encrypts rather than just encodes.

1. Open the administrative console.
2. Click **Security > Global security**.
3. Under Additional properties, click **Custom properties**.

- Perform your own signing and encryption of the default authorization token.

If you want to perform your own signing and encryption of the default authorization token, you must implement the following classes:

- `com.ibm.wsspi.security.ltpa.Token`
- `com.ibm.wsspi.security.ltpa.TokenFactory`

Your token factory implementation instantiates and validates your token implementation. You can use the Lightweight Third Party Authentication (LTPA) keys that are passed into the `initialize` method of the token factory or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API documentation, that is available through a link on the front page of the information center, for more information on implementing your own custom token factory.

- Associate your token factory with the default authorization token.

To associate your token factory with the default authorization token, using the administrative console, complete the following steps:

1. Click **Security > Global security**.
2. Under Additional properties, click **Custom properties**.
3. Locate the `com.ibm.wsspi.security.token.authorizationTokenFactory` property and verify that the value of this property matches your custom token factory implementation.
4. Verify that your implementation classes are put into the `app_server_root/classes` directory so that the WebSphere Application Server class loader can load the classes.
5. Verify that your implementation classes are put into the `${USER_INSTALL_ROOT}/classes` directory so that the WebSphere Application Server class loader can load the classes.

## Example

The following example shows the complete task of obtaining a reference to the default authorization token from the login method, adding attributes to the token, and reading from the existing attributes that are used for authorization.

```

public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
 Map sharedState, Map options)
 {
 // (For more information on initialization, see
 // "Developing custom login modules for a system login configuration for JAAS" on page 1675.)

 // Get a reference to the sharedState map that is passed in during initialization.
 _sharedState = sharedState;
 }

 public boolean login() throws LoginException
 {
 // (For more information on what to do during login, see
 // "Developing custom login modules for a system login configuration for JAAS" on page 1675.)

 // Look for the default AuthorizationToken in the shared state
 defaultAuthzToken = (com.ibm.wsspi.security.token.AuthorizationToken)
 sharedState.get
 (com.ibm.wsspi.security.auth.callback.Constants.WSAUTHZTOKEN_KEY);

 // Might not always have one of these generated. It depends on the login
 // configuration setup.
 if (defaultAuthzToken != null)
 {
 try
 {
 // Add a custom attribute
 defaultAuthzToken.addAttribute("key1", "value1");

 // Determine all of the attributes and values that exist in the token.
 java.util.Enumeration listOfAttributes = defaultAuthzToken.
 getAttributeNames();

 while (listOfAttributes.hasMoreElements())
 {
 String key = (String) listOfAttributes.nextElement();

 String[] values = (String[]) defaultAuthzToken.getAttributes (key);

 for (int i=0; i<values.length; i++)
 {
 System.out.println ("Key: " + key + ", Value[" + i + "]: "
 + values[i]);
 }
 }

 // Read the existing uniqueID attribute.
 String[] uniqueID = defaultAuthzToken.getAttributes
 (com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_UNIQUEID);

 // Get the uniqueID from the String[]
 String unique_id = (uniqueID != null &&
 uniqueID[0] != null) ? uniqueID[0] : "";

 // Read the existing expiration attribute.
 String[] expiration = defaultAuthzToken.getAttributes
 (com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_EXPIRATION);

 // An example of getting a long expiration value from the string array.
 long expire_time = 0;
 if (expiration != null && expiration[0] != null)
 expire_time = Long.parseLong(expiration[0]);

 // Read the existing display name attribute.
 String[] securityName = defaultAuthzToken.getAttributes
 (com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_SECURITYNAME);

 // Get the display name from the String[]
 String display_name = (securityName != null &&
 securityName[0] != null) ? securityName[0] : "";

 // Read the existing long securityName attribute.
 String[] longSecurityName = defaultAuthzToken.getAttributes
 (com.ibm.wsspi.security.token.AttributeNameConstants.
 WSCREDENTIAL_LONGSECURITYNAME);

 // Get the long security name from the String[]
 String long_security_name = (longSecurityName != null &&
 longSecurityName[0] != null) ? longSecurityName[0] : "";

 // Read the existing group attribute.
 String[] groupList = defaultAuthzToken.getAttributes
 (com.ibm.wsspi.security.token.AttributeNameConstants.

```

```

 WSCREDENTIAL_GROUPS);

// Get the groups from the String[]
ArrayList groups = new ArrayList();
if (groupList != null)
{
 for (int i=0; i<groupList.length; i++)
 {
 System.out.println ("group[" + i + "] = " + groupList[i]);
 groups.add(groupList[i]);
 }
}
catch (Exception e)
{
 throw new WSLoginFailedException (e.getMessage(), e);
}
}

public boolean commit() throws LoginException
{
 // (For more information on what to do during commit, see
 // "Developing custom login modules for a system login configuration for JAAS" on page 1675.)
}

private java.util.Map _sharedState = null;
private com.ibm.wsspi.security.token.AuthorizationToken defaultAuthzToken = null;
}

```

## Using the default propagation token to propagate security attributes

A default propagation token is located on the running thread for applications and the security infrastructure to use. The product propagates this default propagation token downstream and the token stays on the thread where the invocation lands at each hop.

### About this task

The data is available from within the container of any resource where the propagation token lands. Remember that you must enable the propagation feature at each server where a request is sent for propagation to work. Make sure that you enable security attribute propagation for all of the cells in your environment where you want propagation

There is a WSSecurityHelper class that has application programming interfaces (APIs) for accessing the PropagationToken attributes. This topic documents the usage scenarios and includes examples. A close relationship exists between the propagation token and the work area feature. The main difference between these features is that after you add attributes to the propagation token, you cannot change the attributes. You cannot change these attributes so that the security runtime can add auditable information and have that information remain there for the life of the invocation. Any time that you add an attribute to a specific key, an ArrayList object is stored to hold that attribute. Any new attribute that is added with the same key is added to the ArrayList object. When you call getAttributes, the ArrayList object is converted to a String array and the order is preserved. The first element in the String array is the first attribute added for that specific key.

In the default propagation token, a change flag is kept that logs any data changes to the token. These changes are tracked to enable WebSphere Application Server to know when to send the authentication information downstream again so that the downstream server has those changes. Normally, Common Secure Interoperability Version 2 (CSIv2) maintains a session between servers for an authenticated client. If the propagation token changes, a new session is generated and subsequently a new authentication occurs. Frequent changes to the propagation token during a method cause frequent downstream calls. If you change the token prior to making many downstream calls or you change the token between each downstream call, you might impact security performance.

## Procedure

- Obtain the server list from the default propagation token.

Every time the propagation token is propagated and used to create the authenticated Subject, either horizontally or downstream, the name of the receiving application server is logged into the propagation token. The format of the host is "Cell:Node:Server", which provides you access to the cell name, node name, and server name of each application server that receives the invocation.

The following code provides you with this list of names and can be called from a Java 2 Platform, Enterprise Edition (J2EE) application.

The format of each server in the list is: *cell.node\_name.server\_name*. The output, for example, is: myManager:node1:server1

```
String[] server_list = null;

// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
 // Gets the server_list string array
 server_list = com.ibm.websphere.security.WSSecurityHelper.getServerList();
 }
 catch (Exception e)
 {
 // Performs normal exception handling for your application
 }

 if (server_list != null)
 {
 // print out each server in the list, server_list[0] is the first server
 for (int i=0; i<server_list.length; i++)
 {
 System.out.println("Server[" + i + "] = " + server_list[i]);
 }
 }
}
```

- Obtain the list of callers, using the `getCallerList` API.

A default propagation token is generated any time an authenticated user is set on the running thread or anyone tries to add attributes to the propagation token. Whenever an authenticated user is set on the thread, the user is logged in the default propagation token. At times, the same user might be logged in multiple times if the RunAs user is different from the caller. The following list provides the rules that are used to determine if a user that is added to the thread gets logged into the propagation token:

- The current Subject must be authenticated. For example, an unauthenticated Subject is not logged.
- The current authenticated Subject is logged if a Subject is not previously logged.
- The current authenticated Subject is logged if the last authenticated Subject that is logged does not contain the same user.
- The current authenticated Subject is logged on each unique application server that is involved in the propagation process.

The following code sample shows how to use the `getCallerList` API.

The format of each caller in the list is: *cell:node\_name:server\_name:realm:port\_number/securityName*. The output, for example, is: myManager:node1:server1:ldap.austin.ibm.com:389/jsmith.

```
String[] caller_list = null;
```

```

// If security is disabled on this application server, do not check the caller list
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
 // Gets the caller_list string array
 caller_list = com.ibm.websphere.security.WSSecurityHelper.getCallerList();
 }
 catch (Exception e)
 {
 // Performs normal exception handling for your application
 }

 if (caller_list != null)
 {
 // Prints out each caller in the list, caller_list[0] is the first caller
 for (int i=0; i<caller_list.length;i++)
 {
 System.out.println("Caller[" + i + "] = " + caller_list[i]);
 }
 }
}

```

- Obtain the security name of the first authenticated user, using the `getFirst Caller` API.

Whenever you want to know which authenticated caller started the request, you can call the `getFirstCaller` method and the caller list is parsed. However, this method returns the security name of the caller only. If you need to know more than the security name, call the `getCallerList` method and retrieve the first entry in the String array. This entry provides all the caller information.

The following code sample retrieves the security name of the first authenticated caller using the `getFirstCaller` API.

The output, for example, is: `jsmith`.

```

String first_caller = null;

// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
 // Gets the first caller
 first_caller = com.ibm.websphere.security.WSSecurityHelper.getFirstCaller();

 // Prints out the caller name
 System.out.println("First caller: " + first_caller);
 }
 catch (Exception e)
 {
 // Performs normal exception handling for your application
 }
}

```

- Obtain the name of the first application server for a request, using the `getFirstServer` method.

Whenever you want to know what the first application server is for this request, call the `getFirstServer` method directly.

The following code sample retrieves the name of the first application server using the `getFirstServer` API.

The output, for example, is: myManager:nodel:server1.

```
String first_server = null;

// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
 // Gets the first server
 first_server = com.ibm.websphere.security.WSSecurityHelper.getFirstServer();

 // Prints out the server name
 System.out.println("First server: " + first_server);
 }
 catch (Exception e)
 {
 // Performs normal exception handling for your application
 }
}
```

- Add custom attributes to the default propagation token, using the addPropagationAttribute API.

You can add custom attributes to the default propagation token for application usage. This token follows the request downstream so that the attributes are available when needed. When you use the default propagation token to add attributes, you must understand the following issues:

- Adding information to the propagation token affects CSIV2 session caching. Add information sparingly between remote requests.
- After you add information with a specific key, the information cannot be removed.
- You can add as many values to a specific key as you need. However, all of the values must be available from a returned String array in the order that they were added.
- The propagation token is available only on servers where propagation and security are enabled.
- The Java 2 Security javax.security.auth.AuthPermission wssecurity.addPropagationAttribute attribute is needed to add attributes to the default propagation token.
- An application cannot use keys that begin with either com.ibm.websphere.security or com.ibm.wsspi.security. These prefixes are reserved for system usage.

The following code sample shows how to use the addPropagationAttribute API.

```
// If security is disabled on this application server,
// do not check the status of server security
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
 // Specifies the key and values
 String key = "mykey";
 String value1 = "value1";
 String value2 = "value2";

 // Sets key, value1
 com.ibm.websphere.security.WSSecurityHelper.
 addPropagationAttribute (key, value1);

 // Sets key, value2
 String[] previous_values = com.ibm.websphere.security.WSSecurityHelper.
 addPropagationAttribute (key, value2);
 }
}
```

```

 // Note: previous_values should contain value1
}
catch (Exception e)
{
 // Performs normal exception handling for your application
}
}

```

- Obtain your custom attributes with the `getPropagationAttributes` API.

Custom attributes are added to the default propagation token using the `addPropagationAttribute` API. Retrieve these attributes using the `getPropagationAttributes` API. This token follows the request downstream so the attributes are available when needed. When you use the default propagation token to retrieve attributes, you must understand the following issues:

- The propagation token is available only on servers where propagation and security are enabled.
- The Java 2 Security `javax.security.auth.AuthPermission "wssecurity.getPropagationAttributes"` permission is needed to retrieve attributes from the default propagation token.

See [Adding custom attributes to the default PropagationToken to add attributes using the `addPropagationAttributes` API](#).

The following code sample shows how to use the `getPropagationAttributes` API.

```

// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
 String key = "mykey";
 String[] values = null;

 // Sets key, value1
 values = com.ibm.websphere.security.WSSecurityHelper.
 getPropagationAttributes (key);

 // Prints the values
 for (int i=0; i<values.length; i++)
 {
 System.out.println("Value[" + i + "] = " + values[i]);
 }
 }
 catch (Exception e)
 {
 // Performs normal exception handling for your application
 }
}

```

The output, for example, is:

```

Value[0] = value1
Value[1] = value2

```

- Modify the propagation token factory configuration to use a token factory other than the default token factory.

When WebSphere Application Server generates a default propagation token, the Application Server utilizes the `TokenFactory` class that is specified using the `com.ibm.wsspi.security.token.propagationTokenFactory` property.

The default token factory that is specified for this property is called `com.ibm.ws.security.ltpa.AuthzPropTokenFactory`. This token factory encodes the data in the propagation token and does not encrypt the data. Because the propagation token typically flows over CSiv2 using Secure Sockets Layer (SSL), encrypting the token is not required. However, if you need additional security for the propagation token, you can associate a different token factory implementation with this property to get encryption. For example, if you choose to associate the `com.ibm.ws.security.ltpa.LTPAToken2Factory` token factory with this property, the token is AES encrypted. However, you need to weigh the performance impacts against your security needs. Adding sensitive information to the propagation token is a good reason to change the token factory implementation to something that encrypts rather than just encodes.

1. Open the administrative console.
  2. Click **Security > Global security**.
  3. Click **Custom properties**.
- Perform your own signing and encryption of the default propagation token.

If you want to perform your own signing and encryption of the default propagation token, you must implement the following classes:

- `com.ibm.wsspi.security.ltpa.Token`
- `com.ibm.wsspi.security.ltpa.TokenFactory`

Your token factory implementation instantiates and validates your token implementation. You can choose to use the Lightweight Third Party Authentication (LTPA) keys and have them pass into the `initialize` method of the token factory, or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API documentation, available through a link on the front page of the information center, for more information on implementing your own custom token factory.

- Associate your token factory with the default propagation token.
  1. Open the administrative console.
  2. Click **Security > Global security**.
  3. Click **Custom properties**.
  4. Locate the `com.ibm.wsspi.security.token.propagationTokenFactory` property and verify that the value of this property matches your custom token factory implementation.
  5. Verify that your implementation classes are put into the `app_server_root/classes` directory so that the WebSphere Application Server class loader can load the classes.
  6. Verify that your implementation classes are located in the `${USER_INSTALL_ROOT}/classes` directory so that the WebSphere Application Server class loader can load the classes.

## Example

### Using the default single sign-on token with default or custom token factory to propagate security attributes

Do not use the default single sign-on token in service provider code. This default token is used by the WebSphere Application Server run-time code only.

## Before you begin

Size limitations exist for this token when it is added as an HTTP cookie. If you need to create an HTTP cookie using this token framework, you can implement a custom single sign-on token. To implement a custom single sign-on token see [Implementing a custom single sign-on token for security attribute propagation](#) for more information.

## Procedure

- Modify the single sign-on token factory configuration to use a token factory other than the default token factory.

When the default single sign-on token is generated, the application server utilizes the `TokenFactory` class that is specified using the `com.ibm.wsspi.security.token.singleSignonTokenFactory` property. Use the administrative console to modify the property.

The `com.ibm.ws.security.ltpa.LTPAToken2Factory` token factory is the default that is specified for this property. This token factory creates a single sign-on (SSO) token called `LtpaToken2`, which WebSphere Application Server uses for propagation. This token factory uses the AES/CBC/PKCS5Padding cipher.

1. Open the administrative console.
  2. Click **Security > Global security**.
  3. Under Authentication, click **Custom properties**.
- Perform your own signing and encryption of the default single sign-on token.

If you need to perform your own signing and encryption of the default single sign-on token, you must implement the following classes:

- `com.ibm.wsspi.security.ltpa.Token`
- `com.ibm.wsspi.security.ltpa.TokenFactory`

Your token factory implementation instantiates (`createToken`) and validates (`validateTokenBytes`) your token implementation. You can use the Lightweight Third-Party Authentication (LTPA) keys passed into the `initialize` method of the token factory or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API reference information for more information on implementing your own custom token factory.

- Associate your own token factory with the default single sign-on token.
  1. Open the administrative console.
  2. Click **Security > Global security**.
  3. Under Authentication, click **Custom properties**.
  4. Locate the `com.ibm.wsspi.security.token.singleSignonTokenFactory` property and verify that the value of this property matches your custom `TokenFactory` implementation.
  5. Verify that your implementation classes are put into the `app_server_root/classes` directory so that the WebSphere Application Server class loader can load the classes.
  6. Verify that your implementation classes are located in the `${USER_INSTALL_ROOT}/classes` directory so that the WebSphere Application Server class loader can load the classes.

## Configuring the authentication cache

The security authentication cache affects the frequency of rehashing and the distribution of the hash algorithms.

### About this task

To configure the authentication cache properties, complete the following steps:

#### Procedure

1. Click **Servers > Application Servers > *server\_name***.
2. Under Server infrastructure, click **Java and Process Management > Process definition**.
3. Under Additional properties, click **Java Virtual Machine > Custom Properties**.
4. Click **New** to specify a new custom property.

### What to do next

For information on the supported authentication cache properties, see “Authentication cache settings” on page 1413.

## Configuring Common Secure Interoperability Version 2 (CSIV2) inbound and outbound communication settings

WebSphere Application Server enables you to specify Internet Inter-ORB Protocol (IIOP) authentication for both inbound and outbound authentication requests. For inbound requests, you can specify the type of accepted authentication, such as basic authentication. For outbound requests, you can specify properties such as type of authentication, identity assertion or login configurations that are used for requests to downstream servers.

### About this task

Complete the following steps to configure Common Secure Interoperability Version 2 (CSIV2) and Security Authentication Service (SAS).

**Important:** SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

### Procedure

1. Determine how to configure security inbound and outbound at each point in your infrastructure.

For example, you might have a Java client communicating with an Enterprise JavaBeans (EJB) application server, which in turn communicates to a downstream EJB application server.

A CSIV2 Java client utilizes a configuration file that is specified by the `com.ibm.CORBA.ConfigURL` Java property to configure outbound security.

The upstream EJB application server configures inbound security to handle the correct type of authentication from the Java client. The upstream EJB application server utilizes the outbound security configuration when going to the downstream EJB application server.

This type of authentication might be different than what you expect from the Java client into the upstream EJB application server. Security might be tighter between the pure client and the first EJB server, depending on your infrastructure. The downstream EJB server utilizes the inbound security configuration to accept requests from the upstream EJB server. These two servers require similar configuration options as well. If the downstream EJB application server communicates to other downstream servers, the outbound security might require a special configuration.

2. Specify the type of authentication.

By default, the server supports authentication with a user ID and password.

Both Java client certificate authentication and identity assertion are disabled by default. If you want this type of authentication performed at every tier, use the CSIV2 authentication protocol configuration as is. However, if you have any special requirements where some servers authenticate differently from other servers, consider how to configure CSIV2 to its best advantage.

3. Configure clients and servers.

Configuring a pure Java client is done through a properties file that is specified by the `com.ibm.CORBA.ConfigURL` Java property.

Configuring servers is always done from the administrative console or scripting, either from the security navigation for cell-level configurations or from the server security of the application server for server-level configurations. If you want some servers to authenticate differently from others, modify some of the server-level configurations. When you modify the server-level configurations, you are overriding the cell-level configurations.

### What to do next

Use CSIV2 inbound communications settings for configuring the type of authentication information that is contained in an incoming request or transport.

Use CSIV2 outbound communications settings to specify the features that a server supports when acting as a client to another downstream server.

## Configuring Common Secure Interoperability Version 2 inbound communications

*Inbound communications* refers to the configuration that determines the type of accepted authentication for inbound requests. This authentication is advertised in the interoperable object reference (IOR) that the client retrieves from the name server.

### Procedure

1. Start the administrative console.
2. Click **Security > Global security**.
3. Under RMI/IIOP security, click **CSIV2 inbound communications**.
4. Consider the following layers of security:
  - Identity assertion (attribute layer).

When selected, this server accepts identity tokens from upstream servers. If the server receives an identity token, the identity is taken from an originating client. For example, the identity is in the same form that the originating client presented to the first server. An upstream server sends the identity of the originating client. The format of the identity can be either a principal name, a distinguished name, or a certificate chain. In some cases, the identity is anonymous. It is important to trust the upstream server that sends the identity token because the identity authenticates on this server. Trust of the upstream server is established either using Secure Sockets Layer (SSL) client certificate authentication or basic authentication. You must select one of the two layers of authentication in both inbound and outbound authentication when you choose identity assertion.

**Note:** If your configured registry is Local OS, then the trust is instead established by checking if the upstream server identity is authorized on the downstream server with UPDATE authority to the CBIND class, profile CB.BIND.<optionalSAFProfilePrefix>.<cluster\_short\_name>. The upstream server identity is sent using an SSL client certificate. If SSL is not used, the CBIND check is performed against the started task identity of the upstream server.

**Note:** When identity assertion is enabled, message layer or transport layer should be enabled also. For server-to-server communication, besides enabling transport layer/client authentication, identity assertion or message layer should be enabled also.

For more information, refer to Identity assertion.

- Message layer:

#### **Basic authentication (GSSUP):**

This type of authentication is the most typical. The user ID and password or authenticated token is sent from a pure client or from an upstream server. When a user ID and password are received at the server, they are authenticated with the user registry of the downstream server.

#### **Lightweight Third Party Authentication (LTPA):**

In this case, an LTPA token is sent from the upstream server. Note that if you choose LTPA, then both servers must share the same LTPA keys

#### **Kerberos (KRB5):**

To select Kerberos, the active authentication mechanism must be Kerberos. In this case, a Kerberos token is sent from the upstream server.

For more information, read about Message layer authentication.

- Secure Sockets Layer client certificate authentication (transport layer).

The SSL client certificate is used to authenticate instead of using user ID and Password. If a server delegates an identity to a downstream server, the identity comes from either the message layer (a client authentication token) or the attribute layer (an identity token), and not from the transport layer through the client certificate authentication.

A client has an SSL client certificate that is stored in the key ring file of the client configuration. When SSL client authentication is enabled on this server, the server requests that the client send the SSL client certificate when the connection is established. The certificate chain is available on the socket whenever a request is sent to the server. The server request interceptor gets the certificate chain from the socket and maps this certificate chain to a user in the user registry. This type of authentication is optimal for communicating directly from a client to a server. However, when you have to go downstream, the identity typically flows over the message layer or through identity assertion.

5. Consider the following points when deciding what type of authentication to accept:
  - A server can receive multiple layers simultaneously, so an order of precedence rule decides which identity to use. The identity assertion layer has the highest priority, the message layer follows, and the transport layer has the lowest priority. The SSL client certificate authentication is used when it is the only layer provided. If the message layer and the transport layer are provided, the message layer is used to establish the identity for authorization. The identity assertion layer is used to establish precedence when provided.
  - Does this server usually receive requests from a client, from a server, or both? If the server always receives requests from a client, identity assertion is not needed. You can choose either the message layer, the transport layer, or both. You also can decide when authentication is required or just supported. To select a layer as required, the sending client must supply this layer, or the request is rejected. However, if the layer is only supported, the layer might not be supplied.
  - What kind of client identity is supplied? If the client identity is client certificates authentication and you want the certificate chain to flow downstream so that it maps to the downstream server user registries, identity assertion is the appropriate choice. Identity assertion preserves the format of the originating client. If the originating client authenticated with a user ID and password, a principal identity is sent. If authentication is done with a certificate, the certificate chain is sent.
6. Configure a trusted server list. When identity assertion is selected for inbound requests, insert a pipe-separated (|) list of server administrator IDs to which this server can support identity token submission. For backwards compatibility, you can still use a comma-delimited list. However, if the server ID is a distinguished name (DN), then you must use a pipe-delimited (|) list because a comma delimiter does not work. If you choose to support any server sending an identity token, you can enter an asterisk (\*) in this field. This action is called *presumed trust*. In this case, use SSL client certificate authentication between servers to establish the trust.  
  
**Note:** This step applies if you are using a Lightweight Directory Access Protocol (LDAP) or custom user registry. However, it does not apply when you are using the local operating system user registry or a System Authorization Facility (SAF) user registry.
7. Configure session management. You can choose either *stateful* or *stateless* security. Performance is optimum when choosing stateful sessions. The first method request between a client and server is authenticated. All subsequent requests (or until the credential token expires) reuse the session information, including the credential. A client sends a context ID for subsequent requests. The context ID is scoped to the connection for uniqueness.

## Results

When you finish configuring this panel, you have configured most of the information that a client gathers when determining what to send to this server. A client or server outbound configuration with this server inbound configuration, determines the security that is applied. When you know what clients send, the configuration is simple. However, if you have a diverse set of clients with differing security requirements, your server considers various layers of authentication.

For a J2EE application server, the authentication choice is usually either identity assertion or message layer because you want the identity of the originating client delegated downstream. You cannot easily delegate a client certificate using an SSL connection. It is acceptable to enable the transport layer because additional server security, as the additional client certificate portion of the SSL handshake, adds some overhead to the overall SSL connection establishment.

## What to do next

After you determine which type of authentication data this server might receive, you can determine what to select for outbound security. For more information, see *Configuring Common Secure Interoperability Version 2* outbound authentication.

### ***Common Secure Interoperability Version 2 inbound communications settings:***

Use this page to specify the features that a server supports for a client accessing its resources.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. From Authentication, click **RMI/IOP security > CSiv2 inbound communications**.

Use common secure interoperability (CSI) inbound communications settings for configuring the type of authentication information that is contained in an incoming request or transport.

Authentication features include three layers of authentication that you can use simultaneously:

- **CSiv2 attribute layer.** The attribute layer might contain an identity token, which is an identity from an upstream server that already is authenticated. The identity layer has the highest priority, followed by the message layer, and then the transport layer. If a client sends all three, only the identity layer is used. The only way to use the SSL client certificate as the identity is if it is the only information that is presented during the request. The client picks up the interoperable object reference (IOR) from the namespace and reads the values from the tagged component to determine what the server needs for security.
- **CSiv2 transport layer.** The transport layer, which is the lowest layer, might contain a Secure Sockets Layer (SSL) client certificate as the identity.

#### *Propagate security attributes:*

Specifies support for security attribute propagation during login requests. When you select this option, the application server retains additional information about the login request, such as the authentication strength used, and retains the identity and location of the request originator.

If you do not select this option, the application server does not accept any additional login information to propagate to downstream servers.

**Default:** Enabled

**Important:** When you use the replication services, ensure that the **Propagate security attributes** option is enabled.

#### *Use identity assertion:*

Specifies that identity assertion is a way to assert identities from one server to another during a downstream Enterprise JavaBeans (EJB) invocation.

This server does not authenticate the asserted identity again because it trusts the upstream server. Identity assertion takes precedence over all other types of authentication.

Identity assertion is performed in the attribute layer and is only applicable on servers. The principal determined at the server is based on precedence rules. If identity assertion is used, the identity is always derived from the attribute layer. If basic authentication is used without identity assertion, the identity is always derived from the message layer. Finally, if SSL client certificate authentication is performed without either basic authentication, or identity assertion, then the identity is derived from the transport layer.

The identity asserted is the invocation credential that is determined by the RunAs mode for the enterprise bean. If the RunAs mode is Client, the identity is the client identity. If the RunAs mode is System, the identity is the server identity. If the RunAs mode is Specified, the identity is the one specified. The receiving server receives the identity in an identity token and also receives the sending server identity in a client authentication token. The receiving server validates the sending server identity as a trusted identity through the Trusted Server IDs entry box. Enter a list of pipe-separated (|) principal names, for example, serverid1|serverid2|serverid3.

All identity token types map to the user ID field of the active user registry. For an ITTPrincipal identity token, this token maps one-to-one with the user ID fields. For an ITTDistinguishedName identity token, the value from the first equal sign is mapped to the user ID field. For an ITTCertChain identity token, the value from the first equal sign of the distinguished name is mapped to the user ID field.

When authenticating to an LDAP user registry, the LDAP filters determine how an identity of type ITTCertChain and ITTDistinguishedName get mapped to the registry. If the token type is ITTPrincipal, then the principal gets mapped to the UID field in the LDAP registry.

**Default:** Disabled

The following option is enabled when the active user registry is a Local OS user registry, your z/OS security version is at the appropriate version that supports the distributed identity mapping, and there are no nodes prior to WebSphere Application Server Version 8.0:

#### **Map certificate and DN using SAF distributed identity mapping**

Selecting this option maps an asserted certificate and distinguished name to an SAF user identity using an RACMAP filter.

The default value is unchecked. When checked, the security custom property, com.ibm.websphere.security.certdn.useRACMAPMappingToSAF, is set to true.

**Note:** This option is only visible when the active user registry is Local OS, the cell is not mixed-version (no nodes prior to WebSphere Application Server Version 8.0), and the z/OS security product supports SAF identity mapping (for RACF, this means z/OS version 1.11 or later).

**Note:** If your DN name has a blank space between the attributes, then you should apply the RACF APAR OA34258, or PTF UA59873, and the SAF APAR OA34259, or PTF UA59871, to correctly parse the blanks.

#### *Trusted identities:*

Specifies the trusted identity that is sent from the sending server to the receiving server.

Specifies a pipe-separated (|) list of trusted server administrator user IDs, which are trusted to perform identity assertion to this server. For example, serverid1|serverid2|serverid3. The application server supports the comma (,) character as the list delimiter for backwards compatibility. The application server checks the comma character when the pipe character (|) fails to find a valid trusted server ID.

Use this list to decide whether a server is trusted. Even if the server is on the list, the sending server must still authenticate with the receiving server to accept the identity token of the sending server.

**Data type:** String

#### *Client certificate authentication:*

Specifies that authentication occurs when the initial connection is made between the client and the server during a method request.

In the transport layer, Secure Sockets Layer (SSL) client certificate authentication occurs. In the message layer, basic authentication (user ID and password) is used. Client certificate authentication typically performs better than message layer authentication, but requires some additional setup. These additional steps involve verifying that the server trusts the signer certificate of each client to which it is connected. If the client uses a certificate authority (CA) to create its personal certificate, you only need the CA root certificate in the server signer section of the SSL trust file.

When the certificate is authenticated to a local OS user registry, the certificate is mapped to the user ID in the registry.

The identity from client certificates is used only if no other layer of authentication is presented to the server.

**Never** Specifies that clients cannot attempt Secure Sockets Layer (SSL) client certificate authentication with this server.

#### **Supported**

Specifies that clients connecting to this server can authenticate using SSL client certificates. However, the server can invoke a method without this type of authentication. For example, anonymous or basic authentication can be used instead.

**Note:** When "Supported" is set for CSiv2 Inbound authentication on the server, the client certificate is used for the authentication.

#### **Required**

Specifies that clients connecting to this server must authenticate using SSL client certificates before invoking the method.

The following option is enabled when the active user registry is a Local OS user registry, your z/OS security version is at the appropriate version that supports the distributed identity mapping, and there are no nodes prior to WebSphere Application Server Version 8.0:

#### **Map certificate using SAF distributed identity mapping**

Selecting this option maps a certificate received in the CSiv2 transport layer to an SAF user identity using an RACMAP filter.

The default value is unchecked. When checked, the security custom property, `com.ibm.websphere.security.certificate.useRACMAPMappingToSAF`, is set to true.

**Note:** This option is only visible when the active user registry is Local OS, the cell is not mixed-version (no nodes prior to WebSphere Application Server Version 8.0), and the z/OS security product supports SAF identity mapping (for RACF, this means z/OS version 1.11 or later).

#### *Transport:*

Specifies whether client processes connect to the server using one of its connected transports.

You can choose either Secure Sockets Layer (SSL), TCP/IP or both as the inbound transport that a server supports. If you specify TCP/IP, the server only supports TCP/IP and cannot accept SSL connections. If you specify SSL-supported, this server can support either TCP/IP or SSL connections. If you specify SSL-required, then any server communicating with this one must use SSL.

**Note:** This option is not available on the z/OS platform unless both Version 6.1 and earlier nodes exist in the cell.

## TCP/IP

If you select **TCP/IP**, then the server opens a TCP/IP listener port only and all inbound requests do not have SSL protection.

## SSL-required

If you select **SSL-required**, then the server opens an SSL listener port only and all inbound requests are received using SSL.

## SSL-supported

If you select **SSL-supported**, then the server opens both a TCP/IP and an SSL listener port and most inbound requests are received using SSL.

Provide a fixed port number for the following ports. A zero port number indicates that a dynamic assignment is made at run time.

## ORB\_SSL\_LISTENER\_ADDRESS

**Default:** SSL-Supported  
**Range:** TCP/IP, SSL Required, SSL-Supported

### *SSL settings:*

Specifies a list of predefined SSL settings to choose from for inbound connection.

**Note:** This option is not available on the z/OS platform unless both Version 6.1 and earlier nodes exist in the cell.

**Data type:** String  
**DefaultSSLSettings**  
**Default:** DefaultIOPSSL  
**Range:** Any SSL settings configured in the SSL Configuration Repertoire

### *Message layer authentication:*

The following options are available for message layer authentication:

**Never** Specifies that this server cannot accept authentication using any of the mechanisms selected below.

#### **Supported**

Specifies that a client communicating with this server can authenticate using any of the mechanisms selected below. However, a method might be invoked without this type of authentication. For example, an anonymous or client certificate might be used instead.

#### **Required**

Specifies that clients communicating with this server must specify authentication information using of the mechanisms selected below for any method request.

### *Allow client to server authentication with::*

Specifies client-to-server authentication using Kerberos, LTPA or Basic authentication.

The following options are available for client to server authentication:

#### **Kerberos (KRB5)**

Select to specify Kerberos as the authentication mechanism. You must first configure the Kerberos

authentication mechanism. Read about [Configuring Kerberos as the authentication mechanism](#) using the administrative console for more information.

**LTPA** Select to specify the LTPA token authentication

#### **Basic authentication**

Basic authentication is Generic Security Services Username Password (GSSUP). This type of authentication typically involves sending a user ID and a password from the client to the server for authentication.

If you select **Basic Authentication** and **LTPA**, and the active authentication mechanism is LTPA, a user name, password, and LTPA tokens are accepted.

If you select **Basic Authentication** and **KRB5** and the active authentication mechanism is KRB5, a user name, password, Kerberos token and LTPA tokens are accepted.

If you do not select **Basic Authentication**, a user name and password are not accepted by the server.

#### *Login configuration:*

Specifies the type of system login configuration to use for inbound authentication.

You can add custom login modules by clicking **Security > Global security**. From Authentication, click **Java Authentication and Authorization Service > System logins**.

#### *Stateful sessions:*

Select this option to enable stateful sessions, which are used mostly for performance improvements.

The first contact between a client and server must fully authenticate. However, all subsequent contacts with valid sessions reuse the security information. The client passes a context ID to the server, and the ID is used to look up the session. The context ID is scoped to the connection, which guarantees uniqueness. Whenever the security session is not valid and the authentication retry is enabled, which is the default, the client-side security interceptor invalidates the client-side session and submits the request again without user awareness. This situation might occur if the session does not exist on the server; for example, the server failed and resumed operation. When this value is disabled, each method invocation must authenticate again.

**Default:** Enabled

#### *Trusted authentication realms - inbound:*

Select this link to establish inbound trust for realms. Inbound authentication realm settings are not specific to CSv2; you can also configure which realms to grant inbound trust to for multiple security domains.

Inbound authentication refers to the configuration that determines the type of accepted authentication for inbound requests. This authentication is advertised in the interoperable object reference (IOR) that the client retrieves from the name server.

#### ***Additional Common Secure Interoperability inbound authentication settings:***

Use this page to configure additional authentication settings for requests that are received by this server using the Object Management Group (OMG) Common Secure Interoperability authentication protocol.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.

2. Under Authentication, expand RMI/IOP security and click **CSlv2 inbound authentication**.
3. Under Additional properties, click **z/OS additional settings**.

You can also view this administrative console page, by completing the following steps:

1. Click **Servers > Server Types > WebSphere application servers > server\_name**.
2. Under Security, click **Server security > CSlv2 inbound authentication**.
3. Under Additional properties, click **z/OS additional settings**.

*Client authentication type:*

Specifies the type of client authentication supported for inbound requests.

<b>Data type</b>	String
<b>Default</b>	SAF user ID and password

*SAF identity assertion:*

Specifies that the server permits a trusted upstream server to assert client identities as System Authorization Facility (SAF) user names.

<b>Data type</b>	Boolean
<b>Default</b>	Disabled
<b>Options</b>	Enabled or Disabled

*Distinguished name identity assertion:*

Specifies that the server permits a trusted upstream server to assert client identities as distinguished names.

**Note:** This option is available for global security and not available for server-level security.

<b>Data type</b>	Boolean
<b>Default</b>	Disabled
<b>Options</b>	Enabled or Disabled

*Certificate identity assertion:*

Specifies that the server permits a trusted upstream server to assert client identities as X.509 certificates.

**Note:** This option is available for global security and not available for server-level security.

<b>Data type</b>	Boolean
<b>Default</b>	Disabled
<b>Options</b>	Enabled or Disabled

## Configuring Common Secure Interoperability Version 2 outbound communications

The following choices are available when configuring the Common Secure Interoperability Version 2 (CSlv2) outbound communications panel.

### Before you begin

*Outbound communications* refers to the configuration that determines the type of authentication that is performed for outbound requests to downstream servers. Several *layers* or *methods* of authentication can

occur. The downstream server inbound authentication configuration must support at least one choice made in this server outbound authentication configuration. If nothing is supported, the request might go outbound as unauthenticated. This situation does not create a security problem because the authorization runtime is responsible for preventing access to protected resources. However, if you choose to prevent an unauthenticated credential from going outbound, you might want to designate one of the authentication layers as required, rather than supported. If a downstream server does not support authentication, then when authentication is required, the method request fails to go outbound.

## About this task

The following choices are available in the Common Secure Interoperability Version 2 (CSlv2) outbound communications panel. Remember that you are not required to complete these steps in the displayed order. Rather, these steps are provided to help you understand your choices for configuring outbound communications.

## Procedure

- Select **Identity Assertion** (attribute layer). When selected, this server sends an identity token to a downstream server if the downstream server supports identity assertion. When an originating client authenticates to this server, the authentication information supplied is preserved in the outbound identity token. If the client authenticating to this server uses client certificate authentication, then the identity token format is a certificate chain, containing the exact client certificate chain from the inbound socket. The same scenario is true for other mechanisms of authentication. Read the Identity Assertion topic for more information.
- Select **SSL Client certificate authentication** (transport layer). The main reason to enable outbound Secure Sockets Layer (SSL) client authentication from one server to a downstream server is to create a trusted environment between those servers. For delegating client credentials, use one of the two layers mentioned previously. However, you might want to create SSL personal certificates for all the servers in your domain, and only trust those servers in your SSL truststore file. No other servers or clients can connect to the servers in your domain, except at the tiers where you want them. This process can protect your enterprise bean servers from access by anything other than your servlet servers.

## Example

Typically, the outbound authentication configuration is for an upstream server to communicate with a downstream server. Most likely, the upstream server is a servlet server and the downstream server is an Enterprise JavaBeans (EJB) server. On a servlet server, the client authentication that is performed to access the servlet can be one of many different types of authentication, including client certificate and basic authentication. When receiving basic authentication data, whether through a prompt login or a form-based login, the basic authentication information is typically authenticated to from a credential of the mechanism type that is supported by the server, such as the Lightweight Third Party Authentication (LTPA). When LTPA is the mechanism, a forwardable token exists in the credential. Choose the message layer (BasicAuth) authentication to propagate the client credentials. If the credential is created using a certificate login and you want to preserve sending the certificate downstream, you might decide to go outbound with identity assertion.

### ***Common Secure Interoperability Version 2 outbound communications settings:***

Use this page to specify the features that a server supports when acting as a client to another downstream server.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. From Authentication, click **RMI/IIOP security > CSlv2 outbound communications**.

Authentication features include three layers of authentication that you can use simultaneously:

- **CSlv2 attribute layer.** The attribute layer might contain an identity token, which is an identity from an upstream server that already is authenticated. The identity layer has the highest priority, followed by the message layer, and then the transport layer. If a client sends all three, only the identity layer is used. The only way to use the SSL client certificate as the identity is if it is the only information that is presented during the request. The client picks up the interoperable object reference (IOR) from the namespace and reads the values from the tagged component to determine what the server needs for security.
- **CSlv2 transport layer.** The transport layer, which is the lowest layer, might contain a Secure Sockets Layer (SSL) client certificate as the identity.

*Propagate security attributes:*

Specifies to support security attribute propagation during login requests. When you select this option, the application server retains additional information about the login request, such as the authentication strength used, and retains the identity and location of the request originator.

If you do not select this option, the application server does not accept any additional login information to propagate to downstream servers.

**Default:** Enabled

**Important:** When you use the replication services, ensure that the **Propagate security attributes** option is enabled.

*Use identity assertion:*

Specifies that identity assertion is a way to assert identities from one server to another during a downstream Enterprise JavaBeans (EJB) invocation.

This server does not authenticate the asserted identity again because it trusts the upstream server. Identity assertion takes precedence over all other types of authentication.

Identity assertion is performed in the attribute layer and is only applicable on servers. The principal determined at the server is based on precedence rules. If identity assertion is performed, the identity is always derived from the attribute layer. If basic authentication is used without identity assertion, the identity is always derived from the message layer. Finally, if SSL client certificate authentication is performed without either basic authentication, or identity assertion, then the identity is derived from the transport layer.

The identity asserted is the invocation credential that is determined by the RunAs mode for the enterprise bean. If the RunAs mode is Client, the identity is the client identity. If the RunAs mode is System, the identity is the server identity. If the RunAs mode is Specified, the identity is the one specified. The receiving server receives the identity in an identity token and also receives the sending server identity in a client authentication token. The receiving server validates the sending server identity as a trusted identity through the Trusted Server IDs entry box. Enter a list of pipe-separated (|) principal names, for example, serverid1|serverid2|serverid3.

All identity token types map to the user ID field of the active user registry. For an ITTPrincipal identity token, this token maps one-to-one with the user ID fields. For an ITTDistinguishedName identity token, the value from the first equal sign is mapped to the user ID field. For an ITTCertChain identity token, the value from the first equal sign of the distinguished name is mapped to the user ID field.

When authenticating to an LDAP user registry, the LDAP filters determine how an identity of type ITTCertChain and ITTDistinguishedName get mapped to the registry. If the token type is ITTPrincipal, then the principal gets mapped to the UID field in the LDAP registry.

**Default:** Disabled

*Use server-trusted identity:*

Specifies the server identity that the application server uses to establish trust with the target server. The server identity can be sent using one of the following methods:

- A server ID and password when the server password is specified in the registry configuration.
- A server ID in a Lightweight Third Party Authentication (LTPA) token when the internal server ID is used.

For interoperability with application servers other than WebSphere Application Server, use one of the following methods:

- Configure the server ID and password in the registry.
- Select the **Server-trusted identity** option and specify the trusted identity and password so that an interoperable Generic Security Services Username Password (GSSUP) token is sent instead of an LTPA token.

**Default:** Disabled

*Specify an alternative trusted identity:*

Specifies an alternative user as the trusted identity that is sent to the target servers instead of sending the server identity.

This option is recommended for identity assertion. The identity is automatically trusted when it is sent within the same cell and does not need to be in the trusted identities list within the same cell. However, this identity must be in the registry of the target servers in an external cell, and the user ID must be on the trusted identities list or the identity is rejected during trust evaluation.

**Note:** You must select Basic Authentication under the Message Layer authentication section to send an alternative trusted identity. If you do not select Basic Authentication, then choose the Server Identity instead.

**Default:** Disabled

*Trusted identity:*

Specifies the trusted identity that is sent from the sending server to the receiving server.

If you specify an identity in this field, it can be selected on the panel for your configured user account repository. If you do not specify an identity, a Lightweight Third Party Authentication (LTPA) token is sent between the servers.

Specifies a semicolon-separated (;) or comma-separated (,) list of trusted server IDs, which are trusted to perform identity assertion to this server. For example, serverid1;serverid2;serverid3 or serverid1,serverid2,serverid3.

Use this list to decide whether a server is trusted. Even if the server is on the list, the sending server must still authenticate with the receiving server to accept the identity token of the sending server.

*Password:*

Specifies the password that is associated with the trusted identity.

**Data type:** Text

*Confirm password:*

Confirms the password that is associated with the trusted identity.

**Data type:** Text

*Message layer authentication:*

The following options are available for message layer authentication:

**Never** Specifies that this server cannot accept authentication using any of the mechanisms selected below.

**Supported**

Specifies that a client communicating with this server can authenticate using any of the mechanisms selected below. However, a method might be invoked without this type of authentication. For example, an anonymous or client certificate might be used instead.

**Required**

Specifies that clients communicating with this server must specify authentication information using of the mechanisms selected below for any method request.

*Allow client to server authentication with::*

Specifies client-to-server authentication using Kerberos, LTPA or Basic authentication.

The following options are available for client to server authentication:

**Kerberos (KRB5)**

Select to specify Kerberos as the authentication mechanism. You must first configure the Kerberos authentication mechanism. Read about [Configuring Kerberos as the authentication mechanism](#) using the administrative console for more information.

**LTPA** Select to configure and enable Lightweight Third-Party Authentication (LTPA) token authentication.

**Basic authentication**

Basic authentication is Generic Security Services Username Password (GSSUP). This type of authentication typically involves sending a user ID and a password from the client to the server for authentication.

If you select **Basic Authentication** and **LTPA**, and the active authentication mechanism is LTPA, the server goes with a downstream server with a user name, password or LTPA token.

If you select **Basic Authentication** and **KRB5**, and the active authentication mechanism is KRB5, the server goes with a downstream server with a user name, password, Kerberos token or LTPA token.

If you do not select **Basic Authentication**, the server does not go with a downstream server with a user name and password.

*Transport:*

Specifies whether client processes connect to the server using one of its connected transports.

You can choose to use either Secure Sockets Layer (SSL), TCP/IP or both as the inbound transport that a server supports. If you specify TCP/IP, the server only supports TCP/IP and cannot accept SSL

connections. If you specify SSL-supported, this server can support either TCP/IP or SSL connections. If you specify SSL-required, then any server communicating with this one must use SSL.

For server-to-server communication, it is not enough to enable only the Transport layer. You must also enable either the Message layer or the Attribute layer.

### **TCP/IP**

If you select **TCP/IP**, then the server opens a TCP/IP listener port only and all inbound requests do not have SSL protection.

### **SSL-required**

If you select **SSL-required**, then the server opens an SSL listener port only and all inbound requests are received using SSL.

### **SSL-supported**

If you select **SSL-supported**, then the server opens both a TCP/IP and an SSL listener port and most inbound requests are received using SSL.

Provide a fixed port number for the following ports. A zero port number indicates that a dynamic assignment is made at run time.

### ORB\_SSL\_LISTENER\_ADDRESS

<b>Default:</b>	SSL-Required
<b>Range:</b>	TCP/IP, SSL Required, SSL-Supported

### *SSL settings:*

Specifies a list of predefined SSL settings to choose from for inbound connection.

<b>Data type:</b>	String
<b>DefaultSSLSettings</b>	
<b>Default:</b>	DefaultIOPSSL
<b>Range:</b>	Any SSL settings configured in the SSL Configuration Repertoire

### *Client certificate authentication:*

Specifies whether a client certificate from the configured keystore is used to authenticate to the server when the SSL connection is made between this server and a downstream server, provided that the downstream server supports client certificate authentication.

Typically, client certificate authentication has a higher performance than message layer authentication, but requires some additional setup. These additional steps include verifying that this server has a personal certificate and that the downstream server has the signer certificate of this server.

If you select client certificate authentication, the following options are available:

**Never** Specifies that this server does not attempt Secure Sockets Layer (SSL) client certificate authentication with downstream servers.

### **Supported**

Specifies that this server can use SSL client certificates to authenticate to downstream servers. However, a method can be invoked without this type of authentication. For example, the server can use anonymous or basic authentication instead.

### **Required**

Specifies that this server must use SSL client certificates to authenticate to downstream servers.

**Default:** Enabled

*Login configuration:*

Specifies the type of system login configuration to use for inbound authentication.

You can add custom login modules by clicking **Security > Global security**. From Authentication, click **Java Authentication and Authorization Service > System logins**.

*Stateful sessions:*

Select this option to enable stateful sessions, which are used mostly for performance improvements.

The first contact between a client and server must fully authenticate. However, all subsequent contacts with valid sessions reuse the security information. The client passes a context ID to the server, and the ID is used to look up the session. The context ID is scoped to the connection, which guarantees uniqueness. Whenever the security session is not valid and the authentication retry is enabled, which is the default, the client-side security interceptor invalidates the client-side session and submits the request again without user awareness. This situation might occur if the session does not exist on the server, for example, the server failed and resumed operation. When this value is disabled, every method invocation must authenticate again.

*Enable CSiv2 session cache limit:*

Specifies whether to limit the size of the CSiv2 session cache.

When you enable this option, you must set values for the **Maximum cache size** and **Idle session timeout** options. When you do not enable this option, the CSiv2 session cache is not limited.

In previous versions of the application server, you might have set this value as the `com.ibm.websphere.security.util.csiv2SessionCacheLimitEnabled` custom property. In this product version, it is advisable to set this value using this administrative console panel and not as a custom property.

**Default:** false

*Maximum cache size:*

Specify the maximum size of the session cache after which expired sessions are deleted from the cache.

Expired sessions are defined as sessions that are idle longer than the time that is specified in the **Idle session timeout** field. When you specify a value for the **Maximum cache size** field, consider setting its value between 100 and 1000 entries.

Consider specifying a value for this field if your environment uses Kerberos authentication and has a short clock skew for the configured key distribution center (KDC). In this scenario, a short clock skew is defined as less than 20 minutes. Consider increasing the value of this field if the small cache size causes the garbage collection to run so frequently that it impacts the performance of the application server.

In previous versions of the application server, you might have set this value as the `com.ibm.websphere.security.util.csiv2SessionCacheMaxSize` custom property. In this product version, it is advisable to set this value using this administrative console panel and not as a custom property.

This field only applies if you enable both the **Stateful sessions** and the **Enable CSiv2 session cache limit** options.

**Default:** By default, a value is not set.  
**Range:** 100 to 1000 entries

*Idle session timeout:*

This property specifies the time in milliseconds that a CSiv2 session can remain idle before being deleted. The session is deleted if you select the Enable CSiv2 session cache limit option and the value of the **Maximum cache size** field is exceeded.

This timeout value only applies if you enable both the **Stateful sessions** and the **Enable CSiv2 session cache limit** options. Consider decreasing the value for this field if your environment uses Kerberos authentication and has a short clock skew for the configured key distribution center (KDC). In this scenario, a short clock skew is defined as less than 20 minutes. A small clock skew can result in a larger number of rejected CSiv2 sessions. However, with a smaller value for the **Idle session timeout** field, the application server can clean out these rejected sessions more frequently and potentially reduce the resource shortages.

In previous versions of WebSphere Application Server, you might have set this value as the `com.ibm.websphere.security.util.csiv2SessionCacheIdleTime` custom property. In this product version, it is advisable to set this value using this administrative console panel and not as a custom property. If you previously set it as a custom property, the value was set in milliseconds and converted on this administrative console panel to seconds. On this administrative console panel, you must specify the value in seconds.

**Default:** By default, a value is not set.  
**Range:** 60 to 86,400 seconds

*Custom outbound mapping:*

Enables the use of custom Remote Method Invocation (RMI) outbound login modules.

The custom login module maps or completes other functions before the predefined RMI outbound call.

To declare a custom outbound mapping, complete the following steps:

1. Click **Security > Global security**.
2. From Authentication, click **Java Authentication and Authorization Service > System logins > New**.

*Trusted authentication realms - outbound:*

If the RMI/IOP communication is across different realms, use this link to add outbound trusted realms.

The credential tokens are only sent to the realms that are trusted. In addition, the receiving server should trust this realm using the inbound trusted realms configuration to validate the LTPA token.

**Additional Common Secure Interoperability outbound authentication settings:**

Use this page to configure additional authentication settings for requests that are received by this server using the Object Management Group (OMG) Common Secure Interoperability authentication protocol.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, expand RMI/IOP security and click **CSiv2 outbound authentication**.
3. Under Additional properties, click **z/OS additional settings**.

You can also view this administrative console page by completing the following steps for the server level:

1. Click **Servers > Application servers > *server\_name***.
2. Under Security, click **Server security > CSiv2 outbound authentication**.
3. Under Additional properties, click **z/OS additional settings**.

*Client authentication type:*

Specifies the type of client authentication that is supported for outbound requests.

<b>Data type</b>	String
<b>Default</b>	System Authorization Facility (SAF) user ID and password

## Configuring inbound transports

By using this configuration, you can configure a different transport for inbound security versus outbound security.

### Before you begin

*Inbound transports* refer to the types of listener ports and their attributes that are opened to receive requests for this server. Both Common Secure Interoperability Specification, Version 2 (CSiv2) and z/OS Secure Authentication Service (z/SAS) have the ability to configure the transport.

**Important:** z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

CSiv2 and z/SAS support most of the same functions. CSiv2 has the advantage of interoperability with other WebSphere Application Server products and any other platforms that support the CSiv2 protocol.

### About this task

Complete the following steps to configure the Inbound transport panels in the administrative console:

#### Procedure

1. Click **Security > Global security**.
2. Under RMI/IIOP security, click **CSiv2 inbound communications**.
3. Under Transport, select **SSL-required**. You can choose to use either Secure Sockets Layer (SSL), TCP/IP or both as the inbound transport that a server supports. If you specify TCP/IP, the server only supports TCP/IP and cannot accept SSL connections. If you specify SSL-supported, this server can support either TCP/IP or SSL connections. If you specify SSL-required, then any server communicating with this one must use SSL.
4. Click **Apply**.
5. Consider fixing the listener ports that you configured.

You complete this action in a different panel, but think about this action now. Most endpoints are managed at a single location, which is why they do not display in the Inbound transport panels. Managing end points at a single location helps you decrease the number of conflicts in your configuration when you assign the endpoints. The location for SSL end points is at each server. The following port names are defined in the End points panel and are used for Object Request Broker (ORB) security:

- ORB\_SSL\_LISTENER\_ADDRESS - SSL Port
- ORB\_LISTENER\_ADDRESS - IIOP port

For an application server, click **Servers > Application servers > *server\_name***. Under Communications, click **Ports**. The Ports panel is displayed for the specified server.

The Object Request Broker (ORB) on WebSphere Application Server uses a listener port for Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) communications, and is statically specified using configuration dialogs or during migration. The ORB\_LISTENER\_ADDRESS and the BOOTSTRAP\_ADDRESS must specify the same port. If you are working with a firewall, you must specify a static port for the ORB listener and open that port on the firewall so that communication can pass through the specified port. The endPoint property for setting the ORB listener port is: ORB\_LISTENER\_ADDRESS.

Complete the following steps using the administrative console to specify the ORB\_LISTENER\_ADDRESS port or ports.

- a. Click **Servers > Application Servers > server\_name**. Under Communications, click **Ports > New**.
- b. Select **ORB\_LISTENER\_ADDRESS** from the **Port name** field in the Configuration panel.
- c. Enter the IP address or "\*" in the **Host** field. For example the IP address can be 155.123.88.201.

**Important:** DNS host names are not supported for the ORB\_LISTENER\_ADDRESS value.

- d. Enter the port number in the **Port** field. The port number specifies the port for which the service is configured to accept client requests. The port value is used with the host name. Using the previous example, the port number might be 9000.
6. Click **Security > Global security**. Under RMI/IIOP security, click **z/SAS authentication** to select the SSL settings used for inbound requests from z/SAS clients.

## Results

The inbound transport configuration is complete. With this configuration, you can configure a different transport for inbound security versus outbound security. For example, if the application server is the first server that is used by users, the security configuration might be more secure. When requests go to back-end enterprise bean servers, you might lessen the security for performance reasons when you go outbound. With this flexibility you can design the right transport infrastructure to meet your needs.

## What to do next

When you finish configuring security, perform the following steps to save, synchronize, and restart the servers:

1. Click **Save** in the administrative console to save any modifications to the configuration.
2. Stop and restart all servers, when synchronized.

### ***Common Secure Interoperability Version 2 transport inbound settings:***

Use this page to specify which listener ports to open and which Secure Sockets Layer (SSL) settings to use. These specifications determine which transport a client or upstream server uses to communicate with this server for incoming requests.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, click **RMI/IIOP security > CSiv2 inbound transport**.

*Transport:*

Specifies whether client processes connect to the server using one of its connected transports.

You can choose to use either Secure Sockets Layer (SSL), TCP/IP or both as the inbound transport that a server supports. If you specify TCP/IP, the server only supports TCP/IP and cannot accept SSL connections. If you specify SSL-supported, this server can support either TCP/IP or SSL connections. If you specify SSL-required, then any server communicating with this one must use SSL.

If you specify SSL-supported or SSL-required, decide which set of SSL configuration settings you want to use for the inbound configuration. This decision determines which key file and trust file are used for inbound connections to this server.

**Note:** This option is not available on the z/OS platform unless there are both Version 6.1 and earlier nodes in the cell.

### TCP/IP

If you select **TCP/IP**, then the server opens a TCP/IP listener port only and all inbound requests do not have SSL protection.

### SSL-required

If you select **SSL-required**, then the server opens an SSL listener port only and all inbound requests are received using SSL.

**Important:** SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

### SSL-supported

If you select **SSL-supported**, then the server opens both a TCP/IP and an SSL listener port and most inbound requests are received using SSL.

Provide a fixed port number for the following ports. A zero port number indicates that a dynamic assignment is made at runtime.

ORB\_SSL\_LISTENER\_ADDRESS

<b>Default:</b>	SSL Required
<b>Range:</b>	TCP/IP, SSL Required, SSL-Supported

### SSL settings:

Specifies a list of predefined SSL settings to choose from for inbound connections.

**Note:** This option is not available on the z/OS platform unless there are both Version 6.1 and earlier nodes in the cell.

These settings are configured at the SSL Repertoire panel. To access the SSL Repertoire panel, complete the following steps:

1. Clicking **Security > SSL certificate and key management**.
2. Under configuration settings, click **Manage endpoint security configurations and trust zones**.
3. Expand Inbound and click *inbound\_configuration*.
4. Under Related items, click **SSL configurations**.

<b>Data type:</b>	String
<b>DefaultSSLSettings</b>	
<b>Default:</b>	DefaultIOPSSL
<b>Range:</b>	Any SSL settings configured in the SSL Configuration Repertoire

### Centrally managed:

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations rather than spreading them across the configuration documents.

**Default:** Enabled

*Use specific SSL alias:*

Specifies the SSL configuration alias to use for LDAP outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI platform.

*z/OS SSL settings:*

Specifies a list of predefined Secure Sockets Layer (SSL) settings for inbound connections. Configure these settings on the SSL panel by clicking Secure communications on the administrative console.

***z/OS Secure Authentication Service settings:***

Use this page to specify authentication settings for requests that are received and sent by a server that uses the z/OS authentication protocol. Use the z/OS Secure Authentication Service (z/SAS) protocol to communicate securely to enterprise beans.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security** .
2. Under Authentication expand RMI/IIOP, click **z/SAS authentication**.

**Attention:** The panel associated with this article displays only when you have a Version 6.1 server in your environment.

**Attention:** The panel associated with this article displays only when you have a Version 6.1 or lower level server in a Version 6.1 cell.

You can also view this administrative console page by completing the following steps:

1. Click **Servers > Server Types > WebSphere application servers > server\_name**.
2. Under Security, click **Server security > z/SAS authentication**.

**Note:** z/SAS protocols are ignored unless the active user registry is local operating system. z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

*Basic authentication:*

Specifies that clients to this server can provide a System Authorization Facility (SAF) user ID and password over a Secure Sockets Layer (SSL) connection. This option requires a valid system SSL repertoire selection on the SSL settings option.

<b>Data type</b>	Boolean
<b>Default</b>	Disabled
<b>Range</b>	Enabled or Disabled

*Client certificate:*

Specifies that clients to this server can authenticate using SSL client certificates. The client certificates must be capable of mapping to a SAF user ID. You must connect the public certificate of the client certificate authority to the server key ring. The client certificate option requires a valid system SSL repertoire selection on the SSL settings option.

<b>Data type</b>	Boolean
<b>Default</b>	Disabled
<b>Range</b>	Enabled or Disabled

*User ID and password:*

Specifies that clients can connect to this server with a SAF user ID and password without requiring a connection sent over an SSL session.

<b>Data type</b>	Boolean
<b>Default</b>	Disabled
<b>Range</b>	Enabled or Disabled

*Identity assertion inbound:*

Specifies that inbound requests using SAF user IDs that are forwarded by Application Server for z/OS can be accepted.

The immediate downstream server establishes its identity by sending a digital certificate. Identity assertion is available only if client certificates are supported. When you enable this setting, you must select an SSL setting.

<b>Data type</b>	Boolean
<b>Default</b>	Disabled
<b>Range</b>	Enabled or Disabled

*Identity assertion outbound:*

Specifies that outbound requests that originate from this server can forward authenticated client user IDs over an SSL connection to another application server for z/OS in which it has established trust.

This option requires a valid system SSL repertoire selection on the SSL settings option.

<b>Data type</b>	Boolean
<b>Default</b>	Disabled
<b>Range</b>	Enabled or Disabled

*Support unauthenticated clients:*

Specifies that the server accepts Internet Inter-ORB Protocol (IIOP) requests without any authentication information.

If you enable this property, specify the Remote identity setting to associate a user ID with requests from a remote server.

<b>Data type</b>	Boolean
<b>Default</b>	Disabled
<b>Range</b>	Enabled or Disabled

### SSL settings:

Specifies a predefined list of SSL settings for connections. Configure these settings on the SSL repertoire panel.

<b>Data type</b>	String
<b>Default</b>	None

## Configuring outbound transports

By using this configuration, you can configure a different transport for inbound security versus outbound security.

### Before you begin

*Outbound transports* refers to the transport that is used to connect to a downstream server. When you configure the outbound transport, consider the transports that the downstream servers support. If you are considering Secure Sockets Layer (SSL), also consider including the signers of the downstream servers in this server truststore file for the handshake to succeed.

When you select an SSL configuration, that configuration points to keystore and truststore keyrings and keystore and truststore files that contain the necessary signers.

If you configured client certificate authentication for this server by completing the following steps, then the downstream servers contain the signer certificate belonging to the server personal certificate:

1. Click **Security > Global security**.
2. Under RMI/IIOP security, click **CSlv2 outbound communications**.

### About this task

Complete the following steps to configure the outbound transport panels.

### Procedure

1. Select the type of transport and the SSL settings by clicking **Security > Global security**. Under RMI/IIOP security, click **CSlv2 outbound communications**. By selecting the type of transport, you choose the transport to use when connecting to downstream servers. The downstream servers support the transport that you choose. If you choose **SSL-Supported**, the transport that is used is negotiated during the connection. If both the client and server support SSL, always select the **SSL-Supported** option unless the request is considered a special request that does not require SSL, such as if an object request broker (ORB) is a request.
2. Select the **SSL required** option if you want to use Secure Sockets Layer communications with the outbound transport.

If you select the **SSL required** option or the **SSL supported** option, you can select either the **Centrally managed** or **Use specific SSL alias** option.

#### Centrally managed

Enables you to specify an SSL configuration for particular scope such as the cell, node, server, or cluster in one location. To use the **Centrally managed** option, you must specify the SSL configuration for the particular set of endpoints. The Manage endpoint security configurations and trust zones panel displays all of the inbound and outbound endpoints that use the SSL protocol. If you expand the Inbound or Outbound section of the panel and click the name of a node, you can specify an SSL configuration that is used for every endpoint on that node. For an outbound transport, you can override the inherited SSL configuration by specifying an SSL configuration for a particular endpoint. To specify an SSL configuration for an outbound transport, click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones** and expand **Outbound**.

### Use specific SSL alias

Select the **Use specific SSL alias** option if you intend to select one of the SSL configurations in the menu below the option.

The default is *DefaultSSLSettings*. To modify or create a new SSL configuration, complete the steps described in “Creating a Secure Sockets Layer configuration” on page 1925.

3. Click **Apply**.

## Results

The outbound transport configuration is complete. With this configuration, you can configure a different transport for inbound security versus outbound security. For example, if the application server is the first server used by end users, the security configuration might be more secure. When requests go to back-end enterprise beans servers, you might consider less security for performance reasons when you go outbound. With this flexibility you can design a transport infrastructure that meets your needs.

## What to do next

When you finish configuring security, perform the following steps to save, synchronize, and restart the servers.

- Click **Save** in the administrative console to save any modifications to the configuration.
- Stop and restart all servers, after synchronization.

### **Common Secure Interoperability Version 2 outbound transport settings:**

Use this page to specify which transports and Secure Sockets Layer (SSL) settings this server uses when communicating with downstream servers for outbound requests.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, click **RMI/IIOP security > CSiv2 outbound transport**.

You also can view this administrative console by completing the following steps:

1. Click **Servers > Server Types > WebSphere application servers > server\_name**.
2. Under Security, click **Server security**.
3. Under Additional properties, click **CSiv2 outbound transport**.

### *Transport:*

Specifies whether the client processes connect to the server using one of the server-connected transports.

You can choose to use either SSL, TCP/IP, or Both as the outbound transport that a server supports. If you specify TCP/IP, the server supports only TCP/IP and cannot initiate SSL connections with downstream servers. If you specify SSL-supported, this server can initiate either TCP/IP or SSL connections. If you specify SSL-required, this server must use SSL to initiate connections to downstream servers. When you do specify SSL, decide which set of SSL configuration settings you want to use for the outbound configuration.

Consider the following options:

#### **TCP/IP**

If you select this option, the server opens TCP/IP connections with downstream servers only.

#### **SSL-required**

If you select this option, the server opens SSL connections with downstream servers.

## SSL-supported

If you select this option, the server opens SSL connections with any downstream server that supports them and opens TCP/IP connections with any downstream servers that do not support SSL.

**Default:** SSL-supported  
**Range:** TCP/IP, SSL-required, SSL-supported

### *SSL settings:*

Specifies a list of predefined SSL settings for outbound connections. These settings are configured at the SSL Configuration Repertoires panel.

To access the panel, complete the following steps:

1. Click **Security > SSL certificate and key management**.
2. Under Configuration settings, click **Manage endpoint security configurations and trust zones**.
3. Expand Outbound > *outbound\_configuration\_name*.
4. Under Related items, click **SSL configurations**.

**Data type:** String  
**Range:** Any SSL settings that are configured in the SSL Configuration Repertoires panel

**Note:** This field is available only if a Version 6.1 server exists in your environment.

### *SSL enabled:*

Specifies whether secure socket communication is enabled to the server.

### *Centrally managed:*

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations rather than spreading them across the configuration documents.

**Default:** Enabled

### *Use specific SSL alias:*

Specifies the SSL configuration alias that you want to use for outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI (LDAP) protocol.

## Configuring inbound messages

You can use the administrative console to configure inbound messages for CSiv2.

### Procedure

1. In the administrative console, click **Security > Global security**.
2. Under Authentication, expand **RMI/HOP security**.
3. Click **CSiv2 inbound communication**.

- Optional: Click **Propagate security attributes** or **Use identity assertion**. The **Propagate security attributes** option enables support for security attribute propagation during login requests. When you select this option, the application server retains additional information about the login request, such as the authentication strength used, and retains the identity and location of the request originator.

The **Use identity assertion** option specifies that identity assertion is a way to assert identities from one server to another during a downstream Enterprise JavaBeans (EJB) invocation.

- Under CSiv2 Message layer authentication, select **Supported**, **Never** or **Required**.

**Never** Specifies that this server cannot accept an authentication mechanism that you select under **Allow client to server authentication with:**.

#### **Supported**

Specifies that clients communicating with this server can specify an authentication mechanism that you select under **Allow client to server authentication with:**. However, a method might be invoked without this type of authentication. For example, an anonymous or client certificate might be used instead.

#### **Required**

Specifies that clients communicating with this server must specify an authentication mechanism that you select under **Allow client to server authentication with:**.

- Under **Allow client to server authentication with:**, select **Kerberos**, **LTPA** and or **Basic authentication**. You can optionally select:

#### **Kerberos**

Select to enable authentication using the Kerberos token.

**LTPA** Select to enable authentication using the Lightweight Third-Party Authentication (LTPA) token.

#### **Basic authentication**

This type of authentication typically involves sending a user ID and a password from the client to the server for authentication. This is also known as Generic Security Services Username Password (GSSUP).

This authentication also involves delegating a credential token from an already authenticated credential, provided the credential type is forwardable; for example, LTPA.

If you select **supported** under **CSiv2 Message layer authentication**, and check **KRB5** and **LTPA** under **Allow client to server authentication with:**, then the server does not accept the user name and password.

- Click **OK**.

## **Results**

You have now configured messages for CSiv2 inbound.

## **Configuring outbound messages**

You can use the administrative console to configure outbound messages for CSiv2.

### **Procedure**

- In the administrative console, click **Security > Global security**.
- Under Authentication, expand **RMI/HOP security**.
- Click **CSiv2 outbound communication**.
- Optional: Click **Propagate security attributes** or **Use identity assertion**. The **Propagate security attributes** option enables support for security attribute propagation during login requests. When you select this option, the application server retains additional information about the login request, such as the authentication strength used, and retains the identity and location of the request originator.  
The **Use identity assertion** option specifies that identity assertion is a way to assert identities from one server to another during a downstream Enterprise JavaBeans (EJB) invocation.

The **Use server trusted identity** option specifies the server identity that the application server uses to establish trust with the target server.

The **Specify an alternative trusted identity** option enables you to specify an alternative user as the trusted identity that is sent to the target servers instead of sending the server identity. If you select this option you must provide the name of the trusted identity and the password that is associated with the trusted identity.

**Note:** You must select Basic Authentication under the Message Layer authentication section to send an alternative trusted identity. If you do not select Basic Authentication, then choose the Server Identity instead.

5. Under CSiv2 Message layer authentication, select **Supported**, **Never** or **Required**.

**Never** Specifies that this server cannot accept an authentication mechanism that you select under **Allow client to server authentication with:**.

#### **Supported**

Specifies that clients communicating with this server can specify an authentication mechanism that you select under **Allow client to server authentication with:**. However, a method might be invoked without this type of authentication. For example, an anonymous or client certificate might be used instead.

#### **Required**

Specifies that clients communicating with this server must specify an authentication mechanism that you select under **Allow client to server authentication with:**.

6. Under **Allow client to server authentication with:**, select **Kerberos**, **LTPA** and or **Basic authentication**. You can optionally select:

#### **Kerberos**

Select to enable authentication using the Kerberos token.

**LTPA** Select to enable authentication using the Lightweight Third-Party Authentication (LTPA) token.

#### **Basic authentication**

This type of authentication typically involves sending a user ID and a password from the client to the server for authentication. This is also known as Generic Security Services Username Password (GSSUP).

This authentication also involves delegating a credential token from an already authenticated credential, provided the credential type is forwardable; for example, LTPA.

If you select **supported** under **CSiv2 Message layer authentication**, and check **KRB5** and **LTPA** under **Allow client to server authentication with:**, then the server does not accept the user name and password.

7. Optional: Select **Custom outbound mapping**. This option enables the use of custom Remote Method Invocation (RMI) outbound login modules.

## **Results**

You have now configured messages for CSiv2 outbound.

## **Common Secure Interoperability Version 2 and Security Authentication Service (SAS) client configuration**

A secure Java client requires configuration properties to determine how to perform security with a server.

These configuration properties are typically put into a properties file somewhere on the client system and referenced by specifying the following system property on the command line of the Java client. For example, this property accepts any valid web address.

```
-Dcom.ibm.CORBA.ConfigURL=file:/WebSphere/V5R0M0/AppServer/sas.client.props
```

When this file is processed by the Object Request Broker (ORB), security can be enabled between the Java client and the target server.

If any problems exist with the client properties file or there is no match with the server security, the Java client examines the server security for non-Common Secure Interoperability Version 2 (CSlv2) security mechanisms that might be available. If no match is found with the old, non-CSlv2 security either, the Java client attempts a nonsecure connection.

Use the following property to configure the CSlv2 authentication protocols:

- “Common Secure Interoperability version 2 (CSlv2) authentication protocol client settings” on page 1747

**Authentication protocol settings for a client configuration:**

You can use settings in the `sas.client.props` file to configure Security Authentication Service (SAS) and Common Secure Interoperability Version 2 (CSlv2) clients.

Use the following settings in the `app_server_root/properties/sas.client.props` file to configure SAS and CSlv2 clients.

**Important:** z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

**Note:** The `sas.client.props` file for WebSphere Application Server Version 8.0 contains some new properties that support BasicAuth and Kerberos, such as:

```
com.ibm.IPC.authenticationTarget=BasicAuth
com.ibm.IPC.loginUserId=
com.ibm.IPC.loginPassword=
com.ibm.IPC.loginSource=prompt
com.ibm.IPC.krb5Service=WAS
com.ibm.IPC.krb5CcacheFile=
com.ibm.IPC.krb5ConfigFile=
```

*com.ibm.CORBA.securityEnabled:*

Use to determine if security is enabled for the client process.

Table 115. *com.ibm.CORBA.securityEnabled*. This table describes the *com.ibm.CORBA.securityEnabled* setting.

Setting	Value
Data Type	Boolean
Default	True
Valid values	True or false

*com.ibm.CORBA.authenticationTarget:*

Use to determine the type of authentication mechanism for sending security information from the client to the server.

If basic authentication is specified, the user ID and password are sent to the server. Using the Secure Sockets Layer (SSL) transport with this type of authentication is recommended; otherwise, the password is not encrypted. The target server must support the specified authentication target.

Table 116. *com.ibm.CORBA.authenticationTarget*. This table describes the *com.ibm.CORBA.authenticationTarget* setting.

Setting	Value
Data type	String

Table 116. *com.ibm.CORBA.authenticationTarget* (continued). This table describes the *com.ibm.CORBA.authenticationTarget* setting.

Setting	Value
Default	BasicAuth
Valid values	BasicAuth, KRB5

*com.ibm.CORBA.validateBasicAuth:*

Use to determine if the user ID and password get validated immediately after the login data is entered when the authenticationTarget property is set to BasicAuth.

In previous releases, BasicAuth logins validated only with the initial method request. During the first request, the user ID and password are sent to the server. This request is the first time that the client can notice an error, if the user ID or password is incorrect. The validateBasicAuth method is specified and the validation of the user ID and password occurs immediately to the security server.

**Note:** Set *com.ibm.CORBA.validateBasicAuth=false* whenever connecting to a z/OS server. This function does not currently work from a distributed client to a z/OS server since the SecurityServer is located using the "UNAUTHENTICATED" principal, which is not accepted on a z/OS system.

For performance reasons, you might want to disable this property if you do not want to verify the user ID and password immediately. If the client program can wait, it is better to have the initial method request flow to the user ID and password. However, program logic might not be this simple because of error handling considerations.

Table 117. *com.ibm.CORBA.validateBasicAuth*. This table describes the *com.ibm.CORBA.validateBasicAuth* setting.

Setting	Value
Data type	Boolean
Default	True
Valid values	True, False

*com.ibm.CORBA.authenticationRetryEnabled:*

Use to specify that a failed login attempt is retried. This property determines if a retry occurs for other errors, such as stateful sessions that are not found on a server or validation failures at the server because of an expiring credential.

The minor code in the exception that is returned to a client determines which errors are retried. The number of retry attempts is dependent upon the *com.ibm.CORBA.authenticationRetryCount* property.

Table 118. *com.ibm.CORBA.authenticationRetryEnabled*. This table describes the *com.ibm.CORBA.authenticationRetryEnabled* setting.

Setting	Value
Data type	Boolean
Default	True
Valid values	True, False

*com.ibm.CORBA.authenticationRetryCount:*

Use to specify the number of retries that occur until either a successful authentication occurs or the maximum retry value is reached.

When the maximum retry value is reached, the authentication exception is returned to the client.

Table 119. *com.ibm.CORBA.authenticationRetryCount*. This table describes the *com.ibm.CORBA.authenticationRetryCount* setting.

Setting	Value
Data type	Integer
Default	3
Range	1-10

*com.ibm.CORBA.loginSource*:

Use to specify how the request interceptor attempts to log in if it does not find an invocation credential already set.

This property is valid only if message layer authentication occurs. If only transport layer authentication occurs, this property is ignored. When specifying properties, the following two additional properties must be defined:

- *com.ibm.CORBA.loginUserid*
- *com.ibm.CORBA.loginPassword*

When performing a programmatic login, it is not necessary to specify none as the login source. The request fails if a credential is set as the invocation credential during a method request.

**Important:** For the z/OS platform, you can edit the properties file, *sas.client.props*, and set the *loginSource* property as follows: *com.ibm.CORBA.loginSource=none*

When you set *com.ibm.CORBA.loginSource=none* for a remote method invocation (RMI) connection, whether using scripting with *wsadmin* or from other clients, the logged-in user's credentials are inherited. There is no need to specify user and/or password at the command line or in the *sas.client.props* properties file. This inherited credential behavior when using *com.ibm.CORBA.loginSource=none* is only available on the z/OS platform.

Table 120. *com.ibm.CORBA.loginSource*. This table describes the *com.ibm.CORBA.loginSource* setting.

Setting	Value
Data type	String
Default	Prompt
Valid values	Prompt, key file, stdin, none, properties

*com.ibm.CORBA.loginUserid*:

Use to specify the user ID when a properties login is configured and message layer authentication occurs.

This property is valid only when *com.ibm.CORBA.loginSource=properties*. Also set the *com.ibm.CORBA.loginPassword* property.

Table 121. *com.ibm.CORBA.loginUserid*. This table describes the *com.ibm.CORBA.loginUserid* setting.

Setting	Value
Data type	String
Range	Any string that is appropriate for a user ID in the configured user registry of the server.

*com.ibm.CORBA.loginPassword*:

Use to specify the password when a properties login is configured and message layer authentication occurs.

This property is valid only when `com.ibm.CORBA.loginSource=properties`. Also set the `com.ibm.CORBA.loginuserid` property.

*Table 122. com.ibm.CORBA.loginPassword. This table describes the com.ibm.CORBA.loginPassword setting.*

Setting	Value
Data type	String
Range	Any string that is appropriate for a password in the configured user registry of the server.

*com.ibm.CORBA.keyFileName:*

Use to specify the key file that is used to log in.

A key file is a file that contains a list of realm, user ID, and password combinations that a client uses to log into multiple realms. The realm that is used is the one found in the interoperable object reference (IOR) for the current method request. The value of this property is used when the `com.ibm.CORBA.loginSource=keyfile` is used.

*Table 123. com.ibm.CORBA.keyFileName. This table describes the com.ibm.CORBA.keyFileName setting.*

Setting	Value
Data type	String
Default	C:/WebSphere/AppServer/properties/wssserver.key
Range	Any fully qualified path and file name of a WebSphere Application Server key file.

*com.ibm.CORBA.loginTimeout:*

Use to specify the length of time that the login prompt stays available before it is considered a failed login.

*Table 124. com.ibm.CORBA.loginTimeout. This table describes the com.ibm.CORBA.loginTimeout setting.*

Setting	Value
Data type	Integer
Units	Seconds
Default	300 (5 minute intervals)
Range	0 - 600 (10 minute intervals)

*com.ibm.CORBA.securityEnabled:*

Use to determine if security is enabled for the client process.

*Table 125. com.ibm.CORBA.securityEnabled. This table describes the com.ibm.CORBA.securityEnabled setting.*

Setting	Value
Data type	Boolean
Default	True
Range	True, False

### **Common Secure Interoperability version 2 (CSlv2) authentication protocol client settings:**

This page documents the properties that are valid for the CSlv2 protocol only.

*com.ibm.CSI.performSSL.Keyring:*

This property is used for providing the name of the Resource Access Control Facility (RACF) keyring used for SSL connections. Changes to this System Authorization Facility (SAF) keyring require changes to the `sas.client.props` file.

For example, you might have to change the following properties:

- `com.ibm.ssl.keyStore=safkeyring:///WASKeyring`
- `com.ibm.ssl.trustStore=safkeyring:///WASKeyring`

Data type:	String
Default:	None
Range:	None

*com.ibm.CORBA.loginUserId:*

Use this property to specify the user ID when a properties login is configured and message layer authentication occurs. This property is only valid when `com.ibm.CORBA.loginSource=properties`. Also, set the `com.ibm.CORBA.loginPassword` property.

Data type:	String
Range:	Any string that is appropriate for a user ID in the configured user registry of the server.

*com.ibm.CORBA.loginPassword:*

Use to specify the password when a properties login is configured and message layer authentication occurs. This property is only valid when `com.ibm.CORBA.loginSource=properties`. Also, set the `com.ibm.CORBA.loginUserId` property.

Data type:	String
Range:	Any string that is appropriate for a password in the configured user registry of the server.

## Authentication protocol for EJB security

WebSphere Application Server Version 8.0 servers support the CSiv2 authentication protocol only. z/SAS is only supported between Version 6.0.x and earlier version servers that have been federated in a Version 8.0 cell. The option to select between z/SAS, CSiv2, or both is only available in the administration console when a Version 6.0.x or earlier release has been federated in a Version 6.1 cell.

The Object Management Group (OMG) has defined the authentication protocol called CSiv2 so that vendors can interoperate securely. CSiv2 is implemented in WebSphere Application Server with more features than z/SAS and it is considered the strategic protocol.

**Important:** z/SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Invoking Enterprise Java Beans (EJB) methods in a secure WebSphere Application Server environment requires an authentication protocol to determine the level of security and the type of authentication that occur between any given client and server for each request. It is the job of the authentication protocol during a method invocation to merge the server authentication requirements that are determined by the object Interoperable Object Reference (IOR) with the client authentication requirements that are determined by the client configuration and come up with an authentication policy specific to that client and server pair.

The authentication policy makes the following decisions, among others, which are all based on the client and server configurations:

- What kind of connection can you make to this server--Secure Sockets Layer (SSL) or TCP/IP?

- If SSL is chosen, how strong is the encryption of the data?
- If SSL is chosen, do you authenticate the client using client certificates?
- Do you authenticate the client with a user ID and password? Does an existing credential exist?
- Do you assert the client identity to downstream servers?
- Given the configuration of the client and server, can a secure request proceed?

You can configure both protocols (z/SAS and CSiv2) to work simultaneously. If a server supports both protocols, it exports an IOR containing tagged components describing the configuration for z/SAS and CSiv2. If a client supports both protocols, it reads tagged components for both CSiv2 and z/SAS. If the client supports both and the server supports both, CSiv2 is used. However, if the server supports z/SAS (for example, it is a previous WebSphere Application Server release) and the client supports both, the client chooses z/SAS for this request because the z/SAS protocol is what both have in common.

CSiv2 is considered enabled on the client with the existence of the `com.ibm.CORBA.ConfigURL` Java property. If the property is not specified or the specified property does not exist, CSiv2 is not enabled.

## Common Secure Interoperability Specification, Version 2

The Common Secure Interoperability Specification, Version 2 (CSiv2) defines the Security Attribute Service (SAS) that enables interoperable authentication and delegation. The CSiv2 and z/SAS protocols are entirely different. The CSiv2 SAS is a subcomponent of CSiv2 that supports SSL and interoperability.

### Security Attribute Service

The Common Secure Interoperability Specification, Version 2 Security Attribute Service (CSiv2 SAS) protocol is designed to exchange its protocol elements in the service context of a General Inter-ORB Protocol (GIOP) request and reply messages that are communicated over a connection-based transport. The protocol is intended for use in environments where transport layer security, such as that available through Secure Sockets Layer (SSL) and Transport Layer Security (TLS), is used to provide message protection (that is, integrity and or confidentiality) and server-to-client authentication. The protocol provides client authentication, delegation, and privilege functionality that might be applied to overcome corresponding deficiencies in an underlying transport. The CSiv2 SAS protocol facilitates interoperability by serving as the higher-level protocol under which secure transports can be unified.

### Connection and request interceptors

The authentication protocols that are used by WebSphere Application Server are add-on Interoperable Inter-ORB Protocol (IIOP) services. IIOP is a request-and-reply communications protocol that is used to send messages between two Object Request Brokers (ORBs). For each request made by a client ORB to a server ORB, an associated reply is made by the server ORB back to the client ORB. Prior to any request flowing, a connection between the client ORB and the server ORB must be established over the TCP/IP transport (SSL is a secure version of TCP/IP). The client ORB invokes the authentication protocol client connection interceptor, which is used to read the tagged components in the IOR of the object that is located on the server. As mentioned previously, the authentication policy is established here for the request. Given the authentication policy (a coalescing of the server configuration with the client configuration), the strength of the connection is returned to the ORB. The ORB makes the appropriate connection, usually over SSL.

After the connection is established, the client ORB invokes the authentication protocol client request interceptor, which is used to send security information other than what is established by the transport. The security information includes the user ID and password token that are authenticated by the server, an authentication mechanism-specific token that is validated by the server, or an identity assertion token. Identity assertion is a way for one server to trust another server without the need to re-authenticate or re-validate the originating client. However, some work is required for the server to trust the upstream server. This additional security information is sent with the message in a *service context*. A service context has a registered identifier so that the server ORB can identify which protocol is sending the information.

The fact that a service context contains a unique identity is another way for WebSphere Application Server to support both z/SAS and CSIv2 simultaneously because both protocols have different service context IDs. After the client request interceptor finishes adding the service context to the message, the message is sent to the server ORB.

When the message is received by the server ORB, the ORB invokes the authentication protocol server request interceptor. This interceptor looks for the service context ID known by the protocol. When both z/SAS and CSIv2 are supported by a server, two different server request interceptors are invoked and both interceptors look for different service context IDs.

However, only one finds a service context for any given request. When the server request interceptor finds a service context, it reads the information in the service context. A method is invoked to the security server to authenticate or validate client identity. The security server either rejects the information or returns a credential. A credential contains additional information about the client that is retrieved from the user registry so that authorization can make the appropriate decision. Authorization is the process of determining if the user can invoke the request based on the roles that are applied to the method and the roles given to the user.

If a service context is not found by the CSIv2 server request interceptor, the interceptor process looks at the transport connection to see if a client certificate chain is sent. This process is done when SSL client authentication is configured between the client and server.

If the user registry is Lightweight Directory Access Protocol (LDAP), the search filters defined in the LDAP registry configuration determine how the certificate maps to an entry in the registry. If the user registry is local OS, the certificate is mapped to a System Authorization Facility (SAF) user ID. You then can map the user ID, using the issuers name or the subjects name, with the SAF certificate mapping facility.

If the certificate does not map, no credential is created and the request is rejected. When valid security information is not presented, the method request is rejected and a NO\_PERMISSION exception is sent back with the reply. However, when no security information is presented, an unauthenticated credential is created for the request and the authorization engine determines if the method gets invoked. For an unauthenticated credential to invoke an Enterprise JavaBeans (EJB) method, either no security roles are defined for the method or a special Everyone role is defined for the method.

When the method invocation is completed in the EJB container, the server request interceptor is invoked again to complete server authentication and a new reply service context is created to inform the client request interceptor of the outcome. This process is typically for making the request *stateful*. When a stateful request is made, only the first request between a client and server requires that security information is sent. All subsequent method requests need to send a unique context ID only so that the server can look up the credential that is stored in a session table. The context ID is unique within the connection between a client and server.

Finally, the method request cycle is completed by the client request interceptor receiving a reply from the server with a reply service context providing information so that the client-side stateful context ID can be confirmed and reused.

The client and the server support both stateful and stateless sessions and this is not configurable.

. *Authentication protocol flow*

## **Authentication policy for each request**

The authentication policy of a given request determines the security protection between a client and a server. A client or server authentication protocol configuration can describe required features, supported features, and non-supported features. When a client requires a feature, it can talk only to servers that

either require or support that feature. When a server requires a feature, it can talk only to clients that either require or support that feature. When a client supports a feature, it can talk to a server that supports or requires that feature, but can also talk to servers that do not support the feature. When a server supports a feature, it can talk to a client that supports or requires the feature, but can also talk to clients that do not support the feature or chose not to support the feature.

For example, for a client to support client certificate authentication, some setup is required to either generate a self-signed certificate or to get one from a certificate authority (CA). Some clients might not need to complete these actions, therefore, you can configure this feature as not supported. By making this decision, the client cannot communicate with a secure server that requires client certificate authentication. Instead, this client can choose to use the user ID and password as the method of authenticating itself to the server.

Typically, supporting a feature is the most common way of configuring features. It is also the most successful during runtime because it is more forgiving than requiring a feature. Knowing how secure servers are configured in your domain, you can choose the right combination for the client to ensure successful method invocations and still get the most security. If you know that all of your servers support both client certificate and user ID and password authentication for the client, you might want to require one and not support the other. If both the user ID and password and the client certificate are supported on the client and server, both are performed, but user ID and password take precedence at the server. This action is based on the CSiv2 specification requirements.

## **Authentication protocol support**

Use this page to reference information regarding supported authentication protocols.

### **Authentication protocol support for z/OS**

Beginning with WebSphere Application Server Version 8.0, the WebSphere Application Server Version 8.0 servers only support the Common Secure Interoperability Version 2 (CSiv2) authentication protocol. Secure Authentication Service for z/OS (z/SAS) is only supported between Version 6 and previous version servers that have been federated in a Version 8.0 cell. The option to select between z/SAS, CSiv2, or both will only be made available in the administration console when a Version 6 or previous release has been federated in a Version 8.0 cell.

In future releases, IBM will no longer ship or support the Secure Authentication Service (z/SAS) IIOP security protocol. It is recommended that you use the Common Secure Interoperability version 2 (CSiv2) protocol.

You can configure both protocols to work simultaneously between Version 6.0.x and previous version servers that have been federated in a Version 8.0 cell. If a server supports both protocols, it exports an interoperable object reference (IOR) that contains tagged components describing the configuration for z/SAS and CSiv2. If a client supports both protocols, it reads tagged components for both CSiv2 and z/SAS. If the client and server support both protocols, CSiv2 is used. However, if the server supports z/SAS (for example, the server is a previous WebSphere Application Server release) and the client supports both protocols, the client chooses z/SAS for this request.

CSiv2 is considered enabled on the client with the existence of the `com.ibm.CORBA.ConfigURL` java property. If the property is not specified or the property does not exist, CSiv2 is not enabled.

## **Common Secure Interoperability Version 2 features**

The following Common Secure Interoperability Version 2 (CSiv2) features are available in IBM WebSphere Application Server: message layer authentication, identity assertion, and security attribute propagation.

- Identity Assertion

Supports a downstream server in accepting the client identity that is established on an upstream server, without having to authenticate again. The downstream server trusts the upstream server.

- Message Layer Authentication

Authenticates credential information and sends that information across the network so that a receiving server can interpret it.

- Security attribute propagation

Supports the use of the authorization token to propagate serialized Subject contents and PropagationToken contents with the request. You can propagate these objects using a pure client or a server login that adds custom objects to the Subject. Propagating security attributes prevents downstream logins from having to make user registry calls to look up these attributes.

Propagating security attributes is also useful when the security attributes contain information that is only available at the time of authentication. This information cannot be located using the user registry on downstream servers.

## Identity assertion to the downstream server

When a client authenticates to a server, the received credential is set. When the authorization engine checks the credential to determine whether access is permitted, it also sets the *invocation* credential. *Identity assertion* is the invocation credential that is asserted to the downstream server.

When a client authenticates to a server, the received credential is set. When the authorization engine checks the credential to determine whether access is permitted, it also sets the *invocation* credential so that if the Enterprise JavaBeans (EJB) method calls another EJB method that is located on other servers, the invocation credential can be the identity used to invoke the downstream method. Depending on the RunAs mode for the enterprise beans, the invocation credential is set as the originating client identity, the server identity, or a specified different identity. Regardless of the identity that is set, when identity assertion is enabled, it is the invocation credential that is asserted to the downstream server.

The sending server identity is sent using an SSL client certificate. If SSL is not used, the server identity is not sent.

Both identity tokens are needed by the receiving server to accept the asserted identity. The receiving server completes the following actions to accept the asserted identity:

- The server determines whether the sending server identity, sent with a basic authentication token or with an SSL client certificate, is on the trusted principal list of the receiving server. The server determines whether the sending server can send an identity token to the receiving server.
- After it is determined that the sending server is on the trusted list, the server authenticates the sending server to verify its identity.
- The server is authenticated by comparing the user ID and password from the sending server to the receiving server. If the credentials of the sending server are authenticated and on the trusted principal list, then the server proceeds to evaluate the identity token.
- The downstream server checks its defined user registry for the presence of the asserted user ID to gather additional credential information for authorization purposes (for example, group memberships). Thus, the downstream user registry must contain all of the asserted user IDs. Otherwise, identity assertion is not possible. In a stateful server, this action occurs once for the sending server and the receiving server pair where the identity tokens are the same. Subsequent requests are made through a session ID.

**Note:** When the downstream server does not have a user registry with access to the asserted user IDs in its repository, do not use identity assertion because authorization checks will fail. By disabling identity assertion, the authorization checks on the downstream server are not needed.

The target server validates the authority of the sending server to assert an identity by the client certificate. The client certificate is mapped to a Service Access Facility (SAF) user ID, either using the RACDCERT MAP filters or the RACMAP filters defined in the SAF database. The SAF user ID must have UPDATE authority for the CB.BIND.<optionSAFProfilePrefix>.cluster\_short\_name profile in the CBIND class. If a client certificate is not sent, the CBIND check is performed against the started task ID of the sending server.

Evaluation of the identity token consists of the following four identity formats that exist in an identity token:

- Principal name
- Distinguished name
- Certificate chain
- Anonymous identity

The product servers that receive authentication information typically support all four identity types. The sending server decides which one is chosen, based on how the original client authenticated. The existing type depends on how the client originally authenticates to the sending server. For example, if the client uses Secure Sockets Layer (SSL) client authentication to authenticate to the sending server, then the identity token sent to the downstream server contains the certificate chain. With this information, the receiving server can perform its own certificate chain mapping and interoperability is increased with other vendors and platforms.

After the identity format is understood and parsed, the identity maps to a credential. For an `ITTPPrincipal` identity token, this identity maps one-to-one with the user ID fields.

`ITTDistinguishedName` identity tokens and `ITTCertChain` identity tokens are mapped in the same way. Both types of identity tokens use a certificate that is mapped to a SAF user ID using the `RACDCERT` or equivalent mapping functions, like `RACMAP` filters. The mapping can be based on the Subject name or the Issuers name.

**Note:** There is a restriction for using identity assertion with KRB token to downstream. If you use identity assertion with Kerberos enabled, the identity assertion does not have the Kerberos authentication token (`KRBAuthnToken`) when going to downstream servers. It uses LTPA for authentication instead.

## Identity assertions with trust validation

If you want an application or system provider to perform an identity assertion with trust validation, it can be accomplished by use of the Java Authentication and Authorization Service (JAAS) login framework, where trust validation is performed in one login module and credential creation in another. These two custom login modules are used to create a JAAS login configuration that performs a login to an identity assertion.

Two custom login module are required:

- A user-implemented trust association login module. This login module performs whatever trust verification the user requires. When trust is verified, the trust verification status and the login identity must be placed in a map in the share state of the login module to enable the credential creation login module to use that information. The map must be stored in the `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state` property. State maps contain the following information:
  - `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trusted` – set to `true`, if trusted, and `false`, if not trusted.
  - `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal` – contains the principal of the identity.
  - `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates` – contains the certificate of the identity
- The `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule` module performs the credential creation. It requires that the trust state information be in the login context's shared state. This login module is protected by the Java 2 security runtime permissions for the following:
  - `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.initialize`
  - `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.login`

`IdentityAssertionLoginModule` searches for the trust information in the shared state property, `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state`. This is a map that contains the trust status and the identity used to login. The map includes the following:

- `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trusted` – if set to `true` it is trusted, `false` if not trusted.
- `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal` – if a principal is used, it contains the principal of the identity necessary to login.
- `com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates` – if a certificate is used, it contains an array of a certificate chain that includes the identity necessary to login.

A `WSLoginFailedException` is returned if the state, trust, or identity information is missing. The login module then performs a login of the identity. The subject now contains the new identity.

## Message layer authentication

Defines the credential information and sends that information across the network so that a receiving server can interpret it.

When you send authentication information across the network using a token the transmission is considered message layer authentication because the data is sent with the message inside a service context.

A pure Java client uses Kerberos (KRB5) or basic authentication, or Generic Security Services Username Password (GSSUP), as the authentication mechanism to establish client identity.

However, a servlet can use either basic authentication (GSSUP) or the authentication mechanism of the server, Kerberos (KRB5) or Lightweight Third Party Authentication (LTPA), to send security information in the message layer. Use KRB5 or LTPA by authenticating or by mapping the basic authentication credentials to the security mechanism of the server.

The security token that is contained in a token-based credential is authentication mechanism-specific. The way that the token is interpreted is only known by the authentication mechanism. Therefore, each authentication mechanism has an object ID (OID) representing it. The OID and the client token are sent to the server, so that the server knows which mechanism to use when reading and validating the token. The following list contains the OIDs for each mechanism:

BasicAuth (GSSUP): `oid:2.23.130.1.1.1`  
 KRB5: `OID: 1.2.840.113554.1.2.2`  
 LTPA: `oid:1.3.18.0.2.30.2`  
 SWAM: No OID because it is not forwardable

**Note:** SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

On the server, the authentication mechanisms can interpret the token and create a credential, or they can authenticate basic authentication data from the client, and create a credential. Either way, the created credential is the *received* credential that the authorization check uses to determine if the user has access to invoke the method. You can specify the authentication mechanism by using the following property on the client side:

- `com.ibm.CORBA.authenticationTarget`

Basic authentication (BasicAuth) and KRB5 are currently the only valid values. You can configure the server through the administrative console.

**Note:** When **perform basic authentication** is enabled, if the client is not similarly configured (and does not pass a credential such as a user ID and password).

## Configuring authentication retries

Situations occur where you want a prompt to display again if you entered your user ID and password incorrectly or you want a method to retry when a particular error occurs back at the client. If you can correct the error by information at the client side, the system automatically performs a retry without the client seeing the failure, if the system is configured appropriately.

Some of these errors include:

- Entering a user ID and password that are not valid
- Having an expired credential on the server
- Failing to find the stateful session on the server

By default, authentication retries are enabled and perform three retries before returning the error to the client. Use the `com.ibm.CORBA.authenticationRetryEnabled` property (`True` or `False`) to enable or disable authentication retries. Use the `com.ibm.CORBA.authenticationRetryCount` property to specify the number of retry attempts.

## Immediate validating of a basic authentication login

In WebSphere Application Server Version 6.x, a behavior is defined during `request_login` for a `BasicAuth` login. In releases prior to Version 5, a `BasicAuth` login takes the user ID and password entered through the `loginSource` method and creates a `BasicAuth` credential. If either the user ID or the password is not valid, the client program does not find out until the first method request is attempted. When the user ID or password is specified during a prompt or programmatic login, the user ID and password are authenticated by default with the security server, with a `True` or `False` returned as the result. If `False`, an `org.omg.SecurityLevel2.LoginFailed` exception is returned to the client indicating that the user ID and password are not valid. If `True`, then the `BasicAuth` credential is returned to the caller of the `request_login`. To disable this feature on the pure client, specify `com.ibm.CORBA.validateBasicAuth=false`. By default, this feature is set to `True`. On the server side, specify this property in the security dynamic properties.

**Note:** Set `com.ibm.CORBA.validateBasicAuth=false` whenever connecting to a z/OS server. This function does not currently work from a distributed client to a z/OS server since the `SecurityServer` is located using the "UNAUTHENTICATED" principal, which is not accepted on a z/OS system.

## Using Microsoft Active Directory for authentication

WebSphere Application Server supports the Microsoft Active Directory. Many installations use the Microsoft Active Directory as their primary component for managing user authentication and user data. Authenticating a user across multiple repositories or across a distributed Lightweight Directory Access Protocol (LDAP), such as a Microsoft Active Directory forest can be challenging. In any search of the whole registry, if there is more than one match at run time, authentication fails because ambiguous matches result.

### About this task

User IDs are guaranteed to be unique within a single domain, but there is no automatic guarantee that a given user ID is unique across a tree or a forest. The following figure exemplifies the condition of a given user ID not being unique across a tree or forest.

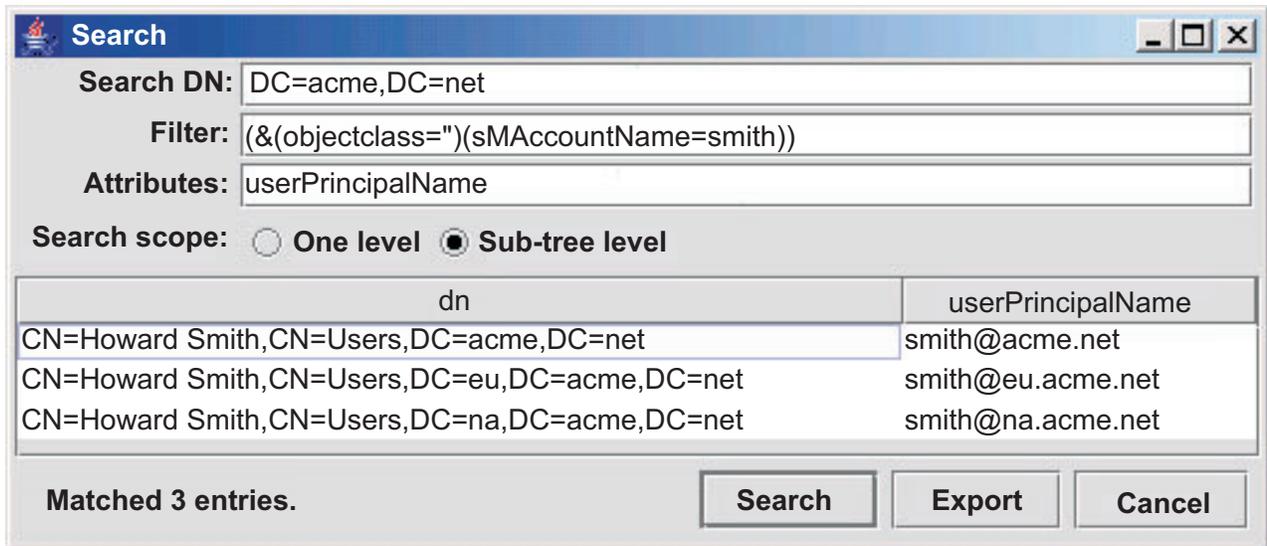

Figure 22. Forest search strategy.. Search illustration of a non-unique sMAccountName across the entire forest.

Authenticating users across trees or forests can be a difficult task and the following steps should be performed.

### Procedure

1. Analyze the Microsoft Active Directory construct that defines your installation. Your analysis can conclude with the following forms:
  - Single LDAP registry - Simple configuration.
  - Federated repository (a forest )- Typical configuration.
  - Merger of federated repositories (a merger of trees into a forest )- Less typical configuration
  - Combination of user and group forests - Rare configuration
2. Develop strategies for user look up that match your Microsoft Active Directory installation. Remember that user IDs are guaranteed to be unique within a single domain, but there is no automatic guarantee that a given user ID is unique across a tree or a forest.
3. Evaluate with testing to ensure that your authentication search strategies successfully authenticate users in your Microsoft Active Directory installation.

### Results

You will be in the position to authenticate users with LDAP registries in a Microsoft Active Directory forest.

### What to do next

**gotcha:** When you select any of these scenarios, consult appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuration planning.

### Authentication using Microsoft Active Directory

Many installations use the Microsoft Active Directory as their primary component for managing user authentication and user data. One portion of the Microsoft Active Directory provides a Lightweight Directory Access Protocol (LDAP) service. WebSphere Application Server supports LDAP and, therefore, WebSphere Application Server supports the Microsoft Active Directory.

While the Microsoft Active Directory is fully LDAP-compliant, it exposes LDAP information in ways that can make it difficult to obtain directory information for WebSphere Application Server.

WebSphere Application Server operates in a way that assumes that a single LDAP directory contains all the information necessary to operate. With complex Microsoft Active Directory configurations, this is not the case. WebSphere Application Server - Microsoft Active Directory installations must handle unique challenges because of the way data is spread throughout the domain controllers in a forest.

Microsoft Active Directory installations frequently incorporate the use of a forest. As such, security questions pertaining to user ID uniqueness, reliably obtaining user group information, and group membership spread across forests become important.

The following figure highlights a typical Microsoft Active Directory installation environment.

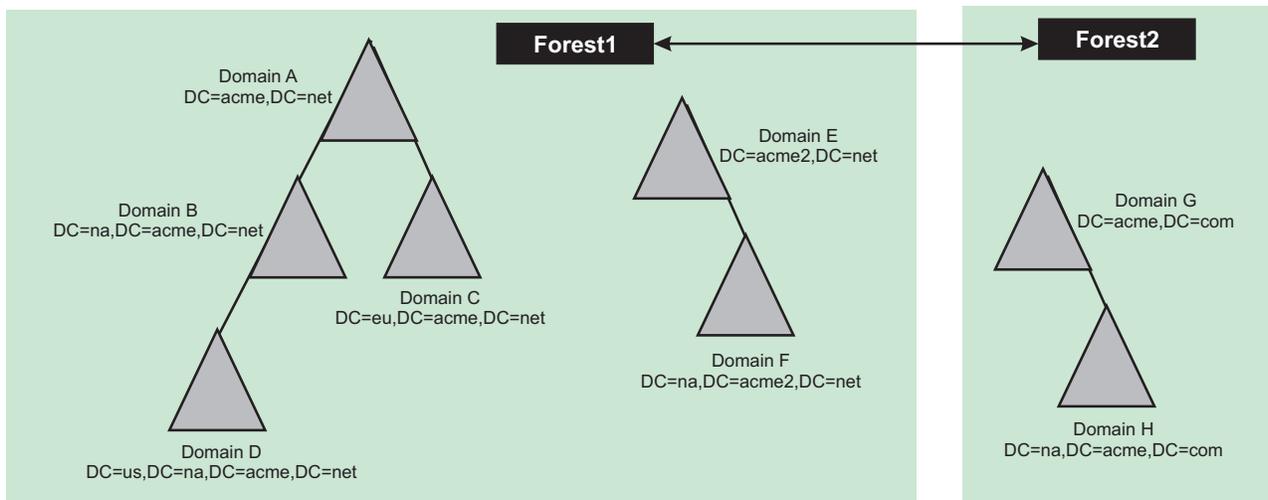

Figure 23. Microsoft Active Directory forests. An illustration of Microsoft Active Directory forests.

This figure illustrates two forests of one or more trees. A tree can contain one or more domains where the domain is the single atomic unit that forms the basis for the constructed environment. Each domain is made up of the primary domain components of the distinguished name (DN), for example, dc=acme, dc=com. A forest can extend trust to other forests (This trust is based on Kerberos.).

## Microsoft Active Directory configurations with WebSphere Application Server

There can be a variety of Microsoft Active Directory configurations for WebSphere Application Server, which include:

- Simple configuration
- Typical configuration
- Less typical configurations
- Rare configurations

### Simple configuration

The simplest configuration consists of a stand-alone LDAP registry representing a single domain. This configuration represents the closest fit between WebSphere Application Server and the Microsoft Active Directory. In this configuration, Microsoft Active Directory is supported through the WebSphere Application Server stand-alone LDAP user registry implementation. Alternatively, you can access this single Microsoft Active Directory domain through a federated repositories registry, which contains a single LDAP repository.

### Typical Configuration

Beyond the simple single domain Microsoft Active Directory configuration, a typical Microsoft Active Directory configuration consists of a single tree in a forest where each branch of the tree is a domain. An example of this configuration, which consists of a single tree of four domains (A, B, C, D), is shown in the following example:

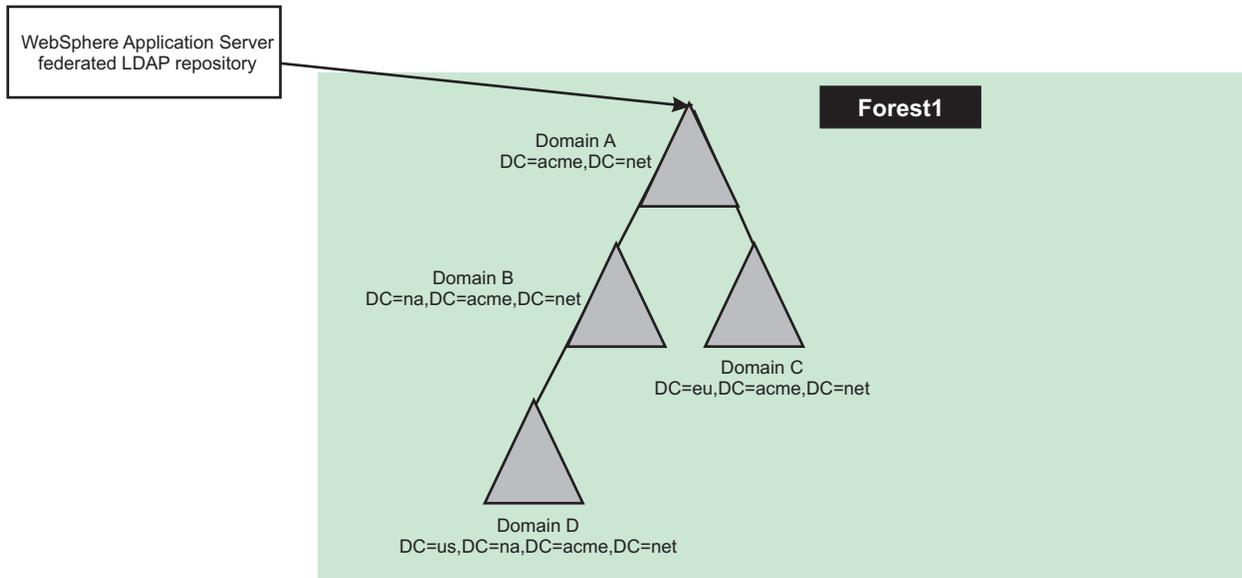

Figure 24. Typical forest configuration. An illustration of a typical forest configuration.

Configurations, such as this configuration, frequently have domains that are organized by geography or organizational unit. The WebSphere Application Server registry configuration that is necessary to use this "single tree" Microsoft Active Directory implementation needs to use the federated repositories. This configuration contains an LDAP registry to map entries from multiple individual user repositories into a single virtual repository. These configurations create a federated user repository with a single named realm and an LDAP subtree within the single repository. The root of the repository is mapped to a base entry within the federated repository, which is the starting point within the hierarchical namespace of the virtual realm. LDAP searches in this configuration proceed with binding to the top domain object and following LDAP referrals.

**gotcha:** The stand-alone LDAP registry in WebSphere Application Server does not support LDAP referrals and cannot be used in a WebSphere Application Server - Microsoft Active Directory configuration.

### Less typical configurations

Less typical WebSphere Application Server - Microsoft Active Directory configurations evolve from mergers of organizations units in a larger enterprise. Where a single forest of domains once served the enterprise, the merger of several new organizational units can add trees to the forest or even add more than a single forest to the environment. In this environment, the WebSphere Application Server LDAP configuration requires more careful design. You must use the federated repositories registry in such an environment with separate LDAP repositories mapped to the top of each tree in the forest. Again, if a Microsoft Active Directory tree exists under the top-level domain, LDAP referrals must be enabled for the LDAP registry. The forest resulting from a merger can look like the following figure:

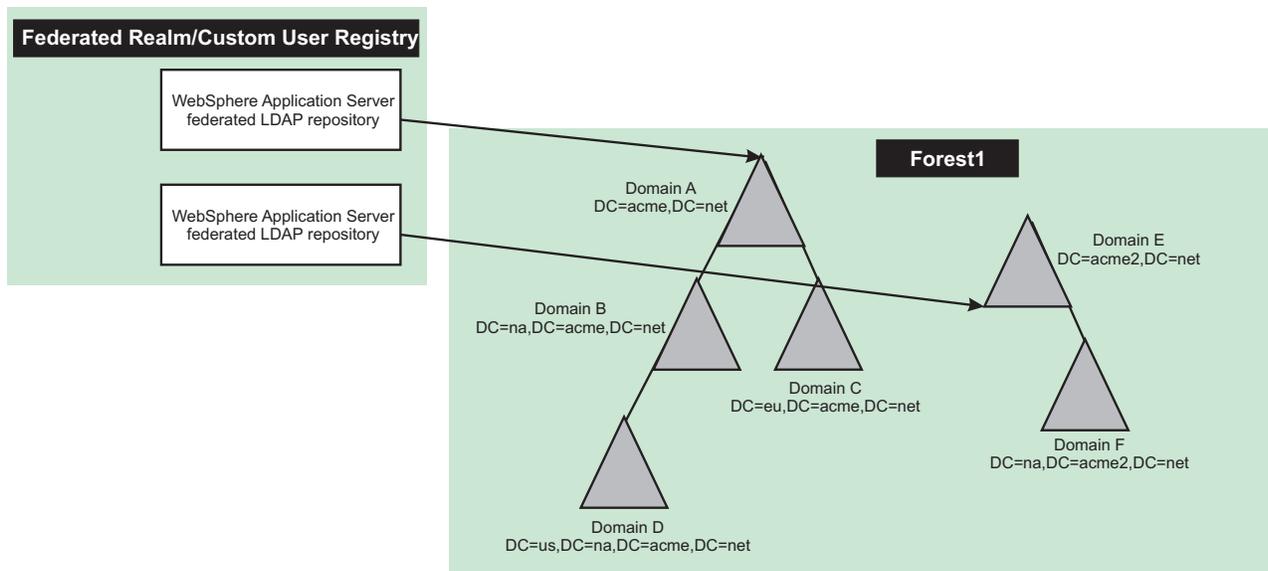

Figure 25. Less typical configurations. Less typical configurations that depict the merger of trees

### Rare configurations

Rare configurations consist of Microsoft Active Directory domains that are configured where there is a combination of a user forest and a group forest. Users are imported as ForeignSecurityPrincipals objects in the group forest. The groups contain the distinguished names (DN) of the ForeignSecurityPrincipals objects as members.

In this form of configuration, direct group lookups do not occur. Lookups are relegated to a static group query across multiple registries. This configuration requires a custom user registry. However, WebSphere Application Server registries do not support this type of configuration. See the following figure.

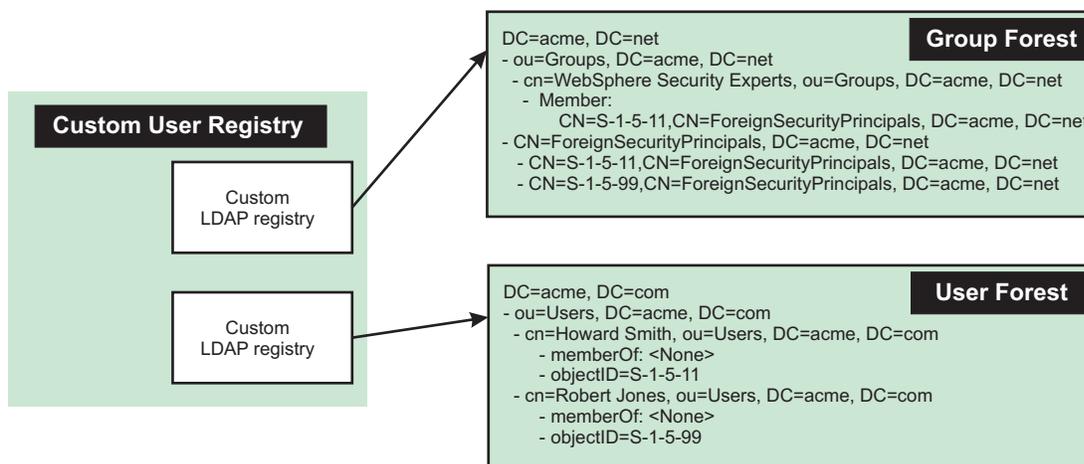

Figure 26. Resource model forest. An illustration of a resource model forest.

### Using a Microsoft Active Directory forest as LDAP - user filter

Authenticating a user across multiple repositories, or across a distributed LDAP, such as a Microsoft Active Directory forest configuration can be challenging. In any search of the whole registry, authentication fails if there is more than one match at run time because ambiguous matches result. In multiple Microsoft Active

Directory domain environment, the WebSphere Application Server administrator must consider that the default unique ID in the Microsoft Active Directory is the sAMAccountName attribute of a user. User IDs are guaranteed to be unique within a single domain, but it is not possible to guarantee that a given user ID is unique across a tree or a forest. See the topic, "Authenticating users with LDAP registries in a Microsoft Active Directory forest" to understand how to search for user IDs within a Microsoft Active Directory forest using the sAMAccountName attribute of a user.

**gotcha:** Before selecting any of these scenarios, consult appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuration planning.

## Groups spanning domains with Microsoft Active Directory

The domains and forests functional levels of the Microsoft Active Directory control which configurations are available for use. How you configure Microsoft Active Directory affects how group membership is determined within WebSphere Application Server. Using groups to configure your Microsoft Active Directory installation with the product allows flexible management.

A breakdown follows of applicable functional levels that apply to a Microsoft Active Directory installation with the product.

- Domain Functional Levels
  - Native
    - Supported by Windows Server 2008 and Windows Server 2008 R2
    - Default in Windows 2008

You must use native domain functional levels to support group nesting, and universal groups. Forest functional levels do not directly affect group membership. The Windows 2008 operating system is the exception.

- Forest Functional Levels
  - Windows Server 2008 or Windows Server 2008 R2
    - All domains operate at the Windows Server 2008 **domain functional level**.

If the forest functional level is set to Windows Server 2008, then that also makes the domain functional level for all domains to be Windows Server 2008 Native level, which adds to the group nesting and Universal groups features to Microsoft Active Directory.

## Microsoft Active Directory groups

In a domain, Microsoft Active Directory provides support for different types of groups and group scopes. Groups in Microsoft Active Directory are containers with other objects within them as members. Those objects can be user objects, other group objects, which is group nesting, and other objects types, such as computers. The group type determines the type of task that you manage with the group. The group scope determines whether the group can have members from multiple domains or a single domain. In summary:

- Groups are typically a collection of user accounts.
- Members receive permission given to groups.
- Users can be members of multiple groups.
- Groups can be members of other groups, which are nested groups.

**gotcha:** In WebSphere Application Server, security roles of the individual, which map to application permissions or authorizations, must be bound to either users or groups at application deployment time. From an administrative point of view, it is preferable to assign permissions once for a group instead of assigning permissions repeatedly for each user account. Then the ability to act in a given role is under the control of the directory administrator, instead of the WebSphere administrator. Because the job of the directory administrator is to create and delete users, change group memberships for users, and other tasks, this approach is generally the correct division of responsibilities.

**Group types** determine how the group is used. The Microsoft Active Directory group types are:

- **Security groups:** Microsoft Active Directory uses security groups for granting permissions to gain access to resources.
- **Distribution groups:** Distribution groups are used by Windows-based applications as lists for nonsecurity-related functions. Distribution groups are used for sending email messages to groups of users. You cannot grant Windows permissions to security groups.

Although WebSphere Application Server can use either type of group, security groups are typically bound to WebSphere Application Server security roles.

**Group scopes** describe which type of objects can be arranged together within a group. Group nesting describes when one group is a member of other groups. The Microsoft Active Directory group scopes are:

- **Domain local group:**
  - **Windows usage:** Members of this group can come from any domain, but can access Windows resources only in the local domain. Use this scope to grant permissions to domain resources that are located in the same domain in which you created the domain local group. Domain local groups can exist in all mixed, native, and interim functional level of domains and forests.
  - **Restriction:** You cannot define group nesting in a domain local group. A domain local group cannot be a member of another domain local group or any other group in the same domain.
  - **WebSphere usage:** Users are not typically placed in domain - local groups due to these restrictions. WebSphere Application Server security roles are not typically bound to domain local groups.
- **Global Group:**
  - **Windows usage:** Members of this group originate from a local domain, but can access Windows resources in any domain. The global group is used to organize users who share similar Windows network access requirements. You can add members only from the domain in which the global group is created. You can use this group to assign permissions to gain access to Windows resources that are located in any domain in the domain, tree, or forest.

You can group users with similar function under global scope and give permission to access a Windows resource, such as a printer or shared folder and files, that is available in local or another domain in the same forest. You can use global groups to grant permission to gain access to Windows resources that are located in any domain in a single forest as their memberships are limited. You can add user accounts and global groups only from the domain in which global group is created.

Nesting is possible for global groups within other groups as you can add a global group into another global group from any domain. Members of a global group can be members of a domain - local group. Global groups exist in all mixed, native, and interim functional levels of domains and forests.

**WebSphere Application Server usage:** Global groups are visible on every domain controller, but memberships are only visible for local users. That is, you can see your group memberships only if you query your home domain controller. A global group should contain groups of users. Global groups are intended to be included in universal groups.

- **Universal Group:**
  - **Windows usage:** Members in this group can come from any domain and access Windows resources in multiple domains. Universal group memberships are not limited like global groups. All domain user accounts and groups can be members of a universal group.
  - **Restrictions:**
    - Universal groups are available when the domain is at a Windows mixed functional level.
    - It can be expensive to replicate this data across the forest. Group definitions and deletions are relatively rare compared to the equivalent user actions, and nested group membership changes are typically rare compared to memberships of users within groups,

**gotcha:** Consult appropriate Microsoft Active Directory information concerning any implications of replicating data across forests.

– **WebSphere usage:**

- Universal Groups and their memberships are visible on every domain controller in the forest.
- Universal groups are also visible when using the Global Catalog. To be useful, all user objects must be directly in the universal group,

**Universal group guidelines**

1. Assign permissions to universal groups for Windows resources in any domain in the network.
2. Use universal groups only when their membership is static. Changes in membership can cause excessive network traffic between domain controllers. Membership of universal groups can be replicated to many domain controllers.
3. Add global groups from several domains to a universal group.
4. Assign permissions for access to a Windows resource to the universal group and for use by WebSphere Application Server group membership resolution across multiple domains.
5. Use a universal group in the same way as a domain local group to assign resource permissions.

**gotcha:** When you select any of these scenarios, consult the appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuration planning.

**Microsoft Active Directory Global Catalog**

A *Global Catalog* is a Global Catalog Server. A Global Catalog holds a full set of attributes for the domain in which it resides and a subset of attributes for all objects in the Microsoft Active Directory Forest. The primary two functions of a Global Catalog within the Microsoft Active Directory are logon capability and Microsoft Active Directory queries.

A Global Catalog in a Microsoft Active Directory installation with the product is a single Lightweight Directory Access Protocol (LDAP) repository that contains a subset of user information from all the domains in the forest. This information includes user IDs, authentication information, and groups, but not all the group information.

You can use the Global Catalog on any domain controller in the forest, even in subdomains. The Global Catalog is a solution to the WebSphere Application Server limitation of a "single registry". There are limitations to the Global Catalog. Users from the local domain controller contain group "memberOf" information. Users from a foreign domain controller contain limited "memberOf" information because the global group information is not replicated to every domain controller.

**Nested global groups in universal groups**

This is a typical structure of group membership and consists of the following characteristics:

- Users are distributed across domain controllers in a forest containing multiple domain controllers.
- Users are defined in global groups within their own local domain controller.
- A universal group contains the global groups, which reflects a Java Platform Enterprise Edition (Java EE) role that maps to a set of users spread across *multiple* domain controllers.

The following figure illustrates nested global groups in universal groups.

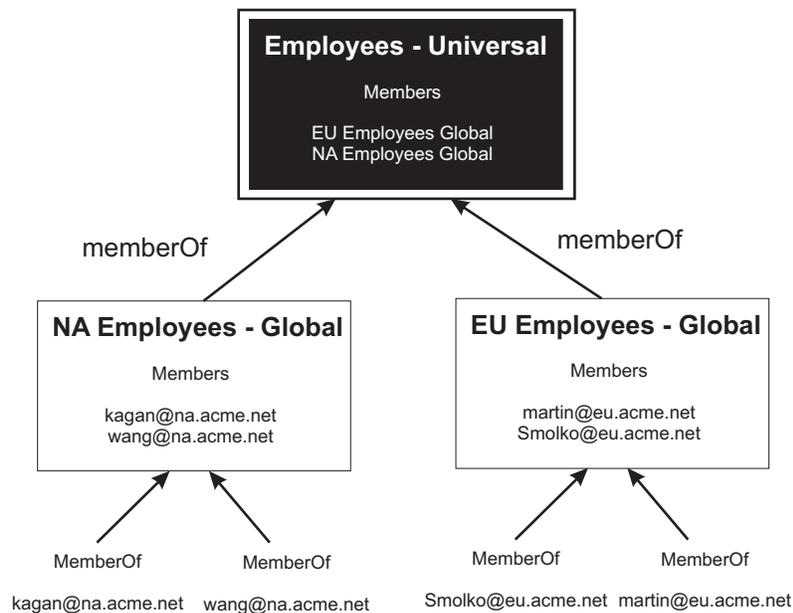

Figure 27. Nested global groups in universal groups. This figure illustrates nested global groups in universal groups.

It is a challenge to develop methods of configuring WebSphere Application Server to be able to find users and their group memberships when the information is spread across multiple domain controllers. One method requires that WebSphere Application Server follow LDAP referrals to find the home domain controller for each user and that WebSphere Application Server perform nested group queries.

**gotcha:** This approach does not use the Global Catalog.

Another method and the simplest approach has universal groups that contain users and uses a Global Catalog, which requires using referrals. The figure that follows illustrates this method.

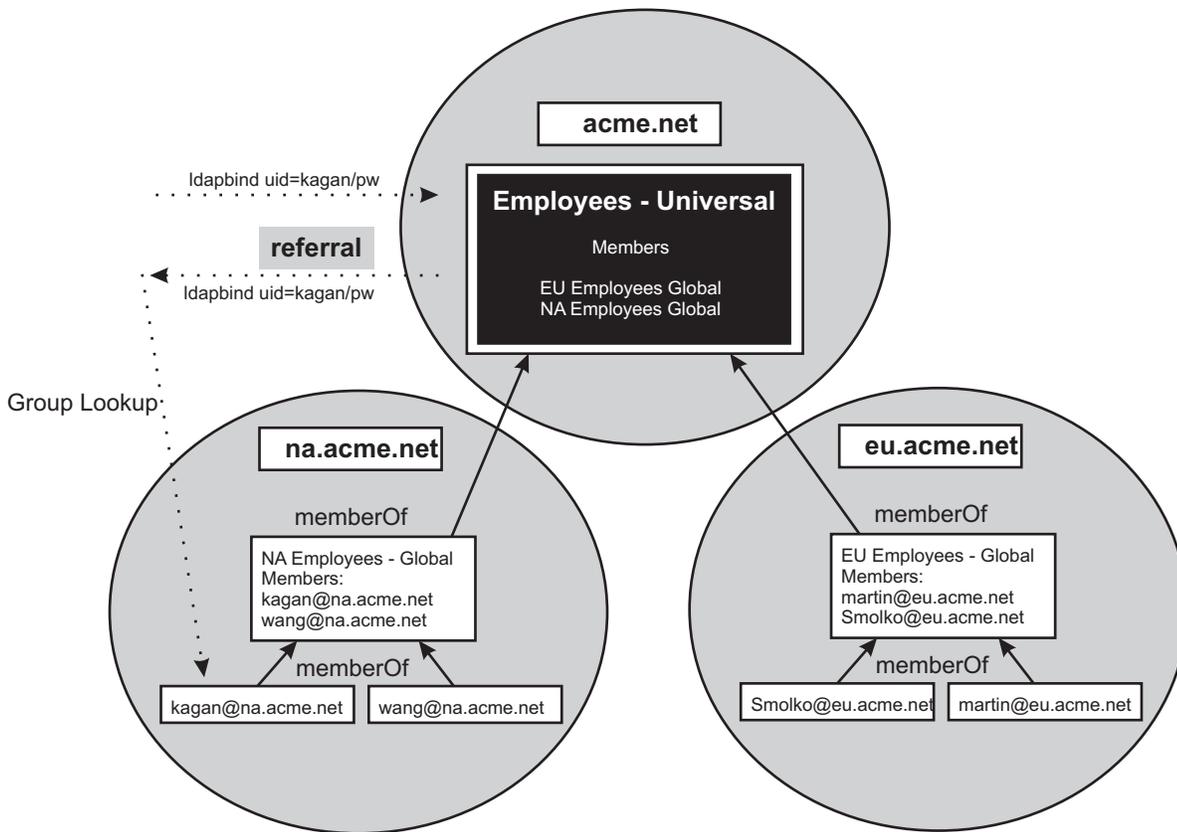

Figure 28. Locating group memberships. This figure illustrates the process of locating group memberships.

A variation on this method is to not use universal groups. You can use this approach when universal groups are not available.

**gotcha:** This approach does not use the Global Catalog.

You might consider using the Microsoft Active Directory Global Catalog as the WebSphere Application Server registry. There are three scenarios; however, the first two scenarios demonstrate how failures occur.

1. If you configure WebSphere Application Server to use Global Catalog as its LDAP registry and follow referrals, then individual users are visible in each domain controller. Because a user must exist only once in the registry, all logins fail.
2. If you configure WebSphere Application Server to use Global Catalog as its LDAP registry and do not follow referrals and the individual users are within global groups, then group membership is incomplete. See the following figure, which illustrates this limitation.

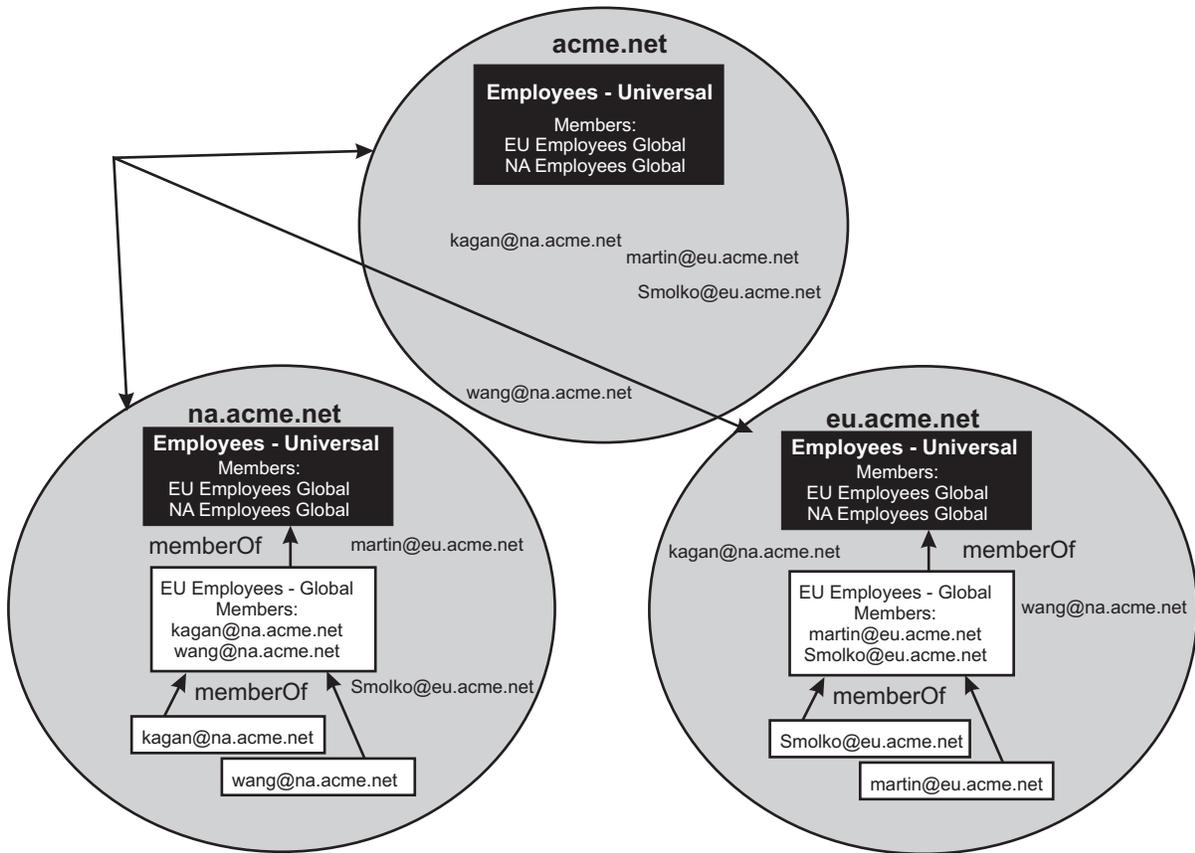

Figure 29. Global catalog (without using referrals). An illustration of a Global Catalog without using referrals

- When you configure WebSphere Application Server to use Global Catalog as its LDAP registry, do not follow referrals, and users are directly contained within universal global groups, then group membership is complete.

**gotcha:** When you select any of these scenarios, consult appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuration planning.

### Options for finding group membership within a Microsoft Active Directory forest

Locating and finding group membership with the Microsoft Active Directory forest is necessary for authenticating users. There are several ways to approach finding group membership within the Microsoft Active Directory forest.

The following figure depicts an example of group membership with the Microsoft Active Directory forest. This figure is used to explain ways to find group membership.

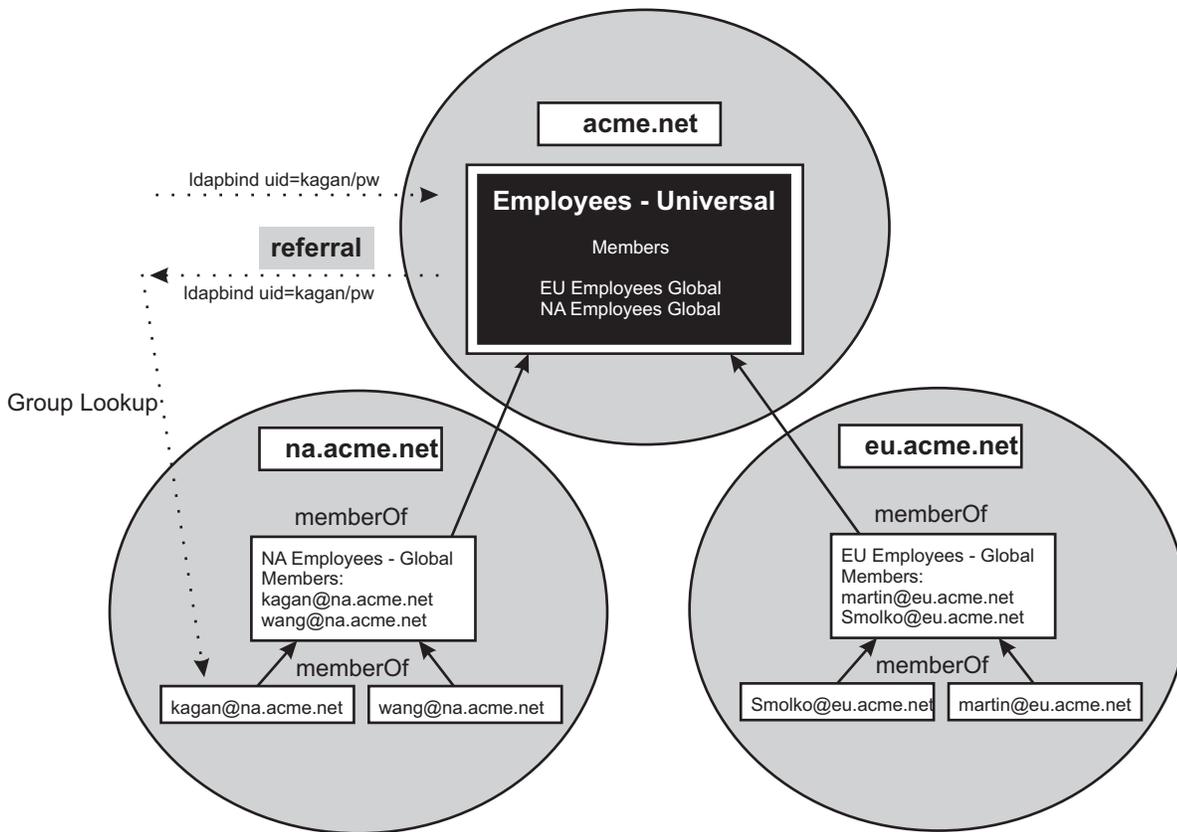

Figure 30. Finding group membership.. An illustration of ways to find group membership.

- **Option 1** does not use nested groups, and the following steps describe the process of locating group membership using a hypothetical organizational structure.
  - Create a global group of **NA employees**.
  - Create a global group of **EU employees**.
  - Map the Java Platform Enterprise Edition (Java EE) role to **NA employees + EU employees**. This mapping can become unmanageable if there are too many sub domains
  - Enable referrals.

In WebSphere Application Server Version 6.1, use federated repositories, specifically:

- Use a federated realm.
- Add the Microsoft Active Directory top-level domain controller to the repository. Do not add sub-domain controllers. Doing this results in multiple matches when searches for user IDs occur. The multiple matches cause user logins to fail.
- Select "**Support referrals to other LDAP servers**" = "follow".

- **Option 2** uses universal groups.
  - Put individual users into the universal group, **Employees**.

**Requirements:**

- The Windows 2003 Native domain functional levels is required.
- Userids must be directly contained within universal groups.
- Map Java EE role to **Employees**.
- Connect to any global catalog in the forest.

**Tip:** This option reduces the amount of directory lookup traffic. WebSphere Application Server does not have to follow all the referrals across the directory tree. That is, each domain controller can fully resolve the group information locally.

- **Option 3** uses nested groups.
  - Create the universal group, **Employees**.
  - Create **NA Employees** and **EU Employees** as global groups and make them members in the **Employees** universal group.

**Requirements:** Windows Native Domain functional levels.

- Map Java JEE role to "Employees".
- Enable referrals.

For WebSphere Application Server Version 6.1, use federated repositories, specifically:

- Use a federated realm.
- Add the Active Directory top-level domain controller to the repository. Do not add sub-domain controllers, as this will result in multiple matches when searches for userids occur, and logins will fail.
- Select "Support referrals to other LDAP servers" = "follow".
- Enable nested groups.

**Tip:** This option offers the optimal approach when using WebSphere Application Server Versions 6.1 or later. Before WebSphere Application Server version 6.1, referrals were not officially supported.

## Summary

The following table summarizes how to find group membership within a Microsoft Active Directory forest.

*Table 126. Finding group membership.. The following table identifies group membership levels supported in a Microsoft Active Directory forest.*

Group Membership	Map Java EE Roles To	Bind to Which LDAP	Enable	Supported in WebSphere Application Server Version	Comments
Global Groups	Collection of global groups	Top domain controller using port 389/636	Referrals	<ul style="list-style-type: none"> <li>• Federated repositories in WebSphere Application Server</li> </ul>	
Universal groups	Universal groups	Any Global catalog, using port 3268		All	
Global groups in universal groups	Universal groups	Top domain controller using port 389/636	referrals, nesting	<ul style="list-style-type: none"> <li>• Federated repositories in WebSphere Application Server</li> </ul>	Cannot use Windows mixed domain functional level

## Configuring to use objectCategory attribute

A federated repository uses the objectCategory attribute by default for Active Directory user search filters. You can ensure that the federated repository is configured to use the objectCategory attribute. For example, the federated repositories configuration file, wimconfig.xml, should be as shown in the following example:

```
<supportedLDAPEntryType name="user" searchFilter="(objectCategory=user)"...>
<supportedLDAPEntryType name="Group" searchFilter="(objectCategory=Group)"...>
```

Configure the user filter and group filter (advanced properties) like the following example:

```
User Filter: (&(sAMAccountName=%v)(objectCategory=user))
Group Filter: (&cn=%v)(objectCategory=group)
```

Follow the following instructions from the administrative console to complete the search filter with the objectCategory attribute.

1. Click **Security**.
2. Select **Global security**.
3. Under Available realm definitions, use the drop-down list to select **Federated repositories**.
4. Click **Configure**.
5. Under Related items, click **Manage repositories**.
6. Select **Forest > LDAP entity types > PersonAccount**. Under General Properties, find the **Search filter** box.
7. Fill in the search filter.  
(objectCategory=user)

**gotcha:** When you select any of these scenarios to use, consult the appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuration planning.

## Authenticating users with LDAP registries in a Microsoft Active Directory forest

Authenticating a user across multiple repositories, or across a distributed Lightweight Directory Access Protocol (LDAP) repository, such as a Microsoft Active Directory forest can be challenging. In any search of the whole user registry, if there is more than one match at run time, authentication fails because of ambiguous match results.

### Before you begin

In any multiple Microsoft Active Directory domain environment, the WebSphere Application Server administrator must consider that the default unique ID in the Microsoft Active Directory is the sAMAccountName attribute of a user.

### About this task

User IDs are guaranteed to be unique within a single domain. However they are not guaranteed across a tree or a forest. For example, suppose the user ID, *smith*, is added in the forest and in each subdomain. The search for sAMAccountName=smith returns three matches. WebSphere Application Server does not authenticate this user when there is more than one possible match in the registry.

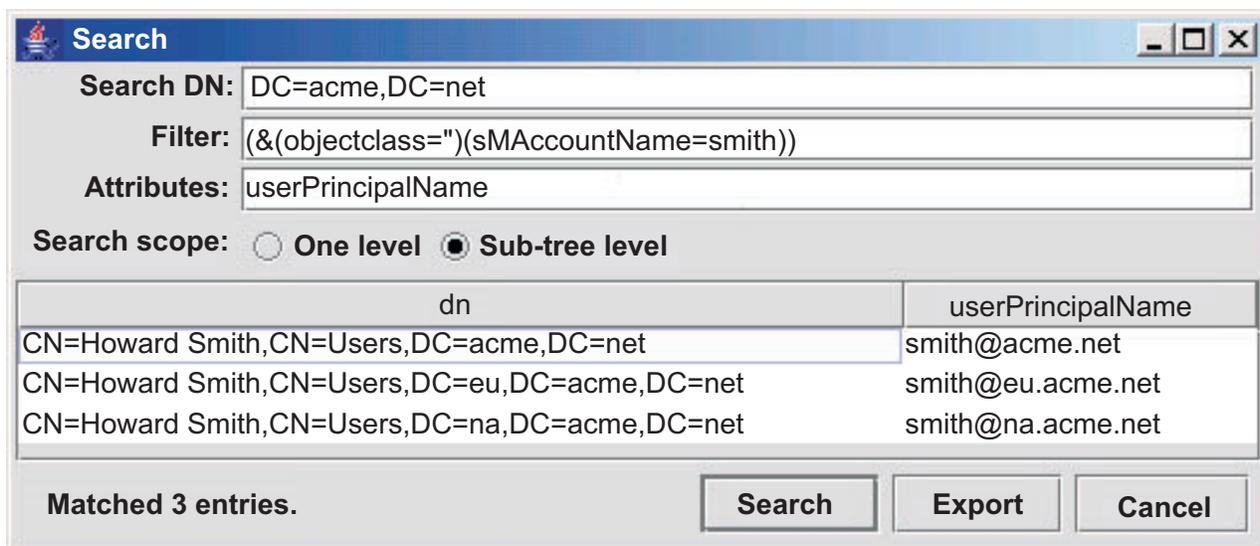

Figure 31. Forest search strategy.. Search illustration of a non-unique sMAccountName across the entire forest.

You can mitigate this condition by changing the user filter to be based on the userPrincipalName attribute of the user, which is unique across the forest, instead of being based on their sMAccountName attribute. However, users must then know to log in using their userPrincipalName, which they might not know.

The specific procedure to establish a user filter on a LDAP user registry depends on the type of LDAP registry. The following examples illustrate a procedure for a stand-alone LDAP registry and a procedure for a federated repository registry.

## Procedure

1. **Establish a user filter on a stand-alone LDAP registry:** You can set the user filter on the Advance Lightweight Access Protocol (LDAP) user registry settings page to search for userPrincipalName instead of sMAccountName value.

For example:

```
(&(objectClass=user)(userPrincipalName=%w))
```

2. **Establish a user filter on a federated repositories registry:** You can change the log-in property in the LDAP repository to uid;cn, for example, by using the administrative console.

- a. Click **Security**.
- b. Select **Global security**.
- c. Under Available realm definitions, use the drop-down list to select **Federated repositories**.
- d. Click **Configure**.
- e. Under Related items, click **Manage repositories**.
- f. Under General Properties, add the following information:

**Repository identifier**

forest

**Directory type**

Microsoft WIndows Server 2003 Active Directory

**Primary host name**

forest.acme.net

**Port** 389

**Failover server used when primary is not available**

Delete

**Bind distinguished name**

cn=wasbind, CN=Users, DC=ib

**Bind password**

\*\*\*\*\*

**Login properties**

uid;cn

3. Click **OK** and **Save** to save the changes to the master configuration.
4. Locate the {WAS\_HOME}\profiles\{profileName}\config\cells\{cellName}\wim\config\wimconfig.xml or profile\_root/conf/cells/<cell>/wim/config/wimconfig.xml file in the deployment manager configuration.
5. Edit the wimconfig.xml file.
  - a. Find the <config:attributeConfiguration> attribute in the file.
  - b. Add the following lines:

```
<config:attributes name="userPrincipalName" propertyName="cn">
<config:entityTypes>PersonAccount</config:entityTypes>
</config:attributes>
```
6. Save the wimconfig.xml file.
7. Run the profile\_root/bin/syncNode.bat or profile\_root/syncNode.bar/sh script on all of the nodes in the configuration.

**Results**

**gotcha:** When you select any of these scenarios, consult appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuration planning.

---

**Authorizing access to resources**

WebSphere Application Server provides many different methods for authorizing accessing resources. For example, you can assign roles to users and configure a built-in or external authorization provider.

**About this task**

You can create an application, an Enterprise JavaBeans (EJB) module, or a web module and secure them using assembly tools.

To authorize user or group access to resources, read the following articles:

**Procedure**

1. Secure you application during assembly and deployment. For more information on how to create a secure application using an assembly tool, such as the IBM Rational Application Developer, see the information about securing applications during assembly and deployment.
2. Authorize access to Java Platform, Enterprise Edition (Java EE) resources. WebSphere Application Server supports authorization that is based on the Java Authorization Contract for Containers (JACC) specification in addition to the default authorization. When security is enabled in WebSphere Application Server, the default authorization is used unless a JACC provider is specified. For more information, see "Authorization providers" on page 1784.
3. Authorize access to administrative resources. You can assign users and groups to predefined administrative roles such as the monitor, configurator, operator, administrator, auditor and iscadmins roles. These roles determine which tasks a user can perform in the administrative console. For more information, see "Authorizing access to administrative roles" on page 1853.

## What to do next

After authorizing access to resources, configure the Application Server for secure communication. For more information, see “Securing communications” on page 1880.

## Authorization technology

Authorization information determines whether a user or group has the necessary privileges to access resources.

WebSphere Application Server supports many authorization technologies including the following:

- Authorization involving the web container and Java Platform, Enterprise Edition (Java EE) technology
- Authorization involving an enterprise bean application and Java EE technology
- Authorization involving web services and Java EE technology
- Java Message Service (JMS)
- Java Authorization Contract for Containers (JACC)

WebSphere Application Server supports both a default authorization provider and an authorization provider that is based on the Java Authorization Contract for Containers (JACC) specification. The JACC-based authorization provider enables third-party security providers to handle the Java EE authorization. For more information, see “JACC support in WebSphere Application Server” on page 1784.

- Java Authentication and Authorization Service (JAAS)

For more information, see “Java Authentication and Authorization Service” on page 1671.

- Java 2 security

For more information, see “Java 2 security” on page 1315.

- Naming and administrative authorization
- Pluggable authorization

WebSphere Application Server supports an authorization infrastructure that enables you to plug in an external authorization provider. For more information, see “Enabling an external JACC provider” on page 1823.

- System Authorization Facility (SAF)

As an alternative to WebSphere Application Server authorization, you can use SAF-based authorization, such as the RACF EJBROLE profile, to control client access to Java Platform, Enterprise Edition (Java EE) roles in EJB and web applications. For more information, see “System Authorization Facility for role-based authorization” on page 1800.

In this release of WebSphere Application Server, you can use SAF security to associate a SAF user ID with a distributed identity. See Using distributed identity mapping for SAF for more information.

## Administrative roles and naming service authorization

WebSphere Application Server extends the Java Platform, Enterprise Edition (Java EE) security role-based access control to protect the product administrative and naming subsystems.

### Administrative roles

A number of administrative roles are defined to provide the degrees of authority that are needed to perform certain WebSphere Application Server administrative functions from either the administrative console or the system management scripting interface called wsadmin. The authorization policy is only enforced when administrative security is enabled. The following table describes the administrative roles:

Table 127. Administrative roles that are available through the administrative console and wsadmin.

This table lists administrative roles that are available through the administrative console and wsadmin.

Role	Description
Monitor	<p>An individual or group that uses the monitor role has the least amount of privileges. A monitor can complete the following tasks:</p> <ul style="list-style-type: none"> <li>• View the WebSphere Application Server configuration.</li> <li>• View the current state of the Application Server.</li> </ul>
Configurator	<p>An individual or group that uses the configurator role has the monitor privilege plus the ability to change the WebSphere Application Server configuration. The configurator can perform all the day-to-day configuration tasks. For example, a configurator can complete the following tasks:</p> <ul style="list-style-type: none"> <li>• Create a resource.</li> <li>• Map an application server.</li> <li>• Install and uninstall an application.</li> <li>• Deploy an application.</li> <li>• Assign users and groups-to-role mapping for applications.</li> <li>• Set up Java 2 security permissions for applications.</li> <li>• Customize the Common Secure Interoperability Version 2 (CSIv2), Secure Authentication Service (SAS), and Secure Sockets Layer (SSL) configurations.</li> </ul> <p><b>Important:</b> SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.</p>
Operator	<p>An individual or group that uses the operator role has monitor privileges plus ability to change the runtime state. For example, an operator can complete the following tasks:</p> <ul style="list-style-type: none"> <li>• Stop and start the server.</li> <li>• Monitor the server status in the administrative console.</li> </ul>
Administrator	<p>An individual or group that uses the administrator role has the operator and configurator privileges plus additional privileges that are granted solely to the administrator role. For example, an administrator can complete the following tasks:</p> <ul style="list-style-type: none"> <li>• Modify the server user ID and password.</li> <li>• Configure authentication and authorization mechanisms.</li> <li>• Enable or disable administrative security.</li> </ul> <p><b>Note:</b> In previous releases of WebSphere Application Server, the <b>Enable administrative security</b> option is known as the <b>Enable global security</b> option.</p> <ul style="list-style-type: none"> <li>• Enforce Java 2 security using the <b>Use Java 2 security to restrict application access to local resources</b> option.</li> <li>• Change the Lightweight Third Party Authentication (LTPA) password and generate keys.</li> <li>• Create, update, or delete users in the federated repositories configuration.</li> <li>• Create, update, or delete groups in the federated repositories configuration.</li> </ul> <p><b>Note:</b> An administrator cannot map users and groups to the administrator roles.</p>
Adminsecuritymanager	<p>Only users who are granted this role can map users to administrative roles. Also, when fine-grained administrative security is used, only users who are granted this role can manage authorization groups. See “Administrative roles” on page 1780 for more information.</p>
Deployer	<p>Users who are granted this role can perform both configuration actions and runtime operations on applications.</p>

Table 127. Administrative roles that are available through the administrative console and wsadmin (continued).

This table lists administrative roles that are available through the administrative console and wsadmin.

Role	Description
Auditor	<p>Users granted this role can view and modify the configuration settings for the security auditing subsystem. For example, a user with the auditor role can complete the following tasks:</p> <ul style="list-style-type: none"> <li>• Enable and disable the security auditing subsystem.</li> <li>• Select the event factory implementation to be used with the event factory plug-in point.</li> <li>• Select and configure the service provide, or emitter. or both to be used with the service provider plug-in point.</li> <li>• Set the audit policy that describes the behavior of the application server in the event of an error with the security auditing subsystem.</li> <li>• Define which security events are to be audited.</li> </ul> <p>The auditor role includes the monitor role. This allows the auditor to view but not change the rest of the security configuration.</p>

Table 128. Additional administrative role that is available through the administrative console.

This table lists an additional administrative role that is available through the administrative console.

Role	Description
iscadmins	<p>This role is only available for administrative console users and not for wsadmin users. Users who are granted this role have administrator privileges for managing users and groups in the federated repositories. For example, a user of the iscadmins role can complete the following tasks:</p> <ul style="list-style-type: none"> <li>• Create, update, or delete users in the federated repositories configuration.</li> <li>• Create, update, or delete groups in the federated repositories configuration.</li> </ul>

Table 129. Additional administrative role that is available through wsadmin.

This table lists an additional administrative role that is available through the administrative console.

Role	Description
Deployer	<p>This role is only available for wsadmin users and not for administrative console users. Users who are granted this role can perform both configuration actions and run-time operations on applications.</p>

When administrative security is enabled, the administrative subsystem role-based access control is enforced. The administrative subsystem includes the security server, the administrative console, the wsadmin scripting tool, and all the Java Management Extensions (JMX) MBeans. When administrative security is enabled, both the administrative console and the administrative scripting tool require users to provide the required authentication data. Moreover, the administrative console is designed so the control functions that display on the pages are adjusted, according to the security roles that a user has. For example, a user who has only the monitor role can see only the non-sensitive configuration data. A user with the operator role can change the system state.

When you are changing registries (for example, from a federated repository to LDAP), make sure you remove the information that pertains to the previously configured registry for console users and console groups.

WebSphere Application Server for z/OS security customization dialogs prime the administrative subsystem to accept the MVS identities of all the started WebSphere Application Server system tasks (for example, controllers, servants, and so on) as WebSphere administrators and the configured administrator identity. If a federated repository, a stand-alone Lightweight Directory Access Protocol (LDAP) registry, or a stand-alone custom registry is specified, the configured server identities are used for work that is run by the system instead of for work that is run by the started task identities.

**SAF authorization for administrative roles:** The value of the `com.ibm.security.SAF.authorization` setting controls whether SAF EJBROLE profiles or the console settings are used to control access to administration profiles rather than the console users. When property, `com.ibm.security.SAF.authorization`, is set to `true`, SAF authorization is selected and SAF EJBROLE profiles are used to control access to administrative roles.

**Note:** With System Authorization Facility (SAF) authorization any values in the console users and console groups are ignored.

**WebSphere authorization for administrative roles:** If WebSphere Application Server authorization rather than SAF authorization is used to restrict access to Java Platform, Enterprise Edition (Java EE) roles, WebSphere Application Server for z/OS automatically maps the server identity that is specified when enabling administrative security to the administrative role. When administrative security is enabled, WebSphere Application Servers for z/OS runs under the server identity that is defined under the active user registry configuration. Although it is not shown on the administrative console and in other tools, a special Server subject is mapped to the administrator role.

- The WebSphere Application Server run-time code, which runs under the server identity, requires authorization for some run-time operations. You can either explicitly enter the server identity and password or the identity can be auto-generated. In the former case, the server identity is a valid user in the registry. In the latter case, use the `internalServerId` feature to generate a server identity automatically. The configuration panel for each user registry enables you to make this choice. For an `internalServerId`, enter the administrator ID or `adminID` in the **Primary administrative user name** field. This `adminID` is a valid user in the registry, and the password for this ID is not required and is not saved in the configuration. See "Internal server ID" in the section below.
- If no explicit users or groups are assigned to administrative roles, you can log into the administrative console or to the `wsadmin` scripting tool using the server identity or `adminID` when using the `internalServerId` feature to perform administrative operations and to assign other users or groups to administrative roles. This is possible because the server identity (or the `adminID`) is assigned automatically to the `adminsecuritymanager` role. Only the users/groups associated with the `adminsecuritymanager` can manage the users/groups to all administrative roles. Once you login using the server identity (or `adminID`), the administrative security policy allows you to perform the operations such as:
  - Change server ID and server password
  - Enable or disable WebSphere Application Server administrative security
  - Enforce Java 2 security using the **Use Java 2 security to restrict application access to local resources** option.
  - Change the LTPA password or generate keys
- A special configuration is not required to enable the server identity as specified when enabling administrative security for administrative use because the server identity is automatically mapped to the administrator role. You can add or remove users and groups to or from the administrative roles from the WebSphere Application Server administrative console. However, you must restart the server for the changes to take effect. A best practice is to map a group, rather than specific users, to administrative roles because this approach is more flexible and easier to administer. By mapping a group to an administrative role, adding or removing users to or from the group occurs outside of WebSphere Application Server and does not require a server restart for the change to take effect.

### Primary administrative user name

The Version 6.1 release of WebSphere Application Server and subsequent releases require an administrative user, distinguished from the server user identity, to improve auditability of administrative actions. The user name specifies a user with administrative privileges that is defined in the local operating system.

### Server user identity

The Version 6.1 release of WebSphere Application Server and subsequent releases distinguish the server identity from the administrative user identity to improve auditability. The server user identity is used for authenticating server-to-server communications.

### **Internal server ID**

The internal server ID enables the automatic generation of the user identity for server-to-server authentication. Automatic generation of the server identity supports improved auditability for cells only for Version 6.1 or later nodes. In the Version 6.1 release of WebSphere Application Server, you can save the internally-generated server ID because the Security WebSphere Common Configuration Model (WCCM) model contains a new tag, `internalServerId`. You do not need to specify a server user ID and a password during security configuration except in a mixed-cell environment. An internally-generated server ID adds a further level of protection to the server environment because the server password is not exposed as it is in releases prior to Version 6.1. However, to maintain backwards compatibility, you must specify the server user ID if you use earlier versions of WebSphere Application Server.

When enabling security, you can assign one or more users and groups to naming roles. For more information, see *Assigning users to naming roles*. However, before assigning users to naming roles, configure the active user registry. User and group validation depends on the active user registry. For more information, see *Configuring user registries*.

### **Special subject**

In addition to mapping users or groups, you can map a *special-subject* to the administrative roles. A special-subject is a generalization of a particular class of users. The `AllAuthenticated` or the `AllAuthenticatedInTrustedRealms` (when cross realm is involved) special subjects mean that the access check of the administrative role ensures that the user making the request is at least authenticated. The `Everyone` special subject means that anyone, authenticated or not, can perform the action as if security is not enabled.

### **Naming service authorization**

CosNaming security offers increased granularity of security control over CosNaming functions. CosNaming functions are available on CosNaming servers such as the WebSphere Application Server. These functions affect the content of the WebSphere Application Server name space. Generally, you have two ways in which client programs result in CosNaming calls. The first is through the Java Naming and Directory Interface (JNDI) call. The second is with common object request broker architecture (CORBA) clients invoking CosNaming methods directly.

Four security roles are introduced :

- `CosNamingRead`
- `CosNamingWrite`
- `CosNamingCreate`
- `CosNamingDelete`

The roles have authority levels from low to high:

#### **CosNamingRead**

You can query the WebSphere Application Server name space, using, for example, the JNDI lookup method. The special-subject, `Everyone`, is the default policy for this role.

#### **CosNamingWrite**

You can perform write operations such as JNDI bind, rebind, or unbind, and `CosNamingRead` operations. As a default policy, `Subjects` are not assigned this role.

#### **CosNamingCreate**

You can create new objects in the name space through such operations as JNDI `createSubcontext` and `CosNamingWrite` operations. As a default policy, `Subjects` are not assigned this role.

## **CosNamingDelete**

You can destroy objects in the name space, for example using the JNDI `destroySubcontext` method and `CosNamingCreate` operations. As a default policy, Subjects are not assigned this role.

When you configure a local operating system registry with WebSphere Application Server for z/OS, factors require some additional considerations. Refer to “Selecting a registry or repository” on page 1416 and “Configuring local operating system registries” on page 1418 for more information. If you specify federated repositories, a stand-alone LDAP registry, or a stand-alone custom registry, you must remove the local operating system customization by deleting the pre-configured WebSphere Application Server configuration group and administrator identity from the console group and delete the console users.

A Server special-subject is assigned to all of the four CosNaming roles by default. The Server special-subject provides a WebSphere Application Server process, which runs under the server identity, to access all the CosNaming operations. The Server special-subject does not display and cannot be modified through the administrative console or other administrative tools.

Special configuration is not required to enable the server identity as specified when enabling administrative security for administrative use because the server identity is automatically mapped to the administrator role.

Configuration is not required to enable the server identity (as specified) when enabling administrative security for administrative use because the server identity is automatically mapped to the administrator role. Users, groups, or the special subjects `AllAuthenticated` and `Everyone` can be added or removed to or from the naming roles from the WebSphere Application Server administrative console at any time. However, a server restart is required for the changes to take effect. When SAF Authorization is chosen, a server restart is not needed to authorize additional users or groups.

A best practice is to map groups or one of the special-subjects, rather than specific users, to naming roles because it is more flexible and easier to administer in the long run. By mapping a group to a naming role, adding or removing users to or from the group occurs outside of WebSphere Application Server and does not require a server restart for the change to take effect.

The CosNaming authorization policy is only enforced when administrative security is enabled. When administrative security is enabled, attempts to do CosNaming operations without the proper role assignment result in an `org.omg.CORBA.NO_PERMISSION` exception from the CosNaming server.

Although the ability exists to greatly restrict access to the name space by changing the default policy, unexpected `org.omg.CORBA.NO_PERMISSION` exceptions can occur at runtime. Typically, Java EE applications access the name space and the identity they use is that of the user that authenticated to WebSphere Application Server when accessing the Java EE application. Unless the Java EE application provider clearly communicates the expected naming roles, use caution when changing the default naming authorization policy.

### ***Administrative roles for business level applications:***

The Java 2 Platform, Enterprise Edition (J2EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem. This protection applies to those administrative roles associated with business level applications.

Deploying business level applications on a server configured to hold business level applications requires a number of administrative roles that are defined to provide degrees of authority when performing certain administrative functions from either the Web-based administrative console or the system management scripting interface. The authorization policy is only enforced when administrative security is enabled. The following table describes the system management scripting command used for business level applications and the corresponding administrative role that is required in using the command:

Table 130. Business level application - administrative roles. Business level application - administrative roles

Command	Role Required
startBLA	Cell deployer, Cell operator, BLA deployer, BLA operator, Target deployer, Target operator
stopBLA	Cell deployer, Cell operator, BLA deployer, BLA operator, Target deployer, Target operator
createEmptyBLA	Cell configurator, Cell deployer
editBLA	Cell configurator, Cell deployer, BLA deployer
viewBLA	Cell monitor, BLA monitor
listBLAs	Cell monitor, BLA monitor(s)
deleteBLA	Cell configurator, Cell deployer, BLA developer
importAsset	Cell configurator, Cell deployer
editAsset	Cell configurator, Cell deployer, Asset deployer
viewAsset	Cell monitor, Asset monitor(s)
listAssets	Cell monitor, Asset monitor
exportAsset	Cell monitor, Asset monitor
deleteAsset	Cell configurator, Cell deployer, Asset deployer
updateAsset	Cell configurator, Cell deployer, Asset deployer
addCompUnit	Cell configurator, Cell deployer, BLA deployer <i>(for the BLA to add the composition unit)</i>  + Asset-deployer <i>(for the asset to create the composition unit from)</i>  + Target-deployer <i>(for each target the composition unit is deployed to)</i>  + Relationship-deployer <i>(for each relationship the composition unit depends on that will result in creating a composition unit from the dependency asset)</i>
editCompUnit	Cell configurator, Cell deployer, BLA deployer <i>(for the BLA this composition unit belongs to)</i>  + Target deployer <i>(for each target that this composition unit is deployed to)</i>
viewCompUnit	Cell monitor, BLA monitor
listCompUnit	Cell monitor, BLA monitor
deleteCompUnit	Cell configurator, Cell deployer, BLA deployer <i>(for the BLA this composition unit belongs to)</i>  + Target deployer <i>(for each target that this composition unit is deployed to)</i>
setCompUnitTargetAutoStart	Cell configurator, Cell deployer
listControlOps	Cell monitor, BLA monitor
getBLAStatus	Cell monitor, BLA monitor

Table 130. Business level application - administrative roles (continued). Business level application - administrative roles

<p>Where:</p> <ul style="list-style-type: none"><li>• BLA deployer specifies the deployer role for the BLA that is being managed.</li><li>• BLA monitor specifies the monitor role for the BLA that is being managed.</li><li>• BLA operator specifies the operator role for the BLA that is being managed.</li><li>• Asset deployer specifies the deployer role for the asset that is being managed.</li><li>• Asset monitor specifies the monitor role for the asset that is being managed.</li><li>• Target deployer specifies the deployer for the target that the composition unit is being deployed to.</li><li>• Target operator specifies the operator role for the target that the composition unit is being deployed to.</li></ul>

## Role-based authorization

Use authorization information to determine whether a caller has the necessary privileges to request a service.

The following figure illustrates the process that is used during authorization.

Web resource access from a web client is handled by a web collaborator. The Enterprise JavaBeans (EJB) resource access from a Java client, whether an enterprise bean or a servlet, is handled by an EJB collaborator. The EJB collaborator and the web collaborator extract the client credentials from the object request broker (ORB) current object. The client credentials are set during the authentication process as received credentials in the ORB current object. The resource and the received credentials are presented to the WSAccessManager access manager to check whether access is permitted to the client for accessing the requested resource.

The access manager module contains two main modules:

- The resource permission module helps determine the required roles for a given resource. This module uses a resource-to-roles mapping table that is built by the security runtime during application startup. To build the resource-to-role mapping table, the security runtime reads the deployment descriptor of the enterprise beans or the Web module (ejb-jar.xml file or web.xml file)
- The authorization table module consults a role-to-user or group table to determine whether a client is granted one of the required roles. The role-to-user or group mapping table, also known as the *authorization table*, is created by the security runtime during application startup.

To build the authorization table, the security run time reads the application binding file, the `ibm-application-bnd.xmi` file, or the `ibm-application-bnd.xml` file, as appropriate.

The authorization table can also be built when accessing the EJBROLE profiles at the time of authorization using the Security Access Facility (such as RACF).

**Note:** For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named `ibm-*-ext.xmi` or `ibm-*-bnd.xmi` where \* is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.

- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

Use authorization information to determine whether a caller has the necessary privilege to request a service. You can store authorization information many ways. For example, with each resource, you can store an access-control list, which contains a list of users and user privileges. Another way to store the information is to associate a list of resources and the corresponding privileges with each user. This list is called a *capability list*.

WebSphere Application Server uses the Java 2 Platform, Enterprise Edition (J2EE) authorization model. In this model, authorization information is organized as follows:

During the assembly of an application, permission to invoke methods is granted to one or more roles. A role is a set of permissions; for example, in a banking application, roles can include teller, supervisor, clerk, and other industry-related positions. The teller role is associated with permissions to run methods that are related to managing the money in an account, such as the withdraw and deposit methods. The teller role is not granted permission to close accounts; this permission is given to the supervisor role. The application assembler defines a list of method permissions for each role. This list is stored in the deployment descriptor for the application.

Three *special subjects* are not defined by the J2EE model: `AllAuthenticatedUsers`, `AllAuthenticatedInTrustedRealms`, and `Everyone`. A special subject is a product-defined entity that is defined outside of the user registry. This entity is used to generically represent a class of users or groups in the registry.

- The `AllAuthenticatedUsers` subject permits all authenticated users to access protected methods. As long as the user can authenticate successfully, the user is permitted access to the protected resource.
- The `AllAuthenticatedInTrustedRealms` subject permits all authenticated foreign users (those that are bound to other realms) to access protected methods. As long as the user can authenticate successfully, the user is permitted access to the protected resource.
- The `Everyone` subject permits unrestricted access to a protected resource. Users do not have to authenticate to get access; this special subject provides access to protected methods as if the resources are unprotected.

**gotcha:** When WebSphere Application Server is configured using SAF, special subjects are ignored. These functions are available within SAF. The functions are simulated by the definition of the unauthenticated user ID in RACF with a `RESTRICTED` property. If an `EJBROLE` profile is created with a Universal Access (UACC) of `READ`, all authenticated users have access with the exception of the unauthenticated user ID.

During the deployment of an application, real users or groups of users are assigned to the roles. When a user is assigned to a role, the user gets all the method permissions that are granted to that role.

Depending on your environment, some restrictions might exist. For example, when utilizing SAF, checks are always made against the SAF database. If authentication is not done before an access check against a given role starts, a default SAF identity is used for the check. Unless a valid default user ID is configured in the `com.ibm.SAF.authorization` property, access is not granted.

The administrator is responsible for managing these roles.

Users can be assigned to more than one role; the permissions that are granted to the user are the union of the permissions granted to each role. Additionally, if the authentication mechanism supports the grouping of users, these groups can be assigned to roles. Assigning a group to a role has the same effect as assigning each individual user to the role.

A best practice during deployment is to assign groups instead of individual users to roles. If you are using bindings rather than SAF EJBROLES for authorization and you need to change the binding value, you must restart the server to pick up new values. If you are using SAF EJBROLES, the application server automatically detects the changes. For further information, see System Authorization Facility for role-based authorization

At runtime, WebSphere Application Server authorizes incoming requests based on the user's identification information and the mapping of the user to roles. If the user belongs to any role that has permission to run a method, the request is authorized. If the user does not belong to any role that has permission, the request is denied.

The J2EE approach represents a declarative approach to authorization, but it also recognizes that you cannot deal with all situations declaratively. For these situations, methods are provided for determining user and role information programmatically. For enterprise beans, the following two methods are supported by WebSphere Application Server:

- **getCallerPrincipal**: This method retrieves the user identification information.
- **isCallerInRole**: This method checks the user identification information against a specific role.

For servlets, the following methods are supported by WebSphere Application Server:

- getRemoteUser
- isUserInRole
- getUserPrincipal

These methods correspond in purpose to the enterprise bean methods.

For more information on the J2EE security authorization model, see the following website:  
<http://java.sun.com>

## Administrative roles

The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

A number of administrative roles are defined to provide degrees of authority that are needed to perform certain administrative functions from either the Web-based administrative console or the system management scripting interface. The authorization policy is only enforced when administrative security is enabled. The following table describes the administrative roles:

*Table 131. Administrative roles. Administrative roles*

Role	Description
Monitor	An individual or group that uses the monitor role has the least amount of privileges. A monitor can complete the following tasks: <ul style="list-style-type: none"><li>• View the WebSphere Application Server configuration.</li><li>• View the current state of the Application Server.</li></ul>

Table 131. Administrative roles (continued). Administrative roles

Configurator	<p>An individual or group that uses the configurator role has the monitor privilege plus the ability to change the WebSphere Application Server configuration. The configurator can perform all the daily configuration tasks. For example, a configurator can complete the following tasks:</p> <ul style="list-style-type: none"> <li>• Create a resource.</li> <li>• Map an application server.</li> <li>• Install and uninstall an application.</li> <li>• Deploy an application.</li> <li>• Assign users and groups-to-role mapping for applications.</li> <li>• Set up Java 2 security permissions for applications.</li> <li>• Customize the Common Secure Interoperability Version 2 (CSIv2), Security Authentication Service (SAS), and Secure Sockets Layer (SSL) configurations.</li> </ul> <p><b>Important:</b> SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.</p>
Operator	<p>An individual or group that uses the operator role has monitor privileges plus ability to change the runtime state. For example, an operator can complete the following tasks:</p> <ul style="list-style-type: none"> <li>• Stop and start the server.</li> <li>• Monitor the server status in the administrative console.</li> </ul>
Administrator	<p>An individual or group that uses the administrator role has the operator and configurator privileges, plus additional privileges that are granted solely to the administrator role. For example, an administrator can complete the following tasks:</p> <ul style="list-style-type: none"> <li>• Modify the server user ID and password.</li> <li>• Configure authentication and authorization mechanisms.</li> <li>• Enable or disable administrative security.</li> <li>• Enable or disable Java 2 security.</li> <li>• Change the Lightweight Third Party Authentication (LTPA) password and generate keys.</li> <li>• Create, update, or delete users in the federated repositories configuration.</li> <li>• Create, update, or delete groups in the federated repositories configuration.</li> </ul> <p><b>Important:</b> An administrator cannot map users and groups to the administrator roles without also having the adminsecuritymanager role.</p>
iscadmins	<p>This role is only available for administrative console users, not for wsadmin users. Users who are granted this role have administrator privileges for managing users and groups in the federated repositories. For example, a user of the iscadmins role can complete the following tasks:</p> <ul style="list-style-type: none"> <li>• Create, update, or delete users in the federated repositories configuration.</li> <li>• Create, update, or delete groups in the federated repositories configuration.</li> </ul>
Deployer	<p>Users granted this role can complete both configuration actions and runtime operations on applications. See the “Deployer role” on page 1782 section for more details.</p>
Admin Security Manager	<p>You can assign users and groups to the Admin Security Manager role on the cell level through wsadmin scripts and the administrative console. Using the Admin Security Manager role, you can assign users and groups to the administrative user roles and administrative group roles. However, an administrator cannot assign users and groups to the administrative user roles and administrative group roles including the Admin Security Manager role. See the “Admin Security Manager role” on page 1783 section for more details.</p>

Table 131. Administrative roles (continued). Administrative roles

Auditor	<p>Users granted this role can view and modify the configuration settings for the security auditing subsystem. For example, a user with the auditor role can complete the following tasks:</p> <ul style="list-style-type: none"> <li>• Enable and disable the security auditing subsystem.</li> <li>• Select the event factory implementation to be used with the event factory plug-in point.</li> <li>• Select and configure the service provide, or emitter. or both to be used with the service provider plug-in point.</li> <li>• Set the audit policy that describes the behavior of the application server in the event of an error with the security auditing subsystem.</li> <li>• Define which security events are to be audited.</li> </ul> <p>The auditor role includes the monitor role. This allows the auditor to view but not change the rest of the security configuration. See the “Auditor role” on page 1783 section for more details.</p>
---------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

The server ID that is specified and the administrative ID, if specified, when enabling administrative security is automatically mapped to the administrator role.

Users and groups can be added or removed from administrative roles using the WebSphere Application Server administrative console by a user given the appropriate authority. The Primary administrative user name must be used to log on to the administrative console to change the administrative user and group roles other than the auditor role. Only a user with the auditor role can change the auditor user and group roles. When security auditing is initially enabled, the Primary administrative user is also given the auditor role, and can manage all of the administrative user and group roles including the those in the auditor role. A best practice is to map a group or groups, rather than specific users, to administrative roles because it is more flexible and easier to administer.

In addition to mapping user or groups, a special-subject can also be mapped to the administrative roles. A special-subject subject is a generalization of a particular class of users. The AllAuthenticated special subject means that the access check of the administrative role ensures that the user making the request is at least authenticated. The Everyone special subject means that anyone, authenticated or not, can perform the action, as if security was not enabled.

## Deployer role

A user that is granted a deployer role can complete all of the configuration and runtime operations on an application. A deployer role can be subsets of both configurator and operator roles. However, a user granted a deployer role cannot configure or operate any other resources, such as a server, node.

When fine-grained administrative security is used, only a user granted a deployer role to an application can configure and operate that application.

Cell-level configurators can configure applications. Cell-level operators can also operate (start and stop) applications. However, a user granted a deployer role at cell level can also complete configuration and operation on all applications.

Table 132. Deployer role capabilities.

This table lists the deployer role capabilities when fine-grained administrative security is used.

Operation	Required Roles ( Any one)
Install application	Cell-configurator, target-deployer
Uninstall application	Cell-configurator, application-deployer, target-deployer
List application	Cell-monitor, application-monitor

Table 132. Deployer role capabilities (continued).

This table lists the deployer role capabilities when fine-grained administrative security is used.

Operation	Required Roles ( Any one)
Edit, update and redeploy application	Cell-configurator, application-deployer
Export application	Cell-monitor, application-monitor
Start or stop application	Cell-operator, application-deployer

Where:

### Cell-configurator

Specifies the configurator role at cell level.

### Application-deployer

Specifies the deployer role for the application that is being managed.

### Target-deployer

Specifies the deployer role for all servers or clusters for which an application is targeted. If you have a target-deployer role, you can install a new application on the target. However, to edit or update the installed application, you must be included in the authorization group of the installed application-deployer.

The target-deployer cannot explicitly start or stop a new application. However, when a target-deployer starts a server on a target, all of the applications that have their auto-start attribute set to yes are started when the server starts.

It is recommended that the application-deployer set this attribute to true if the application-deployer does not want the application to be started by the target-deployer.

## Admin Security Manager role

The Admin Security Manager role separates administrative security administration from other application administration.

By default, serverId and adminID, if specified, are assigned to this role in the cell level authorization table. This role implies a monitor role. However, an administrator role does not imply the Admin Security Manager role.

When fine-grained admin security is used, only a user granted this role at cell level can manage administrative authorization groups. However, a user granted this role for each administrative authorization group can map users to administrative roles for those groups. The following list summarizes the capabilities of the Admin Security Manager role at different levels, such as the cell and administrative authorization group levels.

Table 133. Admin Security Manager role capabilities.

This table lists Admin Security Manager role capabilities.

Action	Role
Map users to administrative roles for cell level	Only the Admin Security Manager of the cell
Map users to administrative roles for an authorization group	Only the Admin Security Manager of that authorization group or the Admin Security Manager of the cell
Manage authorization groups, create, delete, add resource to an authorization group, or remove resource from an authorization group or list	Only the Admin Security Manager of the cell

## Auditor role

The auditor role separates security auditing administration from administrative security and other application administration.

The auditor role was added to allow distinct separation of the authority of an auditor from the authority of the administrator. The auditor role can be granted to administrators to combine their authority. When security is first enabled, the auditor role is assigned to the primary administrator. If in your situation the separation of authority is required, administrators can remove the auditor role from themselves and assign the auditor role to other users.

A fine grained security for the auditor role is not implemented, which results in the auditor role requiring the monitor role. This process allows the auditor to read but not modify the panels managed by the administrator. The auditor has full authority to read and modify the panels associated with the security auditing subsystem. The administrator will have the monitor role for those panels, however, the administrator cannot modify those panels.

## Authorization providers

WebSphere Application Server supports authorization that is based on the Java Authorization Contract for Containers (JACC) specification in addition to the default authorization.

JACC is a specification introduced in Java Platform, Enterprise Edition (Java EE)1.4. It enables third-party security providers to manage authorization in the application server.

**Note:** In WebSphere Application Server version 7.0, Java Authorization Contract for Containers (JACC) specification 1.4 was applied. In JACC specification 1.4, we support Java EE5 that includes Servlet 2.5 and EJB 3. The biggest functional change with the introduction of JACC specification 1.4 is the inclusion of annotations for propagating security policy information.

**Note:** For WebSphere Application Server for z/OS, if SAF- based authorization is implemented, the implementation at this point does not use or implement the JACC Policy provider interface.

When security is enabled in WebSphere Application Server, the default authorization is used unless a JACC provider is specified. The default authorization does not require special setup, and the default authorization engine makes all of the authorization decisions. However, if a JACC provider is configured and set up for WebSphere Application Server to use, all of the enterprise beans and web authorization decisions are delegated to the JACC provider.

WebSphere Application Server supports security for Java EE applications and also for its administrative components. Java EE applications, such as Web and Enterprise JavaBeans (EJB) components are protected and authorized per the Java EE specification. The administrative components are internal to WebSphere Application Server and are protected by the role-based authorizer. The administrative components include the administrative console, MBeans, and other components such as naming and security. For more information on administrative security, see “Role-based authorization” on page 1778.

When a JACC provider is used for authorization in WebSphere Application Server, all of the Java EE application-based authorization decisions are delegated to the provider per the JACC specification. However, all administrative security authorization decisions are made by the WebSphere Application Server default authorization engine. The JACC provider is not called to make the authorization decisions for administrative security.

When a protected Java EE resource is accessed, the authorization decision to give access to the principal is the same whether using the default authorization engine or a JACC provider. Both of the authorization models satisfy the J2EE specification, and function the same. Choose a JACC provider only when you want to work with an external security provider such as Tivoli Access Manager. In this instance, the security provider must support the JACC specification and be set up to work with WebSphere Application Server. Setting up and configuring a JACC provider requires additional configuration steps, depending on the provider. Unless you have an external security provider that you can use with WebSphere Application Server, use the default authorization.

### ***JACC support in WebSphere Application Server:***

WebSphere Application Server supports the Java Authorization Contract for Containers (JACC) specification, which enables third-party security providers to handle the Java Platform, Enterprise Edition (Java EE) authorization.

The JACC specification requires that both the containers in the application server and the provider satisfy some requirements. Specifically, the containers are required to propagate the security policy information to the provider during the application deployment and to call the provider for all authorization decisions. The providers are required to store the policy information in their repository during application deployment. The providers then use this information to make authorization decisions when called by the container.

### **JACC access decisions**

When security is enabled and an enterprise bean or web resource is accessed, the Enterprise JavaBeans (EJB) container or web container calls the security runtime to make an authorization decision on whether to permit access. When using an external provider, the access decision is delegated to that provider.

According to the Java Authorization Contract for Containers (JACC) specification, the appropriate permission object is created, the appropriate policy context handlers are registered, and the appropriate policy context identifier (contextID) is set. A call is made to the `java.security.Policy` object method that is implemented by the provider to make the access decision.

The following sections describe how the provider is called for both the enterprise bean and the web resources.

#### **Access decisions for enterprise beans**

When security is enabled, and an EJB method is accessed, the EJB container delegates the authorization check to the security runtime. If JACC is enabled, the security runtime uses the following process to perform the authorization check:

1. Creates the `EJBMethodPermission` object using the bean name, method name, interface name, and the method signature.
2. Creates the context ID and sets it on the thread by using the `PolicyContext.setContextID(contextID)` method.
3. Registers the required policy context handlers, including the Subject policy context handler.
4. Creates the `ProtectionDomain` object with principal in the Subject. If no principal exists, null is passed for the principal name.
5. The access decision is delegated to the JACC provider by calling the `implies` method of the `Policy` object, which is implemented by the provider. The `EJBMethodPermission` and the `ProtectionDomain` objects are passed to this method.
6. The `isCallerInRole` access check also follows the same process, except that an `EJBRoleRefPermission` object is created instead of an `EJBMethodPermission` object.

#### **Access decisions for web resources**

When security is enabled and configured to use a JACC provider, and when a web resource such as a servlet or a JavaServer Pages (JSP) file is accessed, the security runtime delegates the authorization decision to the JACC provider by using the following process:

1. A `WebResourcePermission` object is created to see if the URI is cleared. If the provider honors the Everyone subject it is also selected here.
  - a. The `WebResourcePermission` object is constructed with the `urlPattern` and the HTTP method accessed.
  - b. A `ProtectionDomain` object with a null principal name is created.

- c. The JACC provider `Policy.implies` method is called with the permission and the protection domain. If the URI access is cleared or given access to the Everyone subject, the provider permits access (return `true`) in the `implies` method. Access is then granted without further checks.
2. If access is not granted in the previous step, a `WebUserDataPermission` object is created and used to see if the Uniform Resource Identifier (URI) is precluded, excluded or must be redirected using the HTTPS protocol.
  - a. The `WebUserDataPermission` object is constructed with the `urlPattern` accessed, the HTTP method invoked, and the transport type of the request. If the request is over HTTPS, the transport type is set to `CONFIDENTIAL`; otherwise, null is passed.
  - b. A `ProtectionDomain` object with a null principal name is created.
  - c. The JACC provider `Policy.implies` method is called with the permission and the protection domain. If the request is using the HTTPS protocol and the `implies` method returns `false`, the HTTP 403 error is returned to imply excluded and precluded permission. In this case no further checks are performed. If the request is not using the HTTPS protocol, and the `implies` returns `false`, the request is redirected over HTTPS.
3. The security runtime attempts to authenticate the user. If the authentication information already exists (for example, LTPA token), it is used. Otherwise, the user's credentials must be entered.
4. After the user credentials are validated, a final authorization check is performed to see if the user is granted access privileges to the URI.
  - a. As in Step 1, the `WebResourcePermission` object is created. The `ProtectionDomain` object now contains the Principal that is attempting to access the URI. The Subject policy context handler also contains the user's information, which can be used for the access check.
  - b. The provider `implies` method is called using the `Permission` object and the `ProtectionDomain` object created previously. If the user is granted permission to access the resource, the `implies` method returns `true`. If the user is not granted access, the `implies` method returns `false`.

Even if the order listed previously is changed later (for example, to improve performance) the end result is the same. For example, if the resource is precluded or excluded, the end result is that the resource cannot be accessed.

For more information on these access permissions, see the JSR-000115 Java Authorization Contract for Containers (Final Release).

### Using information from the Subject for access decision

If the provider relies on the WebSphere Application Server generated Subject for access decision, the provider can query the public credentials in the Subject to obtain the `WSCredential` credential. The `WSCredential` API is used to obtain information about the user, including the name and the groups that the user belongs to. This information is used to make the access decision.

If the provider adds the required information to the Subject, WebSphere Application Server can use the information to make the access decision. The provider might add the information by using the Trust Association Interface feature or by plugging login modules into the Application Server.

The security attribute propagation section contains additional documentation on how to add the WebSphere Application Server required information to the Subject. For more information, see "Propagating security attributes among application servers" on page 1705.

### Dynamic module updates in JACC

WebSphere Application Server supports dynamic updates to web modules under certain conditions. If a web module is updated, deleted or added to an application, only that module is stopped and started as appropriate. The other existing modules in the application are not impacted, and the application itself is not stopped and then restarted.

When using the default authorization engine, any security policies are modified in the web modules and the application is stopped and then restarted. When using the Java Authorization Contract for Containers (JACC) based authorization, the behavior depends on the functionality that a provider supports. If a provider can handle dynamic changes to the web modules, then only the web modules are impacted. Otherwise, the entire application is stopped and restarted for the new changes in the web modules to take effect.

A provider can indicate if it supports the dynamic updates by configuring the **Supports dynamic module updates** option in the JACC configuration model (see “Authorizing access to Java EE resources using Tivoli Access Manager” on page 1817 for more information). This option can be enabled or disabled using the administrative console or by scripting. It is expected that most providers store the policy information in their external repository, which makes it possible for them to support these dynamic updates. This option should be enabled by default for most providers.

When the **Supports dynamic module updates** option is enabled, if a web module that contains security roles is dynamically added, modified, or deleted, only the specific web modules are impacted and restarted. If the option is disabled, the entire application is restarted. When dynamic updates are performed, the security policy information of the modules impacted are propagated to the provider. For more information about security policy propagation, see “JACC policy propagation” on page 1789.

### **Initialization of the JACC provider**

If a Java Authorization Contract for Containers (JACC) provider requires initialization during server startup, for example, to enable the client code to communicate to the server code, the provider can implement the `com.ibm.wsspi.security.authorization.InitializeJACCProvider` interface. See “Interfaces that support JACC” on page 1836 for more information.

When this interface is implemented, it is called during server startup. Any custom properties in the JACC configuration model are propagated to the `initialize` method of this implementation. The custom properties can be entered using either the administrative console or by scripting.

During server shutdown, the `cleanup` method is called for any clean-up work that a provider requires. Implementation of this interface is strictly optional, and is used only if the provider requires initialization during server startup.

### **Mixed node environment and JACC**

Authorization using Java Authorization Contract for Containers (JACC) is a new feature in WebSphere Application Server Version 6.0.x. Also, the JACC configuration is set up at the cell level and is applicable for all the nodes and servers in that cell.

If you are planning to use the JACC-based authorization, the cell must contain Version 6.0.x and later nodes only. This restriction implies that a mixed node environment containing a set of Version 5.x nodes in a Version 6.0.x or later cell is not supported.

### ***JACC providers:***

The Java Authorization Contract for Containers (JACC) is a specification that was first introduced in Java Platform, Enterprise Edition (Java EE) Version 1.4 through the Java Specifications Request (JSR) 115 process. JACC specification 1.4 is included for WebSphere Application Server version 7.0 for Java EE 5 support.. This specification defines a contract between Java EE 5 containers and authorization providers.

The contract enables third-party authorization providers to plug into Java EE 5 application servers, such as WebSphere Application Server, to make the authorization decisions when a Java EE 5 resource is accessed. The access decisions are made through the standard `java.security.Policy` object.

To plug in to WebSphere Application Server, the third-party JACC provider must implement the policy class, policy configuration factory class, and policy configuration interface, which are all required by the JACC specification.

**Note:** For WebSphere Application Server for z/OS, if System Authorization Facility (SAF)-based authorization is implemented, the implementation at this point does not use or implement the JACC Policy provider interface.

The JACC specification does not specify how to handle the authorization table information between the container and the provider. It is the responsibility of the provider to provide some management facilities to handle this information. The container is not required to provide the authorization table information in the binding file to the provider.

WebSphere Application Server provides the RoleConfigurationFactory and the RoleConfiguration role configuration interfaces to help the provider obtain information from the binding file, as well as an initialization interface (InitializeJACCProvider). The implementation of these interfaces is optional. See “Interfaces that support JACC” on page 1836 for more information about these interfaces.

### **Tivoli Access Manager as the default JACC provider for WebSphere Application Server**

The JACC provider in WebSphere Application Server is implemented by both the client and the server pieces of the Tivoli Access Manager. The client piece of Tivoli Access Manager is embedded in WebSphere Application Server. The server piece is located on a separate installable CD that is shipped as part of the WebSphere Application Server, Network Deployment (ND) package.

The JACC provider is not the default authorization. You must configure WebSphere Application Server to use the JACC provider.

#### ***JACC policy context handlers:***

WebSphere Application Server supports all of the policy context handlers that are required by the Java Authorization Contract for Containers (JACC) specification. However, due to performance impacts, the Enterprise JavaBeans (EJB) arguments policy context handler is not activated unless it is specifically required by the provider. Performance impacts result if objects must be created for each argument of each EJB method.

If the provider supports and requires this context handler, select the **Requires the EJB arguments policy context handler for access decisions** check box in the External JACC provider link under the Authorization providers panel or by using scripting. Any changes to this option are effective after the servers are restarted. By default this option is disabled. Disable this option when using Tivoli Access Manager as the JACC provider, because the argument values are not required for access decisions.

#### ***JACC policy context identifiers (ContextID) format:***

A policy context identifier is defined as a unique string that represents a policy context. A policy context contains all of the security policy statements as defined by the Java Contract for Containers (JACC) specification that affect access to the resources in a web or Enterprise JavaBeans (EJB) module.

During policy propagation to the JACC provider, a PolicyConfiguration object is created for each policy context. The object is populated with the policy statements, represented by the JACC permission objects that correspond to the context. The object is propagated to the JACC provider using the JACC specification APIs.

WebSphere Application Server makes the contextID unique by using the href:cellName/appName/moduleName string as the contextID format for the modules. The href part of the string indicates that a hierarchical name is passed as the context ID. The cellName represents the name of the deployment

manager cell or the base cell where the application is installed. After an application is installed in one cell (for example, in a base application server where the cell name is base1) and is added to a deployment manager cell whose name is cell1 by using addNode, the context ID for the modules in the application contain base1 (not cell1) as the cell name because the application is initially installed in base1.

The appName part of the string in the context ID represents the application name containing the module. The moduleName refers to the name of the module.

As an example, the context ID for the module Increment.jar file in an application named DefaultApplication that is installed in cell1 is the href:cell1/DefaultApplication/Increment.jar file.

### ***JACC policy propagation:***

When an application is installed or deployed in WebSphere Application Server, the security policy information in the application is propagated to the provider when the configuration is saved. The context ID for the application is saved in its application.xml file, that is used for propagating the policy to the Java Authorization Contract for Containers (JACC) provider, and also for access decisions for Java Platform, Enterprise Edition (Java EE) resources.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log, SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

When an application is uninstalled, the security policy information in the application is removed from the provider when the configuration is saved.

If the provider implemented the RoleConfiguration interface, the security policy information that is propagated to the policy provider also contains the authorization table information. See “Interfaces that support JACC” on page 1836 for more information about this interface.

If an application does not contain security policy information, the PolicyConfiguration (and the RoleConfiguration, if implemented) objects do not contain any information. The existence of empty PolicyConfiguration and RoleConfiguration objects indicates that security policy information for the module does not exist.

After an application is installed, it can be updated without being uninstalled and reinstalled. For example, a new module can be added to an existing application, or an existing module can be modified. In this instance, the information in the impacted modules is propagated to the provider by default. A module is impacted when the deployment descriptor of the module or annotations within the module are changed as part of the update. If the provider supports the RoleConfiguration interfaces, the entire authorization table for that application is propagated to the provider.

If the security information is not propagated to the provider during application updates, you can set the com.ibm.websphere.security.jacc.propagateonappupdate Java virtual machine (JVM) property to false in the deployment manager, in a Network Deployment environment, or the unmanaged base application server. If this property is set to false, any updates to an existing application in the server are not propagated to the provider. You also can set this property on a per-application basis using the custom properties of an application. The wsadmin tool can be used to set the custom property of an application. If this property is set at the application level, any updates to that application are not propagated to the provider. If the update to an application is a full update, for example, a new application enterprise archive (EAR) file is used to replace the existing one, and the provider is refreshed with the entire application security policy information.

When an application is installed and saved, the security policy information in that application is updated in the provider from the deployment manager. The application is not propagated to its respective nodes until the synchronization command is issued and completed. Also, when an application is uninstalled and saved at the deployment manager, the policy for that application is removed from the JACC provider.

However, unless the synchronization command is issued and completed from the deployment manager to the nodes hosting the application, the applications are still running in the respective nodes. In this instance, deny any access to this application because the JACC provider does not contain the required information to make the access decision for that application. Any updates to the application already installed as described previously are also propagated to the provider from the deployment manager. The changes in the provider are not synchronized with the applications in the nodes until the synchronization is completed.

As mentioned earlier, the security policy information is propagated to the JACC provider during the save operation. The `SystemOut.log` file indicates the success or failure of the propagation to the provider. Check the log file after the installation to ensure that the propagation had no problems. If the propagation had any problems, access to the application fails when Tivoli Access Manager is used as the JACC provider.

If the security policy information for the application is successfully propagated to the provider, the audit statements with the message key `SECJ0415I` appear. However, if there was a problem propagating the security policy information to the provider (for example: network problems, JACC provider is not available), the `SystemOut.log` files contain the error message with the message keys `SECJ0396E` during install or `SECJ0398E` during modification. The installation of the application is not stopped due to a failure to propagate the security policy to the JACC provider. Also, in the case of failure, no exception or error messages appear during the save operation. When the problem causing this failure is fixed, run the **propagatePolicyToJaccProvider** tool to propagate the security policy information to the provider without reinstalling the application. For more information, see Propagating security policy of installed applications to a JACC provider using `wsadmin` scripting.

### ***JACC registration of the provider implementation classes:***

The JACC specification states that providers can plug in their provider using the `javax.security.jacc.policy.provider` and the `javax.security.jacc.PolicyConfigurationFactory.provider` system properties.

The `javax.security.jacc.policy.provider` property is used to set the policy object of the provider, while the `javax.security.jacc.PolicyConfigurationFactory.provider` property is used to set the provider `PolicyConfigurationFactory` implementation.

Although both system properties are supported in WebSphere Application Server, it is highly recommended that you use the configuration model that is provided. You can set these values using either the JACC configuration panel (see “Authorizing access to Java EE resources using Tivoli Access Manager” on page 1817 for more information) or by using `wsadmin` scripting. One of the advantages of using the configuration model instead of the system properties is that the information is entered in one place at the cell level, and is propagated to all nodes during synchronization. Also, as part of the configuration model, additional properties can be entered, as described in the JACC configuration panel.

Using the configuration model is especially recommended in the case of a WebSphere Application Server, Network Deployment (ND) environment where multiple application servers can exist in the configuration. If the system properties are used, you must ensure that each of the Java virtual machine (JVM) processes in the configuration set these properties. If the configuration model is used, the information is propagated to all processes through the synchronization process of the application server.

### ***Role-based security with embedded Tivoli Access Manager:***

The Java Platform, Enterprise Edition (Java EE) role-based authorization model uses the concepts of roles and resources. An example is provided here.

Table 134. Roles.

This table is an example of role-based security with embedded Tivoli Access Manager.

Roles	Methods		
	getBalance	deposit	closeAccount
Teller	granted	granted	
Cashier	granted		
Supervisor			granted

In the example of the banking application that is conceptualized in the previous table, three roles are defined: teller, cashier, and supervisor. Permission to perform the getBalance, deposit, and closeAccount application methods are mapped to these roles. From the example, you can see that users assigned the role, Supervisor, can run the closeAccount method, whereas the other two roles are unable to run this method.

The term, principal, within WebSphere Application Server security refers to a person or a process that performs activities. Groups are logical collections of principals that are configured in WebSphere Application Server to promote the ease of applying security. Roles can be mapped to principals, groups, or both.

Table 135. Roles methods. The entry that is invoked in the following table indicates that the principal or group can invoke any methods that are granted to that role.

Principal/Group	Roles		
	Teller	Cashier	Supervisor
TellerGroup	Invoke		
CashierGroup		Invoke	
SupervisorGroup			
Frank: A principal who is not a member of any of the previous groups		Invoke	Invoke

In the previous example, the principal Frank, can invoke the getBalance and the closeAccount methods, but cannot invoke the deposit method because this method is not granted either the Cashier or the Supervisor role.

At the time of application deployment, the Java Authorization Contract for Container (JACC) provider of Tivoli Access Manager populates the Tivoli Access Manager-protected object space with any security policy information that is contained in the application deployment descriptor and or annotations. This security information is used to determine access whenever the WebSphere Application Server resource is requested.

By default, the Tivoli Access Manager access check is performed using the role name, the cell name, the application name, and the module name.

Tivoli Access Manager access control lists (ACLs) determine which application roles are assigned to a principal. ACLs are attached to the applications in the Tivoli Access Manager-protected object space at the time of application deployment.

Principal-to-role mappings are managed from the WebSphere Application Server administrative console and are never modified using Tivoli Access Manager. Direct updates to ACLs are performed for administrative security users only.

The following sequence of events occur:

1. During application deployment, policy information is sent to the JACC provider of Tivoli Access Manager . This policy information contains permission-to-role mappings and role-to-principal and role-to-group mapping information.
2. The JACC provider of Tivoli Access Manager converts the information into the required format, and passes this information to the Tivoli Access Manager policy server.
3. The policy server adds entries to the Tivoli Access Manager-protected object space to represent the roles that are defined for the application and the permission-to-role mappings. A permission is represented as a Tivoli Access Manager-protected object and the role that is granted to this object is attached as an extended attribute.

### ***Tivoli Access Manager integration as the JACC provider:***

Tivoli Access Manager uses the Java Authorization Contract for Container (JACC) model in WebSphere Application Server to perform access checks.

Tivoli Access Manager consists of the following components:

- Run time
- Client configuration
- Authorization table support
- Access check
- Authentication using the PDLoginModule module

### **Tivoli Access Manager run-time changes that are used to support JACC**

For the run-time changes, Tivoli Access Manager implements the PolicyConfigurationFactory and the PolicyConfiguration interfaces, as required by JACC. During the application installation, the security policy information in the deployment descriptor and the authorization table information in the binding files are propagated to the Tivoli provider using these interfaces. The Tivoli provider stores the policy and the authorization table information in the Tivoli Access Manager policy server by calling the respective Tivoli Access Manager application programming interfaces (API).

Tivoli Access Manager also implements the RoleConfigurationFactory and the RoleConfiguration interfaces. These interfaces are used to ensure that the authorization table information is passed to the provider with the policy information. See “Interfaces that support JACC” on page 1836 for more information about these interfaces.

### **Tivoli Access Manager client configuration**

To configure the Tivoli Access Manager client, you can use either the administrative console or wsadmin scripting. You can access the administrative console panels for the Tivoli Access Manager client configuration by clicking **Security > Global security > External authorization providers**. Under Related Items, click **External JACC provider**. The Tivoli client must be set up to use the Tivoli Access Manager JACC Provider.

For more information about how to configure the Tivoli Access Manager client, see “Tivoli Access Manager JACC provider configuration” on page 1826.

### **Authorization table support**

Tivoli Access Manager uses the RoleConfiguration interface to ensure that the authorization table information is passed to the Tivoli Access Manager provider when the application is installed or deployed. When an application is deployed or edited, the set of users and groups for the user or group-to-role mapping are obtained from the Tivoli Access Manager server, which shares the same Lightweight Directory Access Protocol (LDAP) server as WebSphere Application Server. This sharing is accomplished by

plugging into the application management users or groups-to-role administrative console panels. The management APIs are called to obtain users and groups rather than relying on the WebSphere Application Server-configured LDAP registry.

The user or group-to-role mapping is on the application level, not on the node level.

### **Access check**

When WebSphere Application Server is configured to use the JACC provider for Tivoli Access Manager, it passes the information to Tivoli Access Manager to make the access decision. The Tivoli Access Manager policy implementation queries the local replica of the access control list (ACL) database for the access decision.

### **Authentication using the PDLoginModule module**

The custom login module in WebSphere Application Server can do the authentication. This login module is plugged in before the WebSphere Application Server-provided login modules. The custom login modules can provide information that can be stored in the Subject. If the required information is stored, no additional registry calls are made to obtain that information.

As part of the JACC integration, the Tivoli Access Manager-provided PDLoginModule module is also used to plug into WebSphere Application Server for Lightweight Third Party Authentication (LTPA), Kerberos (KRB5) and Simple WebSphere Authentication Mechanism (SWAM) authentication. The PDLoginModule module is modified to authenticate with the user ID or password. The module is also used to fill in the required attributes in the Subject so that no registry calls are made by the login modules in WebSphere Application Server. The information that is placed in the Subject is available for the Tivoli Access Manager policy object to use for access checking.

**Note:** SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

**Note:** When using Kerberos authentication mechanism and Tivoli Access Manager, TAM loginModule creates the PDPrincipal without first going through the Tivoli Access Manager authentication process. Also when using Kerberos authentication mechanism and Tivoli Access Manager, the Tivoli Access Manager policy is not enforced starting in WebSphere Application Server Version 7.0.

### ***Tivoli Access Manager security for WebSphere Application Server:***

WebSphere Application Server provides embedded IBM Tivoli Access Manager client technology to secure your WebSphere Application Server-managed resources.

The benefits of using Tivoli Access Manager that are described here are only applicable when Tivoli Access Manager client code is used with the Tivoli Access Manager server:

- Robust container-based authorization
- Centralized policy management
- Management of common identities, user profiles, and authorization mechanisms
- Single-point security management for Java Platform, Enterprise Edition (Java EE) compliant and non-compliant Java EE resources using the administrative console for Tivoli Access Manager Web Portal Manager
- No requirements for coding or deployment changes to applications
- Easy management of users, groups, and roles using the WebSphere Application Server administrative console

WebSphere Application Server supports the Java Authorization Contract for Containers (JACC) specification. JACC details the contract requirements for Java EE containers and authorization providers.

With this contract, authorization providers can perform the access decisions for resources in Java EE application servers such as WebSphere Application Server. The Tivoli Access Manager security utility that is embedded within WebSphere Application Server is JACC-compliant and is used to:

- Add security policy information when applications are deployed
- Authorize access to WebSphere Application Server-secured resources.

When applications are deployed, the embedded Tivoli Access Manager client takes any policy and or user and role information that is stored within the application deployment descriptor or using annotations and stores it within the Tivoli Access Manager Policy Server.

The Tivoli Access Manager JACC provider is also called when a user requests access to a resource that is managed by WebSphere Application Server.

### **Embedded Tivoli Access Manager client architecture**

The previous figure illustrates the following sequence of events:

1. Users that access protected resources are authenticated using the Tivoli Access Manager login module that is configured for use when the embedded Tivoli Access Manager client is enabled.
2. The WebSphere Application Server container uses information from the Java EE application deployment descriptor and annotations to determine the required role membership.
3. WebSphere Application Server uses the embedded Tivoli Access Manager client to request an authorization decision from the Tivoli Access Manager authorization server. Additional context information, when present, is also passed to the authorization server. This context information is comprised of the cell name, Java EE application name, and Java EE module name. If the Tivoli Access Manager policy database has policies that are specified for any of the context information, the authorization server uses this information to make the authorization decision.
4. The authorization server consults the permissions that are defined for the specified user within the Tivoli Access Manager-protected object space. The protected object space is part of the policy database.
5. The Tivoli Access Manager authorization server returns the access decision to the embedded Tivoli Access Manager client.
6. WebSphere Application Server either grants or denies access to the protected method or resource, based on the decision that is returned from the Tivoli Access Manager authorization server.

At its core, Tivoli Access Manager provides an authentication and authorization framework. You can learn more about Tivoli Access Manager, including the information that is necessary to make deployment decisions, by reviewing the product documentation. The following guides are available in the IBM Tivoli Access Manager for e-business Information Center:

- *IBM Tivoli Access Manager for e-business Installation Guide*

This guide describes how to plan, install, and configure a Tivoli Access Manager secure domain. Using a series of easy installation scripts, you can quickly deploy a fully functional secure domain. These scripts are very useful when prototyping the deployment of a secure domain.

To access this guide in the IBM Tivoli Access Manager for e-business information center, click **Access Manager for e-business > Installation and upgrade information > Installation Guide**.

- *IBM Tivoli Access Manager for e-business Administration Guide*

This document presents an overview of the Tivoli Access Manager security model for managing protected resources. This guide describes how to configure the Tivoli Access Manager servers that make access control decisions. In addition, detailed instructions describe how to perform important tasks, such as declaring security policies, defining protected object spaces, and administering user and group profiles.

To access this guide in the IBM Tivoli Access Manager for e-business information center, click **Access Manager for e-business >Administration Information > Administration Guide**.

**Tivoli Access Manager provides centralized administration of multiple servers.**

The previous figure is an example architecture showing WebSphere Application Servers secured by Tivoli Access Manager.

The participating WebSphere Application Servers use a local replica of the Tivoli Access Manager policy database to make authorization decisions for incoming requests. The local policy databases are replicas of the master policy database. The master policy database is installed as part of the Tivoli Access Manager installation. Having policy database replicas on each participating WebSphere Application Server node optimizes performance when making authorization decisions and provides failover capability.

Although the authorization server can also be installed on the same system as WebSphere Application Server, this configuration is not illustrated in the diagram.

All instances of Tivoli Access Manager and WebSphere Application Server in the example architecture share the Lightweight Directory Access Protocol (LDAP) user registry on Machine E.

The LDAP registries that are supported by WebSphere Application Server are also supported by Tivoli Access Manager.

It is possible to have separate WebSphere Application Server profiles on the same host that is configured for different Tivoli Access Manager servers. Such an architecture requires that the profiles are configured for separate Java SE Runtime Environments (JRE 6) and therefore you need multiple JREs installed on the same host.

**Security annotations:**

Annotations are a powerful programming mechanism resulting from the JSR-175 recommendation. An annotation is a standard way to include supported security behaviors while allowing, the source code and configuration files to be generated automatically.

In Java Platform, Enterprise Edition (Java EE) 5 and above, The security roles and policies can be defined using annotations as well as within the deployment descriptor. During the installation of the application, the security policies and roles defined using annotations are merged with the security policies and roles defined within the deployment descriptor. This merge is performed by the Annotations Metadata Manager (AMM) facility. When the metadata is merged, the following inheritance rules are followed.

*Table 136. Metadata merger inheritance rules.*

*This table lists the metadata merger inheritance rules.*

Scenario	Rules
Security metadata in deployment descriptor only	No merge is needed, the security metadata from the deployment descriptor is propagated.
Security metadata in annotations only	No merge is needed, the security metadata defined with annotations is propagated.
Security metadata in deployment descriptor and annotations	The metadata from the deployment descriptor and annotations is merged. The metadata in annotations is overridden by the same type of data from the deployment descriptor.

Six security annotations are currently supported. For each annotation, a MergeAction implementation is defined.

- **@DeclareRoles** (Servlet 2.5 and greater and EJB 3)  
The MergeAction implementation finds all the classes annotated with the DeclareRoles annotation. Within each annotated class for each role name specified, if the security roles listed in the deployment descriptor does not contain a SecurityRole with the annotated role name, a new SecurityRole is created and added to this list of security roles.
- **@RunAs** (Servlet 2.5 and greater and EJB 3)  
The MergeAction implementation finds all the classes with the RunAs annotation. For each annotated class, it finds the Servlet or the Enterprise Java Bean (EJB) associated with the given class. It then determines if a run-as element is defined in the deployment descriptor for the servlet or EJB. If one is not found, a new run-as element is created and added to the deployment descriptor. If a run-as element is found, this run-as element will be used instead of creating a new one. The role name used in the RunAs annotation must be defined in the deployment descriptor.
- **@DenyAll** (EJB 3 only)  
The MergeAction implementation finds all the methods annotated with the DenyAll annotation. For each annotated method, if the method is not included in the deployment descriptor list of excluded methods, and a MethodPermission does not exist in the deployment descriptor, a new MethodElement is created and added to this list of excluded methods in the deployment descriptor.
- **@PermitAll** (EJB 3 only)  
The MergeAction implementation finds all the classes and the methods with the PermitAll annotation. For each annotated class, it finds the Enterprise Java Bean (EJB) associated with the given class. It then searches the subset of the MethodElements in the list of all the MethodPermissions defined in the deployment descriptor for this EJB. If a MethodElement with a wildcard method name (“\*”) is not found and a wildcard method does not exist in the list of excluded methods or in the list of MethodElements with security roles, a new MethodPermission and a new MethodElement are created. The new MethodPermission is marked unchecked and is added to the MethodPermission list in the deployment descriptor. The new MethodElement is added to the MethodElement list of the newly created unchecked MethodPermission. Similar action is done for all annotated methods. Instead of a wildcard MethodElement, the method signature must match exactly the signature of the annotated method.
- **@RolesAllowed** (EJB 3 only)  
The MergeAction implementation finds all of the classes and methods with the RolesAllowed annotation. For each annotated class, it finds the EJB associated with the given class. It then finds the subset of the MethodElements in the list of all the MethodPermissions defined in the deployment descriptor for this EJB. If a MethodElement with a wildcard method name (“\*”) is not found, and a wildcard method does not exist in the list of excluded methods or in the list of unchecked MethodElements, a new MethodPermission and MethodElement are created. If a MethodPermission for this EJB exists with exactly the same roles as those found in the annotation, this MethodPermission will be used instead of creating a new one. For each role name specified in the annotation, a new SecurityRole is created and added to the SecurityRole list in the MethodPermission, If the MethodPermission was newly created, it is added to the MethodPermission list in the deployment descriptor. The new MethodElement created is added to the MethodElement list of the MethodPermission. Similar processing is done for all annotated methods. Instead of a wildcard MethodElement, the method signature must exactly match the signature of the annotated method. Additionally, for each role name specified in the annotation, if the deployment descriptor list of security roles does not contain a SecurityRole with the annotated role name, a new SecurityRole is also created and added to this list of security roles.
- **@ServletSecurity** (Servlet 3.0 only)

**Note:** Support for ServletSecurity annotation for Servlet 3.0 is new in this release of WebSphere Application Server.

When an application deploys, the ServletSecurity MergeAction implementation finds all servlets with the ServletSecurity annotation. For each annotated servlet, it finds the servlet associated

with the given class base on the `WebServlet` annotation. If `RolesAllowed` in the `ServletSecurity` annotation is not found in the deployment descriptor, it then creates a role-name attribute for the role in the deployment descriptor.

When an application starts, the `WebContainer` inspects all servlets with the `RunAs`, `declareRoles`, and `ServletSecurity` annotations, and sets those annotations on the `setServletSecurity()` method of the `ServletRegistration` annotation. The `WebContainer` notifies the security component to inspect all `ServletRegistration` annotations that have URL patterns and security constraints. The security component then determines if a URL pattern is defined in the deployment descriptor. If one is not defined in the deployment descriptor, the security constraints and `RunAs` role in the URL pattern are created and then used. If an exact match is already defined in the deployment descriptor, the security constraints and `RunAs` role in the URL pattern of the deployment descriptor are used instead of the annotation data.

**Note:** When the web authentication system property, `com.ibm.wsspi.security.web.webAuthReq`, is set to `persisting`, you can log into an unprotected URL if a valid username and password are provided.

**Note:** `ServletSecurity MergeAction` and `WebContainer` require the `WebServlet` annotation to determine the servlet name of the URL pattern. The `ServletSecurity` annotation is omitted if the `WebServlet` annotation is missing, or if a URL pattern is not specified in the `ServletSecurity` annotation.

The `Inherited` servlet annotation is a metadata annotation. Do not specify the `Inherited` annotation in the class. If a subclass does not have security annotation, it automatically inherits security annotation from the parent class. The subclass can overwrite the parent security annotations by specifying its security annotations.

The following example is for all HTTP methods with no constraints:

```
@WebServlet ("/Example")
@ServletSecurity
public class Example extends HttpServlet {

}
```

The following example is for all HTTP methods with no `<auth-constraint>` element and confidential `TransportGuarantee` required:

```
@WebServlet ("/Example")
@ServletSecurity(@HttpConstraint(transportGuarantee =
 TransportGuarantee.CONFIDENTIAL))
public class Example extends HttpServlet {

}
```

The following example is for all HTTP methods with all access denied:

```
@WebServlet ("/Example")
@ServletSecurity(@HttpConstraint(EmptyRoleSemantic.DENY))
public class Example extends HttpServlet {

}
```

The following example is for all HTTP methods except for the GET and POST values with no constraints. For GET, the `<auth-constraint>` element requires membership in ALL ROLE. For POST, all access is denied.

```
@WebServlet (name="Example", urlPatterns={"/Example"})
@ServletSecurity((httpMethodConstraints = {
 @HttpMethodConstraint(value = "GET", rolesAllowed = "ALL ROLE"),
 @HttpMethodConstraint(value="POST", emptyRoleSemantic =
 EmptyRoleSemantic.DENY))
})
public class Example extends HttpServlet {

}
```

The following example is for all HTTP methods except GET, the `<auth-constraint>` element requires membership in ALL ROLE, and the GET method has no constraints.

```

@WebServlet (name="Example", urlPatterns={"/Example"})
@ServletSecurity(value = @HttpConstraint(rolesAllowed = "ALL ROLE"),
 httpMethodConstraints = @HttpMethodConstraint("GET"))
public class Example extends HttpServlet {

}

```

The following example is for all HTTP methods except TRACE, the <auth-constraint> element requires membership in ALL ROLE, and for TRACE, all access is denied.

```

@WebServlet (name="Example", urlPatterns={"/Example"})
@ServletSecurity(value = @HttpConstraint(rolesAllowed = "ALL ROLE"),
 httpMethodConstraints = @HttpMethodConstraint(value="TRACE",
 emptyRoleSemantic = EmptyRoleSemantic.DENY))
public class Example extends HttpServlet {

}

```

### **Java Servlet 3.0 support for security:**

This release of WebSphere Application Server supports all security updates as defined in the Java Servlet 3.0 specification.

**Note:** This release of WebSphere Application Server supports all security updates as defined in the Java Servlet 3.0 specification (JSR-315), including the new servlet security annotations, use of new programmatic security APIs and the dynamic updating of the servlet security configuration.

A significant enhancement is the new annotation support for servlets. A developer can declare the security constraints using annotations as an alternative to declaring them as part of the web.xml file, which is used prior to Java Servlet 3.0. The web.xml file continues to function and overrides any conflicts defined as annotations.

The list of supported Java Servlet 3.0 updates for security includes the following:

- Support for the @ServletSecurity annotation
- Support for the dynamic updating of the @RunAs, @declareRoles, and @ServletSecurity servlet security annotations
- Support for the authenticate, login and logout servlet security methods
- The new com.ibm.websphere.security.displayRealm property specifies whether the HTTP basic authentication login window displays the realm name that is not defined in the application web.xml file.

The following discusses the Java Servlet 3.0 updates for security in more detail:

#### **Support for the @ServletSecurity annotation:**

When an application deploys, the ServletSecurity MergeAction implementation finds all servlets with the ServletSecurity annotation. For each annotated servlet, it finds the servlet associated with the given class base on the@WebServlet annotation. If RolesAllowed in the ServletSecurity annotation is not found in the deployment descriptor, it then creates a role-name attribute for the role in the deployment descriptor.

When an application starts, the WebContainer inspects all servlets with the RunAs, declareRoles, and ServletSecurity annotations, and sets those annotations on the setServletSecurity() method of the ServletRegistration annotation. The WebContainer notifies the security component to inspect all ServletRegistration annotations that have URL patterns and security constraints. The security component then determines if a URL pattern is defined in the deployment descriptor. If one is not defined in the deployment descriptor, the security constraints and RunAs role in the URL pattern are created and then used. If an exact match is already defined in the deployment descriptor, the security constraints and RunAs role in the URL pattern of the deployment descriptor are used instead of the annotation data.

Read the Security annotations topic for more information.

## **Support for the dynamic updating of the @RunAs, @declareRoles, and @ServletSecurity servlet security annotations:**

When an application starts, the web container inspects all servlets with the RunAs, declareRoles, and ServletSecurity annotations, and sets those annotations on the setServletSecurity() method of the ServletRegistration annotation. The web container notifies the security component to inspect all ServletRegistration annotations that have URL patterns and security constraints. The security component then determines if a URL pattern is defined in the deployment descriptor. If an exact match is already defined in the deployment descriptor, the security constraints and RunAs role in the URL pattern of the deployment descriptor are used instead of the dynamic data.

Read the Servlet security dynamic annotations topic for more information.

**Note:** WebSphere Application Server supports both a default authorization provider and an authorization provider that is based on the Java Authorization Contract for Containers (JACC) specification. The JACC-based authorization provider (for example, the Tivoli Access Manager), enables third-party security providers to handle the Java EE authorization. The RunAs, declareRoles, and ServletSecurity annotations are supported for both native authorization and for JACC.

## **Support for the authenticate, login and logout servlet security methods:**

The authenticate method authenticates a user by using the WebSphere Application Server container login mechanism configured for the servlet context.

The login method authenticates a user to the WebSphere Application Server with a user ID and password. If authentication is successful, it creates a user subject on the thread and Lightweight Third Party Authentication (LTPA) cookies (if single sign-on (SSO) is enabled).

The logout method logs the user out of the WebSphere Application Server and invalidates the HTTP session.

Read the Servlet security methods topic for more information.

## **The new com.ibm.websphere.security.displayRealm property specifies whether the HTTP basic authentication login window displays the realm name that is defined in the application web.xml file:**

If the realm name is not defined in the web.xml file, one of the following occurs:

- If the property is set to `false` (the default), the WebSphere realm name display is Default Realm.
- If the property is set to `true`, the WebSphere realm name display is the user registry realm name for the LTPA authentication mechanism or the Kerberos realm name for the Kerberos authentication mechanism.

Read the Security custom properties topic for more information.

## ***Servlet security dynamic annotations:***

When you use the programmatic APIs to add or to create a servlet, the security annotations, RunAs, declareRoles and ServletSecurity, can be dynamically updated through the setRunAsRole(), declareRoles() and setServletSecurity() methods respectively.

**Note:** Support for the dynamic updating of the RunAs, declareRoles, and ServletSecurity servlet security annotations is new in this release of WebSphere Application Server.

When an application starts, the web container inspects all servlets with the RunAs, declareRoles, and ServletSecurity annotations, and sets those annotations on the setServletSecurity() method of the ServletRegistration annotation. The web container notifies the security component to inspect all

ServletRegistration annotations that have URL patterns and security constraints. The security component then determines if a URL pattern is defined in the deployment descriptor. If an exact match is already defined in the deployment descriptor, the security constraints and RunAs role in the URL pattern of the deployment descriptor are used instead of the dynamic data.

**Note:** If the dynamic security annotations, declareRoles, setRunAs and rolesAllowed, are used, the role name must be pre-defined, either through the deployment descriptor or through the declareRoles and or RunAs annotations in the servlet class. During deployment time, you can use the administrative console to map a user or group to this role.

If you have an exact URL pattern match for the ServletSecurity annotation in the security dynamic annotation, the security constraint of the URL pattern in the security dynamic annotation takes precedent. Also, if you call the setServletSecurity() method multiple times with the same URL pattern, the last one takes precedent.

- ServletRegistration.Dynamic.setRunAsRole(String roleName) sets the name of the RunAs role for this servlet registration.
- ServletContext.declareRoles(String roleNames) declares role names that are tested for the isUserInRole() method.
- ServletRegistration.Dynmaic.setServletSecurity(ServletSecurityElement constraint) sets the ServletSecurityElement for this servlet registration.

**Note:** When the web authentication system property, com.ibm.wsspi.security.web.webAuthReq, is set to persisting, you can log into an unprotected URL if a valid username and password are provided.

The following two examples can be used to set the security constraints and RunAs role for dynamic servlets by using the setServletSecurity() method.

In this example, all HTTP elements require membership in the Employee role except for the PUT method. For the PUT method, the <auth-constraint> element requires membership in the Manager role and TransportGuarantee is confidential.

```
HttpConstraintElement constraint = new HttpConstraintElement(TransportGuarantee.NONE,
new String[]{"Employee"});
List<HttpMethodConstraintElement> methodConstraints =
new ArrayList<HttpMethodConstraintElement>();
methodConstraints.add(new HttpMethodConstraintElement("PUT",
new HttpMethodConstraintElement(TransportGuarantee.CONFIDENTIAL, new String[]{"Manager"})));
ServletSecurityElement servletSecurity =
new ServletSecurityElement(constraint, methodConstraints);
```

In this example, all HTTP methods are allowed except for the CUSTOM and GET methods. For the CUSTOM method, the <auth-constraint> element requires membership in the Manager role. For the GET method, the <auth-constraint> element requires membership in the Employee role, and TransportGuarantee is confidential.

```
HttpConstraintElement constraint = new HttpConstraintElement();
List<HttpMethodConstraintElement> methodConstraints =
new ArrayList<HttpMethodConstraintElement>();
methodConstraints.add(new HttpMethodConstraintElement("CUSTOM",
new HttpMethodConstraintElement(TransportGuarantee.NONE, new String[]{"Manager"})));
methodConstraints.add(new HttpMethodConstraintElement("GET",
new HttpMethodConstraintElement(TransportGuarantee.CONFIDENTIAL, new String[]{"Employee"})));
ServletSecurityElement servletSecurity = new ServletSecurityElement(constraint,
methodConstraints);
```

## System Authorization Facility for role-based authorization

There are three choices you have when assigning roles: **(1)** WebSphere Application Server authorization, in which authorization management is performed within the WebSphere Administration using the Security role to user/group mapping panel of the administrative console. **(2)** The System Authorization Facility

(SAF) for role-based authorization (WebSphere Authorization Facility for z/OS only option) , which uses SAF authorization for Java 2 Platform Enterprise Edition (J2EE) roles. **(3)** External Authorization Provider using the pluggable JACC interfaces. When WebSphere Application Server is configured to use SAF Authorization, the authorization management is performed using SAF management facilities and the user or group to J2EE role Management within WebSphere Administration is ignored. SAF class of **EJBROLE** is used (for example, using the RACF EJBROLE profile) to control access by a client to Java 2 Platform, Enterprise Edition (J2EE) roles in EJB and web applications, including the WebSphere Application Server administrative console application.

**Important considerations when using SAF authorization:** When you select SAF for authorization, there are several functional implications to subsequent authorization operations that you need to consider:

- If SAF authorization is selected on the administrative console, it overrides any other authorization choice (such as, Tivoli Access Manager authorization). See “Summary of controls” on page 1274 for more information.
- When SAF authorization is enabled, authorization on any level is always performed by the operating system's security manager (RACF or equivalent product). That is, users need to be authenticated with a security manager (RACF) user ID or a SAF mapping module needs to be used.. See “System Authorization Facility considerations for the operating system and application levels” on page 1271 for more information.
- When SAF authorization is selected during systems customization, administrative EJBROLE profiles for all administrative roles are defined by the RACF jobs generated using the customization dialogs, and SAF authorization can be used as an authorization mechanism for all user registries. See “Controlling access to console users when using a Local OS Registry” on page 1374 for more information.
- When configuring SAF authorization, property, **com.ibm.security.SAF.authorization** is set to true and SAF EJBROLE profiles are used to control access to administrative roles. See “Authorizing access to administrative roles” on page 1853 for more information about authorizing access to administrative roles.
- When SAF authorization is enabled, any values in the console users and console groups are ignored. The **Map security**

**roles to users/groups** functional panel in the administrative console is ignored. See “Administrative roles and naming service authorization” on page 1771 for more information.

- **Everyone** and **All Authenticated** are ignored since they are managed in RACF. See “System Authorization Facility considerations for the operating system and application levels” on page 1271 as well as Security role to user or group mapping for more information.
- When SAF authorization is enabled, the SAF EJBROLE profiles are used to control access to CosNaming functions. During security domain setup in the customization dialog, the CosNaming roles are defined by customization jobs. See “Special considerations for controlling access to naming roles using SAF authorization” on page 1808 for more information on CosNaming functions and SAF authorization as well as referencing “Administrative roles and naming service authorization” on page 1771.
- When SAF authorization is enabled, SAF EJBROLE profiles are used to authorize J2EE roles. For non-local operating system registries, identity mapping must be in place to map WebSphere Application Server identities to SAF identities. See “Controlling access to console users when using a Local OS Registry” on page 1374 for more information
- SAF authorization for J2EE roles is a task that is independent of the application deployment process. See Assigning users and groups to roles for more information.
- The EJBROLE class should be RACLISTed. If the EJBROLE class is not RACLISTed, you must restart the application server to pick up changes made to profiles in the EJBROLE class.

**Note:** When you use SAF authorization, to make sure that any changes in SAF to a user or group membership become effective immediately, call the `purgeUserFromAuthCache SecurityAdmin mbean` method for the modified user. Otherwise, the changes become effective when the cache is refreshed on a periodic basis. As an alternative, you can restart the server.

When SAF authorization is enabled, SAF EJBROLE profiles are used to authorize Java EE roles. For non-local operating system registries, identity mapping must be in place to map WebSphere Application Server identities to SAF identities.

To enable SAF authorization, see “z/OS System Authorization Facility authorization” on page 1805 for more information.

Defining EJBROLES belongs to the application deployment process. If the user ID has at least READ access to the defined EJBROLE profile that corresponds to the Java EE role defined by the application, the user ID is considered to be *in Role*. (Do not be confused by the name EJBROLE. It is used for Java EE roles in both enterprise beans and Web applications.)

When an application deployer uses a role in the deployment descriptor of a component, the role name must be identical to the name of an EJBROLE profile. A security administrator defines EJBROLE profiles and permits SAF users or groups to the profiles. In order to be considered as eligible for a role, a user must have read access to the EJBROLE profile or must be connected to a SAF group that has read access.

The specification of a SAF profile prefix (previously referred to as a z/OS security domain) affects the specific EJBROLE profiles used by WebSphere Application Server for z/OS system resources when SAF authorization is chosen. When a SAF prefix is defined, the Java EE application EJBROLE profiles for the WebSphere Application Server for z/OS runtime are prefixed with the value of this property. This enables you to deploy the same application on different cells in the same sysplex, but have different user to role mappings if desired.

For example, your application has two Java EE role names: `juniorTellers` and `seniorTellers`. These are mixed case roles. In your SAF registry, you have an MVS group called `JTELLER` and `STELLER` and a MVS user ID called `BANKADM`. The `JTELLER` group is required to access to the `juniorTellers` role, and the `STELLER` group is required to access the `seniorTellers` role. The `BANKADM` user ID is required to access both roles.

You have two cells, both defined to use a SAF profile prefix. The prefixes are `PRODCCELL` and `TESTCELL`, respectively. The `TEST1` user ID should have access to both roles, but only in the test environment `TESTCELL`.

If you wanted to deploy the same application in both cells, you must define distinct profiles using a RACF (or equivalent security subsystem) as follows.

If RACF is used as your security server, enable this by issuing the following commands:

```
/* the EJBROLE class must be active, this step is done by the customization dialogs */
SETROPTS CLASSACT(EJBROLE)

/* first define the roles in RACF */
RDEFINE EJBROLE PRODCCELL.juniorTellers UACC(NONE)
RDEFINE EJBROLE PRODCCELL.seniorTellers UACC(NONE)

RDEFINE EJBROLE TESTCELL.juniorTellers UACC(NONE)
RDEFINE EJBROLE TESTCELL.seniorTellers UACC(NONE)

/* permit the appropriate users and groups to the various roles */
PERMIT PRODCCELL.juniorTellers CLASS(EJBROLE) ID(JTELLER BANKADM) ACCESS(READ)
PERMIT PRODCCELL.seniorTellers CLASS(EJBROLE) ID(STELLER BANKADM) ACCESS(READ)

PERMIT TESTCELL.juniorTellers CLASS(EJBROLE) ID(TEST1) ACCESS(READ)
PERMIT TESTCELL.seniorTellers CLASS(EJBROLE) ID(TEST1) ACCESS(READ)

/* refresh the EJBROLE class in RACF */
SETROPTS RACLIST(EJBROLE) REFRESH"
```

## Grouping EJBROLES (GEJBROLE)

The SAF interface also supports a grouping class for the EJBROLE class. This grouping class is called `GEJBROLE`. It is particularly useful when you have a need to give access to the same users or groups for several roles.

The GEJBROLE grouping class provides a capability not natively available in other Java EE servers. Using the Java EE security model, if there are several components or applications that use different role names for similar functions, such as Hire, Promote, or GrantPayraise for managerial functions, there are several options:

- Adjust the application deployment descriptors so that they conform to the roles already defined in the enterprise, such as managers. This process is time consuming and error prone especially because it might require a readjustment of the deployment descriptor each time the application is changed or reinstalled.
- Define the EJBROLE profiles for each of the roles that are required by the application. Then, permit users and groups to access these roles. This process might be extensive for the administrator because the same users and groups might have permissions for several different profiles with similar meanings.
- Use the grouping class to avoid the worst issues with the other two options. You must still define EJBROLE profiles for each of the roles required by the application. Instead of permitting all of the same users and groups to use the new profiles, create a profile, such as supervisors, in the grouping class and add all of the new EJBROLE profiles to it. You can give permission in one place to every user and group that needs access to these roles, such as the supervisors profile. You can further avoid administrative work by adding the existing EJBROLE profile (Managers) to the grouping class profile (Supervisors).

#### **Considerations when implementing GEJBROLES:**

- Plan organizational role profiles in the RACF class GEJBROLES.
- Create the access list by permitting user groups to the GEJBROLE profiles, then add roles to the GEJBROLE profiles.
- A GEJBROLE with only one EJBROLE is OK.
- Do not use a mixture of EJBROLE and GEJBROLE for permitting users to roles.
- If possible, permit users to GEJBROLE profiles only.
- Generally use GEJBROLE in preference to EJBROLE.

#### ***System Authorization Facility user registries:***

System Authorization Facility (SAF) user registries are used for several purposes in WebSphere Application Server for z/OS.

SAF-based user registries are used to:

- Authenticate using basic authentication, identity assertion, or client certificates
- Store information about users and groups
- Retrieve information about users and groups to perform security-related administrative functions including mapping users and groups to security roles.
- Control access to resources such as datasets, commands and ports

Refer to “Selecting a registry or repository” on page 1416 for more information

Using a local operating system or non-local operating system registry implementation, the WebSphere Application Server for z/OS authentication mechanism can use SAF interfaces. SAF interfaces are defined by MVS to enable applications to use system authorization services or user registries to control access to resources such as data sets and MVS commands. SAF either processes security authorization requests directly or works with RACF, or other security products, to process the requests. Note that a local

operating system SAF user registry is not a centralized registry like Lightweight Directory Access Protocol (LDAP), but it is a centralized registry within a sysplex.

**Note:** When a non-local operating system registry is used, WebSphere Application Server for z/OS uses the non-local operating system registry for authentication but still uses the SAF interface to control access to system resources.

With WebSphere Application Server for z/OS, SAF user registries provide digital certificate to user ID mappings using the Resource Access Control Facility (RACF) RACDCERT command. For more information on the RACDCERT command, refer to z/OS Security Server RACF Command Language Reference (SA22-7687-05), available at <http://www.ibm.com/servers/eserver/zseries/zos/bkserv/r5pdf/secserv.html>.

WebSphere Application Server for z/OS localOS User Registry (SAF User Registry) implementation sets the registry realm name from the SAFDFLT profile in the REALM class when the REALM class is active and the SAFDFLT profile is defined. This realm name is specified as the APPLDATA property of the SAFDFLT profile. If the realm name cannot be obtained from the OS security product (such as RACF), the value of `protocol_iiop_daemon_listenIPAddress` is used instead. This can happen, for example, if the REALM class is not active, or if the SAFDFLT profile is not defined.

For any realm name changes to take effect, the entire cell, including the Daemon Address Space, must be recycled for the changes to be effective. There is a UNIX System Services restriction, however. If you list user and group information, only those users with an OMVS segment (where the user and group information is stored) are shown. Refer to “Summary of controls” on page 1274 for more information.

**gotcha:** If you list the groups or users in the user registry for a specific security realm, resource name, or domain name, you must ensure that you add an OMVS segment (where the user and group information is stored) to any group or user that you want to use with WebSphere Application Server.

**Note:** The default and only implementation for a local operating system registry is SAF.

Refer to “Selecting a registry or repository” on page 1416 for general information about selecting user registries.

*z/OS System Authorization Facility authorization:*

Use this page to configure the System Authorization Facility (SAF) and the SAF Authorization properties.

To enable SAF authorization:

1. Click **Security > Global security > External authorization providers**.
2. Select the **System Authorization Facility (SAF)** from the drop-down list under Authorization provider.
3. Click the **Configure** button.

When you select SAF authorization, WebSphere Application Server uses the authorization policy that is stored in the z/OS security product for authorization. If a Lightweight Access Directory Protocol (LDAP) registry or Custom registry is configured and SAF authorization is specified, a mapping to a z/OS principal is required at each login for any protected methods to run:

- If the authentication mechanism is Lightweight Third Party Authentication (LTPA), it is recommended that you update all of the following configuration entries to include a mapping to a valid z/OS principal (such as WEB\_INBOUND, RMI\_INBOUND, and DEFAULT).
- If the authentication mechanism is Simple WebSphere Authentication Mechanism (SWAM), you must update the SWAM configuration entry to include a mapping to a valid z/OS principal.

**Note:** SWAM is deprecated and will be removed in a future release.

The common properties for unauthenticated user, SAF authorization, and SAF EJBROLE message suppression are no longer custom properties.

When you select this option, WebSphere Application Server uses the authorization policy that is stored in the z/OS security product for authorization.

*Unauthenticated user ID:*

Specifies the MVS user ID that is used to represent unprotected servlet requests when SAF authorization is specified or a local operating system registry is configured. This user ID must be a maximum of 8 characters long.

This property definition is used in the following instances:

- For authorization if an unprotected servlet invokes an entity bean
- For identification of an unprotected servlet for invoking a z/OS connector such as Customer Information Control System (CICS) or Information Management System (IMS) that uses a current identity when `res-auth=container`
- When an application-initiated Synch to OS thread function is attempted

For more information, see the following articles in the information center:

- "Understanding application Synch to OS Thread Allowed"
- "When to use application Synch to OS Thread Allowed"

*SAF profile mapper:*

Specifies the name of SAF EJBRole profile to which a Java 2 Platform, Enterprise Edition (J2EE) role name is mapped. The name that you specify implements the `com.ibm.websphere.security.SAFRoleMapper` interface.

The `com.ibm.ws.security.zOS.authz.SAFRoleMapperImpl` implementation class, which is the default SAF role mapper implementation, is initially configured. This initial configuration maps all the characters that are not allowed in a SAF role name, such as the percent (%), ampersand (&), asterisk (\*) and blank characters, to a pound (#) character.

For more information, see the Developing a custom SAF EJB role mapper

*Enable SAF delegation:*

Specifies that the SAF EJBROLE definitions are assigned the MVS user identity that becomes the active identity when you select the RunAs specified role.

Select the **Enable SAF delegation** option only if you select the **Enable SAF Authorization** option as the external authorization provider.

*Use the APPL profile to restrict access to the application server:*

Use the APPL profile to restrict access to WebSphere Application Server.

If you have defined an SAF profile prefix, the APPL profile used is the profile prefix. Otherwise, the APPL profile name is CBS390. All of the z/OS identities using WebSphere services should have READ permission to the APPL profile. This includes all WebSphere Application Server identities, WebSphere Application Server unauthenticated identities, WebSphere Application Server administrative identities, user IDs based on role-to-user mappings, and all user identities for system users. If the APPL class is not active on the z/OS system, then this property has no effect, regardless of its value.

**Default:** Enabled.

*Suppress authorization failed messages from the z/OS security product:*

Specifies whether ICH408I messages are on or off. The default value for this settings is false (unchecked), which does not suppress messages.

System Management Facility (SMF) records access violations no matter what value is specified for this new property. This property affects the generation of access violation messages for both application-defined roles and for application server run-time-defined roles for the naming and administrative subsystems. EJBROLE profile checks are done for both declarative and programmatic checks:

- Declarative checks are coded as security constraints in Web applications and deployment descriptors are coded as security constraints in Enterprise JavaBeans (EJB) files.
- Program logic checks or access checks are performed using the programmatic `isCallerInRole(x)` method for enterprise beans or `isUserInRole(x)` method for Web applications.

**gotcha:**

- If you do not want administrative role messages suppressed when the SMF audit record strategy is set to `Default`, set the `com.ibm.security.SAF.EJBROLE.Audit.Messages.Suppress.Admin` property to `false`. The value specified for this property overrides any other setting that governs message suppression for administrative roles.
- When a third-party authorization such as Tivoli Access Manager or SAF for z/OS is used, the information in the administrative console panel might not represent the data in the provider. Also, any changes to the panel might not be reflected in the provider automatically. Follow the provider's instructions to propagate any changes made to the provider.

For more information on SAF authorization, see "Controlling access to console users when using a Local OS registry" in the information center. For more information on administrative roles, see "Administrative roles" in the information center.

**Default:** Disabled, which does not suppress messages.

*SMF audit record strategy:*

Determines when an audit record is written to the System Management Facility (SMF). On each authorization call, RACF or an equivalent SAF-based product, can write an audit record to SMF with the result of the authorization check.

WebSphere Application Server for z/OS uses the SAF RACROUTE AUTH and RACROUTE FASTAUTH operations and passes the LOG option that is specified in the security configuration. The options are DEFAULT, ASIS, NOFAIL, and NONE.

The following options are available from the drop-down list:

**DEFAULT**

When multiple role constraints are specified, such as a user must be in one of a set of roles, all of the roles except for the last role is checked with the NOFAIL option. If the authorization is granted in one of the roles before the last role, WebSphere Application Server writes an authorization success record. If the authorization is not successful in these roles, the last role is checked with the ASIS log option. If the user is authorized to the last role, a success record might be written. If the user is not authorized, a failure record might be written.

**ASIS** Specifies that the audit events are recorded in the manner that is specified in the profile that protects the resource or in the manner that is specified by the SETROPTS options.

**NOFAIL**

Specifies that failures are not recorded. Authorization failure messages are not issued, but successful authorization audit records might be written.

**NONE** Specifies that neither successes or failures are recorded.

Only one authorization failed record is written for a failed J2EE authorization check even if several SAF authorization calls are made. For more information on the LOG options for SAF RACROUTE AUTH and RACROUTE FASTAUTH, see the RACF or equivalent SAF-based product documentation.

*SAF profile prefix:*

Specifies a prefix which will be added to all the SAF EJBROLE profiles used for the Java EE roles. This prefix is also used as the APPL profile name and is inserted into the profile name used for CBIND checks. There is no default value for the SAF profile prefix field. If a prefix is not explicitly specified, then no prefix is added to the SAF EJBROLE profiles, the default value of CBS390 will be used as the APPL profile name, and nothing is inserted into the profile name for CBIND checks.

You can use APPL profile to restrict access to WebSphere Application Server

If you have defined an SAF profile prefix, the APPL profile used is the profile prefix. Otherwise, the APPL profile name is CBS390. All of the z/OS identities using WebSphere services should have READ permission to the APPL profile. This includes all WebSphere Application Server identities, WebSphere Application Server unauthenticated identities, WebSphere Application Server administrative identities, user IDs based on role-to-user mappings, and all user identities for system users. Note that if the APPL class is not active on the z/OS system, then this property has no effect, regardless of its value.

**Note:** The SAF profile prefix corresponds to the property, **com.ibm.security.SAF.profilePrefix.name**, in the security.xml file.

***Special considerations for controlling access to naming roles using SAF authorization:***

There are special considerations in WebSphere Application Server for controlling access to naming roles.

**Considerations for assigning users to naming roles**

You can use either System Authorization Facility (SAF) authorization (EJBROLE profiles) or WebSphere Application Server authorization to control access to naming roles. To enable SAF authorization, see “z/OS System Authorization Facility authorization” on page 1805 for more information. For a discussion of the CosNaming roles, see Administrative console and naming service authorization. You can also refer to Assigning users to naming roles.

**Using SAF authorization to control access to naming roles**

When SAF authorization is enabled, SAF EJBROLE profiles are used to control access to CosNaming functions. If you selected **Use a z/OS security product** during profile creation in the z/OS Profile Management Tool and you additionally specify a value for the SAF profile prefix (previously referred to as the z/OS security domain), then the following CosNaming roles were defined by the customization jobs:

```
RDEFINE EJBROLE (optionalSecurityDomainName.)CosNamingRead
UACC(READ)
RDEFINE EJBROLE (optionalSecurityDomainName.)CosNamingWrite
UACC(NONE)
RDEFINE EJBROLE (optionalSecurityDomainName.)CosNamingCreate
UACC(NONE)
RDEFINE EJBROLE (optionalSecurityDomainName.)CosNamingDelete
UACC(NONE)
```

```

PERMIT (optionalSecurityDomainName.)CosNamingRead CLASS(EJBROLE)
ID(WSGUEST) ACCESS(READ)
PERMIT (optionalSecurityDomainName.)CosNamingWrite CLASS(EJBROLE)
ID(WSCFG1) ACCESS(READ)
PERMIT (optionalSecurityDomainName.)CosNamingCreate CLASS(EJBROLE)
ID(WSCFG1) ACCESS(READ)
PERMIT (optionalSecurityDomainName.)CosNamingDelete CLASS(EJBROLE)
ID(WSCFG1) ACCESS(READ)

```

If you decide, at a future date, to enable SAF authorization, you must issue these RACF commands to enable proper WebSphere Application Server operation. Change the value WSGUEST if you have chosen a different unauthenticated user ID. Change the value WSCFG1 if you have chosen a different configuration group. WSGUEST must be given explicit READ access because it is a restricted userid.

The default access granted by the customization job permits all authenticated users to update the name space. This type of authorizations might be a broader level of authority than you want to provide. Minimally, you must enable the configuration group for WebSphere Application Server (servers and administrators) to have read access to all of the profiles and permit all WebSphere Application Server for z/OS clients to have read access to the CosNamingRead profile.

If additional users require access to CosNaming roles, you can permit a user to have any of the previous roles, as indicated, by issuing the following RACF command:

```

PERMIT (optionalSAFProfilePrefix.)rolename CLASS(EJBROLE) ID(mvsid) ACCESS(READ)

```

### Using WebSphere Application Server authorization to control access to naming roles

When SAF authorization is not enabled, WebSphere Application Server authorization and the administrative console are used to control access to CosNaming functions.

For information on assigning users to naming roles, refer to Assigning users to naming roles.

### System Authorization Facility (SAF) delegation:

System Authorization Facility (SAF) delegation minimizes the need to store user Ids and passwords in many locations in the configuration.

WebSphere Application Server supports the function of delegation. Delegation allows a user identity to be represented as a Java EE role. For example, you can establish an application to be run with a RunAs role of *RoleA*. *RoleA* can then be mapped as *UserA*. WebSphere Application Server then establishes the identity context as *UserA*, and *RoleA* is defined in the deployment descriptor. Within such an arrangement in place, SAF delegation uses the specified Java EE role, *RoleA*, to determine the thread identity and then synchronizes processing with the user Id, *UserA*. *UserA* is specified in the SAF EJBROLE profile's APPLDATA value of the RDEFINE RACF command. The REDEFINE command in this example would be as follows:

```

RDEFINE EJBROLE rolea UACC(NONE) APPLDATA(usera)

```

SAF delegation requires that SAF authorization be enabled. The SAF security administrator would be responsible for the assignment of Users to the role. See “z/OS System Authorization Facility authorization” on page 1805 for the steps that permit SAF delegation.

**Note:** If you have SAF delegation enabled and Kerberos is your active authentication mechanism, when the application requests the run-as role, the runAs subject that is created on the server does not contain the Kerberos credential. As a result, the request falls back to LTPA.

### Using distributed identity mapping for SAF

In this release of WebSphere Application Server, you can use z/OS System Authorization Facility (SAF) security to associate a SAF user ID with a distributed identity.

## About this task

When you use this feature, you can maintain the original identity information of a user for audit purposes and have less to configure in WebSphere Application Server.

You can log in to a WebSphere Application Server application with the distributed identity of the user. The filters defined in the z/OS security product then determine the mapping of the distributed identity to a SAF user.

**Note:** The SAF distributed identity mapping feature is not supported in a mixed-version cell (nodes prior to WebSphere Application Server Version 8.0).

## Procedure

1. Review the Distributed identity mapping using SAF topic. Decide which scenario applies to your configuration and make any necessary changes.

**Note:** Before you configure distributed identity mapping, you must first remove unnecessary Java Authentication and Authorization Service (JAAS) login modules. Ensure that you do not have the `com.ibm.ws.security.common.auth.module.MapPlatformSubject` login JAAS module configured in WebSphere Application Server. Use the administrative console or `wsadmin` scripting to remove this login module, or you can use the provided Jython script, `removeMapPlatformSubject.py`, which searches for and removes this login module from the appropriate login entries. For more information about how to use this script, read the `removeMapPlatformSubject` script topic.

2. Configure the RACMAP filters in the z/OS security product to establish the mapping of distributed identities to SAF users. Read the Distributed identity filters configuration in z/OS security topic for more information.

### ***Distributed identity mapping using SAF:***

The distributed identity mapping feature using System Authorization Facility (SAF) for z/OS provides some major benefits, and is new in this version of WebSphere Application Server.

**Note:** This release of WebSphere Application Server enables you to use z/OS System Authorization Facility (SAF) security to associate a SAF user ID with a distributed identity. When you use this feature, you can maintain the original identity information of a user for audit purposes and have less to configure in WebSphere Application Server.

Your z/OS security product must be at the appropriate version that supports the distributed identity mapping. The correct SAF version is 7760 or later. For Resource Access Control Facility (RACF), you must be at z/OS version 1.11 or later.

Some advantages in using this feature include:

- If you are using a non-Local OS registry, such as Lightweight Directory Access Protocol (LDAP), and are using either SAF authorization, z/OS thread identity synchronization (SyncToThread) or the connection manager RunAs thread identity option, you can directly map the LDAP user to a SAF user in the z/OS security product with the RACMAP SAF profiles. No mapping modules are required; therefore do not configure these modules in WebSphere Application Server. SMF audit records contain both the LDAP user name and the mapped SAF user ID.
- If you are using Local OS registry, and are using Kerberos or Simple and Protected GSS-API Negotiation (SPNEGO), you can directly map the Kerberos principal to an SAF user in the z/OS security product. No mapping modules are required; therefore do not configure these modules in WebSphere Application Server. SMF audit records contain both the Kerberos principal and the mapped SAF user ID.

**Note:** The SAF distributed identity mapping feature is not supported in a mixed-version cell (nodes prior to WebSphere Application Server Version 8.0).

## Benefits when using distributed identity mapping

Distributed identity mapping in SAF provides two major benefits:

- When a user is audited on the z/OS operating system using SMF, the audit record contains both the distributed identity and the mapped SAF user ID. This improves cross-platform interoperability and provides value for both host centric and heterogeneous application environments.
- The mapping of distributed identities is handled by the z/OS security administrator. There is no need to configure mapping modules in the WebSphere Application Server configuration.

## When to use distributed identity mapping

The following scenarios describe how you can use the new distributed identity mapping feature in SAF.

- **Scenario 1:** When you have a non-Local OS registry configured with either SAF authorization, z/OS thread identity synchronization (SyncToThread) or the connection manager RunAs thread identity option, you can use this feature to map your registry user to an SAF user. In previous releases, this process had to be done with Java Authentication and Authorization Service (JAAS) login modules that were configured in WebSphere Application Server.

The advantages of using distributed identity mapping are that the SMF audit records will contain both the distributed user and the SAF user, and that the mapping is controlled by the z/OS Security administrator.

When mapping a non-Local OS registry user, the distributed user name is the value returned by the WebSphere Application Server `WSCredential.getUniqueSecurityName()` API. The realm name is determined by the WebSphere Application Server `WSCredential.getRealmName()` API.

To enable distributed identity mapping for this scenario, no further changes are needed in the security configuration.

**Note:** For scenario 1, if you are using the Federated Repositories registry configured with the UserRegistry bridge, you can still take advantage of the SAF distributed identity mapping feature. If you log in with a SAF user, it is not mapped. However, if you log in with a distributed user, it is mapped to a SAF user.

- **Scenario 2:** When you have a Local OS registry configured on the z/OS platform with Kerberos or SPNEGO enabled, you can map the Kerberos principal name to a SAF user using the distributed identity mapping feature. In previous releases, you could use either a JAAS mapping login module that was configured in WebSphere Application Server or the KERB segment of the SAF user in the z/OS security product.

The advantage of using distributed identity mapping is that the SMF records will contain both the Kerberos user and the mapped SAF user.

When mapping a Kerberos user, the distributed user name is the Kerberos principal name. The realm name is the Kerberos realm name of the Kerberos Key Distribution Center (KDC). For more information on creating distributed identity filters in the z/OS security product, read the Distributed identity filters configuration in z/OS security topic.

To enable distributed identity mapping for this scenario, you must select the radio button for "Use the RACMAP profiles in the SAF product for distributed identity mapping" on the administrative console panel Kerberos authentication settings page. To make this change with **wsadmin** scripting, set the security custom property `com.ibm.websphere.security.krb.useRACMAPMappingToSAF=true`.

- **Scenario 3:** When you have a Local OS registry configured, you can map an asserted certificate or an asserted distinguished name to a SAF user.

In previous releases, the first attribute of the asserted DN name was mapped to a SAF user. The advantage of using the distributed identity mapping for an asserted DN is the added flexibility for mapping users, the mapping is controlled by the z/OS security administrator, and the SMF audit records

will contain both the asserted DN name and the mapped SAF user ID. In previous releases, an asserted certificate was mapped to a SAF user by using the RACDCERT MAP function in SAF. The advantage of using the distributed identity mapping is that the SMF audit records will contain both the certificate DN name and the mapped SAF user ID. Additionally, the SAF database saves space by not having to store the digital certificates.

When mapping an asserted certificate or DN name in SAF, the distributed user is the DN name and the realm name is the current SAF realm.

To enable distributed identity mapping for this scenario, you must check the checkbox for "Map certificate and DN using SAF distributed identity mapping" in the administrative console panel Common Secure Interoperability Version 2 inbound communications settings. To make this change with wsadmin scripting, set the security custom property `com.ibm.websphere.security.certdn.useRACMAPMappingToSAF=true`

- **Scenario 4:** When you have a Local OS registry configured, you can map a certificate received in the CSIV2 transport layer to a SAF user.

In previous releases, a certificate was mapped to a SAF user by using the RACDCERT MAP function in SAF. The advantage of using the distributed identity mapping is that the SMF audit records will contain both the certificate DN name and the mapped SAF user ID.

When mapping a certificate received in the CSIV2 transport layer, the distributed user is the DN name and the realm name is the current SAF realm..Additionally, the SAF database saves space by not having to store the digital certificates.

To enable distributed identity mapping for this scenario, you must check the checkbox for "Map certificate using SAF distributed identity mapping" in the administrative console panel Common Secure Interoperability Version 2 inbound communications settings. To make this change with wsadmin scripting, set the security custom property `com.ibm.websphere.security.certificate.useRACMAPMappingToSAF=true`.

**Note:** If your DN name has a blank space between the attributes, then you should apply the RACF APAR OA34258, or PTF UA59873, and the SAF APAR OA34259, or PTF UA59871, to correctly parse the blanks.

Table 137. Distributed identity mapping scenarios. The following table summarizes the configuration for each of the distributed identity mapping scenarios.

Scenario	SAF version	User registry	SAF authorization=true or SyncToThread=true or runAs=true?	JAAS mapping module configured?	Kerberos or SPNEGO enabled
Scenario 1	7760 or later (z/OS 1.11 or later for RACF)	non-Local OS	yes	no	n/a
Scenario 2	7760 or later (z/OS 1.11 or later for RACF)	Local OS	yes	no	yes
Scenario 3	7760 or later (z/OS 1.11 or later for RACF)	Local OS	yes	no	n/a
Scenario 4	7760 or later (z/OS 1.11 or later for RACF)	Local OS	yes	no	n/a

## Considerations when configuring distributed identity mapping

When you configure distributed identity mapping, you must complete the following actions:

- **Determine the SAF version.** You must first ensure that your z/OS security version is at SAF version 7760 or later. If you are using RACF, you must be at z/OS version 1.11 or later. A new AdminTask, `isSAFVersionValidForIdentityMapping()`, is provided to help determine this. Additionally, the informational message, SECJ6233I, is printed in the server job log, which indicates the current SAF version.
- **Remove unnecessary JAAS login modules.** You must ensure that you do not have the `com.ibm.ws.security.common.auth.module.MapPlatformSubject` login JAAS module configured in your WebSphere configuration. In previous releases of WebSphere Application Server, this is how mapping a distributed user to a SAF user was completed. As long as you have this login module configured, the security configuration continues to use the previous method for mapping a distributed user to a SAF user. If you are configuring a new WebSphere Application Server Version 8.0 cell, this JAAS login module is not configured by default; therefore, no further action is necessary. However, if you have migrated your cell to WebSphere Application Server Version 8.0, the JAAS login module likely exists and should be removed. You can use the administrative console or **wsadmin** scripting to remove this login module. You can also use the provided Jython script, `removeMapPlatformSubject.py`, which searches for and removes this login module from the appropriate login entries. For more information on how to use this script, read the `removeMapPlatformSubject` script topic.

To delete the JAAS login module on the administrative console, complete the following steps:

1. Click **Security > Global security > Java Authentication and Authorization Service > System logins**.
  2. Click **DEFAULT**.
  3. Select the checkbox for `com.ibm.ws.security.common.auth.module.MapPlatformSubject` login JAAS module, then click **Delete**.
  4. Click **OK**.
  5. Repeat for steps 2-4 for the System logins of `WEB_INBOUND`, `RMI_INBOUND` and `SWAM_ZOSMAPPING`.
- **Map SAF users in the z/OS security product.** Use the `RACMAP` command in the z/OS security product to configure a distributed identity filter. Use this filter to map multiple distributed users to one SAF user, or you can have a one-to-one mapping. The distributed identity filter consists of two parts: the distributed user name and the realm name of the registry where the distributed user exists.

**Note:** In some cases, changes to the `RACMAP` filters do not take effect immediately on the WebSphere server. Read “Activating `RACMAP` filter changes for an authenticated user” in the Distributed identity filters configuration in z/OS security topic for more details.

When configuring the SAF distributed identity mapping feature at the security domain level, note the realm name for that domain. You can choose to provide a realm name or to use the system-generated realm name. Regardless of which option you choose, this is the realm name that you must use when defining the mappings in the SAF registry.

- **Make the necessary changes to the security configuration.** Read scenarios 1-4 listed above to determine additional changes you might need to make to the security configuration.

### ***Distributed identity filters configuration in z/OS security:***

Before you can map distributed identities to System Authorization Facility (SAF) users, you must first configure distributed identity filters in the z/OS security product for WebSphere Application Server.

The distributed identity filter in the SAF class `RACMAP` consists of the distributed user name and the realm name of the distributed user name. You can configure the filters to map many distributed identities to one SAF user, or you can have a one-to-one mapping.

The following syntax for creating a distributed identity filter using the `RACMAP` command exists:

```
RACMAP ID(<SAFUser>) MAP USERDIDFILTER(NAME('<distributedUserId>'))
REGISTRY(NAME('<distributedRealmName>')) WITHLABEL('<someLabel>')
```

The <SAFUser> element is the SAF user in the z/OS security product, <distributedUserId> is the distributed identity, <distributedRealmName> is the realm name of the distributed identity and <someLabel> is a text field that describes this distributed identity filter.

Use the following command to activate the IDIDMAP class. This command only needs to be run once at the beginning:

```
SETOPTS CLASSACT(IDIDMAP) RACLIST(IDIDMAP)
```

Use the following command after any changes are made to RACMAP profiles for the changes to take effect:

```
SETOPTS RACLIST(IDIDMAP) REFRESH
```

**Note:** In some cases, changes to the RACMAP filters do not take effect immediately on the WebSphere server. See the section below, “Activating RACMAP filter changes for an authenticated user” for more details.

### Mapping distributed users to SAF users:

If you have configured a non-local OS registry, you can map a distributed user, such as a Lightweight Directory Access Protocol (LDAP) user, to an SAF user. The distributed user name that WebSphere Application Server uses when mapping to an SAF user is the value returned by the `WSCredential.getUniqueSecurityName()` API. This method returns the unique user name as it applies to the configured user registry. For LDAP, this would be the full distinguished name (DN). For a custom configuration, this is whatever the `getUniqueUserId()` API in the custom registry returns. For federated repositories, this is the `uniqueName` property in virtual member manager.

The distributed realm name used by WebSphere Application Server is determined by the `WSCredential.getRealmName()` API. The realm name that is returned depends on the user registry that is being configured. For LDAP, the realm name is the `ldapHostName:ldapPortNumber`. For custom user registry, it is whatever you have configured the `getRealm()` method to return in your implementation. For federated repositories, the realm name is the realm you specified on the realm name field of the federated repositories panel.

In the following example, the LDAP user, `LDAPUser1`, is mapped to the SAF user, `USER1`:

```
RACMAP ID(USER1) MAP USERDIDFILTER(NAME('CN=LDAPUser1,o=ibm,c=us'))
REGISTRY(NAME('ccwin12.austin.ibm.com:389'))
WITHLABEL('Mapping LDAP LDAPUser1 to USER1')
```

In this example, the custom user registry user, `CustomUser3`, is mapped to the SAF user, `USER3`:

```
RACMAP ID(USER3) MAP USERDIDFILTER(NAME('CustomUser3'))
REGISTRY(NAME('customRealm')) WITHLABEL('Mapping custom CustomUser3 to USER3')
```

In this example, the federated repositories user, `wimUser5`, is mapped to the SAF user, `USER5`:

```
RACMAP ID(USER5) MAP USERDIDFILTER(NAME('uid=wimUser5,o=defaultWIMFileBasedRealm'))
REGISTRY(NAME('defaultWIMFileBasedRealm')) WITHLABEL('Mapping custom wimUser5 to USER5')
```

### Mapping Kerberos principals to SAF users:

If you have a local OS registry configured on z/OS operating systems with the Kerberos authentication mechanism, you might want to map a Kerberos user to a SAF user. In this case, the distributed identity is the Kerberos principal name. The distributed realm name is the Kerberos realm name of the KDC.

The following example maps a Kerberos user to a SAF user:

```
kerberosUser@KRB390.IBM.COM to the SAF user WSADMIN:
RACMAP ID(WSADMIN) MAP USERDIDFILTER(NAME('kerberosUser'))
REGISTRY(NAME('KRB390.IBM.COM')) WITHLABEL('Mapping Kerberos kerberosUser to WSADMIN')
```

## Mapping multiple distributed identities to one SAF user:

You can use the wildcard (\*) to create a filter that maps multiple distributed identities to one SAF user. you can specify the wildcard (\*) for the distributed identity name and realm name. For example, if you want each user from your LDAP server, accountingUnit.acme.ibm.com, to be mapped to the SAF user ACCT, you can define a filter as in the following example:

```
RACMAP ID(ACCT) MAP USERDIDFILTER(NAME('*'))
REGISTRY(NAME('accountingUnit.acme.ibm.com:389'))
WITHLABEL('Mapping accounting users to ACCT')
```

If the distributed identity name is a distinguished name, you can omit attributes of the DN value when creating the filter, starting with the most specific attributes. For example, you can create a filter that maps all LDAP users that have the attributes O=ibm,C=us to the SAF user, ACCT2, as in the following example:

```
RACMAP ID(ACCT2) MAP USERDIDFILTER(NAME('O=ibm,C=us'))
REGISTRY(NAME('accountingUnit.acme.ibm.com:389'))
WITHLABEL('Mapping US accounting users to ACCT2')
```

## Mapping certificates and distinguished names to SAF users

The distributed identity is the distinguished name or attributes of the distinguished name. The distributed realm name is the current realm. For example:

```
RACMAP ID(ACCT3) MAP USERDIDFILTER(NAME('O=ibm,C=us'))
REGISTRY(NAME('localOSRealm'))
WITHLABEL('Mapping certificate or distinguished names to ACCT3')
```

## Creating a default distributed identity filter:

You might want to define a default filter that maps any distributed identity that is not found in any of the other filters to a SAF user with the RESTRICTED attribute.

The following example demonstrates how to create a default filter:

```
RACMAP ID(WSGUEST) MAP USERDIDFILTER(NAME('*'))
REGISTRY(NAME('*')) WITHLABEL('The default filter')
```

## Activating RACMAP filter changes for an authenticated user:

When a user authenticates with the registry, the user is also added to the authentication cache. Any changes to the RACMAP filters in the z/OS security product do not take effect until this user is removed from the authentication cache.

If you want these changes to take effect immediately, call the SecurityAdmin Mbean on the server that you want to update. You can either invoke the purgeUserFromAuthCache operation to remove one specific user, or the clearAuthCache operation to remove all users from the authentication cache. The authentication cache is also cleared once the server is restarted.

Refer to the SecurityAdmin MBean Definition Table for details on the Mbean and its operations.

For example, a distributed identity, LDAPUser1, is not mapped to an SAF user, and attempts to log in to a servlet protected by a role. Since the user ID and password are valid, the user is authenticated and added to the authentication cache. However, since LDAPUser1 is not mapped to an SAF user, a default unauthenticated ID, WSGUEST, is used for authorization.

LDAPUser1 is unable to access the servlet since WSGUEST is not authorized to the servlet role. The z/OS security administrator then defines a RACMAP filter to map LDAPUser1 to the SAF user, USER1. LDAPUser1 still cannot access the servlet until this ID is removed from the authentication cache.

For more information about the RACMAP command, refer to the z/OS Security Server RACF Command Language Reference.

### ***removeMapPlatformSubject* script:**

If you want to use distributed identity mapping for System Authorization Facility (SAF), use the `removeMapPlatformSubject` Jython script that is provided to remove the unnecessary Java Authentication and Authorization Service (JAAS) login module, `MapPlatformSubject`, from the security configuration.

The `removeMapPlatformSubject` script searches for and removes the `com.ibm.ws.security.common.auth.module.MapPlatformSubject` JAAS login module from these login entries: `DEFAULT`, `WEB_INBOUND`, `RMI_INBOUND`, `SWAM_ZOSMAPPING`. You can run this script for the global security configuration or for a specific security domain.

### **Syntax**

The following command syntax exists:

```
wsadmin.sh -conntype NONE -lang jython -f
/path/to/script/removeMapPlatformSubject.py [options]
```

Running this script with no options updates the global security configuration.

### **Parameters**

The following options are available for the `removeMapPlatformSubject` script:

**-securityDomain <securityDomainName>**

Specifies that you want to update only the specified security domain. If this option is not specified, the global security configuration is updated.

**-scripthelp**

Specifies that you want to see a description of the syntax and options that are available. A `-trace` option is also available for debug purposes. The debug output is sent to the stdout stream.

**-trace**

Specifies that you want to create a trace that you can use to debug a problem with the application of this function. The trace output is sent to the stdout stream.

### **Usage scenarios**

The following examples demonstrate correct syntax.

Use this example to remove the login module from the global security configuration:

```
wsadmin.sh -conntype NONE -lang jython -f
/WebSphere/AppServer/bin/removeMapPlatformSubject.py
```

Use this example to remove the login modules from the `server2Domain` security domain:

```
wsadmin.sh -conntype NONE -lang jython -f
/WebSphere/AppServer/bin/removeMapPlatformSubject.py
-securityDomain server2Domain
```

### **Delegations**

*Delegation* is a process security identity propagation from a caller to a called object. As per the Java Platform, Enterprise Edition (Java EE) specification, a servlet and enterprise beans can propagate either the client or remote user identity when invoking enterprise beans, or they can use another specified identity as indicated in the corresponding deployment descriptor.

The extension supports enterprise bean propagation to the server ID when invoking other entity beans. Three types of delegations are possible:

- Delegate (RunAs) client identity
- Delegate (RunAs) specified identity
- Delegate (RunAs) system identity

**Note:** The RunAs system identity delegation only works when server ID and password are used. When the `internalServerId` feature is used, it does not work because runAs with system identity is not supported. You must specify RunAs roles. When `internalServerId` is used, use the `RunAsSpecified` with a user ID and password that is mapped to the administrator role. See “Administrative roles and naming service authorization” on page 1771 for more information about `internalServerId`.

The EJB specification only supports delegation (RunAs) at the Enterprise JavaBeans (EJB) level. But an extension allows EJB method-level RunAs specification. With an EJB method level, the RunAs specification can specify a different RunAs role for different methods within the same enterprise beans.

The RunAs specification is detailed in the deployment descriptor, which is the `ejb-jar.xml` file in the EJB module and the `web.xml` file in the web module. The extension to the RunAs specification is included in the `ibm-ejb-jar-ext.xml` file.

An IBM-specific binding file is available for each application that contains a mapping from the RunAs role to the user. This file is specified in the `ibm-application-bnd.xml` file.

These specifications are read by the runtime during application startup. The following figure illustrates the delegation mechanism, as implemented in the WebSphere Application Server security model.

## Delegation Process

Two tables help in the delegation process:

- Resource to RunAs role mapping table
- RunAs role to user ID and password mapping table

Use the Resource to RunAs role mapping table to get the role that is used by a servlet or by enterprise beans to propagate to the next enterprise beans call.

Use the RunAsRole to user ID and password mapping table to get the user ID that belongs to the RunAs role and its password.

Delegation is performed after successful authentication and authorization. During this process, the delegation module consults the Resource to RunAs role mapping table to get the RunAs role (3). The delegation module consults the RunAs role to user ID and password mapping table to get the user that belongs to the RunAs role (4). The user ID and password is used to create a new credential using the authentication module, which is not shown in the figure.

## Authorizing access to Java EE resources using Tivoli Access Manager

The Java Authorization Contract for Containers (JACC) defines a contract between Java Platform, Enterprise Edition (Java EE) containers and authorization providers. You can use the default authorization,

a System Authorization Facility (SAF) authorization, or an external JACC authorization provider. When security is enabled in WebSphere Application Server, the default authorization is used unless a JACC provider is specified.

## Before you begin

JACC enables any third-party authorization providers to plug into a Java EE application server (such as WebSphere Application Server) to make the authorization decisions when a Java EE resource is accessed. By default, WebSphere Application Server implements the JACC provider by using Tivoli Access Manager as the external authorization provider.

Read the following articles for more detailed information about JACC before you attempt to configure WebSphere Application Server to use a JACC provider:

## Procedure

- “JACC support in WebSphere Application Server” on page 1784
- “JACC providers” on page 1787
- “Tivoli Access Manager integration as the JACC provider” on page 1792

## Using the built-in authorization provider

You can extend the capabilities of WebSphere Application Server by plugging in your own authorization provider. You can use the built-in authorization, a System Authorization Facility (SAF) authorization, or an external JACC authorization provider.

## About this task

For an explanation of the administrative console panels that support these capabilities, see:

## Procedure

- Use the built-in authorization provider. It is recommended that you do not modify any settings on the authorization provider panels if you use the **Built-in authorization** option. For more information, see “External authorization provider settings.”
- Use an external authorization provider. If you use the **External authorization using a JACC provider** option, the external providers must be based on the Java Authorization Contract for Containers (JACC) specification to handle the Java Platform, Enterprise Edition (Java EE) authorization. By default, WebSphere Application Server enables you to configure the Tivoli Access Manager Java Authorization Contract for Containers (JACC) provider as the default external JACC provider. For more information, see “External Java Authorization Contract for Containers provider settings” on page 1819 and “Tivoli Access Manager JACC provider settings” on page 1826.
- Use a System Authorization Facility (SAF). Use the **System Authorization Facility (SAF) authorization** option to specify that SAF EJBROLE profiles be used for user-to-role authorization for both Java Platform, Enterprise Edition (Java EE) applications and the role-based authorization requests (naming and administration) that are associated with application server runtime. This option is available only when your environment contains z/OS nodes. For more information, see “External authorization provider settings” and “z/OS System Authorization Facility authorization” on page 1805.

### ***External authorization provider settings:***

Use this page to enable a Java Authorization Contract for Containers (JACC) provider for authorization decisions.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Click **External authorization providers**.

The application server provides a default authorization engine that performs all of the authorization decisions. In addition, the application server also supports an external authorization provider using the JACC specification to replace the default authorization engine for Java Platform, Enterprise Edition (Java EE) applications.

JACC is part of the Java EE specification, which enables third-party security providers such as Tivoli Access Manager to plug into the application server and make authorization decisions.

**Important:** Unless you have an external JACC provider or want to use a JACC provider for Tivoli Access Manager that can handle Java EE authorizations based on JACC, and it is configured and set up to use with the application server, do not enable **External authorization using a JACC provider**.

*Built-in authorization:*

Use this option all the time unless you want an external security provider such as the Tivoli Access Manager to perform the authorization decision for Java EE applications that are based on the JACC specification.

*External JACC provider:* Use this link to configure the application server to use an external JACC provider. For example, to configure an external JACC provider, the policy class name and the policy configuration factory class name are required by the JACC specification.

The default settings that are contained in this link are used by Tivoli Access Manager for authorization decisions. If you intend to use another provider, modify the settings as appropriate.

*System Authorization Facility (SAF) authorization:*

Use this option to specify that SAF EJBROLE profiles are used for user-to-role authorization for both Java 2 Platform, Enterprise Edition (Java EE) applications and the role-based authorization requests (naming and administration) that are associated with application server runtime. This option is available when your environment contains z/OS nodes only.

**Important:** When you select this option, WebSphere Application Server uses the authorization policy that is stored in the z/OS security product for authorization.

If a Lightweight Access Directory Protocol (LDAP) registry or Custom registry is configured and SAF authorization is specified, a mapping to a z/OS principal is required at each login for any protected methods to run:

- If the authentication mechanism is Lightweight Third Party Authentication (LTPA), it is recommended that you update all of the following configuration entries to include a mapping to a valid z/OS principal (such as WEB\_INBOUND, RMI\_INBOUND, and DEFAULT).
- If the authentication mechanism is Simple WebSphere Authentication Mechanism (SWAM), you must update the SWAM configuration entry to include a mapping to a valid z/OS principal.

**Note:** SWAM is deprecated and will be removed in a future release.

***External Java Authorization Contract for Containers provider settings:***

Use this page to configure the application server to use an external Java Authorization Contract for Containers (JACC) provider. For example, the policy class name and the policy configuration factory class name are required by the JACC specification.

Use these settings when you have set up an external security provider that supports the JACC specification to work with the application server. The configuration process involves installing and

configuring the provider server and configuring the client of the provider in the application server to communicate with the server. If the JACC provider is not enabled, these settings will be ignored.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Click **External authorization providers**.
3. Under Authorization provider, click **External JACC provider**.

Use the default settings when you use Tivoli Access Manager as the JACC provider. Install and configure the Tivoli Access Manager server prior to using it with the application server. Use the Tivoli Access Manager properties link under Additional properties, and configure the Tivoli Access Manager client in the application server to use the Tivoli Access Manager server. If you intend to use another provider, modify the settings as appropriate.

*Name:*

Specifies the name that is used to identify the external JACC provider.

This field is required.

**Data type:** String

*Description:*

Provides an optional description for the provider.

**Data type:** String

*Policy class name:*

Specifies a fully qualified class name that represents the `javax.security.jacc.policy.provider` property as per the JACC specification. The class represents the provider-specific implementation of the `java.security.Policy` abstract methods.

The class file must reside in the class path of each application server process. These processes include the application server, node agents and the deployment manager.

Do not add the Java archive (JAR) file, which contains the class file, to the `<WAS_HOME>/lib` directory in a product environment as service releases overwrite files in this directory.

This class is used during authorization decisions. The default class name is for Tivoli Access Manager implementation of the policy file.

This field is required. For information on enabling the JACC provider using this field, see the "Enabling the JACC provider for Tivoli Access Manager" article in the information center.

**Data type:** String  
**Default:** `com.tivoli.pd.as.jacc.TAMPolicy`

*Policy configuration factory class name:*

Specifies a fully qualified class name that represents the `javax.security.jacc.PolicyConfigurationFactory.provider` property as per the JACC specification. The class represents the provider-specific implementation of the `javax.security.jacc.PolicyConfigurationFactory` abstract methods.

The class file must reside in the class path of each application server process. These processes include the application server, node agents and the deployment manager.

Do not add the Java archive (JAR) file, which contains the class file, to the `<WAS_HOME>/lib` directory in a product environment as service releases overwrite files in this directory.

This class represents the provider-specific implementation of the `PolicyConfigurationFactory` abstract class. This class is used to propagate the security policy information to the JACC provider during the installation of the J2EE application. The default class name is for the Tivoli Access Manager implementation of the policy configuration factory class name.

This field is required.

<b>Data type:</b>	String
<b>Default:</b>	<code>com.tivoli.pd.as.jacc.TAMPolicyConfigurationFactory</code>

*Role configuration factory class name:*

Specifies a fully qualified class name that implements the `com.ibm.wsspi.security.authorization.RoleConfigurationFactory` interface.

The class file must reside in the class path of each application server process. These processes include the application server, node agents and the deployment manager.

Do not add the Java archive (JAR) file, which contains the class file, to the `<WAS_HOME>/lib` directory in a product environment as service releases overwrite files in this directory.

When you implement this class, the authorization table information in the binding file is propagated to the provider during the installation of the J2EE application. The default class name is for the Tivoli Access Manager implementation of the role configuration factory class name.

This field is optional. For information on enabling the JACC provider using this field, see the "Enabling the JACC provider for Tivoli Access Manager" article in the information center.

<b>Data type:</b>	String
<b>Default:</b>	<code>com.tivoli.pd.as.jacc.TAMRoleConfigurationFactory</code>

*Provider initialization class name:*

Specifies a fully qualified class name that implements the `com.ibm.wsspi.security.authorization.InitializeJACCProvider` interface.

The class file must reside in the class path of each application server process. These processes include the application server, node agents and the deployment manager.

Do not add the Java archive (JAR) file, which contains the class file, to the `<WAS_HOME>/lib` directory in a product environment as service releases overwrite files in this directory.

When implemented, this class is called at the start and the stop of all the application server processes. You can use this class for any required initialization that is needed by the provider client code to

communicate with the provider server. The properties that are entered in the custom properties link are passed to the provider when the process starts up. The default class name is for the Tivoli Access Manager implementation of the provider initialization class name.

This field is optional. For information on enabling the JACC provider using this field, see the "Enabling the JACC provider for Tivoli Access Manager" article in the information center.

**Data type:** String  
**Default:** com.tivoli.pd.as.jacc.cfg.TAMConfigInitialize

*Requires the EJB arguments policy context handler for access decisions:*

Specifies whether the JACC provider requires the EJBArgumentsPolicyContextHandler handler to make access decisions.

Because this option has an impact on performance, do not set it unless it is required by the provider. Normally, this handler is required only when the provider supports instance-based authorization. Tivoli Access Manager does not support this option for J2EE applications.

**Default:** Disabled

*Supports dynamic module updates:*

Specifies whether you can apply changes made to security policies of web modules in a running application, dynamically without affecting the rest of the application.

If this option is enabled, the security policies of the added or modified web modules are propagated to the JACC provider and only the affected web modules are started.

If this option is disabled, then the security policies of the entire application are propagated to the JACC provider for any module-level changes. The entire application is restarted for the changes to take effect.

Typically, this option is enabled for an external JACC provider.

**Default:** Enabled

*Custom properties:*

Specifies the properties that are required by the provider.

These properties are propagated to the provider during the startup process when the provider initialization class name is initialized. If the provider does not implement the provider initialization class name as described previously, the properties are not used.

The Tivoli Access Manager implementation does not require that you enter any properties in this link.

*Tivoli Access Manager properties:*

Specifies properties that are required by the Tivoli Access Manager implementation.

These properties are used to set up the communication between the application server and the Tivoli Access Manager server. You must install and configure the Tivoli Access Manager server before entering these properties.

## Enabling an external JACC provider

Use this topic to enable an external JACC provider using the administrative console.

### Before you begin

The Java Authorization Contract for Containers (JACC) defines a contract between Java Platform, Enterprise Edition (Java EE) containers and authorization providers. This contract enables any third-party authorization providers to plug into a Java EE 5 application server, such as WebSphere Application Server to make the authorization decisions when a Java EE resource is accessed.

### Procedure

1. From the WebSphere Application Server administrative console, click **Security > Global security > External authorization providers**.
2. Under Related items, click **External JACC provider**.
3. The fields are set for Tivoli Access Manager by default. If you do not plan to use Tivoli Access Manager as the JACC provider, replace these fields with the details for your own external JACC provider.
4. If any custom properties are required by the JACC provider, click **Custom properties** under Additional properties and enter the properties. When using the Tivoli Access Manager, use the **Tivoli Access Manager properties** link instead of the Custom properties link. For more information, see “Configuring the JACC provider for Tivoli Access Manager using the administrative console.”
5. On the External authorization providers panel, select the **External authorization using a JACC provider** option and click **OK**.
6. Complete the remaining steps to enable security. If you are using Tivoli Access Manager, you must select LDAP as the user registry and use the same LDAP server. For more information on configuring LDAP registries, see “Configuring Lightweight Directory Access Protocol user registries” on page 1423.
7. Verify that all of the changes are synchronized across all nodes.
8. In a multinode environment, stop and start the deployment manager configuration.  
Issue the following commands:

```
profile_root/bin/stopManager.bat
-username user_name
-password password
```

```
profile_root/bin/startManager.bat
```

9. Restart all servers to make these changes effective.

### **Configuring the JACC provider for Tivoli Access Manager using the administrative console:**

Use this task to configure Tivoli Access Manager as the Java Authorization Contract for Containers (JACC) provider using the administrative console.

### Before you begin

Before configuring Tivoli Access Manager as the JACC provider, verify that all of the managed servers, including node agents, are started

Prior to completing the following steps, verify that you have previously created a security administrative user. For more information, see “Creating the security administrative user for Tivoli Access Manager” on page 1825.

### About this task

The following configuration is performed on the management server. When you click either **Apply** or **OK**, configuration information is checked for consistency, saved, and applied if successful.

This configuration information is propagated to the nodes when synchronization is performed. Restart the nodes for the configuration changes to take effect.

To configure Tivoli Access Manager as the JACC provider using the administrative console, complete the following steps:

### Procedure

1. Start the WebSphere Application Server administrative console by clicking `http://yourhost.domain:port_number/ibm/console` after starting WebSphere Application Server. If security is currently disabled, log in with any user ID. If security is currently enabled, log in with a predefined administrative ID and password. This ID is typically the server user ID that is specified when you configure the user registry.
2. Click **Security > Global security > External authorization providers**.
3. Under General properties, select **External authorization using a JACC provider**.
4. Under Related items, click **External JACC provider**.
5. Under Additional properties, click **Tivoli Access Manager Properties**. The Tivoli Access Manager JACC provider configuration screen is displayed.
6. Enter the following information:

#### **Enable embedded Tivoli Access Manager**

Select this option to enable Tivoli Access Manager.

#### **Ignore errors during embedded Tivoli Access Manager disablement**

Select this option when you want to unconfigure the JACC provider. Do not select this option during configuration.

#### **Client listening port set**

WebSphere Application Server must listen using a TCP/IP port for authorization database updates from the policy server. More than one process can run on a particular node or machine. More than one authorization server can be specified by separating the entries with commas. Specifying more than one authorization server at a time is useful for reasons of failover and performance. Enter the listening ports used by Tivoli Access Manager clients, separated by a comma. If a range of ports is specified, separate the lower and higher values by a colon (:) (for example, 7999, 9990:999).

#### **Policy server**

Enter the name of the Tivoli Access Manager policy server and the connection port. Use the `policy_server:port` form. The policy communication port is set at the time of the Tivoli Access Manager configuration, and the default is 7135.

#### **Authorization servers**

Enter the name of the Tivoli Access Manager authorization server. Use the `auth_server:port:priority` form. The authorization server communication port is set at the time of the Tivoli Access Manager configuration, and the default is 7136. The priority value is determined by the order of the authorization server use (for example, `auth_server1:7136:1` and `auth_server2:7137:2`). A priority value of 1 is required when configuring against a single authorization server.

#### **Administrator user name**

Enter the Tivoli Access Manager administrator user name that was created when Tivoli Access Manager was configured; it is usually `sec_master`.

#### **Administrator user password**

Enter the Tivoli Access Manager administrator password.

#### **User registry distinguished name suffix**

Enter the distinguished name suffix for the user registry that is shared between Tivoli Access Manager and WebSphere Application Server, for example, `o=ibm, c=us`.

## Security domain

You can create more than one security domain in Tivoli Access Manager, each with its own administrative user. Users, groups and other objects are created within a specific domain, and are not permitted to access resource in another domain. Enter the name of the Tivoli Access Manager security domain that is used to store WebSphere Application Server users and groups.

If a security domain is not established at the time of the Tivoli Access Manager configuration, leave the value as Default.

## Administrator user distinguished name

Enter the full distinguished name of the WebSphere Application Server security administrator ID (for example, cn=wasadmin, o=organization, c=country). The ID name must match the Server user ID on the Lightweight Directory Access Protocol (LDAP) User Registry panel in the administrative console. To access the LDAP User Registry panel, click **Security > Global security**. Under **User account repository**, choose **Standalone LDAP registry** as the available realm definition. Then click **Configure**.

7. When all information is entered, click **OK** to save the configuration properties. The configuration parameters are checked for validity and the configuration is attempted at the host server or cell manager.

## Results

After you click **OK**, WebSphere Application Server completes the following actions:

- Validates the configuration parameters.
- Configures the host server or cell manager.

These processes might take some time depending on network traffic or the speed of your machine.

## What to do next

If the configuration is successful, the parameters are copied to all subordinate servers, including the node agents. To complete the embedded Tivoli Access Manager client configuration, you must restart all of the servers, including the host server, and enable WebSphere Application Server security.

*Creating the security administrative user for Tivoli Access Manager:*

Enabling security requires the creation of a WebSphere Application Server administrative user. Use the Tivoli Access Manager command-line pdadmin utility to create the Tivoli Access Manager administrative user for WebSphere Application Server. This utility is available on the policy server host machine.

## About this task

Follow these steps to use the pdadmin utility.

## Procedure

1. From a command line, start the pdadmin utility as the Tivoli Access Manager administrative user, sec\_master:

```
pdadmin -a sec_master -p sec_master_password
```

2. Create a WebSphere Application Server security user. For example, the following instructions create a new user, *wasadmin*. The command is entered as one continuous line:

```
pdadmin> user create wasadmin cn=wasadmin,o=organization,
c=country wasadmin wasadmin myPassword
```

Substitute values for organization and country that are valid for your Lightweight Directory Access Protocol (LDAP) user registry.

3. Enable the account for the WebSphere Application Server security administrative user by issuing the following command:

```
pdadmin> user modify wasadmin account-valid yes
```

### What to do next

Configure the Java Authorization Contract for Container (JACC) provider for Tivoli Access Manager. For more information, see “Tivoli Access Manager JACC provider configuration.”

#### *Tivoli Access Manager JACC provider configuration:*

You can configure the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager to deliver authentication and authorization protection for your applications or for authentication only. Most deployments that use the JACC provider for Tivoli Access Manager to configure Tivoli Access Manager provide both authentication and authorization functionality.

If you want Tivoli Access Manager to provide authentication, but leave authorization as part of WebSphere Application Server's native security, add the `com.tivoli.pd.as.amwas.DisableAddAuthorizationTableEntry=true` property to the `amwas.amjacc.template.properties` file. The file is located in the `profile_root/config/cells/cell_name` directory.

After this property is set, perform the tasks for setting Tivoli Access Manager Security, as documented.

You can configure the JACC provider for Tivoli Access Manager using either the WebSphere Application Server administrative console or the **wsadmin** command-line utility.

- For details on configuring the JACC provider for Tivoli Access Manager using the administrative console, refer to “Configuring the JACC provider for Tivoli Access Manager using the administrative console” on page 1823.
- For details on configuring the Tivoli Access Manager JACC provider using the **wsadmin** command line utility, refer to Configuring the JACC provider for Tivoli Access Manager using the wsadmin utility.

The JACC configuration files for Tivoli Access Manager that are common across multiple WebSphere Application Server profiles are created by default under the `java/jre` directory. When you install WebSphere Application Server, you are given permissions to read and write to the files in this directory.

This situation is not ideal because configuration of the JACC provider for Tivoli Access Manager fails in these situations. To avoid this situation, you can add the following property to the `profile_root/config/cells/cell_name/amwas.amjacc.template.properties` file:  
`com.tivoli.pd.as.jacc.CommonFileLocation=new location` where *new location* is a fully qualified directory name.

This property applies read and write permissions to the `java/jre` directory.

The **wsadmin** command is available to reconfigure the Java Authorization Contract for Containers (JACC) Tivoli Access Manager interface:

```
$AdminTask reconfigureTAM -interactive
```

This command effectively prompts you through the process of unconfiguring the interface and then reconfiguring it.

#### *Tivoli Access Manager JACC provider settings:*

Use this page to configure the Java Authorization Contract for Container (JACC) provider for Tivoli Access Manager.

**Note:** When a third-party authorization such as Tivoli Access Manager or SAF for z/OS is used, the information in the administrative console panel might not represent the data in the provider. Also, any changes to the panel might not be reflected in the provider automatically. Follow the provider's instructions to propagate any changes made to the provider.

To view the JACC provider settings for Tivoli Access Manager, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, click **External authorization providers**.
3. Under Authorization provider, click **External JACC provider**.
4. Click **Configure** to configure the properties for Tivoli Access Manager.

*Enable embedded Tivoli Access Manager:*

Enables or disables the embedded Tivoli Access Manager client configuration.

**Default:** Disabled  
**Range:** Enabled or Disabled

**Note:** If you want to disable Tivoli Access Manager as the JACC provider, clear this option and also select **Default authorization**.

*Ignore errors during embedded Tivoli Access Manager disablement:*

Specifies whether to ignore error messages during the unconfiguration process.

If you check this check box and click **OK** or **Apply**, when you unconfigure the embedded Tivoli Access Manager, any unconfiguration errors are ignored and the process completes. If you do not check this check box, unconfiguration errors cause the unconfiguration process to stop.

This option is applicable only when re-configuring an embedded Tivoli Access Manager client or disabling an embedded Tivoli Access Manager.

**Default:** Disabled  
**Range:** Enabled or Disabled

*Client listening port set:*

Enter the ports that are used as listening ports by Tivoli Access Manager clients.

The application server needs to listen on a TCP/IP port for authorization database updates from the policy server. More than one process can run on a particular node and machine, so a list of ports is required for use by the processes. If you specify a range of ports, separate the lower and higher values by a colon (:). The first 20% of the range is reserved for the deployment manager. Single ports and port ranges are specified on separate lines. An example list might look like the following example:

```
7999
8900:8999
```

**Note:** Each of the servants might need to open up a listener port.

*Policy server:*

Enter the name, fully-qualified domain name, or IP address of the Tivoli Access Manager policy server and the connection port.

Use the form *policy\_server.port*. The policy server communication port was set at the time of the Tivoli Access Manager configuration. The default is 7135.

*Authorization servers:*

Enter the name, fully-qualified domain name, or IP address of the Tivoli Access Manager authorization server. Use the form, *auth\_server.port:priority*.

The authorization server communication port is set at the time of Tivoli Access Manager configuration. The default is 7136. You can specify more than one authorization server by entering each server on a new line. Configuring more than one authorization server provides for failover. The priority value is the order of authorization server use. For example:

```
auth_server1.mycompany.com:7136:1
auth_server2.mycompany.com:7137:2
```

A priority of 1 is still required when configuring a single authorization server.

*Administrator user name:*

Enter the Tivoli Access Manager administration user ID, as created at the time of Tivoli Access Manager configuration. This ID is usually, *sec\_master*.

*Administrator user password:*

Enter the Tivoli Access Manager administration password for the user ID that is entered in the **Administrator user name** field.

*User registry distinguished name suffix:*

Enter the distinguished name suffix for the user registry to share between Tivoli Access Manager and the application server. For example: *o=organization,c=country*

*Security domain:*

Enter the name of the Tivoli Access Manager security domain that is used to store application server users and groups.

Specification of the Tivoli Access Manager domain is required because more than one security domain can be created in Tivoli Access Manager with its own administrative user. Users, groups, and other objects are created within a specific domain and are not permitted to access resources in another domain. If a security domain is not established at the time of Tivoli Access Manager configuration, leave the value as *Default*.

**Default:** Default

*Administrator user distinguished name:*

Enter the fully distinguished name of the security administrator ID for the application server. For example, *cn=wasadmin,o=organization,c=country*

*JACC provider configuration properties for Tivoli Access Manager:*

The JACC provider configuration properties detailed below may require configuration.

The Java property files are created in the *profile\_root/etc/tam* directory.

Two properties files might require configuration:

- `amwas.node_name_server_name.amjacc.properties` contains properties that are used by the JACC provider of Tivoli Access Manager.
- `amwas.node_name_server_name.pdjlog.properties` contains logging properties that are created from the `amwas.pdjlog.template.properties` file for the specific node and server combination at the time of configuration.

Use `amwas.node_name_server_name.amjacc.properties` file to configure static role caching, dynamic role caching, object caching, and role-based policy framework properties.

*Static role caching properties:*

The static role cache holds role memberships that do not expire.

These properties are in the `profile_root/etc/tam/amwas.node_name_server_name.amjacc.properties` file.

The `profile_root` directory is the value of the `profilePath` parameter at profile creation time.

*com.tivoli.pd.as.cache.EnableStaticRoleCaching=true:*

Enables or disables static role caching. Static role caching is enabled by default.

*com.tivoli.pd.as.cache.StaticRoleCache=com.tivoli.pd.as.cache.StaticRoleCacheImpl:*

This property holds the implementation class of the static role cache. You do not need to change this property, although the opportunity exists to implement your own cache, if necessary.

*com.tivoli.pd.as.cache.StaticRoleCache.Roles=Administrator,Operator,Monitor,Deployer:*

Defines the administration roles for WebSphere Application Server.

**Tip:** Enhance Application performance by adding the static roles: **CosNamingRead**, **CosNamingWrite**, **CosNamingCreate**, **CosNamingDelete**. These roles support for improved lookup performance within the application naming service.

*Dynamic role caching properties:*

The dynamic role cache holds role memberships that expire.

These properties are in the `profile_root/etc/tam/amwas.node_name_server_name.amjacc.properties` file.

The `profile_root` directory is the value of the `profilePath` parameter at profile creation time.

*com.tivoli.pd.as.cache.EnableDynamicRoleCaching=true:*

Enables or disables dynamic role caching. Dynamic role caching is enabled by default.

*com.tivoli.pd.as.cache.DynamicRoleCache=com.tivoli.pd.as.cache.DynamicRoleCacheImpl:*

This property holds the implementation class of the dynamic role cache. You do not need to change this property, although the opportunity exists to implement your own cache, if necessary.

*com.tivoli.pd.as.cache.DynamicRoleCache.MaxUsers=100000:*

The maximum number of users that the cache supports before a cache cleanup is performed. The default number of users is 100000.

*com.tivoli.pd.as.cache.DynamicRoleCache.NumBuckets=20:*

The number of tables that is used internally by the dynamic role cache. The default is 20. When a large number of threads use the cache, increase the value to tune and optimize cache performance.

*com.tivoli.pd.as.cache.DynamicRoleCache.PrincipalLifeTime=10:*

The period of time in minutes that a principal entry is stored in the cache. The default time is 10 minutes. The term, *principal*, here refers to the Tivoli Access Manager credential that is returned from a unique Lightweight Directory Access Protocol user.

*com.tivoli.pd.as.cache.DynamicRoleCache.RoleLifetime=20:*

The period of time in seconds that a role is stored in the role list for a user before it is discarded. The default is 20 seconds.

*Object caching properties:*

The object cache is used to cache all Tivoli Access Manager objects, including their extended attributes. This bypasses the need to query the Tivoli Access Manager authorization server for each resource request.

These properties are in the *profile\_root/etc/tam/amwas.node\_name\_server\_name.amjacc.properties* file.

The *profile\_root* directory is the value of the *profilePath* parameter when the profile is created.

These object cache properties cannot be changed after configuration. If any require changing, it should be done before configuration of the nodes in the cell. Changes need to be made in the template properties file before any configuration actions are performed. Properties changed after configuration might cause access decisions to fail.

*com.tivoli.pd.as.cache.EnableObjectCaching=true:*

This property enables or disables object caching. The default value is true.

*com.tivoli.pd.as.cache.ObjectCache=com.tivoli.pd.as.cache.ObjectCacheImpl:*

This property is the class used to perform object caching. You can implement your own object cache if required. This can be done by implementing the *com.tivoli.pd.as.cache.IObjectCache* interface. The default is *com.tivoli.pd.as.cache.ObjectCacheImpl*.

*com.tivoli.pd.as.cache.ObjectCache.NumBuckets=20:*

This property specifies the number of buckets used to store object cache entries in the underlying hash table. The default is 20.

*com.tivoli.pd.as.cache.ObjectCache.MaxResources=10000:*

This property specifies the total number of entries for all buckets in the cache. This figure, divided by NumBuckets determines the maximum size of each bucket. The default is 10000.

*com.tivoli.pd.as.cache.ObjectCache.ResourceLifeTime=20:*

This property specifies the length of time in minutes that objects are kept in the object cache. The default is 20.

*Role-based policy framework properties:*

Although it is very unlikely that you will need to change these properties, use this file to reference supported properties within the role-based policy framework.

The role-based policy framework parameters are located in the Java Authorization Contract for Containers (JACC) configuration file and in the authorization configuration file. They are set at the time of JACC provider configuration and authorization server configuration. The role-based policy framework settings for the authorization table and the JACC provider can be modified separately for each WebSphere Application Server instance. The `amwas.node_server.authztable.properties` configuration file is generated from the authorization table. The `amwas.node_name_server_name.amjacc.properties` configuration file is generated from the JACC provider. Both files are stored in the `profile_root/etc/tam` directory. It is very unlikely that you might need to change these properties. The properties are described here for reference.

The settings cannot be changed after configuration. Make changes in the template properties file before any configuration actions are performed. Properties that are changed after configuration will cause access decisions to fail.

*com.tivoli.pd.as.rbpf.AMAAction=i:*

This property is used to signify that a user is granted access to a role. This value is added to a Tivoli Access Manager access control list (ACL) and places invoke access on roles for users and groups.

*com.tivoli.pd.as.rbpf.AMAActionGroup=WebAppServer:*

This property sets the Tivoli Access Manager action group that serves as a container for the action that is specified by the `com.tivoli.pd.as.rbpf.AMAAction` property. The permission set in the `com.tivoli.pd.as.rbpf.AMAAction` property goes into this action group.

*com.tivoli.pd.as.rbpf.PosRoot=WebAppServer:*

This property is used to determine where roles are stored in the protected object space.

*com.tivoli.pd.as.rbpf.ProductId=deployedResources:*

This property specifies the location under the root location that is specified in the `posroot` property to separate other products in the protected object space. Embedded Tivoli Access Manager objects are found in the `/WebAppServer/deployedResources` directory. The default value is `deployedResources`.

*com.tivoli.pd.as.rbpf.ResourceContainerName=Resources:*

This property specifies the Tivoli Access Manager object space container name for the protected resources. The default location is the `/WebAppServer/deployedResources/Resources` directory.

*com.tivoli.pd.as.rbpf.RoleContainerName=Roles:*

This property specifies the Tivoli Access Manager protected object space container name for the security roles. The default location is the `/WebAppServer/deployedResources/Roles` directory.

*System-dependent configuration properties:*

Do not change these system-dependent configuration properties. These properties are included in this article for reference only.

These properties are in the `app_server_root/etc/amwas.node_name_server_name.amjacc.properties` file.

The `profile_root` variable is the value of the `profilePath` parameter when the profile is created.

*com.tivoli.pd.as.rbpf.AmasSession.CfgURL=file:/\$WAS\_HOME/profiles/profile\_name/etc/tam/  
amwas.node\_server.pdperm.properties:*

This entry is generated by the Java Authorization Contract for Containers (JACC) provider configuration. This argument specifies the location of the file that contains information about the JACC provider of Tivoli Access Manager. Do not change this entry or the properties in the `amwas.node_server.pdperm.properties` file.

*com.tivoli.pd.as.rbpf.AmasSession.CfgURL=file:/user\_root/etc/tam/amwas.node\_server.pdperm.properties:*

This entry is generated by the Java Authorization Contract for Containers (JACC) provider configuration. It specifies the location of the file that contains information about the Tivoli Access Manager JACC provider. Do not change this entry or the properties in the `amwas.node_server.pdperm.properties` file.

*com.tivoli.pd.as.rbpf.AmasSession.LoggingURL=file:/\$WAS\_HOME/profiles/profile\_name/etc/tam/  
amwas.node\_server.pdjlog.properties:*

This entry contains the location of the logging configuration file for the JACC provider of Tivoli Access Manager. The referenced file is generated by the JACC provider of Tivoli Access Manager configuration. Do not change this entry.

*com.tivoli.pd.as.rbpf.AmasSession.LoggingURL=file:/user\_root/etc/tam/  
amwas.node\_server.pdjlog.properties:*

This entry contains the location of the logging configuration file for the Tivoli Access Manager JACC provider. The file referenced is generated by the Tivoli Access Manager JACC provider configuration. Do not change this entry.

### ***Administering security users and roles with Tivoli Access Manager:***

Use these steps to manage user-to-role mappings and user-to-group mappings for applications.

#### **About this task**

User-to-role mapping and user-to-group mapping for the JACC provider of Tivoli Access Manager are performed using the WebSphere Application Server administrative console.

#### **Procedure**

1. Click **Applications > Enterprise applications > *application\_name***.
2. Under Additional properties, click **Security role to user/group mapping**. The user and groups management screen is displayed.
3. Select the role that requires user or group management and use **Lookup users** or **Lookup groups** to manage the users or groups for the selected role. The native role mapping uses the `MapRolesToUsers` administrative task. If you are using Tivoli Access Manager, use the `TAMMapRolesToUsers` administrative task instead. The syntax and options for the Tivoli version are the same as those used in the native version. For more information, see “Role-based security with embedded Tivoli Access Manager” on page 1790 and “Configuring Tivoli Access Manager groups.”

### ***Configuring Tivoli Access Manager groups:***

Use these steps to configure the WebSphere Application Server administrative console to add objects of the `accessGroup` class to the list of object classes that represent user registry groups.

## About this task

You can use the WebSphere Application Server administrative console to specify security policies for applications that run in the WebSphere Application Server environment. You can also use the WebSphere Application Server administrative console to specify security policies for other web resources, based on the entities that are stored in the user registry.

Tivoli Access Manager adds the `accessGroup` object class to the registry. Tivoli Access Manager administrators can use the `pdadmin` utility, which is available only on the policy server host in the PD.RTE fileset, to create new groups. These new groups are added to the registry as the `accessGroup` object class.

The WebSphere Application Server administrative console is not configured by default to recognize objects of the `accessGroup` class as user registry groups. You can configure the WebSphere Application Server administrative console to add this object class to the list of object classes that represent user registry groups. To do this configuration, complete the following instructions:

### Procedure

1. From the WebSphere Application Server administrative console, access the advanced settings for configuring security by clicking **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
4. Modify the **Group Filter** field. Add the following entry: `(objectclass=accessGroup)`  
The Group Filter field looks like the following example:

```
(&(cn=%w)(|(objectclass=groupOfNames)
(objectclass=groupOfUniqueNames)(objectclass=accessGroup)))
```

5. Modify the **Group Member ID Map** field. Add the following entry: `accessGroup:member`. The Group Member ID Map field looks like the following example:

```
groupOfNames:member;groupOfUniqueNames:uniqueMember;
accessGroup:member
```

6. Stop and restart WebSphere Application Server.

### **Configuring additional authorization servers for Tivoli Access Manager:**

Tivoli Access Manager secure domains can contain more than one authorization server. Having multiple authorization servers is useful for providing a failover capability as well as improving performance when the volume of access requests is large.

### Procedure

1. Refer to the *Tivoli Access Manager Base Administration Guide* for details on installing and configuring authorization servers. This document is available in the IBM Tivoli Access Manager for e-business information center.
2. Re-configure the Java Authorization Contract for Containers (JACC) provider using the `$AdminTask reconfigureTAM interactive wsadmin` command. Enter all new and existing options. The following table lists the information that you are asked to provide for the `reconfigureTAM` command. The table also lists the properties that apply to the `configureTAM` and `unconfigureTAM` commands.

Table 138. Commands for configuring, reconfiguring, and unconfiguring Tivoli Access Manager. The following table lists the information that you are asked to provide for the `configureTAM` command. The table also lists the properties that apply to the `unconfigureTAM` and `reconfigureTAM` commands.

Property	Default	Relevant command	Description
WebSphere Application Server node name	*	<ul style="list-style-type: none"> <li>configureTAM</li> <li>reconfigureTAM</li> <li>unconfigureTAM</li> </ul>	Specify a single node or enter an asterisk (*) to run the configuration task on all of the application server instances including the deployment manager, node agents, and servers.
Tivoli Access Manager Policy Server	Default port: 7135	<ul style="list-style-type: none"> <li>configureTAM</li> <li>reconfigureTAM</li> </ul>	Enter the name of the Tivoli Access Manager policy server and the connection port. Use the format, <code>policy_server : port</code> . The policy server communication port is set at the time of Tivoli Access Manager configuration.
Tivoli Access Manager Authorization Server	Default port: 7136	<ul style="list-style-type: none"> <li>configureTAM</li> <li>reconfigureTAM</li> </ul>	Enter the name, port, and priority of each configured Tivoli Access Manager authorization server. Use the format <code>auth_server : port : priority</code> . The authorization server communication port is set at the time of Tivoli Access Manager configuration. You can specify more than one authorization server by separating the entries with commas. Having more than one authorization server configured is useful for failover and performance. The priority value is the order of authorization server use. For example: <code>auth_server1:7136:1,auth_server2:7137:2</code> . A priority of 1 is still required when you use a single authorization server.
WebSphere Application Server administrator's distinguished name		<ul style="list-style-type: none"> <li>configureTAM</li> <li>reconfigureTAM</li> </ul>	Enter the full distinguished name of the security primary administrator ID for WebSphere Application Server as created in the "Creating the security administrative user" topic in the <i>Securing applications and their environment</i> PDF. For example: <code>cn=wasadmin,o=organization,c=country</code>
Tivoli Access Manager user registry distinguished name suffix		<ul style="list-style-type: none"> <li>configureTAM</li> <li>reconfigureTAM</li> </ul>	Enter the suffix that you have set up in the user registry to contain the user and groups for Tivoli Access Manager. For example: <code>o=organization,c=country</code>
Tivoli Access Manager administrator's user name	sec_master	<ul style="list-style-type: none"> <li>configureTAM</li> <li>reconfigureTAM</li> <li>unconfigureTAM</li> </ul>	Enter the Tivoli Access Manager administration user ID that you created when you configured Tivoli Access Manager. This ID is usually <code>sec_master</code> .
Tivoli Access Manager administrator's user password		<ul style="list-style-type: none"> <li>configureTAM</li> <li>reconfigureTAM</li> <li>unconfigureTAM</li> </ul>	Enter the password that is associated with the Tivoli Access Manager administration user ID.
Tivoli Access Manager security domain	Default	<ul style="list-style-type: none"> <li>configureTAM</li> <li>reconfigureTAM</li> </ul>	Enter the name of the Tivoli Access Manager security domain that is used to store users and groups. If a security domain is not already established at the time of Tivoli Access Manager configuration, click <b>Return</b> to accept the default.
Embedded Tivoli Access Manager listening port set	8900:8999	<ul style="list-style-type: none"> <li>configureTAM</li> <li>reconfigureTAM</li> </ul>	WebSphere Application Server needs to listen on a TCP/IP port for authorization database updates from the policy server. More than one process can run on a particular node and machine so a list of ports is required for the processes. Enter the ports that are used as listening ports by Tivoli Access Manager clients, separated by a comma. If you specify a range of ports, separate the lower and higher values by a colon. For example, <code>7999, 9990:9999</code> .
Defer	No	<ul style="list-style-type: none"> <li>configureTAM</li> <li>reconfigureTAM</li> <li>unconfigureTAM</li> </ul>	Set this option to <i>yes</i> if you want to defer the configuration of the management server until the next restart. Set the option to <i>no</i> if you want the configuration of the management server to occur immediately. Managed servers are configured on their next restart.
Force	No	<ul style="list-style-type: none"> <li>reconfigureTAM</li> <li>unconfigureTAM</li> </ul>	Set this value to <i>yes</i> if you want to ignore errors during the unconfiguration process and allow the entire process to complete. Set the value to <i>no</i> if you want errors to stop the unconfiguration process. This option is especially useful if the environment needs to be cleaned up and problems are occurring that do not allow the entire cleanup process to complete successfully.

### Logging Tivoli Access Manager security:

Use this topic to enable the trace specification to indicate tracing at the required level.

### About this task

The Java Authorization Contract for Containers (JACC) for Tivoli Access Manager provider messages are logged to the configured trace output location, and messages are written to standard out `SystemOut.log` file. When trace is enabled, all logging, both trace and messaging, is sent to the `trace.log` file.

**Note:** These messages are sent to CTRACE. CTRACE can write them to a CTRACE dataset, memory buffer, and/or the SYSPRINT data set for the region's started task.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log`, `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using

HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

## Procedure

1. The `amwas.node_server.pdjlog.properties` file must be updated and the **isLogging** attribute set to `true` for the required component. For example, to enable tracing for the JACC provider for Tivoli Access Manager, set the following line to `true`:  
`amwas.node_server.pdjlog.properties:baseGroup.AMWASWebTraceLogger.isLogging=true`
2. Enable tracing for the JACC provider of Tivoli Access Manager components in the WebSphere Application Server administrative console by completing the following steps:
  - a. Click **Troubleshooting > Logs and Trace > server\_name**.
  - b. Under Logs and Trace tasks, click **Diagnostic trace**.
  - c. Select the **Enable Log** option.
  - d. Click **Apply**.
  - e. Click **Troubleshooting > Logs and Trace > server\_name**.
  - f. Click **Change Log Detail Levels**.
  - g. Click **Components**. Tracing for all components can be enabled using the **com.tivoli.pd.as.\*** command. Tracing for separate components can be enabled using the following commands:
    - **com.tivoli.pd.as.rbpf.\*** for role-based policy framework tracing
    - **com.tivoli.pd.as.jacc.\*** for JACC provider tracing
    - **com.tivoli.pd.as.pdwas.\*** for the authorization table
    - **com.tivoli.pd.as.cfg.\*** for configuration
    - **com.tivoli.pd.as.cache.\*** for cachingFor more information, see `../ae/utrb_loglevel.dita`.
  - h. Click **Apply**.

## What to do next

The trace specification now indicates that tracing is enabled at the required level. Save the configuration and restart the server for the changes to take effect.

### *Tivoli Access Manager loggers:*

The Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager uses the JLog logging framework as does the Java runtime environment for Tivoli Access Manager. You can enable tracing and messaging selectively for specific JACC providers for Tivoli Access Manager components.

The JACC for Tivoli Access Manager provider messages are logged to the configured trace output location, and messages are written to standard out `SystemOut.log` file. When trace is enabled, all logging, both trace and messaging, is sent to the `trace.log` file.

**Note:** These messages are sent to CTRACE. CTRACE can write them to a CTRACE dataset, memory buffer, and/or the SYSPRINT data set for the region's started task.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log`, `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Tracing and message logging for the JACC provider for Tivoli Access Manager are configured in the `amwas.node_server.pdjlog.properties` properties file, which is located in the `profile_root/etc/tam` directory. This file contains logging properties from the `amwas.pdjlog.template.properties` template file for the specific node and server combination at the time of JACC provider for Tivoli Access Manager configuration.

The contents of this file let the user control:

- Whether tracing is enabled or disabled for the JACC provider of Tivoli Access Manager components.
- Whether message logging is enabled or disabled for the JACC provider of Tivoli Access Manager components.

The `amwas.node_server.pdjlog.properties` file defines several loggers, each of which is associated with one JACC provider of Tivoli Access Manager component. These loggers include:

*Table 139. Tivoli Access Manager loggers. This table describes the Tivoli Access Manager loggers.*

Logger Name	Description
AmasRBPFTraceLogger AmasRBPFFMessageLogger	Logs messages and trace for the role-based policy framework. This underlying framework is used by embedded Tivoli Access Manager to make access decisions.
AmasCacheTraceLogger AmasCacheMessageLogger	Logs messages and trace for the policy caches that are used by the role-based policy framework.
AMWASWebTraceLogger AMWASWebMessageLogger	Logs messages and trace for the WebSphere Application Server authorization plug-in.
AMWASConfigTraceLogger AMWASConfigMessageLogger	Logs messages and trace for the configuration actions of the JACC provider for Tivoli Access Manager .
JACCTraceLogger JACCMessageLogger	Logs messages and trace for the JACC provider activity of Tivoli Access Manager .

**Note:** Tracing can have a significant impact on system performance. Enable tracing only when diagnosing the cause of a problem.

The implementation of these loggers routes messages to the WebSphere Application Server logging sub-system. All messages are written to the WebSphere Application Server `trace.log` file.

For each logger, the `amwas.node_server.pdjlog.properties` file defines an `isLogging` attribute which, when set to `true`, enables logging for the specific component. A value of `false` disables logging for that component.

The `amwas.node_server.pdjlog.properties` file defines the parent loggers `MessageLogger` and `TraceLogger` that also have an `isLogging` attribute. If the child loggers do not specify this `isLogging` attribute, they inherit the value of their respective parent. When the JACC provider for Tivoli Access Manager is enabled, the `isLogging` attribute is set to `true` for the `MessageLogger` and set to `false` for the `TraceLogger` logger. Message logging is enabled for all components and tracing is disabled for all components, by default.

To turn on tracing for a JACC provider component, see [Logging Tivoli Access Manager security](#).

### **Interfaces that support JACC:**

WebSphere Application Server provides the `RoleConfigurationFactory` and the `RoleConfiguration` interfaces, which are similar to `PolicyConfigurationFactory` and `PolicyConfiguration` interfaces so the information that is stored in the bindings file can be propagated to the provider during installation. The implementation of these interfaces is optional.

### **RoleConfiguration interface**

Use the `RoleConfiguration` interface to propagate the authorization information to the provider. This interface is similar to the `PolicyConfiguration` interface that is found in Java Authorization Contact for Containers (JACC).

```

RoleConfiguration
 - com.ibm.wsspi.security.authorization.RoleConfiguration

/**
 * This interface is used to propagate the authorization table information
 * in the binding file during application installation. Implementation of this interface is
 * optional. When a JACC provider implements this interface during an application, both
 * the policy and the authorization table information are propagated to the provider.
 * If this is not implemented, only the policy information is propagated as per
 * the JACC specification.
 * @ibm-spi
 * @ibm-support-class-A1
 */

public interface RoleConfiguration

/**
 * Add the users to the role in RoleConfiguration.
 * The role is created, if it does not exist in RoleConfiguration.
 * @param role the role name.
 * @param users the list of the user names.
 * @exception RoleConfigurationException if the users cannot be added.
 */
public void addUsersToRole(String role, List users)
throws RoleConfigurationException

/**

throws RoleConfigurationException

/**
 * Add the all authenticated users to the role in RoleConfiguration.
 * The role is created if it does not exist in RoleConfiguration.
 * @param role the role name.
 * @exception RoleConfigurationException if the authentication users cannot
 * be added.
 */
public void addAuthenticatedUsersToRole(String role)
throws RoleConfigurationException

/**
 * Remove the all authenticated users to the role in RoleConfiguration.
 * @param role the role name.
 * @exception RoleConfigurationException if the authentication users cannot
 * be removed.
 */
public void removeAuthenticatedUsersFromRole(String role)
throws RoleConfigurationException

/**
 * This commits the changes in Roleconfiguration.
 * @exception RoleConfigurationException if the changes cannot be

```

```

* committed.
*/
public void commit()
throws RoleConfigurationException

/**
* This deletes the RoleConfiguration from the RoleConfiguration Factory.
* @exception RoleConfigurationException if the RoleConfiguration cannot
* be deleted.
*/
public void delete()
throws RoleConfigurationException

/**
* This returns the contextID of the RoleConfiguration.
* @exception RoleConfigurationException if the contextID cannot be
* obtained.
*/
public String getContextID()
throws RoleConfigurationException

```

## RoleConfigurationFactory interface

The RoleConfigurationFactory interface is similar to the PolicyConfigurationFactory interface that is introduced by JACC, and is used to obtain RoleConfiguration objects based on the contextID IDs.

```

RoleConfigurationFactory
- com.ibm.wsspi.security.authorization.RoleConfigurationFactory

/**
* This interface is used to instantiate the com.ibm.wsspi.security.authorization.RoleConfiguration
* objects based on the context identifier similar to the policy context identifier.
* Implementation of this interface is required only if the RoleConfiguration interface is implemented.
*
* @ibm-spi
* @ibm-support-class-A1
*/

public interface RoleConfigurationFactory
/**
* This gets a RoleConfiguration with contextID from the
* RoleConfigurationFactory. If the RoleConfiguration does not exist
* for the contextID in the RoleConfigurationFactory, a new
* RoleConfiguration with contextID is created in the
* RoleConfigurationFactory. The contextID is similar to
* PolicyContextID, but it does not contain the module name.
* If remove is true, the old RoleConfiguration is removed and a new
* RoleConfiguration is created, and returns with the contextID.
* @return the RoleConfiguration object for this contextID
* @param contextID the context ID of RoleConfiguration
* @param remove true or false
* @exception RoleConfigurationException if RoleConfiguration
* cannot be obtained.
**/
public abstract com.ibm.ws.security.policy.RoleConfiguration
 getRoleConfiguration(String contextID, boolean remove)
 throws RoleConfigurationException

```

## InitializeJACCProvider provider

When implemented by the provider, this interface is called by every process where the JACC provider can be used for authorization. All additional properties that are entered during the authorization check are passed to the provider. For example, the provider can use this information to initialize client code to communicate with their server or repository. The cleanup method is called during server shutdown to clean up the configuration.

## Declaration

```
public interface InitializeJACCProvider
```

## Description

This interface has two methods. The JACC provider can implement the interface, and WebSphere Application Server calls it to initialize the JACC provider. The name of the implementation class is obtained from the value of the initializeJACCProviderClassName system property.

This class must reside in a Java archive (JAR) file on the class path of each server that uses this provider.

```
InitializeJACCProvider
- com.ibm.wsspi.security.authorization.InitializeJACCProvider

/**
 * Initializes the JACC provider
 * @return 0 for success.
 * @param props the custom properties that are included for this provider will
 * pass to the implementation class.
 * @exception Exception for any problems encountered.
 */
public int initialize(java.util.Properties props)
throws Exception

/**
 * This method is for the JACC provider cleanup and will be called during a process stop.
 */
public void cleanup()
```

### **Enabling the JACC provider for Tivoli Access Manager:**

The Java Authorization Contract for Container (JACC) provider for Tivoli Access Manager is configured by default. Use this topic to enable the JACC provider for Tivoli Access Manager.

### **About this task**

**Restriction:** Do not perform this task if you are configuring the JACC provider for Tivoli Access Manager to supply authentication services only. Only perform this task for installations that require both Tivoli Access Manager authentication and authorization protection.

The JACC provider for Tivoli Access Manager is configured by default. To enable the JACC provider for Tivoli Access Manager, complete the following steps:

### **Procedure**

1. Click **Security > Global security > External authorization providers**.
2. Select the **External authorization using a JACC provider** option, then click **Apply**.
3. Under Related Items, click **External JACC provider**. The JACC provider settings for Tivoli Access Manager are displayed.
4. Verify that the correct settings are present to work with your Tivoli Access Manager configuration. The following list shows the JACC provider configuration settings for Tivoli Access Manager.

*Table 140. JACC provider configuration settings for Tivoli Access Manager. This table describes the JACC provider configuration settings for Tivoli Access Manager.*

Field	Value
<b>Name</b>	Tivoli Access Manager
<b>Description</b>	This field is optional and used as a reference.
<b>J2EE policy class name</b>	com.tivoli.pd.as.jacc.TAMPolicy
<b>Policy configuration factory class name</b>	com.tivoli.pd.as.jacc.TAMPolicyConfigurationFactory
<b>Role configuration factory class name</b>	com.tivoli.pd.as.jacc.TAMRoleConfigurationFactory
<b>JACC provider initialization class name</b>	com.tivoli.pd.as.jacc.cfg.TAMConfigInitialize
<b>Requires the EJB arguments policy context handler for access decisions</b>	false
<b>Supports dynamic module updates</b>	true

For more information, see “External Java Authorization Contract for Containers provider settings” on page 1819.

5. Under Additional properties, click **Tivoli Access Manager properties** and set the properties that are associated with the embedded Tivoli Access Manager. The following table explains the properties that are needed for the embedded Tivoli Access Manager. Some fields do not have default values.

Table 141. Tivoli Access Manger properties. This table lists the Tivoli Access Manger properties.

Name	Default value	Description
<b>Enable embedded Tivoli Access Manager</b>	Unchecked	When you select this check box, the embedded Tivoli Access Manager is configured or reconfigured. When you clear this check box, the embedded Tivoli Access Manager is unconfigured.
<b>Ignore errors during embedded Tivoli Access Manager disablement</b>	Unchecked	If you check this check box and click <b>OK</b> or <b>Apply</b> , when you unconfigure the embedded Tivoli Access Manager, any unconfiguration errors are ignored and the process completes. If you do not check this check box, unconfiguration errors cause the unconfiguration process to stop.
<b>Client listening port</b>	8900:8999	When the embedded Tivoli Access Manager is configured and running, it requires several ports to listen for updates to the access control list database for Tivoli Access Manager. The value in this field is a range of port numbers that Tivoli Access Manager can use for this purpose. The first 20% of this range is reserved for the deployment manager. You can enter multiple ranges or individual port numbers in a line separated list. For example:  8900:8999 9100:9200 9999
<b>Policy server</b>		This field value specifies the name and port number of the configure and running Tivoli Access Manager policy server. The format is server:port  For example:snapper.ibm.com:7135
<b>Authorization servers</b>		This field contains the names, port numbers, and priorities of all of the configured and running Tivoli Access Manager authorization servers. This field must contain at least one authorization server. If multiple authorization servers are listed, those servers are used for failover. The server with priority 1 is used first with failover to server priority 2 and so on. The format is server:port:priority with each authorization server listed on a different line. For example:  snapper.ibm.com:7136:1 turtle.ibm.com:7136:2
<b>Authorization user name</b>	sec_master	This field value specifies the administrative user name for Tivoli Access Manager.
<b>Administrator user password</b>		This field value specifies the password for Tivoli Access Manager.
<b>User registry distinguished name suffix</b>		This field value is the suffix that is set up in the user registry to contain the users and groups for Tivoli Access Manager. For example using IBM Tivoli Directory Server:  o=ibm,c=au
<b>Security domain</b>	Default	This field value specifies the configured security domain to use for the embedded Tivoli Access Manager.
<b>Administrator user distinguished name</b>		This field specifies the fully distinguished user name of the primary administrative user for WebSphere Application Server security. For example using IBM Tivoli Directory Server:  cn=wasadmin,o=ibm,c=au

For more information, see “Tivoli Access Manager JACC provider settings” on page 1826.

6. Click **OK**.
7. Save the settings by clicking **Save** at the top of the page.
8. Log out of the WebSphere Application Server administrative console.
9. Restart WebSphere Application Server. The security configuration is now replicated to managed servers and node agents. These other servers within a cell also require restarting before the security changes take effect.

### **Enabling embedded Tivoli Access Manager:**

Embedded Tivoli Access Manager is not enabled by default, and you need to configure it for use.

### **About this task**

Enabling Tivoli Access Manager security within WebSphere Application Server requires:

- A supported Lightweight Directory Access Protocol (LDAP) installed somewhere on your network. This user registry contains the user and group information for both Tivoli Access Manager and WebSphere Application Server.
- Tivoli Access Manager server exists and is configured to use the user registry. For details on the installation and configuration of Tivoli Access Manager, refer to the IBM Tivoli Access Manager for e-business information center.

**Note:** WebSphere Application Server contains an embedded client for Tivoli Access Manager. To use Tivoli Access Manager, you must also configure the Tivoli Access Manager server.

However, the server version must be the same version or later as the client version. For information on the supported version of Tivoli Access Manager, see WebSphere Application Server - Supported Prerequisites.

Tivoli Access Manager server is bundled with WebSphere Application Server.

- WebSphere Application Server is installed either in a single server model or as WebSphere Application Server, Network Deployment.
- When administrative security is configured with a Federal Information Processing Standard (FIPS) provider, the Tivoli Access Manager server must be configured for FIPS as well

Complete the following steps to enable embedded Tivoli Access Manager security:

#### **Procedure**

1. Create the security administrative user.  
For more information, see the *Securing applications and their environment* PDF.
2. Configure the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager .  
For more information, see the *Securing applications and their environment* PDF.
3. Enable WebSphere Application Server security. When you are using Tivoli Access Manager you must configure LDAP as the user registry.  
For more information, see the *Securing applications and their environment* PDF.
4. Enable the JACC provider for Tivoli Access Manager.  
For more information, see the *Securing applications and their environment* PDF.

#### ***TAMConfig command group for the AdminTask object:***

You can use the Jython or Jacl scripting languages to configure embedded IBM Tivoli Access Manager with the wsadmin tool. The commands and parameters in the TAMConfig group can be used to configure or unconfigure Tivoli Access Manager.

The TAMConfig command group for the AdminTask object includes the following commands:

- “configureTAM” on page 1842
- “listTAMSettings” on page 1842
- “modifyTAM” on page 1842
- “reconfigureTAM” on page 1843
- “unconfigureTAM” on page 1844
- “configureTAMTAI” on page 1844
- “unconfigureTAMTAI” on page 1846
- “configureTAMTAIProperties” on page 1847
- “unconfigureTAMTAIProperties” on page 1849
- “configureTAMTAIPdjrte” on page 1850
- “unconfigureTAMTAIPdjrte” on page 1851

## **configureTAM**

Use the configureTAM command to manually configure the Tivoli Access Manager.

Target object

None.

Required parameters

None.

Optional parameters

None.

Examples

### **Interactive mode example usage:**

- Using Jacl:

```
$AdminTask configureTAM {-interactive}
```

- Using Jython:

```
AdminTask.configureTAM('-interactive')
```

## **listTAMSettings**

The listSSLRepertoires command displays the current embedded Tivoli Access Manager configuration settings.

Target object

None.

Required parameters

None.

Optional parameters

None.

Examples

### **Interactive mode example usage:**

- Using Jacl:

```
$AdminTask listTAMSettings {-interactive}
```

- Using Jython:

```
print AdminTask.listTAMSettings('-interactive')
```

## **modifyTAM**

The modifyTAM command modifies embedded Tivoli Access Manager configuration settings.

Target object

None.

Required parameters

**-adminPasswd**

Specifies the Tivoli Access Manager administrator password. (String, required)

Optional parameters

**-adminUid**

Specifies the Tivoli Access Manager user name. (String, optional)

**-nodeName**

Specifies the target node or nodes. Set the value as the \* asterisk character to specify all nodes. (String, optional)

Examples

**Interactive mode example usage:**

- Using Jacl:

```
$AdminTask modifyTAM {-adminPasswd my11password}
```

- Using Jython:

```
AdminTask.modifyTAM('-adminPasswd my11password')
```

- Using Jython list:

```
AdminTask.modifyTAM(['-adminPasswd', 'my11password'])
```

**Interactive mode example usage:**

- Using Jacl:

```
$AdminTask modifyTAM {-interactive}
```

- Using Jython:

```
AdminTask.modifyTAM('-interactive')
```

**reconfigureTAM**

The reconfigureTAM command reconfigures the Java Authorization Contract for Containers (JACC) Tivoli Access Manager settings.

Target object

None.

Required parameters

None.

Optional parameters

None.

Examples

**Interactive mode example usage:**

- Using Jacl:

```
$AdminTask reconfigureTAM {-interactive}
```

- Using Jython:

```
AdminTask.reconfigureTAM('-interactive')
```

## unconfigureTAM

The unconfigureTAM command removes configuration data for the Java Authorization Contract for Containers (JACC) Tivoli Access Manager.

Required parameters

None.

Optional parameters

None.

Examples

### Interactive mode example usage:

- Using Jacl:

```
$AdminTask unconfigureTAM {-interactive}
```

- Using Jython:

```
AdminTask.unconfigureTAM('-interactive')
```

## configureTAMTAI

The configureTAMTAI command configures the embedded Tivoli Access Manager trust association interceptor (TAI) with classname TAMTrustAsociationInterceptorPlus.

Target object

None.

Required parameters

### -policySvr

This property specifies the name of the Tivoli Access Manager policy server with which the application server communicates. The server is specified by a fully-qualified host name, the SSL port number, and the rank. The default SSL port number is 7135. For example: myauth.mycompany.com:7135:1.

### -authSvrs

This property specifies the name of the Tivoli Access Manager authorization server with which the application server communicates. The server is specified by a fully-qualified host name, the SSL port number, and the rank. The default SSL port number is 7136. For example: myauth.mycompany.com:7136:1. You can specify multiple servers if the entries are separated by a comma (,).

### -adminPasswd

This property specifies the password of the Tivoli Access Manager administrator user that is associated with the -adminUid parameter. The password restrictions depend upon the password policy for your Tivoli Access Manager configuration.

### -loginId

The WebSEAL trusted user as created in "Creating a trusted user account in Tivoli Access Manager". See the Configuring single sign-on using trust association interceptor ++ article for more information. The format of the username is the short name representation.

Optional parameters

### -adminUid

This property specifies the Tivoli Access Manager administrator name. If this option is not specified,

sec\_master is the default. A valid administrative ID is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the administrative ID.

For example, for U.S. English, the valid characters are the letters a-Z, the numbers 0-9, a period (.), an underscore (\_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (\*). The minimum and maximum lengths of the administrative ID, if there are limits, are imposed by the underlying registry.

#### **-secDomain**

This property specifies the Tivoli Access Manager domain name to which the administrator is authenticated. This domain must exist and an administrator ID and password must be valid for this domain. The application server is specified in this domain. If the application server is not specified, the default value is Default. The local domain value is retrieved from the configuration file.

A valid domain name is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the domain name.

For example, for U.S. English, the valid characters for domain names are the letters a-Z, the numbers 0-9, a period (.), an underscore (\_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (\*). The minimum and maximum lengths of the domain name, if there are limits, are imposed by the underlying registry.

#### **-checkViaHeader**

You can configure TAI so that the via header can be ignored when validating trust for a request. Set this property to false if none of the hosts in the via header need to be trusted. When set to false, you do not need to set the trusted host names and host ports properties. The only mandatory property to check when the via header is false is com.ibm.websphere.security.webseal.loginId. The default value of the check via header property is false. When using Tivoli Access Manager plug-in for web servers, set this property to false.

**Note:** The via header is part of the standard HTTP header that records the server names that the request passed through.

#### **-id**

This property specifies a comma-separated list of headers that exists in the request. If all of the configured headers do not exist in the request, trust cannot be established. The default value for the ID property is iv-creds. Any other values set in WebSphere Application Server are added to the list along with iv-creds, separated by commas.

#### **-hostnames**

Do not set this property if you are using the Tivoli Access Manager plug-in for web servers. This property specifies the host names (case-sensitive) that are both trusted and expected in the request header. Requests arriving from unlisted hosts might not be trusted. If the checkViaHeader property is not set, or is set to false, then the trusted host names property has no influence. If the checkViaHeader property is set to true, and the trusted host names property is not set, the TAI initialization fails.

#### **-ports**

Do not set this property if you are using the Tivoli Access Manager plug-in for web servers. This property is a comma-separated list of trusted host ports. Requests that arrive from unlisted ports might not be trusted. If the checkViaHeader property is not set, or is set to false, then this property has no influence. If the checkViaHeader property is set to true, and the trusted host ports property is not set in WebSphere Application Server, the TAI initialization fails.

#### **-viaDepth**

This property indicates a positive integer that specifies the number of source hosts in the via header to check for trust. By default, every host in the via header is checked, and if any host is not trusted, trust cannot be established. The viaDepth property is used when only some of the hosts in the via header have to be trusted. The setting indicates the number of hosts that are required to be trusted.

For example, consider the following header:

If in via: HTTP/1.1 webseal1:7002, 1.1 webseal2:7001 If the viaDepth property is not set, is set to 2 or is set to 0, and a request with the previous via header is received then both webseal1:7002 and webseal2:7001 need to be trusted. The following configuration then applies:

```
com.ibm.websphere.security.webseal.hostnames = webseal1,webseal2
```

If in com.ibm.websphere.security.webseal.ports = 7002,7001 If the viaDepth property is set to 1, and the previous request is received, then only the last host in the via header needs to be trusted. The following configuration then applies:

```
com.ibm.websphere.security.webseal.hostnames = webseal2
com.ibm.websphere.security.webseal.ports = 7001
```

The viaDepth property is set to 0 by default, which means that all of the hosts in the via header are checked for trust.

#### **-ssoPwdExpiry**

After trust is established for a request, the single sign-on user password is cached, eliminating the need to have the TAI re-authenticate the single sign-on user with Tivoli Access Manager for every request. You can modify the cache timeout period by setting the single sign-on password expiry property to the required time in seconds. If the password expiry property is set to 0, the cached password never expires. The default value for the password expiry property is 600.

#### **-ignoreProxy**

This property can be used to tell the TAI to ignore proxies as trusted hosts. If set to true the comments field of the hosts entry in the via header is checked to determine if a host is a proxy. Remember that not all proxies insert comments in the via header indicating that they are proxies. The default value of the ignoreProxy property is false. If the checkViaHeader property is set to false, then the ignoreProxy property has no influence in establishing trust.

#### **-configURL**

For the TAI to establish trust for a request, it requires that the SvrSslCfg task be run for the Java Virtual Machine on the Application Server and result in the creation of a properties file. If this properties file is not at the default URL, which is file://java.home/PdPerm.properties, the correct URL of the properties file must be set in the configuration URL property. If this property is not set, and the SvrSslCfg-generated properties file is not in the default location, the TAI initialization fails. The default value for the config URL property is file://\${WAS\_INSTALL\_ROOT}/java/jre/PdPerm.properties.

#### **-defer**

This property indicates whether the Tivoli Access Manager configuration portion of this task should be run immediately or deferred until the startup of the WebSphere Application Server. The default value is no.

**Note:** The TAI properties are updated immediately regardless of this setting.

### Examples

#### **Interactive mode example usage:**

- Using Jacl:

```
$AdminTask configureTAMTAI {-interactive}
```

- Using Jython:

```
AdminTask.configureTAMTAI('-interactive')
```

#### **unconfigureTAMTAI**

The unconfigureTAMTAI command unconfigures the embedded Tivoli Access Manager Trust Association Interceptor with classname TAMTrustAsociationInterceptorPlus. This task does not include removing any custom properties from the security configuration.

Target object

None.

Required parameters

**-adminPasswd**

Specifies the password of the Tivoli Access Manager administrator user that is associated with the -adminUid parameter. The password restrictions depend upon the password policy for your Tivoli Access Manager configuration.

Optional parameters

**-adminUid**

Specifies the Tivoli Access Manager administrator name. If this option is not specified, sec\_master is the default. A valid administrative ID is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the administrative ID.

For example, for U.S. English the valid characters are the letters a-Z, the numbers 0-9, a period (.), an underscore (\_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (\*). The minimum and maximum lengths of the administrative ID, if there are limits, are imposed by the underlying registry.

**-force**

Indicates whether or not this task should stop when an error is encountered. The default value is no.

**-defer**

Indicates whether this task should be run immediately or deferred until the startup of the WebSphere Application Server. The default value is no.

Examples

**Interactive mode example usage:**

- Using Jacl:

```
$AdminTask unconfigureTAMTAI {-interactive}
```

- Using Jython:

```
AdminTask.unconfigureTAMTAI('-interactive')
```

**configureTAMTAIProperties**

The configureTAMTAIProperties command adds the custom properties to the security configuration for the embedded Tivoli Access Manager Trust Association Interceptor with classname TAMTrustAsociationInterceptorPlus.

Target object

None.

Required parameters

**-loginId**

The WebSEAL trusted user is created as discussed in "Creating a trusted user account in Tivoli Access Manager". See the Configuring single sign-on using trust association interceptor ++ article for more information. The format of the username is the short name representation.

Optional parameters

### **-checkViaHeader**

You can configure TAI so that the via header can be ignored when validating trust for a request. Set this property to false if none of the hosts in the via header need to be trusted. When set to false you do not need to set the trusted host names and host ports properties. The only mandatory property to check when via header is false is com.ibm.websphere.security.webseal.loginId. The default value of the check via header property is false. When using Tivoli Access Manager plug-in for web servers, set this property to false.

**Note:** The via header is part of the standard HTTP header that records the server names that the request passed through.

### **-id**

This property indicates a comma-separated list of headers that exists in the request. If all of the configured headers do not exist in the request, trust cannot be established. The default value for the ID property is iv-creds. Any other values set in WebSphere Application Server are added to the list along with iv-creds, separated by commas.

### **-hostnames**

Do not set this property if using Tivoli Access Manager plug-in for web servers. The property specifies the host names (case-sensitive) that are both trusted and expected in the request header. Requests arriving from unlisted hosts might not be trusted. If the checkViaHeader property is not set, or is set to false, then the trusted host names property has no influence. If the checkViaHeader property is set to true, and the trusted host names property is not set, the TAI initialization fails.

### **-ports**

Do not set this property if you are using the Tivoli Access Manager plug-in for web servers. This property is a comma-separated list of trusted host ports. Requests that arrive from unlisted ports might not be trusted. If the checkViaHeader property is not set, or is set to false, then this property has no influence. If the checkViaHeader property is set to true, and the trusted host ports property is not set in WebSphere Application Server, the TAI initialization fails.

### **-viaDepth**

This property indicates a positive integer that specifies the number of source hosts in the via header to check for trust. By default, every host in the via header is checked, and if any host is not trusted, trust cannot be established. The viaDepth property is used only when some of the hosts in the via header have to be trusted. The setting indicates the number of hosts that are required to be trusted.

As an example, consider the following header:

If in via: HTTP/1.1 webseal1:7002, 1.1 webseal2:7001If the viaDepth property is not set, is set to 2 or is set to 0, and a request with the previous via header is received then both webseal1:7002 and webseal2:7001 need to be trusted. The following configuration then applies:

```
com.ibm.websphere.security.webseal.hostnames = webseal1,webseal2
```

If in com.ibm.websphere.security.webseal.ports = 7002,7001If the viaDepth property is set to 1, and the previous request is received, then only the last host in the via header needs to be trusted. The following configuration then applies:

```
com.ibm.websphere.security.webseal.hostnames = webseal2
com.ibm.websphere.security.webseal.ports = 7001
```

The viaDepth property is set to 0 by default, which means that all of the hosts in the via header are checked for trust.

### **-ssoPwdExpiry**

This property can be used to tell the TAI to ignore proxies as trusted hosts. If set to true, the comments field of the hosts entry in the via header is checked to determine if a host is a proxy. Remember that not all proxies insert comments in the via header indicating that they are proxies. The default value of the ignoreProxy property is false. If the checkViaHeader property is set to false, then the ignoreProxy property has no influence in establishing trust

### **-viaDepth**

This property indicates a positive integer that specifies the number of source hosts in the via header to check for trust. By default, every host in the via header is checked, and if any host is not trusted, trust cannot be established. The viaDepth property is used only when some of the hosts in the via header have to be trusted. The setting indicates the number of hosts that are required to be trusted.

### **-ssoPwdExpiry**

After trust is established for a request, the single sign-on user password is cached, eliminating the need to have the TAI re-authenticate the single sign-on user with Tivoli Access Manager for every request. You can modify the cache timeout period by setting the single sign-on password expiry property to the required time in seconds. If the password expiry property is set to 0, the cached password never expires. The default value for the password expiry property is 600.

### **-ignoreProxy**

This property can be used to tell the TAI to ignore proxies as trusted hosts. If set to true, the comments field of the hosts entry in the via header is checked to determine if a host is a proxy. Remember that not all proxies insert comments in the via header indicating that they are proxies. The default value of the ignoreProxy property is false. If the checkViaHeader property is set to false, then the ignoreProxy property has no influence in establishing trust.

### **-configURL**

For the TAI to establish trust for a request, it requires that the SvrSslCfg task be run for the Java Virtual Machine on the Application Server and result in the creation of a properties file. If this properties file is not at the default URL, which is `file://java.home/PdPerm.properties`, the correct URL of the properties file must be set in the configuration URL property. If this property is not set, and the SvrSslCfg-generated properties file is not in the default location, the TAI initialization fails. The default value for the config URL property is `file://{WAS_INSTALL_ROOT}/java/jre/PdPerm.properties`.

## Examples

### **Interactive mode example usage:**

- Using Jacl:

```
$AdminTask configureTAMTAIProperties {-interactive}
```

- Using Jython:

```
AdminTask.configureTAMTAIProperties('-interactive')
```

### **unconfigureTAMTAIProperties**

The `unconfigureTAMTAIProperties` command removes the custom properties from the security configuration for the embedded Tivoli Access Manager Trust Association Interceptor with classname `TAMTrustAsociationInterceptorPlus`.

#### Target object

None.

#### Required parameters

None.

#### Optional parameters

None.

#### Examples

## Interactive mode example usage:

- Using Jacl:

```
$AdminTask unconfigureTAMTAIProperties {-interactive}
```

- Using Jython:

```
AdminTask.unconfigureTAMTAIProperties('-interactive')
```

## configureTAMTAIPdjrte

The configureTAMTAIPdjrte command performs the tasks necessary to fully configure the Tivoli Access Manager Runtime for Java. The specific tasks run are PDJrteCfg and SvrSslCfg.

### Target object

None.

### Required parameters

#### -policySvr

This property specifies the name of the Tivoli Access Manager policy server with which the application server communicates. The server is specified by fully qualified host name, the SSL port number, and the rank. The default SSL port number is 7135. For example: myauth.mycompany.com:7135:1.

#### -authSvrs

This property specifies the name of the Tivoli Access Manager authorization server with which the application server communicates. The server is specified by fully-qualified host name, the SSL port number, and the rank. The default SSL port number is 7136. For example: myauth.mycompany.com:7136:1. You can specify multiple servers if the entries are separated by a comma (,).

#### -adminPasswd

This property specifies the password of the Tivoli Access Manager administrator user that is associated with the -adminUid parameter. The password restrictions depend upon the password policy for your Tivoli Access Manager configuration.

### Optional parameters

#### -adminUid

This property specifies the Tivoli Access Manager administrator name. If this option is not specified, sec\_master is the default. A valid administrative ID is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the administrative ID.

For example, for U.S. English, the valid characters are the letters a-Z, the numbers 0-9, a period (.), an underscore (\_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (\*). The minimum and maximum lengths of the administrative ID, if there are limits, are imposed by the underlying registry.

#### -secDomain

This property specifies the Tivoli Access Manager domain name to which the administrator is authenticated. This domain must exist and an administrator ID and password must be valid for this domain. The application server is specified in this domain.

If this property is not specified, the default value is Default. The local domain value is retrieved from the configuration file.

A valid domain name is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the domain name.

For example, for U.S. English, the valid characters for domain names are the letters a-Z, the numbers 0-9, a period ( . ), an underscore ( \_ ), a plus sign ( + ), a hyphen ( - ), an at sign ( @ ), an ampersand ( & ), and an asterisk ( \* ). The minimum and maximum lengths of the domain name, if there are limits, are imposed by the underlying registry.

**-defer**

This property indicates whether this task should be run immediately or deferred until the startup of the WebSphere Application Server. The default value is no.

Examples

**Interactive mode example usage:**

- Using Jacl:

```
$AdminTask configureTAMTAIPdjrte {-interactive}
```

- Using Jython:

```
AdminTask.configureTAMTAIPdjrte('-interactive')
```

**unconfigureTAMTAIPdjrte**

The unconfigureTAMTAIPdjrte command performs the tasks necessary to unconfigure the Tivoli Access Manager Runtime for Java. The specific tasks run are PDJrteCfg and SvrSslCfg.

Target object

None.

Required parameters

**-adminPasswd**

This property specifies the password of the Tivoli Access Manager administrator user that is associated with the -adminUid parameter. The password restrictions depend upon the password policy for your Tivoli Access Manager configuration.

Optional parameters

**-adminUid**

This property specifies the Tivoli Access Manager administrator name. If this option is not specified, sec\_master is the default. A valid administrative ID is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the administrative ID.

**-force**

This property indicates whether or not this task should stop when an error is encountered. The default value is no.

**-defer**

This property indicates whether this task should be run immediately or deferred until the startup of the WebSphere Application Server. The default value is no.

Examples

**Interactive mode example usage:**

- Using Jacl:

```
$AdminTask unconfigureTAMTAIPdjrte {-interactive}
```

- Using Jython:

```
AdminTask.unconfigureTAMTAIPdjrte('-interactive')
```

***Disabling embedded Tivoli Access Manager client using the administrative console:***

To unconfigure the JACC provider for Tivoli Access Manager, you can use the WebSphere Application Server administrative console.

### About this task

Ensure that all the managed servers, including node agents, are started. Perform the following process once on the deployment management server. Information from the unconfigure operation is forwarded to managed servers, including node agents, when the server is restarted. The managed servers require their own restart for changes to take effect.

**Note:** It is also possible to unconfigure using the wsadmin command line utility. For details on unconfiguring the embedded Tivoli Access Manager client using the wsadmin command line utility, refer to the information about disabling embedded Tivoli Access Manager client using wsadmin.

### Procedure

1. Restart the deployment manager process.
2. Click **Security > Global security > External authorization providers**.
3. Make sure that the default option, **Default authorization**, is checked, then click **OK**.
4. On the Global security panel, click **External authorization > External JACC provider**.
5. Under Additional properties, click **Tivoli Access Manager Properties**. The configuration screen for the JACC provider for Tivoli Access Manager is displayed.
6. Clear the **Enable embedded Tivoli Access Manager** option. If you want to ignore errors when unconfiguring, select the **Ignore errors during embedded Tivoli Access Manager disablement** option. Select this option only when the Tivoli Access Manager domain is in an irreparable state.
7. Click **OK**.
8. Optional: If you want security enabled without Tivoli Access Manager re-enable administrative security.
9. Optional: Synchronize all nodes.
10. Restart all WebSphere Application Server instances for the changes to take effect.

### ***Forcing the unconfiguration of the Tivoli Access Manager JACC provider:***

If you find you cannot restart WebSphere Application Server after configuring the JACC provider for Tivoli Access Manager a utility is available to clear the security configuration and return WebSphere Application Server to an operable state.

### About this task

The utility removes all of the PDLoginModuleWrapper entries as well as the Tivoli Access Manager authorization table from security.xml and wsjaas.conf files. This utility effectively removes the JACC provider for Tivoli Access Manager.

### Procedure

1. Back up the security.xml and wsjaas.conf files.
2. Enter the following command as one continuous line.

```
app_server_root/java/jre/bin/java
-classpath "app_server_root /$WAS_HOME/plugin/com.ibm.ws.runtime_1.0.0.jar"
com.tivoli.pd.as.jacc.cfg.CleanSecXML
fully_qualified_path/security.xml fully_qualified_path/wsjaas.conf
```

### ***Propagating security policies and roles for previously deployed applications:***

Use this task to propagate security policies and roles to the external Java Authorization Contract for Containers (JACC) provider.

## Before you begin

The external JACC provider must be configured before following these steps.

## About this task

After switching to use the external JACC provider you can follow these steps to avoid having to redeploy your existing applications. Updating using these steps retrieves the security policy and roles from the deployed applications and propagates it to the external JACC provider removing the need for the applications to be redeployed.

## Procedure

1. From the WebSphere Application Server administrative console, click **Security > Global security > External authorization providers**.
2. Select the appropriate security policy and role updating option.
  - Select **Don't update provider** to not propagate any security policies or roles
  - Select **Update with all applications** to propagate security policies and roles for all applications
  - Select **Update with application names listed** to propagate security policies and roles for the selected applications. If multiple applications should be updated, separate the application names with commas.
3. Click **Apply**.

## Results

After completing this task your security policies and roles have been successfully propagated to the external JACC provider.

## Authorizing access to administrative roles

You can assign users and groups to administrative roles to identify users who can perform WebSphere Application Server administrative functions.

## Before you begin

Administrative roles enable you to control access to WebSphere Application Server administrative functions. Refer to the descriptions of these roles in “Administrative roles” on page 1780.

- **Using System Authorization Facility (SAF) authorization to control access to administrative roles:** When the `com.ibm.security.SAF.authorization` is set to `true`, SAF EJBROLE profiles are used to control access to administrative roles. See “System Authorization Facility for role-based authorization” on page 1800 for more information.
- If you select **Use a z/OS security product** during profile creation in the z/OS Profile Management Tool, and you additionally specify a value for the SAF profile prefix (previously referred to as the z/OS security domain), the following administrative roles are defined by the customization jobs. The SAF profile prefix can be specified during profile creation, and the `configGroup` represents the WebSphere Application Server configuration group name that you chose.

```
RDEFINE EJBROLE (optionalSAFProfilePrefix.)administrator UACC(NONE)
RDEFINE EJBROLE (optionalSAFProfilePrefix.)monitor UACC(NONE)
RDEFINE EJBROLE (optionalSAFProfilePrefix.)configurator UACC(NONE)
RDEFINE EJBROLE (optionalSAFProfilePrefix.)operator UACC(NONE)
RDEFINE EJBROLE (optionalSAFProfilePrefix.)auditor UACC(NONE)
```

```
PERMIT (optionalSAFProfilePrefix.)administrator CLASS(EJBROLE) ID(configGroup) ACCESS(READ)
PERMIT (optionalSAFProfilePrefix.)monitor CLASS(EJBROLE) ID(configGroup) ACCESS(READ)
PERMIT (optionalSAFProfilePrefix.)configurator CLASS(EJBROLE) ID(configGroup) ACCESS(READ)
PERMIT (optionalSAFProfilePrefix.)operator CLASS(EJBROLE) ID(configGroup) ACCESS(READ)
PERMIT (optionalSAFProfilePrefix.)auditor CLASS(EJBROLE) ID(configGroup) ACCESS(READ)
```

- If you decide at a later date to turn on SAF authorization, you must issue these Resource Access Control Facility (RACF) commands to enable proper WebSphere Application Server operation. You can give a user access to all administrative functions by connecting to the configuration group:

```
CONNECT mvsid GROUP(configGroup)
```

- You can also assign individual users to specific roles by issuing the following RACF command:

```
PERMIT (optionalSAFProfilePrefix.)rolename CLASS(EJBROLE) ID(mvsid) ACCESS(READ)
```

- You do not need to restart the server for SAF EJBROLE changes to take effect. However, after the SAF changes are made, you must issue the following RACF command, (or the equivalent for your security system), to refresh the security tables:

```
SETOPTS RACLIST(EJBROLE) REFRESH
```

- **Using WebSphere Authorization to control access to administrative roles:** When `com.ibm.security.SAF.authorization` is set to `false`, WebSphere Application Server authorization and the administrative console are used to control access to administrative roles.

## Procedure

1. Click **Users and Groups**. Click either **Administrative User Roles** or **Administrative Group Roles**.
2. To add a user or a group, click **Add** on the Console users or Console groups panel.
3. To add a new administrator user, follow the instructions on the page to specify a user, and select the **Administrator** role. Once the user is added to the Mapped to role list, click **OK**. The specified user is mapped to the security role.
4. To add a new administrative group, follow the instructions on the page to specify either a group name or a Special subject, highlight the **Administrator** role, and click **OK**. The specified group or special subject is mapped to the security role.
5. To remove a user or group assignment, click **Remove** on the Console Users or the Console Groups panel. On the Console Users or the Console Groups panel, select the check box of the user or group to remove and click **OK**.
6. To manage the set of users or groups to display, click **Show filter function** on the User Roles or Group Roles panel. In the **Search term(s)** box, type a value, then click **Go**. For example, `user*` displays only users with the user prefix.
7. After the modifications are complete, click **Save** to save the mappings.
8. Restart the application server for changes to take effect.

## Administrative user roles settings and CORBA naming service user settings

Use the Administrative User Roles page to give users specific authority to administer application servers through tools such as the administrative console or `wsadmin` scripting. The authority requirements are only effective when global security is enabled. Use the Common Object Request Broker Architecture (CORBA) naming service users settings page to manage CORBA naming service users settings.

To view the Console Users administrative console page, complete either of the following steps:

- Click **Security > Global security > Administrative User Roles**.
- Click **Users and Groups > Administrative User Roles**.

**Note:** If you are using local OS, the SIB administrative security panel's searches can use both the "?" and "\*" search characters. However, if you switch to federated repositories, the searches will not work with the "?" character but will with the "\*" character.

To view the CORBA naming service groups administrative console page, click **Environment > Naming > CORBA Naming Service Groups**.

**Note:** When a third-party authorization such as Tivoli Access Manager or System Authorization Facility (SAF) for z/OS is used, the information in this panel might not represent the data in the provider. Also, any changes to this panel might not be reflected in the provider automatically. Follow the provider's instructions to propagate any changes made here to the provider.

Click **Refresh All** to automatically update the node agent and all of the nodes when a new user is created with the Administrator or Admin Security Manager role. When you click **Refresh All**, you do not need to manually restart the node agent under an existing Administrator before the new user is recognized with one of these roles. This button automatically invokes the AuthorizationManager refreshAll MBean method. To invoke this method manually, read about Fine-grained administrative security in heterogeneous and single-server environments.

**User (Administrative user roles):**

Specifies users.

The users that are entered must exist in the configured active user registry.

**Data type:** String

**User (CORBA naming service users):**

Specifies CORBA naming service users.

The users that are entered must exist in the configured active user registry.

**Data type:** String

**Role (Administrative user roles):**

Specifies user roles.

The following administrative roles provide different degrees of authority that are needed to perform certain application server administrative functions:

**Administrator**

The administrator role has operator permissions, configurator permissions, and the permission that is required to access sensitive data including server password, Lightweight Third Party Authentication (LTPA) password and keys, and so on.

**Operator**

The operator role has monitor permissions and can change the run-time state. For example, the operator can start or stop services.

**Configurator**

The configurator role has monitor permissions and can change the WebSphere Application Server configuration.

**Deployer**

The deployer role can complete both configuration actions and run-time operations on applications.

**Monitor**

The monitor role has the least permissions. This role primarily confines the user to viewing the application server configuration and current state.

**adminsecuritymanager**

The adminsecuritymanager role has privileges for managing users and groups from within the administrative console and determines who has access to modify users and groups using administrative role mapping. Only the adminsecuritymanager role can map users and groups to administrative roles, and by default, AdminId is granted to the adminsecuritymanager.

**iscadmins**

The iscadmins role has administrator privileges for managing users and groups from within the administrative console only.

**Note:** To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

**Data type:** String  
**Range:** Administrator, Operator, Configurator, Deployer, Monitor, and iscadmins

**Note:** Other arbitrary administrative roles might also be visible in the administrative console collection table. Other contributors to the console might create these additional roles, which can be used for applications that are deployed to the console.

### ***Role (CORBA naming service users):***

Specifies naming service user roles.

A number of naming roles are defined to provide degrees of authority that are needed to perform certain application server naming service functions. The authorization policy is only enforced when global security is enabled. The following roles are valid: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete.

The roles now have authority levels from low to high:

#### **CosNamingRead**

You can query the application server name space by using, for example, the Java Naming and Directory Interface (JNDI) lookup method. The EVERYONE special-subject is the default policy for this role.

#### **CosNamingWrite**

You can perform write operations such as JNDI bind, rebind, or unbind, plus CosNamingRead operations.

#### **CosNamingCreate**

You can create new objects in the name space through operations such as JNDI createSubcontext and CosNamingWrite operations.

#### **CosNamingDelete**

You can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations.

**Data type:** String  
**Range:** CosNamingRead, CosNamingWrite, CosNamingCreate and CosNamingDelete

### ***Login status (Administrative user roles):***

Specifies whether the user is active or inactive.

## **Administrative group roles and CORBA naming service groups**

Use the Administrative Group Roles page to give groups specific authority to administer application servers through tools such as the administrative console or wsadmin scripting. The authority requirements are only effective when administrative security is enabled. Use the Common Object Request Broker Architecture (CORBA) naming service groups page to manage CORBA Naming Service groups settings.

To view the Console Groups administrative console page, complete either of the following steps:

- Click **Security > Global security > Administrative Group Roles**.
- Click **Users and Groups > Administrative Group Roles**.

To view the CORBA naming service groups administrative console page, click **Environment > Naming > CORBA Naming Service Groups**.

Click **Refresh All** to automatically update the node agent and all of the nodes when a new user is created with the Administrator or Admin Security Manager role. When you click **Refresh All**, you do not need to manually restart the node agent under an existing Administrator before the new user is recognized with one of these roles. This button automatically invokes the AuthorizationManager refreshAll MBean method. To invoke this method manually, read about Fine-grained administrative security in heterogeneous and single-server environments.

**Group (CORBA naming service groups):**

Identifies CORBA naming service groups.

In previous releases of WebSphere Application Server, there were two default groups: ALL AUTHENTICATED and EVERYONE. However, EVERYONE is now the only default group, and it provides CosNamingRead privileges only.

**Data type:** String  
**Range:** EVERYONE

**Role (CORBA naming service groups):**

Identifies naming service group roles.

A number of naming roles are defined to provide the degrees of authority that are needed to perform certain application server naming service functions. The authorization policy is only enforced when global security is enabled.

Four name space security roles are available: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete. The roles have authority levels from low to high:

**Cos Naming Read**

You can query the application server name space using, for example, the Java Naming and Directory Interface (JNDI) lookup method. The EVERYONE special-subject is the default policy for this role.

**Cos Naming Write**

You can perform write operations such as JNDI bind, rebind, or unbind, and CosNamingRead operations. The ALL\_AUTHENTICATED special-subject is the default policy for this role.

**Cos Naming Create**

You can create new objects in the name space through operations such as JNDI createSubcontext and CosNamingWrite operations. The ALL\_AUTHENTICATED special-subject is the default policy for this role.

**Cos Naming Delete**

You can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations. The ALL\_AUTHENTICATED special-subject is the default policy for this role.

**Data type:** String  
**Range:** CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete

**Group (Administrative group roles):**

Specifies groups.

The ALL\_AUTHENTICATED and the EVERYONE groups can have the following role privileges: Administrator, Configurator, Operator, and Monitor.

**Data type:** String  
**Range:** ALL\_AUTHENTICATED, EVERYONE

### **Role (Administrative group roles):**

Specifies user roles.

The following administrative roles provide different degrees of authority needed to perform certain application server administrative functions:

#### **Administrator**

The administrator role has operator permissions, configurator permissions, and the permission that is required to access sensitive data, including server password, Lightweight Third Party Authentication (LTPA) password and keys, and so on.

#### **Operator**

The operator role has monitor permissions and can change the run-time state. For example, the operator can start or stop services.

#### **Configurator**

The configurator role has monitor permissions and can change the application server configuration.

#### **Deployer**

The deployer role can perform both configuration actions and runtime operations on applications.

#### **Monitor**

The monitor role has the least permissions. This role primarily confines the user to viewing the application server configuration and current state.

#### **iscadmins**

The iscadmins role has administrator privileges for managing users and groups from within the administrative console only.

**Note:** To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

#### **Auditor**

The auditor can view and modify the configuration settings for the security auditing subsystem. The auditor role includes the monitor role.

**Data type:** String  
**Range:** Administrator, Operator, Configurator, Monitor, Deployer and iscadmins

**Note:** Other arbitrary administrative roles might also be visible in the administrative console collection table. Other contributors to the console might create these additional roles, which can be used for applications that are deployed to the console.

## **Assigning users to naming roles**

Use this task to assign users to naming roles by using the administrative console.

### **About this task**

The following steps are needed to assign users to naming roles. In the administrative console, click **Environment > Naming**, and click **CORBA Naming Service Users** or **CORBA Naming Service Groups**.

### **Procedure**

1. Click **Add** on the CORBA Naming Service Users or the CORBA Naming Service Groups panel.

2. To add a new naming service user, follow the instructions on the page to specify a user, and select one or more roles. Once the user is added to the "Mapped to role" list, click **OK**. The specified user is mapped to one or more security roles.
3. To add a new naming service group, follow the instructions on the page to specify either a group name or a Special subject, highlight one or more roles, and click **OK**. The specified group or special subject are mapped to one or more the security roles
4. To remove a user or group assignment, go to the **CORBA Naming Service Users** or **CORBA Naming Service Groups** panel. Select the check box next to the user or group that you want to remove and click **Remove**.
5. To manage the set of users or groups to display, expand the **Filter** folder on the right panel, and modify the filter text box. For example, setting the filter to user\* displays only users with the user prefix.
6. After modifications are complete, click **Save** to save the mappings. Restart the server for the changes to take effect.

## Example

The default naming security policy is to grant all users read access to the CosNaming space and to grant any valid user the privilege to modify the contents of the CosNaming space. You can perform the previously mentioned steps to restrict user access to the CosNaming space. However, use caution when changing the naming security policy. Unless a Java Platform, Enterprise Edition (Java EE) application has clearly specified its naming space access requirements, changing the default policy can result in unexpected org.omg.CORBA.NO\_PERMISSION exceptions at runtime.

## Propagating administrative role changes to Tivoli Access Manager

These steps provide an example of how to migrate the admin-authz.xml file.

### About this task

Additions and changes to console users and groups are not automatically added to the Tivoli Access Manager object space after the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager is configured. Changes to console users and groups are saved in the admin-authz.xml file and this file must be migrated before any changes take effect. The JACC provider for Tivoli Access Manager includes the **migrateEAR** migration utility for incorporating console user and group changes into the Tivoli Access Manager object space.

**Note:** The **migrateEAR** utility is used to migrate the changes made to console users and groups after the JACC provider for Tivoli Access Manager is configured. The utility does not need to run for changes and additions to console users and groups made prior to the configuration of the JACC provider for Tivoli Access Manager because the changes made to the admin-authz.xml and naming-authz.xml files are automatically migrated at configuration time. Furthermore, the migration tool does not need to run before deploying standard Java Platform, Enterprise Edition (Java EE) applications; Java EE application policy deployment is also performed automatically.

For example, if you wanted to migrate the admin-authz.xml file, perform the following steps:

### Procedure

1. Set up the environment.  
Before running the migrateEAR utility, set up the environment by running the setupCmdLine.bat or setupCmdLine.sh file that is located in the *app\_server\_root/bin* directory.  
Make sure that the *WAS\_HOME* environment variable is set to the WebSphere Application Server installation directory.
2. Change to the *app\_server\_root/bin* directory where the migrateEAR utility is located.

3. Run the **migrateEAR** utility to migrate the data contained in the `admin-authz.xml` file. Use the parameter descriptions that are listed in “migrateEAR utility for Tivoli Access Manager.”

A status message is displayed when the migration completes. Output of the utility is logged to the `pdwas_migrate.log` file, which is created in the directory where the utility is run. Check the log file after each migration. If the log file displays errors, check the last recorded transaction, correct the source of the error, and rerun the migration utility. If the migration is unsuccessful, verify that you supplied the correct values for the `-c` and `-j` options.

4. WebSphere Application Server does not require a restart for the changes to take effect.

## migrateEAR utility for Tivoli Access Manager

The **migrateEAR** utility migrates changes made to console users and groups in the `admin-authz.xml` and `naming-authz.xml` files into the Tivoli Access Manager object space.

### Syntax

```
migrateEAR
-j fully_qualified_filename
-c pdPerm.properties_file_location
-a Tivoli_Access_Manager_administrator_ID
-p Tivoli_Access_Manager_administrator_password
-w WebSphere_Application_Server_administrator_user_name
-d user_registry_domain_suffix
[-r root_objectspace_name]
[-t ssl_timeout]
[-z role_mapping_location]
```

### Parameters

#### **-a** *Tivoli\_Access\_Manager\_administrator\_ID*

The administrative user identifier. The administrative user must have the privileges required to create users, objects, and access control lists (ACLs). For example, `-a sec_master`.

This parameter is optional. When the parameter is not specified, you are prompted to supply it at run time.

#### **-c** *PdPerm.properties\_file\_location*

The Uniform Resource Indicator (URI) location of the `PdPerm.properties` file that is configured by the `pdwascfg` utility. When WebSphere Application Server is installed in the default location, the URI is:

```
file:profile_root/etc/pd/PdPerm.properties
```

#### **-d** *user\_registry\_domain\_suffix*

The domain suffix for the user registry to use. For example, for Lightweight Directory Access Protocol (LDAP) user registries, this value is the domain suffix, such as: `"o=ibm,c=us"`

You can use the **pdadmin user show** command to display the distinguished name (DN) for a user.

#### **-j** *fully\_qualified\_pathname*

The fully qualified path and file name of the Java 2 Platform, Enterprise Edition application archive file `,admin-authz.xml` or the roles definitions file `naming-authz.xml` that is used for a naming operation authorization. Optionally, this path can also be a directory of an expanded enterprise application. For example, when WebSphere Application Server is installed in the default location, the path to the data files to migrate includes:

```
profile_root/config/cells/cell_name
```

#### **-p** *Tivoli\_Access\_Manager\_administrator\_password*

The password for the Tivoli Access Manager administrative user. The administrative user must have the privileges that are required to create users, objects, and access control lists (ACLs). For example, you can specify the password for the `-a sec_master` administrative user as `-p myPassword`.

When this parameter is not specified, the user is prompted to supply the password for the administrative user name.

**-r** *root\_objectspace\_name*

The space name of the root object. The value is the name of the root of the protected object namespace hierarchy that is created for WebSphere Application Server policy data.

The default value for the root object space is WebAppServer.

Set the Tivoli Access Manager root object space name by modifying the `amwas.amjacc.template.properties` file prior to configuring the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager for the first time. Use this option if the default object space value is not used in the configuration of the Tivoli Access Manager JACC provider for Tivoli Access Manager.

Do not change the Tivoli Access Manager object space name after the Tivoli Access Manager JACC provider is configured.

**-t** *ssl\_timeout*

The number of minutes for the Secure Sockets Layer (SSL) timeout. This parameter is used to disconnect and reconnect the SSL context between the Tivoli Access Manager authorization server and the policy server before the default connection times out.

The default is 60 minutes. The minimum value is 10 minutes. The maximum value cannot exceed the Tivoli Access Manager `ssl-v3-timeout` value. The default value for `ssl-v3-timeout` is 120 minutes.

If you are not familiar with the administration of this value, you can safely use the default value.

**-w** *WebSphere\_Application\_Server\_administrator\_user\_name*

The user name that is configured in the WebSphere Application Server security user registry field as the administrator. This value matches the account that you created or imported in “Creating the security administrative user for Tivoli Access Manager” on page 1825. Access permission for this user is needed to create or update the Tivoli Access Manager protected object space.

When the WebSphere Application Server administrative user does not already exist in the protected object space, it is created or imported. In this case, a random password is generated for the user and the account is set to `not valid`. Change this password to a known value and set the account to `valid`.

A protected object and access control list (ACL) are created. The administrative user is added to the `pdwas-admin` group with the following ACL attributes:

**T** Traverse permission

**i** Invoke permission

### **WebAppServer**

You can overwrite the action group name. The default name is `WebAppServer`. This action group name and the matching root object space can be overwritten when the migration utility is run with the **-r** option.

**-z** *role\_mapping\_location*

The location where the role mapping is to be stored when migrating administration applications. The default location is to place the role mapping in the current directory structure, such as:

```
/WebAppServer/deployedResources
```

Specifying the **-z** option adds another directory level in which to store the role mapping. For example, if you specify **-z Roles** in the `migrateEAR` utility, the role mapping is stored in the directory structure as follows:

```
/WebAppServer/deployedResources/Roles
```

## **Comments**

This utility migrates security policy information from deployment descriptors or enterprise archive files to Tivoli Access Manager for WebSphere Application Server. The script calls `com.tivoli.pdwas.migrate.Migrate` the Java class.

Before invoking the script you must run the **setupCmdLine.bat** or the **setupCmdLine.sh** commands. These files can be found in the `%WAS_HOME%/bin` directory.

The script is dependent on finding the correct environment variables for the location of prerequisite software.

The script calls Java code with the following options:

#### **-Dpdwas.lang.home**

The directory that contains the native language support libraries that are provided with the JACC provider for Tivoli Access Manager. These libraries are located in a subdirectory under the JACC provider for Tivoli Access Manager installation directory. For example: `-Dpdwas.lang.home=%PDWAS_HOME%\java\nls`

#### **-cp %CLASSPATH% com.tivoli.pdwas.migrate.Migrate**

The CLASSPATH variable must be set correctly for your Java installation.

To enable a new user access to the administrative group in WebSphere Application Server, it is recommended that the user be added to the pdwas-admin group after JACC has been enabled. You can enter the administrative primary ID (adminID) in the group. This is required when the serverID is not the same as the adminID.

The following is an example of this command:

```
pdadmin> group modify pdwas-admin add adminID
```

### **Return codes**

The utility can return the following exit status codes:

- 0** The command completed successfully.
- 1** The command failed.

### **Assigning users from a foreign realm to the admin-authz.xml**

Operating with the administrative agent and job manager topology allows more situations where you might need to add an administrative user from a different registry into your administrative authorization table (admin-authz.xml). Each administrative user that needs to be added requires the "accessID" format of the user from the remote registry. When that user finally is active in the local cell, the authorization table will already have that accessID that is required. This task demonstrates how this assignment of users is performed.

### **Procedure**

1. You need to determine the accessId for a user on the remote registry. To do this, you call the following wsadmin task and query based on a user filter. The following example illustrates a query from the registry realm "BIRKT60" with a userFilter of "localuser\*". This query returns any user from this realm that begins with "localuser". The resulting accessId is the one you need to specify in the target administrative authorization table in the following step. Connect to the sending administrative process:

```
wsadmin> $AdminTask listRegistryUsers {-securityRealmName BIRKT60 -displayAccessIds true -userFilter localuser*}
{name BIRKT60\localuser@BIRKT60}
{accessId user:BIRKT60/S-1-5-21-3033296400-14683092-2821094880-1007}
```

2. Add "localuser" to the target admin-authz.xml using the following wsadmin task. Connected to the receiving administrative process:

```
wsadmin> $AdminTask mapUsersToAdminRole {-roleName administrator -userids {localuser }
-accessids {user:BIRKT60/S-1-5-21-3033296400-14683092-2821094880-1007 } }
```

3. Save the changes.

## Results

This task updates the `admin-authz.xml` in the receiving administrative process to allow a "cross-realm authorization" to succeed. The example illustrated here was for a LocalOS registry user. Performing the same task for an LDAP `accessId` produces results that look more like a realm and distinguished name (DN).

**Note:** If you change your realm you must repeat this process with the new realm name.

## Enabling pluggable login modules to map Java EE identities to System Authorization Facility (SAF)

You need to perform several actions to enable any pluggable login modules to correctly map Java EE identities to SAF. These actions include configuring the active WebSphere Application Server user registry and configuring pluggable mapping modules.

### Before you begin

### About this task

### Procedure

- Configure the active WebSphere Application Server user registry as an Lightweight Directory Access Protocol (LDAP) registry or a Custom registry, and use System Authorization Facility (SAF) services such as:
  - System Authorization Facility (SAF) EJBROLE profiles to control WebSphere Application Server authorization. Refer to “Role-based authorization” on page 1778 for more information.
  - Enabling an application to run a WebSphere Application Server application and set the operating system (OS) identity to match the Java EE identity. This is known as application Sync to OS Thread. Refer to “Application Synch to OS Thread Allowed” on page 1309 and “When to use application Synch to OS Thread Allowed” on page 1311 for more information.
  - Using the Java EE client identity as the identity when issuing a Connection Management request for a local native connector such as CICS, Information Management System (IMS), Database 2 (DB2), or Java Messaging Service (JMS). Refer to “Java Platform, Enterprise Edition identity and an operating system thread identity” on page 1311 for more information.
  - Auditing using SMF audit. Refer to the information about using SMF type 80 to prepare for audit support.
- You must configure a pluggable mapping module followed by a WebSphere Application Server for z/OS-supplied module in appropriate system login configurations to use pluggable login modules. If a registry other than local OS is selected and no mapping is done or no valid mapping is available for a particular identity:
  - *SAF authorization is not supported:* If SAF authorization is selected and a method is protected the method fails.
  - *Application Synch to OS thread is not supported:* Requests always run using the user ID of the servant.
  - When `res-auth=container` is specified to native connectors and no alias is identified, a connection management request runs under the servant user ID.
- Pluggable login modules can be used when:
  - The WebSphere Application Server authentication mechanism specified is Simple WebSphere Authentication Mechanism (SWAM) or Lightweight Third-Party Authentication (LTPA). SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.
  - The Internet Inter-ORB protocol (IIOP) authentication protocol negotiated uses Common Secure Interoperability Version 2 (CSIV2).
  - A web request is issued.

## Fine-grained administrative security

In releases prior to WebSphere Application Server version 6.1, users granted administrative roles could administer all of the resources under the cell. WebSphere Application Server is now more fine-grained, meaning that access can be granted to each user per resource.

For example, users can be granted configurator access to a specific instance of a resource only (an application, an application server or a node). Users cannot access any other resources outside of the resources assigned to them. The administrative roles are now per resource rather than to the entire cell. However, there is a cell-wide authorization group for backward compatibility. Users assigned to administrative roles in the cell-wide authorization group can still access all of the resources within the cell.

**Note:** Nodes prior to WebSphere Application Server Version 6.1 in a mixed cell environment are filtered out of resource mapping.

To achieve this instance-based security or fine-grained security, resources that require the same privileges are placed in a group called the *administrative authorization group* or *authorization group*. Users can be granted access to the authorization group by assigning to them the required administrative role.

Fine-grained administrative security can also be used in single-server environments. Various applications in the single server can be grouped and placed in different authorization groups. Therefore, there are different authorization constraints for different applications. Note that the server itself cannot be part of any authorization group in a single-server environment.

You can assign users and groups to the adminsecuritymanager role on the cell level through wsadmin scripts and the administrative console. Using the adminsecuritymanager role, you can assign users and groups to the administrative user roles and administrative group roles.

When fine grained administrative security is used, users granted the adminsecuritymanager role can manage authorization groups. See “Administrative roles and naming service authorization” on page 1771 for detailed explanations of all administrative roles.

An administrator cannot assign users and groups to the administrative user roles and administrative group roles, including the adminsecuritymanager role. See “Administrative roles” on page 1780 for more details.

There are several administrative security commands that can be used to create authorization groups, map resources to authorization groups, and to assign users to administrative roles within the authorization groups. Following are some examples using wsadmin:

- **Create a new authorization group:**

```
$AdminTask createAuthorizationGroup {-authorizationGroupName authGroup1}
```

- **Deleting an authorization group:**

```
$AdminTask deleteAuthorizationGroup {-authorizationGroupName groupName}
```

- **Add resources to an authorization group:**

```
$AdminTask addResourceToAuthorizationGroup
{-authorizationGroupName groupName -resourceName Application=app1}
```

- **Remove resources from an authorization group:**

```
$AdminTask removeResourceFromAuthorizationGroup
{-authorizationGroupName groupName -resourceName Application=app1}
```

- **Add user IDs to roles in an authorization group:**

```
$AdminTask mapUsersToAdminRole {-authorizationGroupName groupName
-roleName administrator -userids user1}
```

- **Add group IDs to roles in an authorization group:**

```
$AdminTask mapGroupsToAdminRole {-authorizationGroupName groupName
-roleName administrator -groupids group1}
```

- **Remove user IDs from roles in an authorization group:**

```
AdminTask removeUsersFromAdminRole {-authorizationGroupName
groupName -roleName administrator -userids user1}
```

- **Remove group IDs from roles in an authorization group:**

```
$AdminTask removeGroupsFromAdminRole {-authorizationGroupName
groupName -roleName administrator -groupids group1}
```

### Resources that can be added to an authorization group

You can add only resources of the following types to an authorization group:

- Cell
- Node
- ServerCluster
- Server
- Application
- NodeGroup

If a resource is not one of the types listed above, its parent resource will be used.

A resource can only belong to one authorization group. However, there is a containment relationship among resources. If a parent resource belongs to a different authorization group than that of its child resource, the child resource implicitly will belong to multiple authorization groups. You cannot add the same resource to more than one authorization group.

The following diagram shows the containment relationship among resources:

The privileges required for actions on resources depend on two factors:

- The authorization group of the administrative resource. If a user is granted access to an authorization group, all of the resources in that group will be included.
- The containment relationship of the resource. If a user is granted access to a parent resource, all of the children resources will be included.

Keystore management requires a user to have cell-level administrative privileges because they are created and managed at the cell level. Fine-grained security access to a specific resource does not allow management of the associated keystores.

*Table 142. Privileges required to access various administrative resources. The privileges required to access various administrative resources are shown in the following table:*

Resource	Action	Required roles
Server	Start, stop, runtime operations	Server-operator, node-operator, cell-operator
Server	New, delete	Node-configurator, cell-configurator
Server	Edit configuration	Server-configurator, node-configurator, cell-configurator
Server	View configuration, runtime status	Server-monitor, node-monitor, cell-monitor
Node	Restart, stop, sync	Node-operator, Cell-operator
Node	Add, delete	Cell-configurator
Node	Edit configuration	Node-configurator, cell-configurator
Node	View configuration, runtime status	Node-monitor, cell-monitor
Cluster	Start, stop, runtime operations	Cluster-operator, cell-operator
Cluster	New, delete	Cell-configurator
Cluster	Edit configuration	Cluster-configurator, cell-configurator

Table 142. Privileges required to access various administrative resources (continued). The privileges required to access various administrative resources are shown in the following table:

Resource	Action	Required roles
Cluster	View configuration, runtime status	Cluster-monitor, cell-monitor
Cluster member	Start, stop, runtime operations	Server-operator, cluster-operator, node-operator, cell-operator
Cluster member	New, delete	Node-configurator, cell-configurator
Cluster member	Edit configuration	Server-configurator, cluster-configurator, node-configurator, cell-configurator
Cluster member	View configuration, runtime status	Server-monitor, cluster-monitor, node-monitor, cell-monitor
Application	All operations	Refer to the section "Deployer roles" in "Administrative roles" on page 1780.
Node, cluster	Add, delete	Cell-configurator

The *server-operator* role is the operator role of the authorization group to which the server instance is part of. Similarly, the *node-operator* role is in the operator role of the authorization group to which the node instance is part of.

To use fine-grained administrative security in the administrative console, a user should be granted a monitor role at the cell level at minimum. However, to login using wsadmin, a user should be granted a monitor role for any authorization group.

### Example: Using fine-grained security.

The following scenarios describe the use of fine-grained administrative security, particularly the new deployment role.

#### Deployment role scenario 1.

In the following scenario, there are four applications configured on server S1, as shown in the following table. Each application must be isolated so that the administrator of one application cannot modify another application. Assume that only user1 can manage application A1, user2 can manage applications A2 and A3, and only user3 can manage application A4.

**Note:** It is not recommended to have an application in one group and its target server in another group. However, that is not always possible. It is common to have many applications on one server. It is still sometimes necessary to isolate the administration of applications running on the same server.

One example is an Application Service Provider (ASP), where a single application server can have multiple vendor applications. In this instance the server administrator is responsible for installing all of the vendor applications. Once applications are installed, each vendor can manage their own application without interfering with other vendor's applications.

Table 143. Deployment role scenario 1 applications.

This table lists the Deployment role scenario 1 applications.

Application	Server	Node
A1	S1	N1
A2	S1	N1
A3	S1	N1
A4	S1	N1

We can configure authorization groups as shown in the diagram below:

In the diagram, application A1 is in authorization group G1, applications A2 and A3 are in authorization group G2, and application A4 is in authorization group G3.

A deployer role is assigned from authorization group G1 to user1, from authorization group G2 to user2, and from authorization group G3 to user3.

Consequently, user1 can perform all of the operations on application A1, user2 on applications A2 and A3, and user3 on application A4. Since all applications share the same server, we cannot put the same server on all authorization groups. Only a cell-level administrator can install an application. After the installation of an application is complete, the deployer of each application can modify their own. To start and stop the server, cell-level administrative authority is required. This type of scenario is useful in an ASP environment.

### Deployment role scenario 2.

In the following scenario, a group of applications require the same administrative roles to one server. In this example, applications A1 and A2 are related applications, and can be administrated by one set of administrators. They are running on the same server (S1). Applications A3 and A4 require a different set of administrators, and are running on servers S2 and S3 respectively.

*Table 144. Deployment role scenario 2 applications.*

*This table lists the Deployment role scenario 2 applications.*

Application	Server	Node
A1	S1	N1
A2	S1	N1
A3	S2	N2
A4	S3	N3

### Scenarios that can be applied directly in customer environments.

Each developer must be able to modify the configuration for their server, and they must be able to install their application onto that server. They also must be able to start and stop the server as well as the application on the server.

Developers also must be able to configure the server so that they can debug any problems they run into. They must have the ability to update or modify the application being developed. The administrative authorization group for this developer includes at least one server and any applications that the developer installs on that server.

In the following example, developers of authorization group G1 have a new application (A11). They can install and target that new application only on servers within authorization group G1. Also, they can place that new application in their authorization group (G1).

### ASP environment scenario.

In this scenario, the customer is an ASP. They have their own customers to whom they provide application serving function. They want to enable their customers to administer and monitor their applications, but not to see or administer applications for different customers. In this example, however, the ASP has internal staff administrators whose job it is to maintain the servers.

This internal ASP staff administrator might need to move an application from one server to another to ensure that an application remains available. The internal ASP staff administrator should be able to stop and start the servers and to change their configuration.

In contrast, the ASP customer administrator should not be able to stop or start servers. However, the ASP customer administrator should be able to update their applications running on those servers. The administrative authorization group for the internal ASP administrator can be the whole cell or can include a subset of servers, nodes, clusters and applications. The administrative authorization group for the customer administrator only includes those applications that the customer has paid to have served by this ASP.

When updating the configuration repository, run the admin scripts from the deployment manager so that the fine grain admin security rules will be in effect when admin scripts are run from the deployment manager side.

The following diagram contains a scenario where two different customers have two different types of applications, and can manage their own applications. However, the servers and nodes on which the applications are running are isolated from their customers. The servers and nodes can only be maintained by the internal administrators. In addition, the customers cannot target their applications on a different server. This can only be performed by the internal administrator or internal deployers.

### **Regional organization scenario.**

In this scenario, the customer is a large global company. The company's nodes and servers are organized so as to provide application serving for different regions (or alternatively, different lines of business). They want representatives from the different regional areas to be able to monitor and administer the nodes and servers associated with that region. However, they do not want the regional administrator to be able to effect any node and server associated with a different region.

The administrative authorization group for each regional representative includes the nodes, servers, clusters and applications associated with that region.

For example, consider a company that provides multiple services, such as a financial institution that provides services like credit card accounts, brokerage accounts, banking accounts, or travel accounts. Each of these services can be separate applications, and the administrator for each of these applications must also be different. The following figure shows one way to configure such a system:

The following figure shows how the resources in such a system can be grouped to isolate administrators from each other:

Note that the nodes are not part of any authorization group. Therefore, a trade application administrator cannot stop a server on any of the nodes, and is prevented from stopping a travel application.

The same system can be configured in another way as shown below:

The following figure shows how the resources in such a system can be grouped to isolate administrators from each other:

## **New Administrative Authorization Group**

Use this page to create a new administrative authorization group and to specify the associated administrative resources.

To view this administrative console page, click **Security > Administrative Authorization Groups > New**.

You must be logged into the administrative console with cell-level **AdminSecurityManager** authority, or the primary administrative ID can make these changes as well.

### ***Name:***

Use to identify the new administrative authorization group. The name should be descriptive of the group's role, or purpose, and should be unique in the cell structure. Using a non-unique name results in an error and a failure to create the new administrative authorization group. This is a required field.

### ***Resources:***

Select the resources from the Resource section to which you want the new administrative authorization group to control access.

Resources that are displayed in black text are available for selection.

Resources that are displayed in grey are already members of a different administrative authorization group. Therefore, these resources are not available for inclusion in the new administrative authorization group. When a resource is a member of a different authorization group, the name of the group displays next to the resource name. For example: server\_1 (group\_1)

The available filtering options are the following. Each option includes all the resources that are associated with that specific filtering option.

### **All scopes**

The default view that displays the authorization group tree.

### **Clusters**

All of the resources associated with the clusters.

### **Web Servers**

All of the resources associated with the web servers.

### **Business-level applications**

All of the resources associated with the business-level applications.

### **Servers**

All of the resources associated with the servers.

### **Nodes**

All of the resources associated with the nodes.

### **Applications**

All of the resources associated with the applications.

### **Assets**

All of the resources associated with the assets.

## Node Groups

All of the resources associated with the node groups.

## Assigned scopes

Displays all of the scopes explicitly assigned to the current authorization group.

## Administrative Authorization Group collection

Use this page to create, delete or to edit an existing administrative authorization group.

To view this administrative console page, click **Security > Administrative Authorization Groups**.

You must be logged into the administrative console with cell-level **AdminSecurityManager** authority, or the primary administrative ID can make these changes as well.

### **Name:**

The name field specifies the current name of the administrative authorization group. You can edit the name of the administrative authorization group during the creation process only. After the authorization group is created, you cannot modify the name. The specified name must be unique within the cell structure. Otherwise, a non-unique name results in an error.

### **New:**

Select to create a new administrative authorization group.

### **Delete:**

Select to remove an existing administrative authorization group.

**Note:** You must select an administrative authorization group before selecting **Delete**.

## System Authorization Facility for fine-grained administrative authorization

When fine-grained administrative security is used, the administrative resources are partitioned to multiple authorization groups. Each authorization group contains its own authorization table, which represents the user-to-administrator role mapping for that authorization group.

The same set of administrative roles exist for all of the authorization groups. However, users mapped to the administrative roles can differ. There are still cell level administrative roles that represent access to all of the resources within the cell.

When Resource Access Control Facility (RACF) or System Authorization Facility (SAF) is used to configure user-to-role mapping, one EJBROLE profile for each role in each authorization group must be defined, as well as the previously defined EJBROLE profiles for the cell level administrator roles. There are six profiles defined in the RACF EJBROLE class for administrative authorization. They are administrator, configurator, monitor, operator, deployer and adminsecuritymanager.

Authorization groups can be created using the WebSphere Application Server configuration tool (wsadmin). After creating an authorization group, user-to-role mapping within the authorization group can also be performed using wsadmin. However, when RACF is used to store the user-to-administrative role mapping, the RACF administrator must perform additional steps to map the user-to-role mappings. For each administrator role within the newly-created authorization group, an EJBROLE profile must be defined. Users must then be granted access to the newly-created EJBROLE profiles.

For example, if the following authorization groups and user-to-role mappings have already been created using wsadmin:

*Table 145. Authorization groups and user-to-role mappings. The table lists the Authorization groups and user-to-role mappings.*

group1	administrator=user1	configurator	operator	monitor	deployer=user3	adminsecuritymanager
group2	administrator=user2	configurator	operator=user4	monitor	deployer	adminsecuritymanager

then the following script can be used to reflect the same information in RACF:

```
/* activate EJBROLE class */
SETROPTS CLASSACT(EJBROLE)

/* Defining EJBROLE profiles for admin roles in group1 and group2 */

/* define the roles in RACF for group1 */
RDEFINE EJBROLE domainName.group1.administrator UACC(NONE)
RDEFINE EJBROLE domainName.group1.configurator UACC(NONE)
RDEFINE EJBROLE domainName.group1.operator UACC(NONE)
RDEFINE EJBROLE domainName.group1.monitor UACC(NONE)
RDEFINE EJBROLE domainName.group1.deployer UACC(NONE)
RDEFINE EJBROLE domainName.group1.adminsecuritymanager UACC(NONE)

/* define the roles in RACF for group2 */
RDEFINE EJBROLE domainName.group2.administrator UACC(NONE)
RDEFINE EJBROLE domainName.group2.configurator UACC(NONE)
RDEFINE EJBROLE domainName.group2.operator UACC(NONE)
RDEFINE EJBROLE domainName.group2.monitor UACC(NONE)
RDEFINE EJBROLE domainName.group2.deployer UACC(NONE)
RDEFINE EJBROLE domainName.group2.adminsecuritymanager UACC(NONE)

/* Mapping users to roles in group1 and group2 */

/* map user1 to administrator role in group1 */
PERMIT domainName.group1.administrator CLASS(EJBROLE) ID(USER1) ACCESS(READ)
/* map user3 to deployer role in group1 */
PERMIT domainName.group1.deployer CLASS(EJBROLE) ID(USER3) ACCESS(READ)

/* map user2 to administrator role in group2 */
PERMIT domainName.group2.administrator CLASS(EJBROLE) ID(USER2) ACCESS(READ)
/* map user4 to operator role in group2 */
PERMIT domainName.group2.operator CLASS(EJBROLE) ID(USER4) ACCESS(READ)

/* refresh the EJBROLE class in RACF */
SETROPTS RACLIST(EJBROLE) REFRESH"
```

where *domainName* represents the security domain of the WebSphere Application Server cell.

Note that the EJBROLE profile for all of the roles in each authorization group should be created regardless of whether any user is mapped to that role.

## Creating a fine-grained administrative authorization group using the administrative console

You can create a fine-grained administrative authorization group by selecting administrative resources to be part of the authorization group. You can assign users or groups to this new administrative authorization group and also give them access to the administrative resources contained within.

### Before you begin

You must be logged into the administrative console with cell-level **Admin Security Manager** authority, or the primary administrative ID can make these changes as well.

## Procedure

1. Navigate to **Security > Administrative Authorization Groups > New**.
2. Type a name for the administrative authorization group into the **Name** field. This is a required field. The name must be unique within the cell structure. If the name is not unique then the new administrative authorization group is not created at the end of this procedure.
3. Select the resources from the Resource section to which you want the new administrative authorization group to control access.

Resources that are displayed in black text are available for selection.

Resources that are displayed in grey are already members of a different administrative authorization group. Therefore, these resources are not available for inclusion in the new administrative authorization group. When a resource is a member of a different authorization group, the name of the group displays next to the resource name. For example: server\_1 (group\_1)

Your filtering options include the following:

- Nodes. (All of the resources associated with the nodes.)
  - Servers. (All of the resources associated with the servers.)
  - Web servers. (All of the resources associated with the web servers.)
  - Clusters. (All of the resources associated with the clusters.)
  - Applications. (All of the resources associated with the applications.)
  - Node groups. (All of the resources associated with the Node Groups.)
  - All scopes. (The default view that displays the authorization group tree.)
  - Assigned scopes. (Displays all of the scopes explicitly assigned to the current authorization group.)
4. Click **OK** or **Apply**.
  5. If you want to associate a user role to this new administrative authorization group, do the following:
    - a. Click **Administrative user roles** located under the Additional Properties section. The available user roles are the following:

### Administrator

An individual or group that uses the administrator role has the operator and configurator privileges plus additional privileges that are granted solely to the administrator role. For example, an administrator can complete the following tasks:

- Modify the server user ID and password.
- Configure authentication and authorization mechanisms.
- Enable or disable administrative security.
- Enable or disable Java 2 security.
- Change the Lightweight Third Party Authentication (LTPA) password and generate keys.
- Create, update, or delete users in the federated repositories configuration.
- Create, update, or delete groups in the federated repositories configuration.

**Note:** An administrator cannot map users and groups to the administrator roles.

### Configurator

An individual or group that uses the configurator role has the monitor privilege plus the ability to change the WebSphere Application Server configuration. The configurator can perform all the day-to-day configuration tasks. For example, a configurator can complete the following tasks:

- Create a resource.
- Map an application server.
- Install and uninstall an application.
- Deploy an application.

- Assign users and groups-to-role mapping for applications.
- Set up Java 2 security permissions for applications.
- Customize the Common Secure Interoperability Version 2 (CSIv2), Secure Authentication Service (SAS), and Secure Sockets Layer (SSL) configurations.

**Important:** SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

### Deployer

Users granted this role can perform both configuration actions and runtime operations on applications..

### Operator

An individual or group that uses the operator role has monitor privileges plus ability to change the runtime state. For example, an operator can complete the following tasks:

- Stop and start the server.
- Monitor the server status in the administrative console.

### Monitor

An individual or group that uses the monitor role has the least amount of privileges. A monitor can complete the following tasks:

- View the WebSphere Application Server configuration.
- View the current state of the Application Server.

### Admin Security Manager

Using the Admin Security Manager role, you can assign users and groups to the administrative user roles and administrative group roles. However, an administrator cannot assign users and groups to the administrative user roles and administrative group roles including the Admin Security Manager roles.

- b. Click **Add....** The New User page is displayed.
  - c. Select the appropriate role(s) from the **Role(s)** list box.
  - d. Select a user or users by entering text in the **Search string** field, and then click **Search..** Click the arrow to add the available user or users to the **Mapped to role** field. You can select multiple users and roles by clicking **Select All**.
  - e. Click **OK**. You are returned to the Administrative User Roles page. The new users are displayed in the Administrative User Roles table along with their appropriate roles.
  - f. Repeat steps B through E for each new user to whom you want to map a role.
6. If you want to associate a group to this new user role, do the following:
- a. Click **Administrative group roles** located under the Additional Properties section.
  - b. Click **Add....** The New Group page is displayed.
  - c. Select the appropriate role or roles from the **Role(s)** list box.
  - d. Select a user or users by entering text in the **Search string** field, and then click **Search..** Click the arrow to add the available user or users to the **Mapped to role** field. You can select multiple users and roles by clicking **Select All**.
  - e. Select either the **Select from special subjects** or **Map Groups As Specified Below** option.  
If you select the **Select from special subjects** option, you can select the EVERYONE, ALL AUTHENTICATED, or ALL AUTHENTICATED IN TRUSTED REALMS values.  
A list of user groups and roles are displayed in the **Available** and **Mapped to role** fields. Select the user groups from the **Available** field and then select the roles from the **Mapped to role** field to which you want the group or groups associated. You can select multiple groups and roles.
  - f. Click **OK**. You are returned to the Administrative Group Roles page. The new group is displayed in the Administrative Group Roles table along with the role of the new group.
  - g. Repeat steps B through E for each new group to whom you want to map a role.

7. If you want to create another administrative authorization group, click **Apply**. The current administrative authorization group is created. Repeat steps 2 through 6 to create another administrative authorization group.
8. If you do not want to create another administrative authorization group, click **OK**.

## Editing a fine-grained administrative authorization group using the administrative console

You can add or remove administrative resources to an administrative authorization group or edit an existing one.

### Before you begin

You must be logged into the administrative console with the cell-level **AdminSecurityManager** authority or as the primary administrative user.

### Procedure

1. Navigate to **Security > Administrative Authorization Groups**. The Administrative Authorization Groups page displays a table that lists all of the current administrative authorization groups available in the cell.
2. Click on the administrative authorization group in the table that you want to edit.
3. To add or remove resources from the administrative authorization group, select or clear them in the Resource section of the edit page. Resources displayed in black text are available for selection or clearing. Resources displayed in grey text are members of a different administrative authorization group and therefore cannot be edited for the current administrative authorization group.

The available filtering options are the following. Each option includes all the resources that are associated with that specific filtering option.

- All scopes. (The default view that displays the authorization group tree.)
- Clusters. (All of the resources associated with the clusters.)
- Web servers. (All of the resources associated with the Web servers.)
- Business-level applications. (All of the resources associated with the business-level applications.)
- Servers. (All of the resources associated with the servers.)
- Nodes. (All of the resources associated with the nodes.)
- Applications. (All of the resources associated with the applications.)
- Assets. (All of the resources associated with the assets.)
- Node groups. (All of the resources associated with the node groups.)
- Assigned scopes. (Displays all of the scopes explicitly assigned to the current authorization group).

Nodes prior to WebSphere Application Server Version 6.1 in a mixed cell environment are filtered out of resource mapping.

4. To remove a user or a group, do the following:
  - a. To delete users, click **Administrative user roles** under the Additional Properties section. To delete groups, click **Administrative group roles** under the Additional Properties section. The appropriate edit page displays a table that lists all of the current users or groups and their associated roles, along with the user's login status.
  - b. Click the check box beside the name of the current user or group and then click **Remove**. The current user or group is no longer associated with the role and the role is no longer listed in the table. It is now ready to have a new user or group assigned to it.
5. If you want to add or to reassign a user or group role to this administrative authorization group, do the following:

- a. To add a user, click **Administrative user roles** under the Additional Properties section. To add a group, click **Administrative group roles** located under the Additional Properties section. The appropriate edit page displays a table that lists all of the current users or groups and their associated roles. The available roles are:

### **Administrator**

An individual or group that uses the administrator role has the operator and configurator privileges plus additional privileges that are granted solely to the administrator role. For example, an administrator can complete the following tasks:

- Modify the server user ID and password.
- Configure authentication and authorization mechanisms.
- Enable or disable administrative security.
- Enable or disable Java 2 security.
- Change the Lightweight Third Party Authentication (LTPA) password and generate keys.
- Create, update, or delete users in the federated repositories configuration.
- Create, update, or delete groups in the federated repositories configuration.

**Note:** An administrator cannot map users and groups to the administrator roles.

### **Configurator**

An individual or group that uses the configurator role has the monitor privilege plus the ability to change the WebSphere Application Server configuration. The configurator can perform all the day-to-day configuration tasks. For example, a configurator can complete the following tasks:

- Create a resource.
- Map an application server.
- Install and uninstall an application.
- Deploy an application.
- Assign users and groups-to-role mapping for applications.
- Set up Java 2 security permissions for applications.
- Customize the Common Secure Interoperability Version 2 (CSIv2), Security Authentication Service (SAS), and Secure Sockets Layer (SSL) configurations.

**Important:** SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

### **Deployer**

Users granted this role can perform both configuration actions and runtime operations on applications.

### **Operator**

An individual or group that uses the operator role has monitor privileges plus ability to change the runtime state. For example, an operator can complete the following tasks:

- Stop and start the server.
- Monitor the server status in the administrative console.

.

### **Monitor**

An individual or group that uses the monitor role has the least amount of privileges. A monitor can complete the following tasks:

- View the WebSphere Application Server configuration.
- View the current state of the Application Server.

### **Admin Security Manager**

Using the Admin Security Manager role, you can assign users and groups to the administrative user roles and administrative group roles. However, an administrator cannot assign users and groups to the administrative user roles and administrative group roles including the Admin Security Manager role.

- b. Click **Add...**
- c. To add a new user or group, follow the instructions on the page to specify either a user name, group name, or Special subject. Highlight the desired role(s), and click **OK**. The specified users, groups, or Special subject are mapped to the security roles.

## **Fine-grained administrative security in heterogeneous and single-server environments**

Fine-grained administrative security can be used in heterogeneous or single-server environments with some restrictions.

### **Fine-grained administrative security in a heterogeneous environment**

In WebSphere Application Server Version 8.0, heterogeneous systems are supported. Specifically, a deployment manager node can run in WebSphere Application Server Version 8.0, some nodes can run WebSphere Application Server Version 7.0, some nodes can run WebSphere Application Server Version 6.1, and other nodes can run WebSphere Application Server Version 6.0.

Because the configurations that are done in the deployment manager node are always WebSphere Application Server Version 8.0 or higher configurations, fine-grained administrative security can be enforced when configuring resources that belong to earlier releases. However, run-time code for versions lower than Version 6.1 cannot enforce fine-grained administrative security. Therefore, any resource instance that is not part of a WebSphere Application Server Version 6.1 or higher node cannot be added to an authorization group.

Fine-grained administrative security in a heterogeneous environment has the following restrictions:

- Only nodes that are running WebSphere Application Server Version 8.0 can be part of an administrative authorization group.
- Only servers that are running in a WebSphere Application Server Version 8.0 node can be part of an administrative authorization group.
- Only applications that are targeted on servers running on WebSphere Application Server Version 8.0 can be part of an administrative authorization group.
- If a cluster spans nodes of multiple releases, it cannot be part of an administrative authorization group.
- If a cluster spans nodes of multiple releases, none of its members can be part of an administrative authorization group.
- If an application is targeted on a cluster that spans multiple releases, that application cannot be part of an administrative authorization group.

### **Fine-grained administrative security in a single-server environment**

You can also use fine-grained administrative security in a single-server environment. Various applications in the single server can be grouped and placed in different authorization groups. Therefore, different authorization constraints might exist for different applications.

### **Life cycle of fine-grained administrative resource**

An administrative resource that was once part of an authorization group continues to be part of that authorization group until one of the following events occurs:

- The administrative resource is removed from the authorization group. In this instance, the administrative resource belongs to the cell-level authorization group.
- The administrative resource is removed from the configuration. In this instance, the administrative resource does not exist in the configuration, but still exists in the authorization group. Remove this administrative resource from the authorization group.

After the administrative resource is removed from the authorization group, the administrative authorizer runtime must be notified by using the AuthorizationManager refreshAll MBean method.

The **refreshAll** command must be invoked after AdminConfig.save() and sync nodes. For example:

#### JACL:

```
// get AuthorizationGroup Mbean
wsadmin> set agBean [$AdminControl queryNames
type=AuthorizationGroupManager,process=dmgr,*]

wsadmin> $AdminControl invoke &agBean refreshAll
```

#### JYTHON:

```
// get AuthorizationGroup Mbean
wsadmin> set agBean
AdminControl.queryNames('type=AuthorizationGroupManager,process=dmgr,*')

wsadmin> AdminControl.invoke(agBean, 'refreshAll')
```

The server restart is no longer needed.

## Using SCA authorization and security identity policies

Use two Service Component Architecture (SCA) declarative policies (*authorization* and *security identity*) to protect SCA components and operations and to declare the security identity under which the SCA components or operations are executed.

### Before you begin

A user registry must be configured and an SCA component must first have been developed. You must also enable application security.

### About this task

**Note:** An authorization policy controls who can access protected SCA components and operations. A security identity policy declares the security identity under which an SCA component or operation is executed. You can limit access to an SCA component or to an operation to particular users or groups. You can also delegate access to another user when executing an SCA component or an operation.

Note the following limitations:

- SCA authorization policy is not supported for composites packaged in web application archives (WAR files).
- The definitions.xml file must be packaged in the same asset as the composites that reference its policy sets.
- Role assignments are scoped to a configuration unit, and are required for all of the roles used in all of the composites within the configuration unit. These role assignments are completely independent of any role assignments made for other configuration units in the same business-level application.
- The target namespace of the policy set and the name of the policy set do not contribute to the name of a role. They are used solely to resolve the policy set reference. This implies that within the same configuration unit, identically-named roles that are defined within different policy sets or different name spaces are treated as the same role.

- If authorization policy is not attached to a given component and operation, the operation runs unprotected.
- It is possible to create conflicts by specifying multiple policy sets in the @policySets attribute or by inheriting policy sets across elements. In this case, the following rules are used:
  - The <denyAll> element takes precedence over <permitAll>, which takes precedence over <allow>.
  - Roles from multiple <allow> elements are aggregated.
- SCA authorization policy does not support authorizing users in foreign realms.

Access to an SCA component is permitted or denied by using the following steps:

## Procedure

1. The policy administrator creates one or more policy sets in the file named definitions.xml as shown in the following example:

```
<definitions xmlns="http://www.osea.org/xmlns/sca/1.0"
 targetNamespace="http://smallvilleBank"
 xmlns:sca="http://www.osea.org/xmlns/sca/1.0">
 <policySet name="StaffAuthorizationPolicy"
 appliesTo="sca:implementation.java"
 xmlns="http://www.osea.org/xmlns/sca/1.0">
 <authorization>
 <allow roles="staff"/>
 </authorization>
 </policySet>
 <policySet name="SupervisorAuthorizationPolicy"
 appliesTo="sca:implementation.java"
 xmlns="http://www.osea.org/xmlns/sca/1.0">
 <authorization>
 <allow roles="supervisor manager specialist"/>
 </authorization>
 <securityIdentity>
 <runAs role="specialist"/>
 </securityIdentity>
 </policySet>
</definitions>
```

2. The assembler attaches the policy to the SCA composite as in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osea.org/xmlns/sca/1.0"
 xmlns:bank="http://smallvilleBank"
 name="AccountServices">
 <component name="AccountAccess">
 <implementation.java class="smallvilleBank.AccountAccessImpl"
 policySets="bank:staffAuthorizationPolicy"/>
 </component>
 <component name="AccountAudit">
 <implementation.java class="smallvilleBank.AccountAuditImpl"
 policySets="bank:supervisorAuthorizationPolicy"/>
 </component>
</composite>
```

3. The deployer assigns users and or groups to the roles that are defined in the composite.
4. The deployer assigns a user to the **runAs** roles that are defined in the composite.

## What to do next

Access to the SCA component is permitted or denied according to the authorization policy.

## Using the SCA RequestContext.getSecuritySubject() API

The Service Component Architecture (SCA) Version 1.0 Java Common Annotations and APIs Specification RequestContext.getSecuritySubject() API programming interface returns a Java Authentication and Authorization (JAAS) subject that represents an authenticated user who accesses the protected SCA service.

## Before you begin

**Note:** SCA service developers can use the RequestContext.getSecuritySubject() API to obtain a JAAS Subject that represents the requester.

If one or more of the following preconditions are not met the SCA request is not authenticated, and the `RequestContext.getSecuritySubject` API returns a null `Subject`:

- Administrative security must be enabled to initialize the security infrastructure.
- Application security must be enabled to enforce security policy and authentication.
- SCA service either has an authentication intent or a `PolicySet` that requires authentication prior to deployment.
- The SCA deployment process must associate a `PolicySet` that contains authentication policy configuration to the SCA service.

## About this task

When using the `RequestContext.getSecuritySubject()` API, perform the following steps:

### Procedure

1. Add an authentication intent or specify a `PolicySet` in the binding element of an SCA service composite file to enforce SCA request authentication, as shown in the following example. The following example uses the "authentication.transport" intent.

```
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
 xmlns:dbsdo="http://tuscany.apache.org/xmlns/sca/databinding/sdo/1.0"
 xmlns:wSDLi="http://www.w3.org/2004/08/wSDL-instance"
 xmlns:qos="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
 name="EchoServiceWithIdentityWSComposite">
 <component name="EchoServiceWithIdentityWSComponent">
 <implementation.java class="test.ws.soa.sca.qos.policy.echoRelayServiceTest.echoService.EchoServiceWithIdentityComponentImpl"/>
 <service name="EchoService">
 <binding.ws uri="EchoServiceWithIdentity"
 wsdlElement="http://echo/wSDL.port(EchoServiceWithIdentity/EchoServiceWithIdentitySoapPort)"
 requires="authentication.transport" />
 </service>
 </component>
</composite>
```

2. Specify the "WSHTTPS default" `PolicySet` in the SCA client composite file. A user name and password are configured for use in outbound requests of the "HTTP Transport" default `PolicySet` binding.

The following example utilizes the `RequestContext.getSecuritySubject` API:

```
import org.osoa.sca.annotations.Context;
import org.osoa.sca.RequestContext;
import javax.security.auth.Subject;
import java.security.Principal;
import java.util.Iterator;
import com.ibm.websphere.security.cred.WSCredential;

@Service(EchoService.class)
public class EchoServiceWithIdentityComponentImpl implements EchoService
{
 @Context
 protected RequestContext requestContext;

 public String echo_String(String input)
 {
 try {
 Subject subject = null;
 String securityName = null;

 if (requestContext != null) {
 subject = requestContext.getSecuritySubject();
 }

 if (subject != null) {
 java.util.Set principalSet = subject.getPrincipals();
 if (principalSet != null && principalSet.size() > 0) {
 Iterator principalIterator = principalSet.iterator();
 if (principalIterator.hasNext()) {
 Principal principal = (java.security.Principal) principalIterator.next();
 securityName = principal.getName();
 }
 }
 }
 }
 }
 ...
}
```

- The principal identity consists of a realm name followed by the identity of the requester as shown in the example below. WebSphere Application Server is configured to use an Lightweight Directory Access Protocol (LDAP) server for authentication. The realm name is the LDAP server host name and the port number:

```
security name = ldap1.austin.ibm.com:389/user2
```

You can obtain various security attributes of the request from the WSCredential object in the subject as shown in the following example:

```
if (subject != null) {
 java.util.Set credSet = subject.getPublicCredentials();
 if (credSet != null && credSet.size() > 0)
 {
 Iterator credIterator = credSet.iterator();
 while (credIterator.hasNext()) {
 Object o = credIterator.next();
 WSCredential cred = null;
 if (o instanceof WSCredential) {
 cred = (WSCredential) o;
 } else {
 if (securityName == null) {
 securityName = new StringBuffer();
 }
 securityName.append("\n>> Found a public credential: " + o.getClass().getName());
 }
 if (cred != null) {
 if (securityName == null) {
 securityName = new StringBuffer();
 }
 securityName.append("\n>> WSCredential security attributes . . .");
 securityName.append("\n>> getAccessId = \t\t" + cred.getAccessId());
 securityName.append("\n>> getGroupIds = \t\t" + cred.getGroupIds());
 securityName.append("\n>> getPrimaryGroupId = \t\t" + cred.getPrimaryGroupId());
 securityName.append("\n>> getRealmName = \t\t" + cred.getRealmName());
 securityName.append("\n>> getRealmSecurityName = \t\t" + cred.getRealmSecurityName());
 securityName.append("\n>> getRealmUniqueSecurityName = \t\t" + cred.getRealmUniqueSecurityName());
 securityName.append("\n>> getSecurityName = \t\t" + cred.getSecurityName());
 securityName.append("\n>> getUniqueSecurityName = \t\t" + cred.getUniqueSecurityName());
 }
 }
 }
}
```

Sample output is shown below:

```
>> WSCredential security attributes . . .
>> getAccessId = user:ldap1.austin.ibm.com:389/cn=user2,o=ibm,c=us
>> getGroupIds = [group:ldap1.austin.ibm.com:389/CN=GROUP2,O=IBM,C=US]
>> getPrimaryGroupId = group:ldap1.austin.ibm.com:389/CN=GROUP2,O=IBM,C=US
>> getRealmName = ldap1.austin.ibm.com:389
>> getRealmSecurityName = ldap1.austin.ibm.com:389/user2
>> getRealmUniqueSecurityName = ldap1.austin.ibm.com:389/cn=user2,o=ibm,c=us
>> getSecurityName = user2
>> getUniqueSecurityName = cn=user2,o=ibm,c=us
```

---

## Securing communications

WebSphere Application Server provides several methods to secure communication between a server and a client.

### About this task

**Note:** WebSphere Application Server provides several methods for securing communication between a server and a client. New in this release are functions that ensure secure communication between a server and a client. These functions focus on certificate management, authentication, and ensuring trust among the application server, administrative agent, and job manager. The new functions include:

- Creating and using a certificate authority (CA) clients to enable a CA to request, query, and revoke certificates.
- Creating and using chained personal certificates to allow a certificate to be signed with a longer life span.
- Creating and revoking certificate authority (CA) certificates to ensure secure communication between the CA client and the CA server.

- Allowing the WebSphere Application Server administrator to create, configure, and enable System Authorization Facility (SAF) keyrings by utilizing the (Open Cryptographic Services Facility) OCSF Data library functions for SAF keyrings.

The following topics are covered in this section:

## Procedure

- Secure communications using Secure Sockets Layer
- Creating an SSL configuration
- Creating a keystore configuration
- Creating a certificate authority (CA) client
- Deleting a certificate authority (CA) client
- Viewing or Modifying a certificate authority (CA) client
- Creating a keystore configuration for a preexisting keystore file
- Creating a self-signed certificate
- Creating a certificate authority request
- Creating writeable SAF keyrings
- Using writeable SAF keyrings
- Extracting a signer certificate from a personal certificate
- Retrieving signers from a remote SSL port
- Adding a signer certificate to a keystore
- Adding a signer certificate to the default signers keystore
- Exchanging signer certificates in a keystore
- Configuring certificate expiration monitoring
- Key management for cryptographic uses
- Creating a key set configuration
- Creating a key set group configuration

## Secure communications using Secure Sockets Layer (SSL)

The Secure Sockets Layer (SSL) protocol provides transport layer security including authenticity, data signing, and data encryption to ensure a secure connection between a client and server that uses WebSphere Application Server. The foundation technology for SSL is *public key cryptography*, which guarantees that when an entity encrypts data using its public key, only entities with the corresponding private key can decrypt that data.

WebSphere Application Server uses Java Secure Sockets Extension (JSSE) as the SSL implementation for secure connections. JSSE is part of the Java 2 Standard Edition (J2SE) specification and is included in the IBM implementation of the Java Runtime Extension (JRE). JSSE handles the handshake negotiation and protection capabilities that are provided by SSL to ensure secure connectivity exists across most protocols. JSSE relies on X.509 certificate-based asymmetric key pairs for secure connection protection and some data encryption. Key pairs effectively encrypt session-based secret keys that encrypt larger blocks of data. The SSL implementation manages the X.509 certificates.

## Managing X.509 certificates

Secure communications for WebSphere Application Server require digitally-signed X.509 certificates. The contents of an X.509 certificate, such as its distinguished name and expiration, are either signed by a certificate authority (CA), signed by a root certificate in **NodeDefaultRootStore** or **DmgrDefaultRootStore**, or are self-signed. When a trusted CA signs an X.509 certificate, WebSphere Application Server identifies the certificate and freely distributes it. A certificate must be signed by a CA

because the certificate represents the identity of an entity to the general public. Server-side ports that accept connections from the general public must use CA-signed certificates. Most clients or browsers already have the signer certificate that can validate the X.509 certificate so signer exchange is not necessary for a successful connection.

You can trust the identity of a self-signed X.509 certificate only within a peer in a controlled environment, such as internal network communications, accepts the signer certificate. To complete a trusted handshake, you must first send a copy of the entity certificate to every peer that connects to the entity.

CA, chained, and self-signed X.509 certificates reside in Java *keystores*. JSSE provides a reference to the keystore in which a certificate resides. You can select from many types of keystores, including Java Cryptographic Extension (JCE)-based and hardware-based keystores. Typically, each JSSE configuration has two Java keystore references: a keystore and a *truststore*. The keystore reference represents a Java keystore object that holds personal certificates. The truststore reference represents a Java keystore object that holds signer certificates.

A personal certificate without a private key is an X.509 certificate that represents the entity that owns it during a handshake. Personal certificates contain both public and private keys. A signer certificate is an X.509 certificate that represents a peer entity or itself. Signer certificates contain just the public key and verify the signature of the identity that is received during a peer-to-peer handshake.

For more information, see “Extracting a signer certificate from a personal certificate” on page 2010

For more information about keystores, see “Keystore configurations for SSL” on page 1896.

## Signer exchange

When you configure an SSL connection, you can exchange signers to establish trust in a *personal certificate* for a specific entity. Signer exchange enables you to extract the X.509 certificate from the peer keystore and add it into the truststore of another entity so that the two peer entities can connect. The signer certificate also can originate from a CA as a root signer certificate or a chained certificate's root signer certificate or an intermediate signer certificate. You can also extract a *signer certificate* directly from a self-signed certificate, which is the X.509 certificate with the public key.

Figure 1 illustrates a hypothetical keystore and truststore configuration. An SSL configuration determines which entities can connect to other entities, and the peer connections that are trusted by an SSL handshake. If you do not have the necessary signer certificate, the handshake fails because the peer cannot be trusted.

Figure 32. Signer exchange

In this example, the truststore for Entity A contains three signers. Entity A can connect to any peer as long as one of the three signers validates its personal certificate. For example, Entity A can connect to Entity B or Entity C because the signers can trust both signed personal certificates. The truststore for Entity-B contains one signer. Entity B is able to connect to Entity C only, and only when the peer endpoint is using certificate Entity-C Cert 1 as its identity. The ports that use the other personal certificate for Entity C are not trusted by Entity B. Entity C can connect to Entity A only.

In the example, the self-signed configuration seems to represent a one-to-one relationship between the signer and the certificate. However, when a CA signs a certificate, it typically signs many at a time. The advantage of using a single CA signer is that it can validate personal certificates that are generated by the CA for use by peers. However, if the signer is a public CA, you must be aware that the signed certificates might have been generated for another company other than your target entity. For your internal

communications, private CAs and self-signed certificates are preferable to public CAs because they enable you to isolate the connections that you want to occur and prevent those that you do not want to occur.

## SSL configurations

An SSL configuration comprises a set of configuration attributes that you can associate with an *endpoint* or set of endpoints in the WebSphere Application Server topology. The SSL configuration enables you to create an SSLContext object, which is the fundamental JSSE object that the server uses to obtain SSL socket factories. You can manage the following configuration attributes:

- An alias for the SSLContext object
- A handshake protocol version
- A keystore reference
- A truststore reference
- A key manager
- One or more trust managers
- A security level selection of a cipher suite grouping or a specific cipher suite list
- A certificate alias choice for client and server connections

To understand the specifics of each SSL configuration attribute, see “SSL configurations” on page 1887.

## Selecting SSL configurations

In previous releases of WebSphere Application Server, you can reference an SSL configuration only by selecting the SSL configuration alias directly. Each secure endpoint was denoted by an alias attribute that references a valid SSL configuration within a repertoire of SSL configurations. When you made a single configuration change, you had to re-configure many alias references across the various processes. Although the current release still supports direct selection, this approach is no longer recommended.

The current release provides improved capabilities for managing SSL configurations and more flexibility when you select SSL configurations. In this release, you can select from the following approaches:

### Programmatic selection

You can set an SSL configuration on the running thread prior to an outbound connection. WebSphere Application Server ensures that most system protocols, including Internet Inter-ORB Protocol (IIOP), Java Message Service (JMS), Hyper Text Transfer Protocol (HTTP), and Lightweight Directory Access Protocol (LDAP), accept the configuration. See “Programmatically specifying an outbound SSL configuration using JSSEHelper API” on page 1957

### Dynamic selection

You can associate an SSL configuration dynamically with a specific target host, port, or outbound protocol by using a predefined selection criteria. When it establishes the connection, WebSphere Application Server checks to see if the target host and port match a predefined criteria that includes the domain portion of the host. Additionally, you can predefine the protocol for a specific outbound SSL configuration and certificate alias selection. See “Dynamic outbound selection of Secure Sockets Layer configurations” on page 1899 for more information.

Dynamic outbound selection of Secure Sockets Layer configurations is based on connection information being available for the server so that the server can match up the outbound protocol, host, or port when the creation of the client socket takes place in `com.ibm.websphere.ssl.protocol.SSLSocketFactory`. For WebSphere admin connectors like SOAP and Remote Method Invocation (RMI), connection information is placed on the thread and is available for dynamic outbound selection to take place. The dynamic outbound selection process relies on connection information being setup when SSL properties are retrieved similar to what is described in “Programmatically specifying an outbound SSL configuration using JSSEHelper API” on page 1957.

When the outbound connection is being made from customer written applications, parts of the connection information may not be available. Some of these applications make API calls to a protocol to make the connection. The API ultimately then calls one of the `createSocket()` methods in `com.ibm.websphere.ssl.protocol.SSLSocketFactory` to complete the process. gotcha: All of the connection information for dynamic outbound selection might not be available, and you may have to adjust the dynamic outbound selection connection filter and fill in an asterisk (\*) for the missing part of the connection information. As an example, the `openConnection()` call on a URL object ultimately calls `createSocket(java.net.Socket socket, String host, int port, boolean autoClose)`. The connection information can be built with the host and port provided, but there is no protocol provided. In this case, a wild card, asterisk (\*), should be used for the protocol part of the dynamic selection connection information.

Most of the `createSocket()` methods take a host or IP address and a port as parameters. The dynamic outbound selection connection filter can be built with the host and port. The default method, `createSocket()`, without any parameters does not contain any information to build the outbound selection connection filter unless the socket factory was instantiated with connection information. If no connection information is available, then you should consider using one of the other methods of selecting a SSL configuration describes in this topic, "Programmatic selection" can be good choice.

### **Direct selection**

You can select an SSL configuration by using a specific alias, as in past releases. This method of selection is maintained for backwards compatibility because many applications and processes rely on alias references.

### **Scope selection**

You can associate an SSL configuration and its certificate alias, which is located in the keystore associated with that SSL configuration, with a WebSphere Application Server management scope. This approach is recommended to manage SSL configurations centrally. You can manage endpoints more efficiently because they are located in one topology view of the cell. The inheritance relationship between scopes reduces the number of SSL configuration assignments that you must set.

Each time you associate an SSL configuration with a cell scope, the node scope within the cell automatically inherits the configuration properties. However, when you assign an SSL configuration to a node, the node configuration overrides the configuration that the node inherits from the cell. Similarly, all of the application servers for a node automatically inherit the SSL configuration for that node unless you override these assignments. Unless you override a specific configuration, the topology relies on the rules of inheritance from the cell level down to the endpoint level for each application server.

**Note:** If your applications are relying on SSL configurations that were set as individual settings for each SSL configuration in the topology, but your application servers have inherited the SSL configuration as deployed from the cell level down to the endpoint level, then there is the possibility of communication errors occurring among servers (for example, handshake errors). You need to ensure that your applications are operating consistent with the central management of SSL configurations.

The topology view displays an inbound tree and outbound tree. You can make different SSL configuration selections for each side of the SSL connection based on what that server connects to as an outbound connection and what the server connects to as an inbound connection. See "Central management of SSL configurations" on page 1900 for more information.

The runtime uses an order of precedence for determining which SSL configuration to choose because you have many ways to select SSL configurations. Consider the following order of precedence when you select a configuration approach:

1. Programmatic selection. If an application sets an SSL configuration on the running thread using the `com.ibm.websphere.ssl.JSSEHelper` application programming interface (API), the SSL configuration is guaranteed the highest precedence.
2. Dynamic selection criteria for outbound host and port or protocol.
3. Direct selection.
4. Scope selection. Scope inheritance guarantees that the endpoint that you select is associated with an SSL configuration and is inherited by every scope beneath it that does not override this selection.

## Default chained certificate configuration

By default, WebSphere Application Server creates a unique chained certificate for each node. The chained certificate is signed with a root, a self-signed certificate stored in the **DmgrDefaultRootStore** or **NodeDefaultRootStore**. WebSphere Application Server no longer relies on a self-signed certificate or the default or dummy certificate that is shipped with the product. The `key.p12` default keystore and the `trust.p12` truststore are stored in the configuration repository within the node directory. The default root certificate is stored in the `root-key.p12` in the configuration repository under the node directory.

All of the nodes put their signer certificates from the default root certificate in this common truststore (`trust.p12`). Additionally, after you federate a node, the default SSL configuration is automatically modified to point to the common truststore, which is located in the cell directory. The node can now communicate with all other servers in the cell.

All default SSL configurations contain a keystore with the name suffix `DefaultKeyStore`, a truststore with the name suffix `DefaultTrustStore` and a rootstore with the name suffix `DefaultRootStore`. These default suffixes instruct the WebSphere Application Server runtime to add the root signer of the personal certificate to the common truststore. If a truststore name does not end with `DefaultKeyStore`, the keystores root signer certificates are not added to the common truststore when you federate the server. You can change the default SSL configuration, but you must ensure that the correct trust is established for administrative connections, among others.

For more information, see “Default chained certificate configuration in SSL” on page 1907.

## Certificate expiration monitoring

Certificate monitoring ensures that the default chained certificate for each node is not allowed to expire. The certificate expiration monitoring function issues a warning before certificates and signers are set to expire. Those certificates and signers that are located in keystores managed by the WebSphere Application Server configuration can be monitored. You can configure the expiration monitor to automatically replace a certificate. A chained certificate will be recreated based on the same data used for the initial creation and sign it with the same root certificate that signed the original certificate. A self-signed certificate or chained certificate is also recreated based upon the same data that is used for the initial creation.

The monitor also can automatically replace old signers with the signers from the new chained or self-signed certificates in keystores that are managed by WebSphere Application Server. The existing signer exchanges that occurred by the runtime during federation and by administration are preserved. For more information, see “Certificate expiration monitoring in SSL” on page 1915.

The expiration monitor is configured to replace chained personal certificates that are signed by a root certificate in **DmgrDefaultRootStore** or **NodeDefaultRootStore**. The certificate is renewed using the same root certificate that was used to sign the original certificate.

The monitor also can automatically replace old signers with the signers from the new self-signed certificates in keystores that are managed by WebSphere Application Server. The existing signer exchanges that occurred by the runtime during federation and by administration are preserved. For more

information, see “Certificate expiration monitoring in SSL” on page 1915.

## WebSphere Application Server clients: signer-exchange requirements

A new chained certificate is generated for each node during its initial startup. To ensure trust, clients must be given the root signers to establish a connection. The introduction of chained certificates in the current release makes this process simpler. Rather than exchanging the signer of a short lived self-signed certificate, you can exchange the long lived root signer which will allow for preserved trust across personal certificate renewals. In addition, you can gain access to the signer certificates of various nodes to which the client must connect with any one of the following options (for more information, see “Secure installation for client signer retrieval in SSL” on page 1910):

- A signer exchange prompt enables you to import signer certificates that are not yet present in the truststores during a connection to a server. By default, this prompt is enabled for administrative connections and can be enabled for any client SSL configuration. When this prompt is enabled, any connection that is made to a server where the signer is not already present offers the signer of the server along with the certificate information and a Secure Hash Algorithm (SHA) digest of the certificate for verification. The user is given a choice whether to accept these credentials. If the credentials are accepted, the signer is added to the truststore of the client until the signer is explicitly removed. The signer exchange prompt does not occur again when connecting to the same server unless the personal certificate changes.

**Attention:** It is unsafe to trust a signer exchange prompt without verifying the SHA digest. An unverified prompt can originate from a browser when a certificate is not trusted.

- You can run a `retrieveSigners` administrative script from a client prior to making connections to servers. To download signers, no administrative authority is required. To upload signers, you must have Administrator role authority. The script downloads all of the signers from a specified server truststore into the specified client truststore and can be called to download only a specific alias from a truststore. You can also call the script to upload signers to server truststores. When you select the `CellDefaultTrustStore` truststore as the specified server truststore and common truststore for a cell, all of the signers for that cell are downloaded to the specified client truststore, which is typically `ClientDefaultTrustStore`. For more information, see “`retrieveSigners` command” on page 1913.
- You can physically distribute to clients the `trust.p12` common truststore that is located in the cell directory of the configuration repository. When doing this distribution, however, you must ensure that the correct password has been specified in the `ssl.client.props` client SSL configuration file. The default password for this truststore is `WebAS`. Change the default password prior to distribution. Physical distribution is not as effective as the previous options. When changes are made to the personal certificates on the server, automated exchange can fail.

## Dynamic SSL configuration changes

The SSL runtime for WebSphere Application Server maintains listeners for most SSL connections. A change to the SSL configuration causes the inbound connection listeners to create a new `SSLContext` object. Existing connections continue to use the current `SSLContext` object. Outbound connections automatically use the new configuration properties when they are attempted.

Make dynamic changes to the SSL configuration during off-peak hours to reduce the possibility of timing-related problems and to prevent the possibility of the server starting again. If you enable the runtime to accept dynamic changes, then change the SSL configuration and save the `security.xml` file. Your changes take effect when the new `security.xml` file reaches each node.

**Note:** If configuration changes cause SSL handshake failures, administrative connectivity failures also can occur, which can lead to outages. In this case, you must re-configure the SSL connections then perform manual node synchronization to correct the problem. You must carefully complete any dynamic changes. It is highly recommended that you perform changes to SSL configurations on a test environment prior to making the same changes to a production system. For more information, see “Dynamic configuration updates in SSL” on page 1918.

## Built-in certificate management

Certificate management that is comparable to iKeyMan functionality is now integrated into the keystore management panels of the administrative console. Use built-in certificate management to manage personal certificates, certificate requests, and signer certificates that are located in keystores. Additionally, you can remotely manage keystores. For example, you can manage a file-based keystore that is located outside the configuration repository on any node from the deployment manager. You also can remotely manage hardware cryptographic keystores from the deployment manager.

With built-in certificate management, you can replace a chained or self-signed certificate along with all of the signer certificates scattered across many truststores and retrieve a signer from a remote port by connecting to the remote SSL host and port and intercepting the signer during the handshake. The certificate is first validated according to the certificate SHA digest, then the administrator must accept the validated certificate before it can be placed into a truststore.

When you make a certificate request, you can send it to a certificate authority (CA). When the certificate is returned, you can accept it within the administrative console. For more information, see “Certificate management in SSL” on page 1920.

**Tip:** Although iKeyMan functionality still ships with WebSphere Application Server, configure keystores from the administrative console using the built-in certificate management functionality. iKeyMan is still an option when it is not convenient to use the administrative console. For more information, see “Certificate management using iKeyman prior to SSL” on page 1919.

## AdminTask configuration management

The SSL configuration management panels in the administrative console rely primarily on administrative tasks, which are maintained and enhanced to support the administrative console function. You can use wsadmin commands from a Java console prompt to automate the management of keystores, SSL configurations, certificates, and so on.

### SSL configurations

Secure Sockets Layer (SSL) configurations contain attributes that enable you to control the behavior of both the client and the server SSL endpoints. You can assign SSL configurations to have specific management scopes. The scope that an SSL configuration inherits depends upon whether you create it using a cell, node, server, or endpoint link in the configuration topology.

When you create an SSL configuration, you can set the following SSL connection attributes:

- Keystore
- Default client certificate for outbound connections
- Default server certificate for inbound connections
- Truststore
- Key manager for selecting a certificate
- Trust manager or managers for establishing trust during the handshake
- Handshaking protocol
- Ciphers for negotiating the handshake
- Client authentication support and requirements

You can manage an SSL configuration using any of the following methods:

- Central management selection
- Direct reference selection
- Dynamic outbound connection selection
- Programmatic selection

Using the administrative console, you can manage all of the SSL configurations for WebSphere Application Server. From the administrative console, click **Security > SSL certificates and key management > Manage endpoint security configurations > Inbound | Outbound > SSL\_configuration**. You can view an SSL configuration at the level it was created and in the inherited scope below that point in the topology. If you want the entire cell to view an SSL configuration, you must create the configuration at the cell level in the topology.

### SSL configuration in the security.xml file

The attributes defining an SSL configuration repertoire entry for a specific management scope are stored in the `security.xml` file. The scope determines the point at which other levels in the cell topology can see the configuration, as shown in the following example:

```
<repertoire xmi:id="SSLConfig_1" alias="NodeDefaultSSLSettings"
managementScope="ManagementScope_1" type="JSSE">
<setting xmi:id="SecureSocketLayer_1" clientAuthentication="false"
clientAuthenticationSupported="false" securityLevel="HIGH" enabledCiphers=""
jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS" keyStore="KeyStore_1"
trustStore="KeyStore_2" trustManager="TrustManager_1" keyManager="KeyManager_1"
clientKeyAlias="default" serverKeyAlias="default"/>
</repertoire>
```

The SSL configuration attributes from the previous code sample are described in Table 1.

*Table 146. security.xml Attributes. This table lists the security.xml Attributes.*

security.xml attribute	Description	Default	Associated SSL property
xmi:id	The xmi:id attribute represents the unique identifier for this XML entry and determines how the SSL configuration is linked to other XML objects, such as SSLConfigGroup. This system-defined value must be unique.	The administrative configuration service defines the default value.	None. This value is used only for XML associations.
alias	The alias attribute defines the name of the SSL configuration. Direct selection uses the alias attribute and the node is not prefixed to the alias. Rather, the management scope takes care of ensuring that the name is unique within the scope.	The default is CellDefaultSSLSettings.	com.ibm.ssl.alias
managementScope	The managementScope attribute defines the management scope for the SSL configuration and determines the visibility of the SSL configuration at runtime.	The default scope is the cell.	The managementScope attribute is not mapped to an SSL property. However, it confirms whether or not the SSL configuration is associated with a process.
type	The type attribute defines the Java Secure Socket Extension (JSSE) or System Secure Sockets Layer (SSSL) configuration option. JSSE is the SSL configuration type for most secure communications within WebSphere Application Server.  Both JSSE and SSSL are valid options. The z/OS daemon still uses SSSL in this release.	The default is JSSE.	com.ibm.ssl.sslType
clientAuthentication	The clientAuthentication attribute determines whether SSL client authentication is required.	The default is false.	com.ibm.ssl.clientAuthentication

Table 146. *security.xml* Attributes (continued). This table lists the *security.xml* Attributes.

security.xml attribute	Description	Default	Associated SSL property
clientAuthenticationSupported	<p>The clientAuthenticationSupported attribute determines whether SSL client authentication is supported. The client does not have to supply a client certificate if it does not have a client certificate.</p> <p><b>Attention:</b> When you set the clientAuthentication attribute to true, you override the value that is set for the clientAuthenticationSupported attribute.</p>	The default is false.	com.ibm.ssl.client.AuthenticationSupported
securityLevel	The securityLevel attribute determines the cipher suite group. Valid values include STRONG (128-bit ciphers), MEDIUM (40-bit ciphers), WEAK (for all ciphers without encryption), and CUSTOM (if the cipher suite group is customized. When you set the enabledCiphers attribute with a specific list of ciphers, the system ignores this attribute.	The default is STRONG.	com.ibm.ssl.securityLevel
enabledCiphers	You can set the enabledCiphers attribute to specify a unique list of cipher suites. Separate each cipher suite in the list with a space.	The default is the securityLevel attribute for cipher suite selection.	com.ibm.ssl.enabledCipherSuites
jsseProvider	The jsseProvider attribute defines a specific JSSE provider.	The default is IBMJSSE2.	com.ibm.ssl.contextProvider
sslProtocol	The sslProtocol attribute defines the SSL handshake protocol. Valid options include: SSLv2 (client-side only), SSLv3, SSL, SSL_TLS, TLSv1, and TLS values. The SSL option includes SSLv2 and SSLv3 values. The TLS option includes the TLSv1 value. SSL_TLS, which is the most interoperable protocol, includes all these values and defaults to a Transport Layer Security (TLS) handshake.	The default is SSL_TLS.	com.ibm.ssl.protocol
keyStore	The keyStore attribute defines the keystore and attributes of the keyStore instance that the SSL configuration uses for key selection.	The default is CellDefaultKeyStore.	For more information, see Keystore configurations.
trustStore	The trustStore attribute defines the key store that the SSL configuration uses for certificate signing verification.	The default is CellDefaultTrustStore.	A trustStore is a logical JSSE term. It signifies a key store that contains signer certificates. Signer certificates validate certificates that are sent to WebSphere Application Server during an SSL handshake.

Table 146. *security.xml* Attributes (continued). This table lists the *security.xml* Attributes.

security.xml attribute	Description	Default	Associated SSL property
keyManager	The keyManager attribute defines the key manager that WebSphere Application Server uses to select keys from a key store. A JSSE key manager controls the javax.net.ssl.X509KeyManager interface. A custom key manager controls the javax.net.ssl.X509KeyManager and the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interfaces. The com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface provides more information from WebSphere Application Server.	The default is IbmX509.	com.ibm.ssl.keyManager defines a well-known key manager and accepts the algorithm and algorithm/provider formats, for example IbmX509 and IbmX509 IBMJSSE2. com.ibm.ssl.customKeyManager defines a custom key manager and takes precedence over the other keyManager properties. This class must implement javax.net.ssl.X509KeyManager and can implement com.ibm.wsspi.ssl.KeyManagerExtendedInfo. For more information, see “Key manager control of X.509 certificate identities” on page 1892
trustManager	The trustManager determines which trust manager or list of trust managers to use for determining whether to trust the peer side of the connection. A JSSE trust manager implements the javax.net.ssl.X509TrustManager interface. A custom trust manager might also implement com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface to get more information from the WebSphere Application Server environment.	The default is IbmPKIX, which can be configured for certificate revocation list (CRL) verification when the certificate contains a CRL distribution point. The other option is IbmX509.	com.ibm.ssl.trustManager defines a well-known trust manager, which is required for most handshake situations. com.ibm.ssl.trustManager performs certificate expiration checking and signature validation. You can define com.ibm.ssl.customTrustManagers with additional custom trust managers that are called during an SSL handshake. Separate additional trust managers with the vertical bar ( ) character. For more information, see “Trust manager control of X.509 certificate trust decisions”

Client SSL configurations are managed using the `ssl.client.props` properties file. The `ssl.client.props` file is located in the `#{USER_INSTALL_ROOT}/properties` directory for each profile. For more information about configuring this file, see the “`ssl.client.props` client configuration file” on page 1967. Specifying any `javax.net.ssl` system properties will override the corresponding property in the `ssl.client.props` file.

**Trust manager control of X.509 certificate trust decisions:**

The role of the trust manager is to validate the Secure Sockets Layer (SSL) certificate that is sent by the peer, which includes verifying the signature and checking the expiration date of the certificate. A Java Secure Socket Extension (JSSE) trust manager determines if the remote peer can be trusted during an SSL handshake.

WebSphere Application Server has the ability to call multiple trust managers during an SSL connection. The default trust manager does the standard certificate validation; custom trust manager plug-ins run customized validation such as host name verification. For more information, see “Example: Developing a custom trust manager for custom SSL trust decisions” on page 1949

When a trust manager is configured in a server-side SSL configuration, the server calls the `isClientTrusted` method. When a trust manager is configured in a client-side SSL configuration, the client calls the `isServerTrusted` method. The peer certificate chain is passed to these methods. If the trust manager chooses not to trust the peer information, it might produce an exception to force a handshake failure.

Optionally, WebSphere Application Server provides the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface so that additional information can be passed to the trust manager. For more information, see the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface.

## Default IbmX509 trust manager

The default IbmX509 trust manager, which is used in the following code sample, establishes trust by performing standard certificate validation.

```
<trustManagers xmi:id="TrustManager_1132357815717" name="IbmX509" provider="IBMJSSE2"
algorithm="IbmX509" managementScope="ManagementScope_1132357815717"/>
```

The trust manager provides a signer certificate to verify the peer certificate that is sent during the handshake. The signers who are added to the truststore for the SSL configuration must be trustworthy. If you do not trust the signers or do not want to allow others to connect to your servers, consider removing default root certificates from certificate authorities (CA). You might also remove any certificates if you cannot verify their origination.

## Default IbmPKIX trust manager

You can use the default IbmPKIX trust manager to replace the IbmX509 trust manager, which is shown in the following code sample:

```
<trustManagers xmi:id="TrustManager_1132357815719" name="IbmPKIX" provider="IBMJSSE2"
algorithm="IbmPKIX" trustManagerClass="" managementScope="ManagementScope_1132357815717">
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1132357815717"
name="com.ibm.security.enableCRLDP" value="true" type="boolean"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1132357815718"
name="com.ibm.jsse2.checkRevocation" value="true" type="boolean"/>
</trustManagers>
```

```
<trustManagers xmi:id="TrustManager_managementNode_2" name="IbmPKIX" provider=
"IBMJSSE2" algorithm="IbmPKIX" trustManagerClass=""
managementScope="ManagementScope_managementNode_1">
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1" name="com.ibm.se
curity.enableCRLDP" value="false" type="boolean" displayNameKey="" nlsRangeKey=
" hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_2" name="com.ibm.js
se2.checkRevocation" value="false" type="boolean" displayNameKey="" nlsRangeKey=
"" hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_3" name="ocsp.enabl
e" value="false" type="String" displayNameKey="" nlsRangeKey="" hoverHelpKey=""
range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_4" name="ocsp.respo
nderURL" value="http://ocsp.example.net:80" type="String" displayNameKey=""
nlsRangeKey="" hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_5" name="ocsp.respo
nderCertSubjectName" value="" type="String" displayNameKey="" nlsRangeKey="" hov
erHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_6" name="ocsp.respo
nderCertIssuerName" value="" type="String" displayNameKey="" nlsRangeKey="" hove
rHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_7" name="ocsp.respo
nderCertSerialNumber" value="" type="String" displayNameKey="" nlsRangeKey="" hov
erHelpKey="" range="" inclusive="false" firstClass="false"/>
</trustManagers>
```

See “Example: Enabling certificate revocation checking with the default IbmPKIX trust manager” on page 1893 for additional information in using the default IbmPKIX trust manager.

In addition to its role of standard certificate verification, the IbmPKIX trust manager checks for OCSP properties and for certificates that contain certificate revocation list (CRL) distribution points. This process is known as extended CRL checking. When you select a trust manager, its associated properties are automatically set as Java System properties so that the IBM CertPath and IBMJSSE2 providers are aware that CRL checking is enabled.

## Custom trust manager

You can define a custom trust manager to perform additional trust checking, which is based upon the needs of the environment. For example, in one environment, you might enable connections from the same Transmission Control Protocol (TCP) subnet only. The `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface provides extended information about the connection that is not provided by the standard Java

Secure Sockets Extension (JSSE) `javax.net.ssl.X509TrustManager` interface. The configured `trustManagerClass` attribute determines which class is instantiated by the runtime, as shown in the following code sample:

```
<trustManagers xmi:id="TrustManager_1132357815718" name="CustomTrustManager"
trustManagerClass="com.ibm.ws.ssl.core.CustomTrustManager"
managementScope="ManagementScope_1132357815717"/>
```

The `trustManagerClass` attribute must implement the `javax.net.ssl.X509TrustManager` interface and, optionally, can implement the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface.

### Disabling the default trust manager

In some cases, you might not want to perform the standard certificate verification that is provided by the `IbmX509` and `IbmPKIX` default trust managers. For example, you might be working with an internal automated test infrastructure that is not concerned with SSL client or server authentication, integrity, or confidentiality. The following sample code shows a basic custom trust manager such as `com.ibm.ws.ssl.core.CustomTrustManager` whose property is set to `true`.

```
com.ibm.ws.ssl.skipDefaultTrustManagerWhenCustomDefined=true
```

You can set this property in the global properties at the top of the `ssl.client.props` file for clients or in the `security.xml` custom properties file for servers. You must configure a custom trust manager when you disable the default trust manager to prevent the server from calling the default trust manager even though it is configured. Disabling the default trust manager is not a common practice. Be sure to test the system with the disabled default trust manager in a test environment first. For more information on setting up a custom trust manager, see “Creating a custom trust manager configuration for SSL” on page 1946

### ***Key manager control of X.509 certificate identities:***

The role of a Java Secure Socket Extension (JSSE) key manager is to retrieve the certificate that is used to identify the client or server during a Secure Sockets Layer (SSL) handshake.

WebSphere Application Server provides a default key manager that can select a certificate from a keystore when you define the following SSL configuration properties:

#### **com.ibm.ssl.keyStoreClientAlias**

Defines the alias that is chosen from the keystore for the client side of a connection. This alias must be present in the keystore.

#### **com.ibm.ssl.keyStoreServerAlias**

Defines the alias that is chosen from the keystore for the server side of a connection. This alias must be present in the keystore.

These two properties are set automatically when you use the administrative console because the default key manager is already configured.

With WebSphere Application Server, you can configure only one key manager at a time for a given SSL configuration. If you want custom certificate selection logic on the client side, you must write a new custom key manager. The custom key manager could provide function that prompts the user to choose a certificate dynamically. Also, you can implement an extended interface so that a key manager can provide information during connection time. For more information on the extended interface, see the `com.ibm.wsspi.ssl.KeyManagerExtendedInfo` interface. For more information on custom key manager development, see “Creating a custom key manager for SSL” on page 1951.

### Default `IbmX509` key manager

The default `IbmX509` key manager chooses a certificate to serve as the identity for an SSL handshake. The key manager is called to enable client authentication on either side of the SSL handshake; frequently on the server-side, and less frequently on the client side according to client and server requirements. If a

keystore is not configured on the client-side and SSL client authentication is enabled, the key manager cannot select a certificate to send to the server. Therefore, the handshake fails.

The following sample code shows the key manager configuration in the `security.xml` file for an IbmX509 key manager.

```
<keyManagers xmi:id="KeyManager_1" name="IbmX509"
provider="IBMJSSE2" algorithm="IbmX509" keyManagerClass=""
managementScope="ManagementScope_1"/>
```

You do not specify the `keyManagerClass` class because the key manager is provided by the IBMJSSE2 provider. However, you can specify whether the key manager is a custom class implementation, in which case you must specify the `keyManager` class, or an algorithm name that WebSphere Application Server can start from the Java security provider framework.

### Custom key manager

The following sample code shows the key manager configuration in the `security.xml` file for a custom class.

```
<keyManagers xmi:id="KeyManager_2" name="CustomKeyManager"
keyManagerClass="com.ibm.ws.ssl.core.CustomKeyManager"
managementScope="ManagementScope_1"/>
```

The custom class must implement the `javax.net.ssl.X509KeyManager` interface and, optionally, implement the `com.ibm.wsspi.ssl.KeyManagerExtendedInfo` interface to retrieve additional WebSphere Application Server information. This interface replaces the function of the default key manager because you can configure only one key manager at a time. Therefore, the custom key manager has sole responsibility for selecting the alias to use from the configured keystore. The benefit of a custom key manager is its ability, on the client side, to prompt for an alias. This process enables the user to decide which certificate to use in situations where the user knows the client certificate identity. For more information, see “Creating a custom key manager for SSL” on page 1951.

#### ***Example: Enabling certificate revocation checking with the default IbmPKIX trust manager:***

The IbmPKIX trust manager is enabled in the WebSphere Application Server by default. The IbmPKIX trust manager allows certificate revocation checking to occur. You enable certificate revocation checking by using the administrative console or by manually updating the `ssl.client.props` file.

### The default IbmPKIX trust manager

The IbmPKIX trust manager is enabled by default, but revocation checking is not enabled by default. The following trust manager definition for IbmPKIX reflects the default condition:

```
<trustManagers xmi:id="TrustManager_managementNode_2" name="IbmPKIX" provider=
"IBMJSSE2" algorithm="IbmPKIX" trustManagerClass=""
managementScope="ManagementScope_managementNode_1">
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1" name="com.ibm.se
curity.enableCRLDP" value="false" type="boolean" displayNameKey="" nlsRangeKey=""
 hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_2" name="com.ibm.js
se2.checkRevocation" value="false" type="boolean" displayNameKey="" nlsRangeKey=""
 hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_3" name="ocsp.enable
e" value="false" type="String" displayNameKey="" nlsRangeKey="" hoverHelpKey=""
range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_4" name="ocsp.respo
nderURL" value="http://ocsp.example.net:80" type="String" displayNameKey=""
nlsRangeKey="" hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_5" name="ocsp.respo
nderCertSubjectName" value="" type="String" displayNameKey="" nlsRangeKey="" hov
erHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_6" name="ocsp.respo
nderCertIssuerName" value="" type="String" displayNameKey="" nlsRangeKey="" hove
```

```
rHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_7" name="ocsp.respo
nderCertSerialNumber" value="" type="String" displayNameKey="" nlsRangeKey="" ho
verHelpKey="" range="" inclusive="false" firstClass="false"/>
</trustManagers>
```

## Enabling certificate revocation checking with the default IbmPKIX trust manager

You can view and change IbmPKIX Trust Manager Custom Properties using the administrative console.

To do this,

- Click **Security > SSL certificate and key management**.
- Under Related Items, click **Trust managers**.
- Click **IbmPKIX**.
- Under Additional Properties, click **Custom properties**.

### IbmPKIX custom properties

#### com.ibm.jsse2.checkRevocation

This property configures revocation checking for the Java Virtual Machine (JVM). This property is set to false by default because the default WebSphere certificates used for SSL communication do not contain certificate revocation list (CRL) distribution points or Online Certificate Status Protocol (OCSP) information.

**Note:** Since this property is a JVM property, this value is in effect for the entire application server. If the property is defined in trust managers at different scopes, the value in effect is used from the most specifically scoped IbmPKIX trust manager. For example, the property for an IbmPKIX trust manager defined at the node level overrides the property for an IbmPKIX trust manager defined at the cell level. This property is ignored for the IbmX509 trust manager.

**default**  
false

#### com.ibm.security.enableCRLDP

This property configures CRL distribution point checking for the PKIX trust manager.

**Note:** If you enable CRL distribution point revocation checking, the certificates used for secure sockets layer (SSL) must contain a valid distribution point and the distribution point must be accessible or else SSL communication will fail and the server will not function correctly.

**default**  
false

For certificates that do not contain an internal CRL distribution point, the following properties can be used so the revocation status will be checked against a remote LDAP server containing the CRL.

#### com.ibm.security.ldap.certstore.host

This property specifies the LDAP server host name containing trusted certificates or certificate revocation lists. The target LDAP server host is used to obtain CA certificates or certificate revocation lists when validating a certificate and the local truststore does not contain the required certificate. The local truststore must contain the required certificates if an LDAP server is not specified. In cases when an LDAP server is used, the root CA certificates must also be located in the local truststore as the LDAP server is not a trusted certificate store.

**Note:** Enabling this property in addition to the com.ibm.jsse2.checkRevocation property enables revocation checking. The remote LDAP server must contain a valid certificate revocation list

and the server must be accessible. If the revocation status cannot be determined then the check will fail and SSL communication will fail and the server will not function correctly.

**default**  
none

**com.ibm.security ldap.certstore.port**

This property specifies the LDAP server port. A port value of 389 will be used by default if no LDAP server port is specified.

**default**  
389

The following Java Development Kit (JDK) properties apply to enabling certificate revocation checking with the default IbmPKIX trust manager:

- ojsp.enable
- ojsp.responder
- ojsp.responderCertSubjectName
- ojsp.responderCertIssuerName
- ojsp.responderCertSerialNumber

These JDK properties can be set using the administrative console. You should reference Java(TM) Certification Path API Programmer's Guide - SDK 6.0 for descriptions of these properties and their allowable settings.

**Note:** In addition to its role of standard certificate verification, the IbmPKIX trust manager checks for certificates that contain CRL distribution points. This process is known as extended CRL checking. By default, CRL distribution point revocation checking is disabled. To enable CRL distribution point revocation checking, you must set the following properties to true using the administrative console:

- com.ibm.security.enableCRLDP
- com.ibm.jsse2.checkRevocation

OCSP properties and CRL properties affect certificate revocation checking. By default OCSP properties are checked first. If there is an error validating the certificate with OCSP, then validation uses a CRL distribution point instead.

When you select a trust manager, its associated properties are automatically set as Java system properties so that the IbmCertPath and IbmJSSE2 providers are aware that CRL checking is enabled or disabled. Similarly, the same applies for OCSP properties, which are java.security.Security properties.

## Client considerations

You can also enable revocation checking for WebSphere application and administrative clients by directly setting the properties in the `ssl.client.props` file. An example of the `ssl.client.props` file follows:

```
#-----
Default Revocation Checking Properties
These properties are used for certificate revocation checking with the IBM
PKIX TrustManager.

To enable CRL Distribution Points extension checking, use the system property
com.ibm.security.enableCRLDP.

OCSP checking is not enabled by default. It is enabled by setting the
ojsp.enable property to "true". Use of the other ojsp properties is optional.

Note: Both OCSP and CRLDP checking is only effective if revocation checking
has also been enabled by setting com.ibm.jsse2.checkRevocation to "true".
```

```
#
#-----
com.ibm.jsse2.checkRevocation=false
com.ibm.security.enableCRLDP=false
#ocsp.enable=true
#ocsp.responderURL=http://ocsp.example.net
#ocsp.responderCertSubjectName=CN=OCSP Responder, O=XYZ Corp
#ocsp.responderCertIssuerName=CN=Enterprise CA, O=XYZ Corp
#ocsp.responderCertSerialNumber=2A:FF:00
```

**Note:** In order for these properties to be effective, you must ensure that the IbmPKIX trust manager is initialized by setting `com.ibm.ssl.trustManager=IbmPKIX`.

In addition, for revocation checking to be processed successfully on the client, you are required to turn off the signer exchange prompt. To do this, change the value of the **com.ibm.ssl.enableSignerExchangePrompt** property to `false`, in the `ssl.client.props` file.

For more information on these properties, see Java(TM) Certification Path API Programmer's Guide - SDK 6.0.

## Keystore configurations for SSL

Use keystore configurations to define how the runtime for WebSphere Application Server loads and manages keystore types for Secure Sockets Layer (SSL) configurations.

By default, the `java.security.Security.getAlgorithms("KeyStore")` attribute does not display a predefined list of keystore types in the administrative console. Instead, WebSphere Application Server retrieves all of the KeyStore types that can be referenced by the `java.security.KeyStore` object, including hardware cryptographic, z/OS platform, IBM i platform, IBM Java Cryptography Extension (IBMJCE), and Java-based content management system (CMS)-provider keystores. If you specify a keystore provider in the `java.security` file or add it to the provider list programmatically, WebSphere Application Server also retrieves custom keystores. The retrieval list depends upon the `java.security` configuration for that platform and process.

## IBMJCE file-based keystores (JCEKS, JKS, and PKCS12)

A typical IBMJCE file-based keystore configuration is shown in the following sample code:

```
<keyStores xmi:id="KeyStore_1" name="NodeDefaultKeyStore"
password="{xor}349dkckdd=" provider="IBMJCE"
location="{USER_INSTALL_ROOT}/config/cells/myhostNode01Cell
/nodes/myhostNode01/key.p12" type="PKCS12" fileBased="true"
hostList="" initializeAtStartup="true" readOnly="false"
description="Default key store for myhostNode01" usage="SSLKeys"
managementScope="ManagementScope_1"/>
```

For more information about default keystore configurations, see “Default chained certificate configuration in SSL” on page 1907.

Table 1 describes the attributes that are used in the sample code.

*Table 147. keystore configurations. This table describes the keystore configurations.*

Attribute name	Default	Description
xmi:id	Varies	A value that is used to reference the keystore from another area in the configuration, for example, from an SSL configuration. Make this value unique within the <code>security.xml</code> file.
name	For JSSE keystore: <code>CellDefaultKeyStore</code> . For JSSE truststore: <code>CellDefaultTrustStore</code> .	A name that is used to identify the keystore by sight. The name can determine if the keystore is a default keystore based upon whether the name ends with <code>DefaultKeyStore</code> or <code>DefaultTrustStore</code> .
password	The default keystore password is <code>WebAS</code> . It is recommended that this be changed as soon as possible. See Updating default key store passwords using scripting for more information.	The password that is used to access the keystore name is also the default that is used to store keys within the keystore.

Table 147. keystore configurations (continued). This table describes the keystore configurations.

Attribute name	Default	Description
description	No default	A description of the keystore.
usage	An attribute specifying what the keystore is used for.	Valid values are: SSLKeys, KeySetKeys, RootKeys, DeletedKeys, DefaultSigners, RSATokenKeys.
provider	The default provider is IBMJCE.	The Java provider that implements the type attribute (for example, PKCS12 type). The provider can be left unspecified and the first provider that implements the keystore type specified is used.
location	The default varies, but typically references a key.p12 file or a trust.p12 file in the node or cell directories of the configuration repository. These files are PKCS12 type keystores.	The keystore location reference. If the keystore is file-based, the location can reference any path in the file system of the node where the keystore is located. However, if the location is outside of the configuration repository, and you want to manage the keystore remotely from the administrative console or from the <b>wsadmin</b> utility, then specify the hostList attribute that contains the host name of the node where it resides.
type	The default Java crypto device keystore type is PKCS12.	This type specifies the keystore. Valid types can be those returned by the java.security.Security.getAlgorithms("KeyStore") attribute. These types include the following keystore types, and availability depends on the process and platform java.security configuration: <ul style="list-style-type: none"> <li>• JKS</li> <li>• JCEKS</li> <li>• PKCS12</li> <li>• PKCS11 (Java crypto device)</li> <li>• CMSKS</li> <li>• IBMi5OSKeyStore</li> <li>• JCERACFKS</li> <li>• JCECCAKS keystores (replacing JCE4758KS) - (z/OS crypto device)</li> </ul>
fileBased	The default is true.	This option is required for default keystores. It indicates a file-system keystore so you can use a FileInputStream or FileOutputStream for loading and storing the keystore.
hostList	The hostList attribute is used to specify a remote hostname so that the keystore can be remotely managed. There are no remotely managed keystores by default. All default keystores are managed locally in the configuration repository and synchronized out to each of the nodes.	The option manages a keystore remotely. You can set the host name of a valid node for a keystore. When you use either the administrative console or the wsadmin utility to manage certificates for this keystore, an MBean call is made to the node where the keystore exists for the approved operation. You can specify multiple hosts, although synchronization of the keystore operations are not guaranteed. For example, one of the hosts that is listed might be down when a specific operation is performed. Therefore, use multiple hosts in this list.
initializeAtStartup	The default is true.	This option informs the runtime to initialize the keystore during startup. This option can be important for hardware cryptographic device acceleration.
readOnly	The default is false.	This option informs the configuration that you cannot write to this keystore. That is, certain update operations on the keystore cannot be attempted and are not allowed. An example of a read-only keystore type is JCERACFKS on the z/OS platform. This type is read-only from the WebSphere certificate management standpoint, but you can also update it using the keystore management facility for RACF. <p>Optionally, you can configure writable keyring support that enables additional keystore configurations for use by the certificate management function. See "Creating writable SAF keyrings" on page 2004 and "Using writable SAF keyrings" on page 2003 for more information on configuring and using writable key store configuration objects.</p>
managementScope	The default scope is the node scope for a base Application Server environment and the cell scope for a Network Deployment environment.	This option references a particular management scope in which you can see this keystore. For example, if a hardware cryptographic device is physically located on a specific node, then create the keystore from a link to that node in the topology view under <b>Security &gt; Security Communications &gt; SSL configurations</b> . You can also use management scope to isolate a keystore reference. In some cases, you might need to allow only a specific application server to reference the keystore; the management scope is for that specific server.

## **z/OS keystores**

WebSphere Application Server supports IBMJCE file-based keystores, Java Cryptography Extension Key Stores (JCEKS), Java Key Stores (JKS), and Public Key Cryptography Standards 12 (PKCS12), and z/OS-specific keystores. The IBMJCE file-based keystore support on z/OS is fully compatible with and similar to the support on the distributed platform.

The IBMJCECCA provider extends and replaces the IBMJCE4758 provider from earlier releases. The IBMJCECCA provider and the IBMJCE4758 provider are functionally equivalent. The IBMJCECCA provider supports four keystores: JCECCAks (JCE4758KS) and JCECCARACFKS (JCE4758RACFKS).

The JCECCAks keystore uses keys that are stored in the z/OS hardware and managed by ICSF. The JCECCARACFKS keystore handles certificates managed and stored in RACF keyrings, and the keys are stored in the z/OS hardware. The JCE4758KS and JCE4758RACFKS keystores are included for downward compatibility and are deprecated. The JCECCAks keystore extends and replaces the JCE4758KS keystore. The JCECCARACFKS keystore extends and replaces the JCE4758RACFKS keystore.

The z/OS platform offers three additional keystores types that can be used for WebSphere Application Server on z/OS:

- JCECCAks keystores (replacing JCE4758KS) use keys that are stored in the z/OS hardware and keys that are managed in Integrated Cryptographic Services Facility (ICSF).
- JCERACFKS keystores are a Resource Access Control Facility (RACF) - based keystores that are used to support keys and certificates that are contained in a RACF keystore. Key material stored in ICSF is not supported with this keystore type.
- JCECCARACFKS (extending and replacing JCE4758RACFKS) keystores are RACF - based keystores that are used to support certificates that are contained in a RACF keystore along with keys stored in z/OS hardware. The ICSF option with RACF RACDCERT must be specified.

### **Notes:**

- The keystore type, JCERACFKS for the IBMJCE provider and JCECCARACFKS for the IBMJCECCA provider, are only available on the z/OS platform where SAF is available.
- You can use the administrative console to extract a personal certificate into HFS as a Base64-encoded ASCII data type or as a Binary DER data type. However, if the keystore type of the SSL configuration is JCERACFKS, a 0 bytes file is created in HFS.
- To be compatible with the JCE keystore in requiring a password, the JCERACFKS require a password but that password must be password. Security for this keystore is not really protected using a password as other keystore types, but rather it is based on the identity of the executing thread for protection with RACF. This password is for the keystore file that you specified in the Path field.

An IBMJCE provider can only support the JCERACFKS keystore in the set of z/OS-specific keystores that are listed previously. The IBMJCE provider cannot use the JCECCAks or JCECCARACFKS keystore material since it is specific to the hardware.

An IBMJCECCA provider can support software key materials for the JCERACFKS, JKS, and JCEKS keystores, and take advantage of the hardware acceleration.

A new keystore class, JceRACFKeyStore, has been added to the IBMJCE and IBMJCECCA providers. Use this class when you retrieve certificates and keys from a keyring because this keystore allows WebSphere Application Server to read from a keyring. However, if the server attempts to write data to the keyring, an IOException is thrown. While the RACFInputStream works with any keystore, it is possible that data stored in RACF could be inadvertently written to an Hierarchical File System (HFS) file if the server uses a keystore other than the JceRACFKeyStore class.

RACFInputStream can access keys and certificates that are stored in a System Authorization Facility (SAF) keyring implementation using either of the following methods:

- Use RACFInputStream directly to pass in a newly-created instance to the JceRACFKeyStore class
- Use URLStreamHandler to call RACFInputStream, then pass the instance to the JceRACFKeyStore class

For more information, see “RACF keyring setup” on page 1372.

All JAVA RACF services, including the JceRACFKeyStore and RACFInputStream, use the R\_datalib (IRRSDL00) service to retrieve certificates from RACF. However, to use this service, you must obtain authorization for R\_datalib before you use any JAVA RACF classes. For more information on how to setup the necessary authorizations, see *z/OS Security Server Callable Services guide*.

## CMS keystores

You can set some provider-specific attributes in CMS keystores.

If the CMSKS provider supports the createStashFileForCMS attribute, and you set the attribute to true for CMSKS keystores, WebSphere Application Server creates an .sth file in the keystore location that is referenced by the attribute. The .sth extension is appended to the keystore name. For example, if the CMSKS keystore is available for a plug-in configuration and you set createStashFileForCMS to true, the stash file that is represented in the following sample code is created in the `${USER_INSTALL_ROOT}\profiles\AppSrv01/config/cells/myhostCell01/nodes/myhostNode01/servers/webserver1/plugin-key.sth` path.

```
<keyStores xmi:id="KeyStore_1132071489571" name="CMSKeyStore"
password="{xor}HRYNFAtRbxEw0zpvbhw6MzM=" provider="IBMCMSPProvider"
location="${USER_INSTALL_ROOT}\profiles\AppSrv01/config/cells/myhostCell01
/nodes/myhostNode01/servers/webserver1/plugin-key.kdb" type="CMSKS"
fileBased="true" createStashFileForCMS="true"
managementScope="ManagementScope_1132071489569"/>
```

When you create a CMS keystore, the CMS provider is IBMi50SJSSEProvider, and the CMS type is IBMi50SKeyStore, as shown in the following sample code:

```
<keyStores xmi:id="KeyStore_1132071489571" name="CMSKeyStore"
password="{xor}HRYNFAtRbxEw0zpvbhw6MzM=" provider="IBMi50SJSSEProvider"
location="${USER_INSTALL_ROOT}\profiles\AppSrv01/config/cells/myhostCell01
/nodes/myhostNode01/servers/webserver1/plugin-key.kdb" type="IBMi50SKeyStore"
fileBased="true" createStashFileForCMS="true"
managementScope="ManagementScope_1132071489569"/>
```

## Hardware cryptographic keystores

For cryptographic device configuration, see “Key management for cryptographic uses” on page 2029.

You can add a slot either as the custom property, `com.ibm.ssl.keyStoreSlot`, or as the configuration attribute, `slot="0"`. The custom property is read before the attribute for backwards compatibility.

## Dynamic outbound selection of Secure Sockets Layer configurations

WebSphere Application Server provides dynamic outbound selection that enables you to choose a specific Secure Sockets Layer (SSL) configuration and certificate alias for each outbound protocol, target host, target port, or any combination of these attributes. You can specify the dynamic selection information for outbound connections from a pure client or from a server that is acting as a client.

Before the SSL runtime for WebSphere Application Server starts an outbound connection, the runtime attempts to match the outbound protocol, target host, and target port attributes with the dynamic outbound selection information that is associated with an SSL configuration and certificate alias in the configuration.

The runtime caches both selection misses and selection hits, so the impact on performance can be minimal. However, a relationship exists between the amount of dynamic outbound selection information and its impact on the initial connection performance.

## Dynamic selection information for outbound administrative SOAP connections

The default dynamic outbound selection configuration specifies that all outbound administrative SOAP connections use the same SSL configuration and certificate alias within the entire cell.

The management scope of the SSL configuration is at the cell level so every process in the cell sees this configuration. When an administrative SOAP client makes an outbound connection, the client provides protocol, target host, and target port information to the SSL runtime, as shown in the following sample code:

```
<dynamicSSLConfigSelections xmi:id="DynamicSSLConfigSelection_1"
name="AdminSSLOutbound" description="Uses the AdminSSL configuration
for all outbound SOAP calls." dynamicSelectionInfo="ADMIN_SOAP,*,*"
certificateAlias="default" sslConfig="SSLConfig_2"
managementScope="ManagementScope_1"/>
```

The SSL runtime checks the configuration and confirms that `certificateAlias="default"` and `sslConfig="SSLConfig_2"` for the `ADMIN_SOAP` protocol when you enable client certificate authentication.

**Note:** The configured target host and port are represented by the `*` character because both the host and the port attributes can be any value.

## Target information during outbound connections

The dynamic outbound selection configurations are only effective when the outbound protocol uses the JSSEHelper application programming interface (API) when you select an SSL configuration with a specified `connectionInfo` hash map. This hash map must contain the following properties:

### **com.ibm.ssl.direction**

The value for outbound connections is `OUTBOUND`.

### **com.ibm.ssl.remoteHost**

The format should match what the protocol provides. Typically this is the canonical Domain Name Space (DNS), but it also could be the IP address.

### **com.ibm.ssl.remotePort**

The port is target port.

### **com.ibm.ssl.endPointName**

The value for an outbound connection must be one of the following protocol strings:

- IIOP
- HTTP
- SIP
- LDAP
- ADMIN\_IPC
- ADMIN\_SOAP
- BUS\_TO\_BUS
- BUS\_CLIENT
- BUS\_TO\_WEBSPPHERE\_MQ
- WEBSPPHERE\_MQ\_CLIENT

## Central management of SSL configurations

By default, Secure Sockets Layer (SSL) configurations for servers are managed from a central location in the topology view of the administrative console. You can associate an SSL configuration and certificate alias with a specific management scope. This method is the most efficient method to manipulate and modify configurations when the server topology changes.

In prior releases, SSL configurations are managed for each process. You have to maintain individual settings for each SSL configuration in the topology. In this release of WebSphere Application Server, management control of your SSL configurations offers more options and additional flexibility. You are able to make coarse-grained changes for the entire topology using the cell-scope and also make fine-grained changes using a particular endpoint name for a specific application server process. Because the SSL configuration associations manifest an inheritance behavior, you can simplify the number of associations by referencing only the highest level management scope that needs a unique configuration.

The topology view provides the scoping mechanism. The SSL configuration inherits its scope, which can be seen as its display in the topology. The scope encompasses the level where you created the configuration and all the levels below that point. For example, when you create an SSL configuration at a specific node, that configuration can be seen by that node agent and by every application server that is part of that node. Any application server or node that is not part of this particular node can not see this SSL configuration.

Your security environment influences issues such as the uniqueness of the SSL configurations, as well as the SSL configuration and the certificate alias placement in the topology. You are also able to configure different certificate aliases and different SSL configurations for inbound connections versus outbound connections.

To configure the inbound and outbound topologies, which must be done separately in the administrative console, click **Security > SSL certificates and key management > Manage endpoint security configurations > Inbound | Outbound**.

## Default centrally managed SSL configuration

It is simpler to manage SSL configurations centrally in the topology view of the administrative console, but you can also use wsadmin scripting within AdminTasks to manage SSL configurations.

The configuration element of the `security.xml` file can be used to manage SSL configuration associations. The `sslConfigGroup` configuration object is the mechanism that is used to associate a connection direction and management scope with a specific SSL configuration and certificate alias. The default `sslConfigGroups` cell attribute has a predefined inbound and outbound cell-scoped configuration that each endpoint in the cell inherits. Because rules of precedence must guide you when you select SSL configurations, see “Secure communications using Secure Sockets Layer (SSL)” on page 1881 before you modify your configurations using wsadmin scripting.

```
<sslConfigGroups xmi:id="SSLConfigGroup_1"
name="myhostCell01" direction="inbound" certificateAlias="default"
sslConfig="SSLConfig_1" managementScope="ManagementScope_1"/>
<sslConfigGroups xmi:id="SSLConfigGroup_2" name="myhostCell01"
direction="outbound" certificateAlias="default" sslConfig="SSLConfig_1"
managementScope="ManagementScope_1"/>

<managementScopes xmi:id="ManagementScope_1"
scopeName="(cell):myhostCell01" scopeType="cell"/>
```

In the previous sample code, the `sslConfigGroups` attribute references the cell management scope. For that example, if a different scope was intended the following list shows the precedence order for selecting management scopes, from the highest order of precedence to the lowest. Each time an endpoint scope is defined, it uses the specified SSL configuration and certificate alias.

### Endpoint scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01:
(node):myhostNode01:(server):server1:(endpoint):ENDPOINT_NAME_IN_SERVERINDEX"
scopeType="endpoint"/>
```

### Server scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell01:
(node):myhostNode01:(server):server1" scopeType="server"/>
```

## Cluster scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell101:
(cluster):myCluster" scopeType="cluster"/>
```

## Node scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell101:
(node):myhostNode01" scopeType="node"/>
```

## Nodegroup scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell101:
(nodegroup):DefaultNodeGroup" scopeType="nodegroup"/>
```

## Cell scope

```
<managementScopes xmi:id="ManagementScope_1" scopeName="(cell):myhostCell101"
scopeType="cell"/>
```

## Secure Sockets Layer node, application server, and cluster isolation

Secure Sockets Layer (SSL) enables you to ensure that any client that attempts to connect to a server during the handshake first performs server authentication. Using SSL configurations at the node, application server, and cluster scopes, you can isolate communication between servers that should not be allowed to communicate with each other over secure ports.

Before you attempt to isolate communications controlled by WebSphere Application Server, you must have a good understanding of the deployment topology and application environment. To isolate a node, application server, or cluster, you must be able to control the signers that are contained in the truststores that are associated with the SSL configuration. When the client does not contain the server signer, it cannot establish a connection to the server. By default, WebSphere uses chained certificates and each node has a unique root certificate signer. Because they the node shares the same root signer, all of the server in that node can connect to each other because they share the same root signer. However, if you use self-signed certificates, the server that created the personal certificate controls the signer, although you do have to manage the self-signed certificates. If you obtain certificates from a certificate authority (CA), you must obtain multiple CA signers because all of the servers can connect to each other if they share the same signer.

Authenticating only the server-side of a connection is not adequate protection when you need to isolate a server. Any client can obtain a signer certificate for the server and add it to its trust store. SSL client authentication must also be enabled between servers so that the server can control its connections by deciding which client certificates it can trust. For more information, see “Enabling Secure Sockets Layer client authentication for a specific inbound endpoint” on page 1961, which applies as well to enabling SSL client authentication at the cell level.

Isolation also requires that you use centrally managed SSL configurations for all or most endpoints in the cell. Centrally managed configurations can be scoped, unlike direct or end point configuration selection, and they enable you to create SSL configurations, key stores, and trust stores at a particular scope. Because of the inheritance hierarchy of WebSphere Application Server cells, if you select only the properties that you need for an SSL configuration, only these properties are defined at your selected scope or lower. For example, if you configure at the node scope, your configuration applies to the application server and individual end point scopes below the node scope. For more information, see “Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes” on page 1959, “Selecting an SSL configuration alias directly from an endpoint configuration” on page 1960, and “Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint” on page 1956

When you configure the key stores, which contain cryptographic keys, you must work at the same scope at which you define the SSL configuration and not at a higher scope. For example, if you create a key store that contains a certificate whose host name is part of the distinguished name (DN), then store that keystore in the node directory of the configuration repository. If you decide to create a certificate for the application server, then store that keystore on the application server in the application server directory.

When you configure the trust stores, which control trust decisions on the server, you must consider how much you want to isolate the application servers. You cannot isolate the application servers from the node agents or the deployment manager. However, you can configure the SOAP connector end points with the same personal certificate or to share trust. Naming persistence requires IIOp connections when they pass through the deployment manager. Because application servers always connect to the node agents when the server starts, the IIOp protocol requires that WebSphere Application Server establish trust between the application servers and the node agents.

## Establishing node SSL isolation

By default, WebSphere Application Server installation uses a single chained certificate for each node so you can isolate nodes easily. A common trust store, which is located in the cell directory of the configuration repository, contains all of the signers for each node that is federated into the cell. After federation, each cell process trusts all of the other cell processes because every SSL configuration references the common trust store.

You can modify the default configuration so that each node has its own trust store, and every application server on the node trusts only the node agent that uses the same personal certificate. You must also add the signer to the node trust store so that WebSphere Application Server can establish trust with the deployment manager. To isolate the node, ensure that the following conditions are met:

- The deployment manager must initiate connections to any process
- The node agent must initiate connections to the deployment manager and its own application servers
- The application servers must initiate connections to the applications servers on the same node, to its own node agent, and the deployment manager

Figure 1 shows Node Agent A contains a key.p12 keystore and a trust.p12 trust store at the node level of the configuration repository for node A.

*Figure 33.*

When you associate an SSL configuration with this keystore and truststore, you break the link with the cell-scoped trust store. To isolate the node completely, repeat this process for each node in the cell. WebSphere Application Server SSL configurations override the cell scope and use the node scope instead so that each process at this scope uses the SSL configuration and certificate alias that you selected at this scope. You establish proper administrative trust by ensuring that nodeA signer is in the common trust store and the cell signer is in the nodeA trust store. The same logic applies to node B as well. For more information, see “Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes” on page 1959.

## Establishing application server SSL isolation

Isolating application server processes from one another is more challenging than isolating nodes. You must consider the following application design and topology conditions:

- An application server process might need to communicate with the node agent and deployment manager
- Isolating application server processes from each other might disable single sign-on capabilities for horizontal propagation

If you configure outbound SSL configurations dynamically, you can accommodate these conditions. When you define a specific outbound protocol, target host, and port for each different SSL configuration, you can override the scoped configuration.

Figure 2 shows how you might isolate an application server completely, although in practice this approach would be more complicated.

Figure 34.

The dynamic configuration enables server1 on Node A to communicate with server 1 on Node B only over IIOp. The dynamic outbound rule is IIOp,nodeBhostname,\* . For more information, see “Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint” on page 1956

## Establishing cluster SSL isolation

You can configure application servers into clusters instead of scoping them centrally at the node or dynamically at the server to establish cluster SSL isolation. While clustered servers can communicate with each other, application servers outside of the cluster cannot communicate with the cluster, thus isolating the clustered servers. For example, you might need to separate applications from different departments while maintaining a basic level of trust among the clustered servers. Using the dynamic outbound SSL configuration method described for servers above, you can easily extend the isolated cluster as needed.

Figure 3 shows a sample cluster configuration where cluster 1 contains a key.p12 with its own self-signed certificate, and a trust.p12 that is located in the config/cells/<cellname>/clusters/<clustername> directory.

Figure 35.

In the example, cluster1 might contain web applications, and cluster2 might contain EJB applications. Considering the various protocols, you decide to enable IIOp traffic between the two clusters. Your task is to define a dynamic outbound SSL configuration at the cluster1 scope with the following properties:

```
IIOp,nodeAhostname,9403|IIOp,nodeAhostname,9404|IIOp,nodeBhostname,9403|IIOp,nodeBhostname,9404
```

You must create another SSL configuration at the cluster1 scope that contains a new trust.p12 file with the cluster2 signer. Consequently, outbound IIOp requests go either to nodeAhostname ports 9403 and 9404 or to nodeBhostname ports 9403 and 9404. The IIOp SSL port numbers on these two application server processes in cluster2 identify the ports.

As you review Figure 3, notice the following features of the cluster isolation configuration:

- The trust.p12 for cluster1 contains signers that allow communications with itself (cluster1 signer), between both node agents (nodeAsigner and nodeBsigner), and with the deployment manager (cell signer).
- The trust.p12 for cluster2 contains signers that allow communications with itself (cluster2 signer), between both node agents (nodeAsigner and nodeBsigner), and with the deployment manager (cell signer).
- Node agent A and Node agent B can communicate with themselves, the deployment manager, and both clusters.

For more information, see “Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint” on page 1956.

Although this article presents an overview of isolation methods from an SSL perspective, you must also ensure that non-SSL ports are closed or applications require the confidentiality constraint in the deployment descriptor. For example, you can set the CSiv2 inbound transport panel to require SSL and disable the channel ports that are not secure from the server ports configuration.

Also, you must enable SSL client authentication for SSL to enforce the isolation requirements on both sides of a connection. Without mutual SSL client authentication, a client can easily obtain a signer for the server programmatically and thus bypass the goal of isolation. With SSL client authentication, the server

would require the client's signer for the connection to succeed. For HTTP/S protocol, the client is typically a browser, a web service, or a URL connection. For the IIOP/S protocol, the client is typically another application server or a Java client. WebSphere Application Server must know the clients to determine if SSL client authentication enablement is possible. Any applications that are available through a public protocol must not enable SSL client authentication because the client may fail to obtain a certificate to authenticate to the server.

**Note:** It is beyond the scope of this article to describe all of the factors you must consider to achieve complete isolation.

## Certificate options during profile creation

Starting in WebSphere Application Server Version 7.0, you have several options available during profile creation concerning the default certificate and root certificate of the server.

The new certificate options enable you to:

- Import the default certificate of the server
- Import the root certificate of the server
- Customize the default certificate subjectDN and validity period of the server
- Customize the root certificate subjectDN and validity period of the server

Two new panels are available during profile creation that enable you to make decisions about the default certificate and root certificate of the server.

The first panel, titled Security Certificate (Part 1), enables you to choose to import a certificate or to have WebSphere Application Server create the default certificate or the default root certificate of the server for you.

The second panel, titled Security Certificate (Part 2), either displays the information from the certificate imported from the previous panel, or, if you choose to have WebSphere Application Server create the certificate, enables you to change the subjectDN and the certificate validity period.

Customization of certificates can also be performed by using the `manageprofile` command and from a silent install response file.

## Importing the default certificate of the server during profile creation

If the default certificate of the server is imported during profile creation, it is added to `NodeDefaultKeyStore` if on a stand-alone application server, or to `CellDefaultKeyStore` if on a deployment manager. The imported certificate signer is added to `NodeDefaultTrustStore` or `CellDefaultTrustStore`.

To import the default certificate of the server, you must have a personal certificate stored and a keystore that you have access to. You must know the location, type and password of the keystore. On the Security Certificate (Part 1) panel, do the following:

1. Select **Import an existing default personal certificate**.
2. Type or select the keystore file name.
3. Enter the password of the keystore.
4. Select a keystore type from the pull-down list.
5. If you have correctly filled in all information from the previous 3 steps, you are able to select a certificate alias from the pull-down list.

The certificate you choose is imported to the default keystore of the server. The next panel, Security Certificate (Part 2) displays the `issuedTo` and `issuedBy` certificate information.

If you use the `manageprofiles` command to import the default certificate, the options are:

- importPersonalCertKS keystore\_path**  
the keystore file location
- importPersonalCertKSType keystore\_type**  
the type of the keystore
- importPersonalCertKSPassword keystore\_password**  
the password to open the keystore
- importPersonalCertKSAlias keystore\_alias**  
the alias of the certificate used from the keystore

## Importing the root certificate of the server during profile creation

If the server root certificate is imported during profile creation, the certificate is added to NodeDefaultRootStore on a stand-alone application server or to DmgrDefaultRootStore on a deployment manager. The signer is pulled from the imported root certificate and added to NodeDefaultTrustStore or CellDefaultTrustStore. The root certificate is used by WebSphere Application Server to sign any chained certificates it creates. If no default certificate is provided during profile creation, WebSphere Application Server uses the root certificate to sign the default certificate of the server.

To import the default certificate of the server, you must have a personal certificate stored and a keystore that you have access to. You must know the location, type and password of the keystore. On the Security Certificate (Part 1) panel, do the following:

1. Select **Import an existing root signing certificate**.
2. Type or select the keystore file name.
3. Enter the password of the keystore.
4. Select a keystore type from the pull-down list.
5. If you have correctly filled in all information from the previous 3 steps, you are able to select a certificate alias from the pull-down list.

The certificate you choose is imported to the root keystore of the server. The next panel, Security Certificate (Part 2) displays the issuedTo and issuedBy certificate information.

If you use the manageprofiles command to import the root certificate, the options are:

- importSigningIcertKS keystore\_path**  
the keystore file location
- importSigningCertKSType keystore\_type**  
the type of the keystore
- importSigningCertKSPassword keystore\_password**  
the password to open the keystore
- importSigningCertKSAlias keystore\_alias**  
the alias of the certificate used from the keystore

## Customizing the default certificate created by WebSphere Application Server

If you choose to let WebSphere Application Server create the default certificate of the server, you can customize the subject distinguished name (DN) and the life span of the certificate.

To customize the default certificate of the server on the Security Certificate (Part 1) panel, do the following:

1. Select **Create a new default personal certificate**.
2. On the next panel, Security Certificate (Part 2), the Issued to distinguished name field contains the WebSphere Application Server default DN. Replace this with your customized DN.

3. In Expiration period in years, select the number of years you want the certificate to be valid for.

If you use the `manageprofiles` command to customize the default certificate, the options are:

**-personalCertDN distinguished\_name**  
the DN to give to the certificate

**-personalCertValidityPeriod validity\_period**  
the life span to give to the certificate

## Customizing the root certificate created by WebSphere Application Server

If you choose to let WebSphere Application Server create the root certificate, you can customize the DN of the certificate and the life span of the certificate.

To customize the root certificate of the server on the Security Certificate (Part 1) panel, do the following:

1. Select **Create a new root signing certificate**.
2. On the next panel, Security Certificate (Part 2), the Issued by distinguished name field contains the WebSphere Application Server default root certificate DN. Replace this with your customized DN.
3. In Expiration period in years, select the number of years you want the root certificate to be valid for.

If you use the `manageprofiles` command to customize the root certificate, the options are:

**-signingCertDN distinguished\_name**  
the DN to give to the root certificate

**-signingCertValidityPeriod validity\_period**  
the life span to give to the root certificate

## Default chained certificate configuration in SSL

When a WebSphere Application Server process starts for the first time, the Secure Sockets Layer (SSL) runtime initializes the default keystores and truststores that are specified in the SSL configuration.

The chained certificates created during profile creation have a 1 year life span by default. The default root certificate used to sign the default chained certificate has a life span of 15 years. The life span of the default and the root certificates can be customized during profile creation. An advantage in this type of chained certificate is that only the signer from the root certificate is needed to establish trust. When the chained certificate is regenerated with the same root certificate, clients using that root signer certificate for trust do not lose their trust.

### Default keystore and truststore properties

WebSphere Application Server creates the `key.p12` default keystore file and the `trust.p12` default truststore file during profile creation. A default, chained certificate is also created in the **key.p12** file. The root signer, or public key, of the chained certificate is extracted from the **key.p12** file and added to the **trust.p12** file. If the files do not exist during process startup, they are recreated during startup.

You can identify keystore and truststore defaults because of their suffixes: **DefaultKeyStore** and **DefaultTrustStore**. Also, in the SSL configuration, you must set the **fileBased** attribute to `true` so that the runtime only uses the default keystores and truststore.

On a base application server, default key and truststores are stored in the node directory of the configuration repository. For example, the default `key.p12` and `trust.p12` stores are created with the default profile name, the `myhostNode01Cell` name, and the `myhostNode01` node name. The keystore and truststore are located in the following directories:

- `${WAS_INSTALL_ROOT}/profile/default/config/cells/myhostNode01Cell/nodes/myhostNode01/key.p12`

- `${WAS_INSTALL_ROOT}/profile/default/config/cells/myhostNode01Cell/nodes/myhostNode01/trust.p12`

The default password is **WebAS** for all default keystores generated by WebSphere Application Server. Change the default password after the initial configuration for a more secure environment.

### Default chained certificate

The default chained certificate of the server along with a root self-signed certificate used to sign the default chained certificate are created during profile creation.

You can recreate the certificates with different information simply by deleting the \*.p12 files in /config and /etc. Change the four properties in the next code example to the values you want the certificates to contain, then restart the processes. This causes the server certificate in /config and the client certificate in /etc to differ.

The certificate properties in the next code example exist in the **ssl.client.props** file, but do not exist in the server configuration. However, you can use these values in the server configuration by adding them as custom security properties in the administrative console. Click **Security > Global security > Custom properties** to change the following properties:

```
com.ibm.ssl.defaultCertReqAlias=default_alias
com.ibm.ssl.defaultCertReqSubjectDN=cn=${hostname},ou=myhostNode01,ou=myhostNode01Cell,o=IBM,c=US
com.ibm.ssl.defaultCertReqDays=365
com.ibm.ssl.defaultCertReqKeySize=1024
com.ibm.ssl.rootCertSubjectDN=cn=${hostname},ou=Root Certificate, ou=myhostNode01,
ou=myhostNode01Cell,o=IBM,c=US
com.ibm.ssl.rootCertValidDays=7300
com.ibm.ssl.rootCertAlias=root
com.ibm.ssl.rootCertKeySize=1024
```

After changing the properties, complete the following actions:

1. Delete the default key.p12 keystore and trust.p12 truststore files for the deployment manager, which contain the default chained certificate. If the keystore and truststore file do not exist, WebSphere Application Server automatically generates them and creates new default certificates using the previously listed property values.
2. Delete the root keystore, which is the root-key.p12 file, to regenerate the root certificate with the previously listed properties.
3. Restart the deployment manager, its node, and all of the servers.
4. Sign each node using the root certificate.
  - If the nodes are not federated, federate each node into the deployment manager using the addNode command. The default certificate for the node is regenerated using the root certificate for the cell.
  - If the nodes are federated, renew the certificate for each node using the root certificate for the cell. You can renew the certificate using the administrative console or using the renewCertificate command. For more information, see the renewing a certificate and the renewCertificate command documentation.

If a default\_alias value already exists, the runtime appends \_#, where the number sign (#) is a number that increases until it is unique in the keystore. \${hostname} is a variable that is resolved to the host name where it was originally created. The default expiration date of chained certificates is one year from their creation date.

The runtime monitors the expiration dates of chained certificates using the certificate expiration monitor. These chained certificates are automatically replaced along with any signer certificates when they are within the expiration threshold, which is typically 30 days before expiration. You can increase the default key size beyond 1024 bits only when the Java runtime environment policy files are unrestricted (that is, not exported). For more information, see “Certificate expiration monitoring in SSL” on page 1915.

### Default keystore and truststore configurations for new Base Application Server processes

The following sample code shows the default SSL configuration for a base application server. References to the default keystores and truststores files are highlighted.

```
<repertoire xmi:id="SSLConfig_1" alias="NodeDefaultSSLSettings"
managementScope="ManagementScope_1">
<setting xmi:id="SecureSocketLayer_1" clientAuthentication="false"
securityLevel="HIGH" enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS"
keyStore="KeyStore_1" trustStore="KeyStore_2" trustManager="TrustManager_1"
keyManager="KeyManager_1"/>
</repertoire>
```

## Default keystore

In the following sample code, the keystore object that represents the default keystore is similar to the XML object.

```
<keyStores xmi:id="KeyStore_1" name="NodeDefaultKeyStore"
password="{xor}349dkckdd=" provider="IBMJCE" location="{WAS_INSTALL_ROOT}/config
/cells/myhostNode01Cell/nodes/myhostNode01/key.p12" type="PKCS12" fileBased="true"
hostList="" initializeAtStartup="true" managementScope="ManagementScope_1"/>
```

The **NodeDefaultKeyStore** keystore contains the personal certificate that represents the identity of the secure endpoint. Any keystore reference can use the `{WAS_INSTALL_ROOT}` variable, which is expanded by the runtime. The PKCS12 default keystore type is in the most interoperable format, which means that it can be imported into most browsers. The `myhostNode01Cell` password is encoded. The management scope determines which server runtime loads the keystore configuration into memory, as shown in the following code sample:

```
<managementScopes xmi:id="ManagementScope_1" scopeName="
(cell):myhostNode01Cell:(node):myhostNode01" scopeType="node"/>
```

Any configuration objects that are stored in the **security.xml** file whose management scopes are outside the current process scope are not loaded in the current process. Instead, the management scope is loaded by servers that are contained within the `myhostNode01` node. Any application server that is on the specific node can view the keystore configuration.

When you list the contents of the **key.p12** file to show the chained certificate, note that the common name (CN) of the distinguished name (DN) is the host name of the resident machine. This listing enables you to verify the host name by its URL connections. Additionally, you can verify the host name from a custom trust manager. For more information, see “Trust manager control of X.509 certificate trust decisions” on page 1890.

## Contents of default keystore

The following sample code shows the contents of the default **key.p12** file in a keytool list:

```
{profile_root}\config\cells\{cellname}\nodes\{nodename}> keytool -list
-v -keystore {WAS_INSTALL_ROOT}/profile/default/config/cells/myhostNode01Cell
/nodes/myhostNode01/key.p12 -storetype PKCS12 -storepass *****
```

```
Keystore type: PKCS12
Keystore provider: IBMJCE
```

Your keystore contains 1 entry

```
Alias name: default
Creation date: Dec 31, 1969
Entry type: keyEntry
Certificate chain length: 2
Certificate[1]:
Owner: CN=myhost.austin.ibm.com, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US
Issuer: CN=myhost.austin.ibm.com, OU=Root Certificate, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US
Serial number: 4e48f29aafa6
Valid from: 2/7/08 1:03 PM until: 2/6/09 1:03 PM
Certificate fingerprints:
 MD5: DB:FE:65:DB:40:13:F4:48:A4:CE:2F:4F:60:A5:FF:2C
 SHA1: A1:D4:DD:4B:DE:7B:45:F7:4D:AA:6A:FC:92:38:78:53:7A:99:F1:DC
Certificate[2]:
Owner: CN=myhost.austin.ibm.com, OU=Root Certificate, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US
Issuer: CN=myhost.austin.ibm.com, OU=Root Certificate, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US
Serial number: 4e48e5fd4eae3
Valid from: 2/7/08 1:03 PM until: 2/2/28 1:03 PM
Certificate fingerprints:
 MD5: A5:9B:05:78:CF:AB:89:94:C9:2E:F1:87:34:B3:FC:75
 SHA1: 43:74:B6:C7:FA:C1:0F:19:F2:51:2B:17:60:0D:34:93:55:BF:D5:D2
```

```

```

The default alias name and the `keyEntry` entry type indicate that the private key is stored with the public key, which represents a complete personal certificate. The certificate is owned

byCN=myhost.austin.ibm.com, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US and it is issued by the default root certificate, which is owned byCN=myhost.austin.ibm.com, OU=Root Certificate, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US By default, the certificate is valid for one year from the date of creation.

Additionally, in some signer-exchange situations, the certificate fingerprint ensures that the sent certificate has not been modified. The fingerprint, which is a hash algorithm output for the certificate, is displayed by the WebSphere Application Server runtime during an automated signer exchange on the client side. The client fingerprint must match the fingerprint that is displayed on the server. The runtime typically uses the SHA1 hash algorithm to generate certificate fingerprints.

## Default truststore

In the following sample code, the keystore object represents the default trust.p12 truststore. The truststore contains signer certificates that are necessary for making trust decisions:

```
<keyStores xmi:id="KeyStore_2" name="NodeDefaultTrustStore"
password="{xor}349dkckdd=" provider="IBMJCE" location="{WAS_INSTALL_ROOT}
/config/cells/myhostNode01Cell/nodes/myhostNode01/trust.p12" type="PKCS12"
fileBased="true" hostList="" initializeAtStartup="true" managementScope="ManagementScope_1"/>
```

## Contents of default truststore

The following sample code shows the contents of the default trust.p12 truststore in a keytool listing. By default, for the sample chained certificate, the root certificate signer is included in the trust store. The root signer alias name and the trustedCertEntry entry type indicate that the certificate is the public key. The private key is not stored in this truststore. In addition, all truststores contain the default DataPower certificate.

```
/${profile_root}\config\cells\${cellname}\nodes\${nodename}> keytool -list
-v -keystore ${WAS_INSTALL_ROOT}/profile/default/config/cells/myhostNode01Cell
/nodes/myhostNode01/trust.p12 -storetype PKCS12 -storepass *****
```

```
Keystore type: PKCS12
Keystore provider: IBMJCE
```

Your keystore contains 2 entries

```
Alias name: root
Creation date: Dec 31, 1969
Entry type: trustedCertEntry
```

```
Owner: CN=myhost.austin.ibm.com, OU=Root Certificate, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US
Issuer: CN=myhost.austin.ibm.com, OU=Root Certificate, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US

```

## Secure installation for client signer retrieval in SSL:

Each profile in the WebSphere Application Server environment contains a unique chained certificate signed by a unique long lived root certificate that was created when the profile was created. This certificate replaces the default self-signed certificate that ships with WebSphere Application Server Version 6.1 as well as the default dummy certificate that ships in releases prior to Version 6.1. When a profile is federated to a deployment manager, the signer for the root signing certificate is added to the common truststore for the cell, establishing trust for all certificates signed by that root certificate.

**Note:** Do not use the dummy keystore and truststore files, which are referenced in this topic, in a production environment. These files contain the same certificates and are used everywhere, which is not secure. Also, change the passwords for the keystore and truststore so that it does not use the WebAS default password.

By default, clients do not trust servers from different profiles in the WebSphere Application Server environment. That is, they do not contain the root signer for these servers. There are some things that you can do to assist in establishing this trust:

1. Enable the signer exchange prompt to except the signer during the connection attempt.
2. Run the **retrieveSigners** utility to download the signers from that system prior to making the connection.
3. Copy the trust.p12 file from the `/config/cells/<cell_name>/nodes/<node_name>` directory of the server profile to the `/etc` directory of the client. Update the SSL configuration to reflect the new file name and password, if they are different. Copying the file provides the client with a trust.p12 that contains all signers from servers in that cell. Also, you might need to perform this step for back-level clients that are still using the `DummyClientTrustFile.jks` file. In this case, you might need to change the `sas.client.props` or `soap.client.props` file to reflect the new truststore, truststore password, and truststore type (PKCS12).

For clients to perform an in-band signer exchange, you must specify the `ssl.client.props` file as a `com.ibm.SSL.ConfigURL` property in the SSL configuration. For managed clients, this is done automatically. Signers are designated either as in-band during the connection or out-of-band during runtime. You must also set the `com.ibm.ssl.enableSignerExchangePrompt` attribute to `true`.

**Tip:** You can configure a certificate expiration monitor to replace server certificates that are about to expire. For more information about how clients can retrieve the new signer from the configuration, see “Certificate expiration monitoring in SSL” on page 1915.

### Using the signer exchange prompt to retrieve signers from a client

When the client does not already have a signer to connect to a process, you can enable the signer exchange prompt. The signer exchange prompt displays once for each unique certificate and for each node. After the signer for the node is added, the signer remains in the client truststore. The following sample code shows the signer exchange prompt retrieving a signer from a client:

```
C:\WASX_e0540.11\AppServer\profiles\AppSrv01\bin\serverStatus -all ADMU0116I: Tool information is being logged in file
C:\WASX_e0540.11\AppServer\profiles\AppSrv01\logs\serverStatus.log ADMU0128I: Starting tool with the
AppSrv01 profile ADMU0503I:
Retrieving server status for all servers ADMU0505I: Servers found in configuration:
ADMU0506I: Server name: dmgr
*** SSL SIGNER EXCHANGE PROMPT *** SSL signer from target host 192.168.1.5 is not found in truststore
C:\WebSphere\AppServer\profiles\AppSrv01\etc\trust.p12.
```

```
Here is the signer information (verify the digest value matches what is displayed at the server):
Subject DN: CN=myhost.austin.ibm.com, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US
Issuer DN: CN=myhost.austin.ibm.com, OU=Root Certificate, OU=myhostNode01Cell, OU=myhostNode01,
O=IBM, C=US
Serial number: 2510775664686266 Expires: Thu Feb 19 15:58:49 CST 2009

```

```
Subject DN: CN=myhost.austin.ibm.com, OU=Root Certificate, OU=myhostNode01Cell,
OU=myhostNode01, O=IBM, C=US Issuer DN: CN=myhost.austin.ibm.com, OU=Root
Certificate, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US Serial number:
2510773295548841 Expires: Tue Feb 15 15:58:46 CST 2028 SHA-1 Digest:
2F:96:70:23:08:58:6F:66:CD:72:61:E3:46:8B:39:D4:AF:62:98:C3
MD5 Digest: 04:53:F8:20:A2:8A:6D:31:D0:1D:18:90:3D:58:B9:9D
Add signer to the truststore now? (y/n) y A retry of the request may need to occur. ADMU0508I:
The Deployment Manager "dmgr" is STARTED
```

To automate this process, see “retrieveSigners command” on page 1913.

When a prompt occurs to accept the signer, a socket timeout can occur and the connection might be broken. For this reason, the message A retry of the request may need to occur. displays after answering the prompt. The message informs the user to resubmit the request. This problem should not happen frequently, and it might be more prevalent for some protocols than others.

A retry of the request may need to occur if the socket times out while waiting for a prompt response. If the retry is required, note that the prompt will not be re-displayed if (y) is entered, which indicates the signer has already been added to the trust store.

Verify the displayed SHA-1 digest, which is the signature of the certificate that is sent by the server. If you look at the certificate on the server, verify that the same SHA-1 digest displays.

You can disable the prompt when you do not want it to display by running the **retrieveSigners** utility to retrieve all of the signers for a particular cell. You can download or upload the signers from any remote keystore to any local keystore by referencing a common truststore with this client script. For more information, see “Default chained certificate configuration in SSL” on page 1907.

### Using the retrieveSigners utility to download signers for a client

You can run the **retrieveSigners** utility to retrieve all of the signers from the remote keystore for a specified client keystore.

The typical remote keystore to reference is CellDefaultTrustStore.

The truststore contains the signers that enable the client to connect to its processes. The **retrieveSigners** utility can point to any keystore in the target configuration, within the scope of the target process, and can download the signers (certificate entries only) to any client keystore in the `ssl.client.props` file.

The following sample code shows the **retrieveSigners** utility in a deployment manager environment.

```
C:\WASX_e0540.11\AppServer\profiles\AppSrv01\bin\retrieveSigners.bat CellDefaultTrustStore
ClientDefaultTrustStore -autoAcceptBootstrapSigner CWPKI0308I: Adding signer alias
"CN=myhost.austin.ibm.com,
O=IBM, C=US" to local keystore "ClientDefaultTrustStore" with the following SHA
digest: 91:A1:A9:2D:F2:7D:70:0F:04:06:73:A3:B4:A4:9C:56:9D:A8:A3:BA CWPKI0308I:
Adding signer alias "default" to
local keystore "ClientDefaultTrustStore" with the following SHA digest:
40:20:CF:BE:B4:B2:9C:F0:96:4D:EE:E5:14:92:9E:37:8D:51:A5:47
```

Use the **-autoAcceptBootstrapSigner** option to enable WebSphere Application Server automatically to retrieve and accept the signer for administrative connections. The SHA-1 digest is printed while the signer is added so you can verify the digest after the operation is complete.

### Obtaining signers for clients and servers from a previous release

**Note:** When a client from a release prior to version 7.0 connects to the current release, the client must obtain signers for a successful handshake. Clients using previous releases of WebSphere Application Server cannot obtain signers as easily as in the current release. You can copy the deployment manager *common* truststore to your back-level client or server, and then re-configure the SSL configuration to directly reference that truststore. This common truststore of type PKCS12 is located in the `/config/cells/<cell_name>/nodes/<node_name>` directory in the configuration repository and has a default password of WebAS.

To collect all of the signers for the cell in a single `trust.p12` keystore file, complete following steps:

1. Copy the trust.p12 keystore file on the server and replicate it on the client. The client references the file directly from the sas.client.props and soap.client.props files that specify the SSL properties for previous releases.
2. Change the client-side keystore password so that it matches the default cell name that is associated with the copied keystore.
3. Change the default keystore type for the trust.p12 file to PKCS12 in the client configuration.

The following two code samples show you a before and an after view of the changes to make.

#### Default SSL configuration of sas.client.props for a previous release

```
com.ibm.ssl.protocol=SSL com.ibm.ssl.keyStore=file:/// C:/SERV1_601_0208/AppServer/profiles/AppSrv01/etc/DummyClientKeyFile.jks com.ibm.ssl.keyStorePassword={xor}CDo9Hgw\= com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.trustStore=
file:/// C:/SERV1_601_0208/AppServer/profiles/AppSrv01/etc/DummyClientTrustFile.jks
com.ibm.ssl.trustStorePassword={xor}CDo9Hgw\=
com.ibm.ssl.trustStoreType=JKS
```

#### SSL configuration changes that are required to common truststore file in the /etc directory of the client

```
com.ibm.ssl.protocol=SSL com.ibm.ssl.keyStore=file:/// C:/SERV1_601_0208/AppServer/profiles/AppSrv01/etc/DummyClientKeyFile.jks com.ibm.ssl.keyStorePassword={xor}CDo9Hgw\= com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.trustStore=file:/// C:/SERV1_601_0208/AppServer/profiles/AppSrv01/etc/trust.p12
com.ibm.ssl.trustStorePassword=myhostNode01Cell com.ibm.ssl.trustStoreType=PKCS12
```

**Tip:** You can run the **PropsFilePasswordEncoder** script, which is located in the /bin directory to encode the password.

You can also make these changes in the soap.client.props file and specify the key.p12 file in place of the DummyClientKeyFile.jks file. However, you must also change the keyStorePassword and keyStoreType values to match those in the default key.p12 file.

In releases of WebSphere Application Server prior to Version 7.0, you must edit the SSL configuration on the server to replace the common truststore. The trust.p12 file, which is used by the server, also must contain the default dummy certificate signer for connections among servers at previous release levels. You might need to manually extract the default certificate from the DummyServerKeyFile.jks file and then import the certificate into the trust.p12 file that you added to the configuration.

*retrieveSigners command:*

The retrieveSigners command creates a new client self-signed certificate, keystore, and SSL configuration in the ssl.client.props file. Using this command you can optionally extract the signer to a file.

For more information about where to run this command, read about Using command tools.

#### Syntax

Use the following command syntax to create a new client self-signed certificate, keystore, and SSL configuration in the ssl.client.props file.

```
retrieveSigners <remoteKeyStoreName> <localKeyStoreName> [options]
```

The <remoteKeyStoreName> and <localKeyStoreName> parameters are required. The following optional parameters are available:

```
[-remoteAlias aliasFromRemoteStore]
[-localAlias storeAsAlias]
[-listRemoteKeyStoreNames] [-listLocalKeyStoreNames]
[-autoAcceptBootstrapSigner] [-uploadSigners] [-host host]
```

```
[-port port] [-conntype JSR160RMI|RMI|SOAP|IPC] [-user user]
[-password password]
[-trace] [-logfile filename]
[-replacelog] [-quiet] [-help]
```

## Parameters

The following parameters are available for the **retrieveSigners** command:

### **-remoteKeyStoreName**

The name of a truststore that is located in the server configuration from which to retrieve the signers. This parameter is typically the CellDefaultTrustStore file for a managed environment or the NodeDefaultTrustStore file for an unmanaged environment.

### **-localKeyStoreName**

The name of the truststore that is located in the ssl.client.props file for the profile to which the retrieved signers is added. This parameter is typically the ClientDefaultTrustStore file for either a managed or unmanaged environment.

### **-remoteAlias <aliasFromRemoteStore>**

Specifies one alias from the remote truststore that you want to retrieve. Otherwise, all signers from the remote truststore are retrieved.

### **-localAlias <storeAsAlias>**

Determines the name of the alias stored in the local truststore. This option is only valid if you specify the `-remoteAlias` option. If you do not specify the `-localAlias` option, then the alias name from the remote truststore is used, if possible. If an alias clash occurs, then the alias name is used and has an incremented number appended to the end of it until a unique alias is found.

### **-listRemoteKeyStoreNames**

Sends a remote request to the server to list all keystores that you can specify for the `remoteKeyStoreName` parameter. Use this command when you are unsure of the name of the remote truststore from which you want to download the signers.

### **-listLocalKeyStoreNames**

Lists the keystores located in the ssl.client.props file that you can specify for the `localKeyStoreName` parameter. This truststore receives the signers from the server. Use this parameter when you are unsure of the name of the local truststore into which you want to retrieve the signers. The default name of the truststore is `ClientDefaultTrustStore` and is located in the ssl.client.props file.

### **-autoAcceptBootstrapSigner**

Automatically adds a signer to make a secure connection to the server. The purpose of the option is to support automation of the command so that you do not need to accept the signer. After the signer is added to the local truststore, an SHA hash prints so that you can verify the certificate.

### **-uploadSigners**

Converts the signer download into a signer upload. The signers from the `localKeyStoreName` parameter is sent to the `remoteKeyStoreName` parameter instead.

### **-host <host>**

Specifies the target host from which the signers are retrieved.

### **-port <port>**

Specifies the target administrative port to which you want to connect. You must specify the port based on the `-conntype` parameter. If the `conntype` is `SOAP`, the default port is 8879. This value can vary for different servers. If the `conntype` is `RMI`, the default port is 2809.

### **-conntype <JSR160RMI|IPC|RMI|Soap>**

Determines the administrative connector type that is used for the MBean call to retrieve the signers.

**Note:** Eventually switch from the RMI connector to the JSR160RMI connector because support for the RMI connector is deprecated.

**-user <user>**

When the `-uploadSigners` flag is used, you are required to specify this option to supply the user name that is authenticated for the MBean operation. If you do not specify this parameter when the `-uploadSigners` flag is used, then you are prompted for credentials by default.

**-password <password>**

When the `-uploadSigners` flag is used, you are required to specify this option to supply the password that is authenticated for the MBean operation. The password goes along with the `-user` parameter.

**-trace**

When specified, this parameter enables tracing of the trace specification necessary to debug this component. By default, the trace is located in the profiles/*profile\_name*/log/retrieveSigners.log file.

**-logfile <filename>**

Overrides the default trace file. By default, the trace will appear in the profiles/*profile\_name*/log/retrieveSigners.log file.

**-replacelog**

Causes the existing trace file to be replaced when the command runs.

**-quiet**

Suppresses most messages from printing to the console.

**-help**

Prints a usage statement.

**-?** Prints a usage statement.

## Usage scenario

The following examples demonstrate correct syntax for using the **retrieveSigners** command:

- The following example lists remote and local keystores:

```
retrieveSigners.bat -listRemoteKeyStoreNames -listLocalKeyStoreNames -conntype RMI -port 2809 [Windows]
```

```
retrieveSigners.sh -listRemoteKeyStoreNames -listLocalKeyStoreNames -conntype RMI -port 2809 [Unix]
```

### Example output

```
CWPKI0306I: The following remote keystores exist on the specified server:
 CMSKeyStore, NodeLTPAKeys, NodeDefaultTrustStore, NodeDefaultKeyStore
CWPKI0307I: The following local keystores exist on the client:
 ClientDefaultKeyStore, ClientDefaultTrustStore
```

- The following example retrieves all signers from NodeDefaultTrustStore:

```
retrieveSigners.bat NodeDefaultTrustStore ClientDefaultTrustStore -autoAcceptBootstrapSigner
-conntype RMI -port 2809 [Windows]
```

```
retrieveSigners.sh NodeDefaultTrustStore ClientDefaultTrustStore -autoAcceptBootstrapSigner
-conntype RMI -port 2809 [Unix]
```

### Example output

```
CWPKI0308I: Adding signer alias "CN=BIRKT40.austin.ibm.com, O=IBM, C=US" to
 local keystore "ClientDefaultTrustStore" with the following SHA
 digest: 40:20:CF:BE:B4:B2:9C:F0:96:4D:EE:E5:14:92:9E:37:8D:51:A5:47
```

## ***Certificate expiration monitoring in SSL:***

The certificate expiration monitor administrative task is a scheduled task that cycles through all the keystores in the security configuration and reports on any certificates that are expired, certificates that fall within the expiration threshold, and certificates that fall within the pre-notification period.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log`, `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using

HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

The certificate expiration monitor also replaces self-signed and chained certificates that have a root in the root keystore if configured to do so. If the monitor is configured to replace certificates, then certificates that are expired or fall in the expiration threshold are replaced. Certificates that are imported from an external Certificate authority (CA) are reported but not replaced.

Certificate expiration monitoring relies on the following definitions:

#### **Expired certificates**

Certificates are created with a finite life span. Self-signed or chained certificates that have reached the end of their life span are reported and replaced, if possible. Certificate authority signed certificates cannot be replaced but will be reported. Replacing CA-signed certificates is the responsibility of the administrator.

#### **Certificates within the expiration threshold**

There is a period of time before a certificate expires. A certificate in this period of time is one within the expiration threshold. The server replaces certificates within the expiration threshold so that the certificate does not expire and cause outages. By default the expiration threshold is 60 days, but can be configured as required.

#### **Pre-notification period**

Before a certificate falls within the expiration threshold there are warnings issued that indicate that the certificate will be replaced, when the expiration threshold date is reached. The period of time prior to the expiration threshold date is called the pre-notification period and is set at 90 days for the certificate.

The certificate expiration monitor performs the following:

1. Clears out the **NodeDefaultDeletedStore** or **DmgrDefaultDeletedStore**. This operation is performed silently without reporting that the certificates are deleted.
2. Checks the root key stores, **DmgrDefaultRootStore** or **NodeDefaultRootStore** and the **DmgrRSATokenRootStore** or **NodeRSATokenRootStore**. If any root certificates are expired, falls in the threshold period, or the pre-notification period, then the certificate is noted in the report.
3. If there are any root certificates that are expired or fall in the threshold period that root certificate is recreated using all the information used to create the original one. Any signer certificates from the original root certificate are replaced with the signers from the new root certificate.
4. If a root certificate is replaced, then all the keystores are checked to see if there are any chained certificates signed with the original root certificate. If there are, then the chain certificate is renewed (recreated with the new root certificate). Any signer certificate from the original certificate is replaced with the signer from the recreated certificate.
5. After all root keystores are processed, the rest of the keystores are checked for expired certificates, certificates in the expiration threshold, or certificates in the pre-notification period. Any certificate falling in any one of these categories is noted in the report.
6. If there are any expired certificates or certificates in the expiration threshold period and these certificates are self-signed certificates or chained certificates created by WebSphere, then they are replaced. If the chained certificates root is not in the root key store then it will be recreated as a default root certificate. Any signer certificates from the original certificate are replaced with the signer from the new certificate."
7. A report is generated and returned, written to a log file, or mailed.

The server default certificate is a chained certificate with a 365 day life span. It is signed with the default root certificate which has a 15 year life span.

You can configure this monitor task to run according to a particular schedule. The schedule produces the next start date that persists in the configuration and, when the date is reached, WebSphere Application Server starts the monitor to check all of the keystores for certificates that meet the expiration threshold. You can start the task manually to run at any time.

The following `security.xml` configuration object specifies when the monitor task starts, determines the certificate expiration threshold, and indicates whether you are notified in an email using Simple Mail Transfer Protocol (SMTP) or in a message log.

```
<wsCertificateExpirationMonitor xmi:id="WSCertificateExpirationMonitor_1"
name="Certificate Expiration Monitor" daysBeforeNotification="30"
isEnabled="true" autoReplace="true" deleteOld="true"
wsNotification="WSNotification_1" wsSchedule="WSSchedule_2"
nextStartDate="1134358204849"/>
```

The expiration monitor replaces self-signed certificates and chained personal certificates that are signed by a root certificate in **DmgrDefaultRootStore** or **NodeDefaultRootStore**. Self-signed certificates are renewed using all the information that was used to create the original self-signed certificate. A chained certificate is renewed using the same root certificate that was used to sign the original certificate.

The expiration monitor automatically replaces only self-signed certificates and chained certificates that are expired or that meet the expiration threshold criteria. To replace all of the signers from the old certificate with the signer that belongs to the new certificate in all the keystores in the configuration for that cell, set the `autoReplace` attribute to `true`. When the `deleteOld` attribute is `true`, the old personal certificate and old signers also are deleted from the keystores. The `isEnabled` attribute determines whether the expiration monitor task runs based upon the `nextStartDate` attribute that is derived from the schedule. The `nextStartDate` attribute is derived from the schedule in milliseconds since 1970, and is identical to the `System.currentTimeMillis()`. If the `nextStartDate` has already passed when an expiration monitor process begins, and the expiration monitor is enabled, the task is started, but a new `nextStartDate` value is established based on the schedule.

The following sample the schedule object shows the frequency attribute as the number of days between each run of the certificate monitor.

```
<wsSchedules xmi:id="WSSchedule_2" name="ExpirationMonitorSchedule"
frequency="30" dayOfWeek="1" hour="21" minute="30"/>
```

The `dayOfWeek` attribute adjusts the schedule to run on a specified day of the week, which is always the same day regardless of whether the frequency is set to 30 or 31 days. Based on 24-hour clock, the hour and minute attributes determine when the expiration monitor is started on the specified day.

The following sample code of the notification object shows the notification configuration, which notifies you after the expiration monitor runs.

```
<wsNotifications xmi:id="WSNotification_1" name="MessageLog" logToSystemOut="true" emailList=""/>
```

For expiration monitor notifications, you can select message log, email using SMTP server, or both methods of notification. When you configure the email option, use the format `user@domain@smtpserver`. If you do not specify an SMTP server, WebSphere Application Server defaults to the same domain as the email address. For example, if you configure `joeuser@ibm.com`, WebSphere Application Server attempts to call `smtp-server.ibm.com`. To specify multiple email addresses using scripting, you must add a pipe (|) character between entries. When you specify the `logToSystemOut` attribute, the expiration monitor results are sent to the message log for the environment, which is typically the `SystemOut.log` file.

The expiration monitor clears out the deleted certificates keystore. The monitor first clears out the deleted keystore. Due to the nature of the PKCS12 keystore, there must be at least one entry in the keystore so the signer certificates from the dummy key store will remain in the deleted keystore. There is no reporting on the certificate being deleted from the deleted keystore.

**Important:** When the expiration monitor replaces certificates, this can dynamically affect the runtime when the following configuration option is enabled:

**Security > SSL certificate and key management.** Under configuration settings, check the checkbox for **Dynamically update the run time when SSL configuration changes occur.**

When enabled, any certificates that are replaced causes the client SSL runtime to begin using the new certificates immediately, which in turn, flushes SSL and keystore caches and causes some ports using SSLServerSockets (RMI/IIOP on distributed and Admin SOAP) to restart. Restarting ports breaks existing connections. These connections can be reconnected after the port restart is completed. Endpoints using the channel framework (HTTP, BUS, RMI/IIOP on z/OS) leave existing connections unaffected but still use the new certificates for new connections.

When the dynamic change property is disabled and before the new certificates become effective, the administrator needs to recycle all processes in the entire cell after each node has the synchronized configuration. Regardless of which method is chosen, you should always check the health of your cell after the certificate expiration monitor has run (based on the schedule specified). The schedule should be set to run the certificate expiration monitor during a maintenance period so that if a restart is required after the certificate replacement, it will not cause unexpected outages.

## Dynamic configuration updates in SSL

During the Secure Sockets Layer (SSL) runtime, dynamic configuration updates affect both inbound and outbound SSL endpoints. For inbound SSL endpoints, the changes that are implemented by the SSL channel are only affected by dynamic changes. For outbound SSL endpoints, all outbound connections inherit the new configuration changes.

In this release, dynamic update functionality provides you with greater flexibility and efficiency. You can change SSL configurations without restarting WebSphere Application Server for the changes to take effect.

To make dynamic changes, in the administrative console click **Security > SSL certificates and key management**, then select the **Dynamically update the runtime when SSL configuration changes occur** check box. You must save your changes and then synchronize the `security.xml` file with remote systems. A remote system must be able to confirm that `dynamicallyUpdateSSLConfig=true` is in the `security.xml` file.

The SSL runtime reloads the modified SSL configuration and creates a new SSLEngine for the modified connections that are associated with inbound endpoints. New outbound connections use the new configuration while existing connections continue to use the old SSLEngine object and are not affected.

**Tip:** Make dynamic changes to the SSL configuration during off-peak hours. Synchronization delays can negatively affect connections when you update SSL configurations during peak hours.

You can turn on and off the `dynamicallyUpdateSSLConfig` attribute in the `security.xml` file to ensure successful updates by doing the following actions:

1. Set `dynamicallyUpdateSSLConfig=On`.
2. Save the updated configuration.
3. Synchronize the `security.xml` file with remote systems.
4. Set the `dynamicallyUpdateSSLConfig` attribute to `Off`.

You must verify that all of the nodes receive the changes before turning off the `dynamicallyUpdateSSLConfig` attribute. Test the changes in a test environment before updating the production environment.

**Tip:** Some SSL changes, especially administrative SSL changes, can cause server outages if you fail to test them first. When a change prevents trust between two endpoints, the endpoints cannot communicate with each other. Additionally, if administrative SSL connection updates cause system

outages, you might need to disable the nodes after you make corrective changes using the deployment manager. From the command line, you can manually synchronize the server to retrieve the new SSL changes, then restart the nodes.

## Management scope configurations

Inbound and outbound management scopes represent opposing directions during the connection handshake process. To view inbound and outbound management scopes, use the topology tree view in the administrative console. You can define Secure Sockets Layer (SSL) configurations to distinguish the connection requirements for each direction inbound or outbound.

When expanded, the topology tree represents inbound and outbound connections for each management scope, cell, node group, node, server, cluster, and endpoint. Inbound endpoints require a server certificate. The SSL configuration specifies the server certificate for server authentication. Outbound endpoints require validated signers. Outbound endpoints connect to one or more target servers; inbound endpoints receive requests from one or more clients. The set of peer endpoints for outbound connections is typically a subset of the set of peer endpoints for inbound connections, which means you must define different requirements for inbound and outbound connections.

The following figure shows an example of two nodes: Node1 and Node2. These two nodes are isolated from one another because their SSL configurations, truststore files, and keystore files are different.

In the example of two nodes, note that Node1 cannot communicate with Node2, but each of the two nodes must be able to communicate with the deployment manager and its administrative functions. With dynamic outbound selection, you can choose an SSL configuration and a certificate alias that reference a common truststore. When a process requires the ADMIN\_SOAP protocol for an outbound connection, the server uses this single SSL configuration. Because all of the scopes under the cell level inherit this configuration, all outbound connections can communicate with the deployment manager. See additional information about dynamic outbound selection of Secure Sockets Layer configurations.

Another way to accomplish this same result is to associate the SSL configuration with the ADMIN\_SOAP endpoint for each individual process, deployment manager, Node1, Node2, Node1Server1, Node1Server2, Node2Server1, and Node2Server2. However, it is recommended that you use dynamic outbound selection because it is more efficient when defining a basic SSL configuration, its keystores, and its truststores at the cell scope. The example shows how to apply the node scope association, but the same principles apply for node groups, clusters, servers, and endpoints.

**Note:** If your topology includes clusters that span nodes or if your applications need to communicate between nodes, the configuration that is shown in the example does not work.

## Certificate management using iKeyman prior to SSL

Starting in WebSphere Application Server Version 6.1, you can manage your certificates from the administrative console. When using versions of WebSphere Application Server prior to Version 6.1, use iKeyman for certificate management. iKeyman is a key management utility.

WebSphere Application Server certificate management requires that you define the keystores in your WebSphere Application Server configuration. With iKeyman, you need access to the keystore file only. You can read a keystore file with personal certificates and signers that is created in iKeyman. A keystore file can be read into the WebSphere Application Server configuration by using the **createKeyStore** command.

The majority of certificate management functions are the same between WebSphere Application Server and iKeyman, especially for personal certificates and signer certificates. However, certificate requests are special. The underlying behavior is different in the two certificate management schemes. Because of the different behavior, when a certificate request is generated from iKeyman, the process must be completed in iKeyman. For example, a certificate that is generated by a certificate request that originated in iKeyman must be received in iKeyman as well.

The same is true for WebSphere Application Server. For example, when a certificate is generated from a certificate request that originated in WebSphere Application Server, the certificate must be received in WebSphere Application Server.

You can perform the following certificate operations using iKeyman:

*Table 148. Available certificate operations using iKeyman. This table describes the available certificate operations using iKeyman.*

Types of certificates	Functions	Description
Personal certificates	Create a self-signed certificate	Creates a self-signed certificate and stores it in a keystore.
	List personal certificates	Lists all the personal certificates in a keystore.
	Get information about a personal certificate	Gets information about a personal certificate.
	Delete a personal certificate	Deletes a personal certificate from a keystore.
	Import a certificate	Imports a certificate from a keystore to a keystore.
	Export a certificate	Exports a certificate from a keystore to another keystore.
	Extract a certificate	Extracts the signer part of a personal certificate to a file.
Signer certificates	Add a signer certificate	Adds a signer certificate from a file to a keystore.
	List signer certificates	Lists all the signer certificates in a keystore.
	Get information about a signer certificate	Gets information about a signer certificate.
	Delete a signer certificate	Deletes a signer certificate from a keystore.
	Extract a signer certificate	Extracts a signer certificate from a keystore, and stores the certificate in a file.
Certificate requests	Create a certificate request	Creates a certificate request that can be sent to a CA.
	List certificate requests	Lists the certificate requests in a keystore.
	Get information about a certificate request	Gets information about a certificate request.
	Delete a certificate request	Deletes a certificate request from a keystore.
	Extract a certificate request	Extracts a certificate request to a file.

## Certificate management in SSL

You can manage certificate operations that involve personal certificates, signer certificates, and personal certificate requests on the administrative console.

### Types of certificates

WebSphere Application Server uses the certificates that reside in keystores to establish trust for a Secure Sockets Layer (SSL) connection. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > SSL\_configuration\_name > Key stores and certificates**, then select an existing or create a new keystore. After selecting a keystore, and depending on the type of certificate you need, choose one of the following types of certificates under Related Items:

- Personal certificate

- Signer certificate
- Certificate Authority (CA) certificates
- Personal certificate request

Table 149. Certificate operations. The following table describes the certificate operations that you can perform on the administrative console

Types of certificates	Functions	Description
Personal certificates	Create a self-signed certificate	Creates a self-signed certificate and stores it in a keystore.
	List personal certificates	Lists all the personal certificates in a keystore.
	Get information about a personal certificate	Gets information about a personal certificate.
	Delete a personal certificate	Deletes a personal certificate from a keystore.
	Import a certificate	Imports a certificate from a keystore to a keystore.
	Export a certificate	Exports a certificate from a keystore to another keystore.
	Extract a certificate	Extracts the signer part of a personal certificate to a file.
	Exchange signer certificates	Exchange signer part of a personal certificate between key store.
	Receive a certificate	Reads a certificate that comes from a certificate authority (CA) into a keystore.
	Replace a certificate	Replaces all occurrences of a personal certificate alias in the WebSphere Application Server configuration with another certificate. Also, replaces all occurrences of the personal certificates signer with the new personal certificate signer.
	Create a chained certificate	Creates a chained certificate and stores it in a keystore.
	Renew a certificate	Renews a certificate with a new public/private key pair and stores it in a keystore.
	Request a CA certificate	Makes a request to a CA using a CA client to obtain a CA certificate.
Certificate authority (CA) certificates	Create CA certificate	Sends a certificate request to an external certificate authority (CA).
	Revoke CA certificate	Sends a revocation request to an external certificate authority (CA).
Signer certificates	Add a signer certificate	Adds a signer certificate from a file to a keystore.
	List signer certificates	Lists all the signer certificates in a keystore.
	Get information about a signer certificate	Gets information about a signer certificate.
	Delete a signer certificate	Deletes a signer certificate from a keystore.
	Extract a signer certificate	Extracts a signer certificate from a keystore, and stores the certificate in a file.
	Retrieve a signer from a port	Retrieves a signer certificate from a port, and stores it in a key store.
Certificate requests	Create a certificate request	Creates a certificate request that can be sent to a CA.
	List certificate requests	Lists the certificate requests in a keystore.

Table 149. Certificate operations (continued). The following table describes the certificate operations that you can perform on the administrative console

Types of certificates	Functions	Description
	Get information about a certificate request	Gets information about a certificate request.
	Delete a certificate request	Deletes a certificate request from a keystore.
	Extract a certificate request	Extracts a certificate request to a file.

## Personal certificates

Table 150. Personal certificate operations. The following table lists the operations that you can perform on personal certificates, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate on the console:

Function	AdminTask object	Administrative console
Create a self-signed certificate	createSelfSignedCertificate	<b>Security &gt; Secure Communications &gt; Key store and certificates &gt; key store &gt; Create a Self-Signed Certificate</b>
List personal certificates	listPersonalCertificates	<b>Security &gt; Secure Communications &gt; Key store and certificates &gt; key store &gt; personal certificates</b>
Get information about a personal certificate	getPersonalCertificate	<b>Security &gt; Secure Communications &gt; Key store and certificates &gt; key store &gt; personal certificates &gt; alias</b>
Delete a personal certificate	deletePersonalCertificate	<b>Security &gt; Secure Communications &gt; Key store and certificates &gt; key store &gt; personal certificates &gt; delete</b>
Import a certificate	importCertificate	<b>Security &gt; Secure Communications &gt; Key store and certificates &gt; key store &gt; personal certificates &gt; import</b>
Export a certificate	exportCertificate	<b>Security &gt; Secure Communications &gt; Key store and certificates &gt; key store &gt; personal certificates &gt; export</b>
Extract a certificate	extractCertificate	<b>Security &gt; Secure Communications &gt; Key store and certificates &gt; key store &gt; personal certificates &gt; extract</b>
Exchange signer certificates	exchangeSignerCertificates	<b>Security &gt; Secure Communications &gt; Key store and certificates &gt; Exchange signers</b>
Create a chained certificate	createChainedCertificate	<b>Security &gt; SSL certificate and key management &gt; Key store and certificates &gt; keystore name &gt; Personal certificates.</b> Click <b>Create</b> button and select <b>Chained certificate</b>
Renew a certificate	renewChainedCertificate	<b>Security &gt; SSL certificate and key management &gt; Key store and certificates &gt; keystore name &gt; Personal certificates.</b> Select a certificate. Click <b>Renew</b> button.
Create a chained Certificate	createChainedCertificate	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; keystore &gt; Create a chained certificate.</b>
Request a CA certificate	requestCACertificate	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; keystore &gt; Request a CA certificate.</b>

## Certificate authority (CA) certificates

Table 151. CA certificate operations. The following table lists the operations that you can perform on CA certificates, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate on the console:

Function	AdminTask object	Administrative console
Create a CA certificate	createCACertificate	<b>Security &gt; Secure Communications &gt; Key store and certificates &gt; key store &gt; Personal certificates &gt; Create &gt; CA-signed certificate</b>
Revoke a CA certificate	revokeCACertificate	<b>Security &gt; Secure Communications &gt; Key store and certificates &gt; key store &gt; Personal certificates personal certificate &gt; Revoke</b>

## Signer certificates

Table 152. Signer certificate operations. The following table lists the operations that you can perform with signer certificates, the AdminTask object that you can use to perform the operation, and how to navigate to the certificate on the console:

Function	AdminTask object	Administrative console
Add a signer certificate	addSignerCertificate	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; key store &gt; signer certificates &gt; Add</b>
List signer certificates	listSignerCertificates	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; key store &gt; signer certificates</b>
Get information about a signer certificate	getSignerCertificate	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; key store &gt; signer certificates &gt; alias</b>
Delete a signer certificate	deleteSignerCertificate	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; key store &gt; signer certificate &gt; delete</b>
Extract a signer certificate to a file	extractSignerCertificate	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; key store &gt; signer certificates &gt; extract</b>
Retrieve a signer certificate from a port	retrieveSignerFromPort	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; key store &gt; signer certificates &gt; retrieve from port</b>

## Personal certificate requests

Table 153. Personal certificate request operations. The following table lists the operations that you can perform on personal certificate requests, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate request on the console:

Function	AdminTask object	Administrative console
Create a personal certificate request	createCertificateRequest	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; key store &gt; Personal certificate Requests &gt; Add</b>
List personal certificate requests	listCertificateRequests	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; key store &gt; Personal certificate requests</b>
Get information about a personal certificate request	getCertificateRequest	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; key store &gt; Personal certificate requests &gt; alias</b>
Delete a personal certificate request	deleteCertificateRequest	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; key store &gt; Personal certificate requests &gt; delete</b>

Table 153. Personal certificate request operations (continued). The following table lists the operations that you can perform on personal certificate requests, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate request on the console:

Function	AdminTask object	Administrative console
Extract a personal certificate request to a file	extractCertificateRequest	<b>Security &gt; Secure communications &gt; Key store and certificates &gt; key store &gt; Personal certificate requests &gt; Extract</b>

## Using the retrieveSigners command in SSL to enable server to server trust

You can add a signer certificate to a server's trust.p12 file, allowing that server to securely communicate with another server. This can be done using the **retrieveSigners** command to add a signer to a server's trust.p12 file after making changes to the ssl.client.props file.

### Before you begin

The server that will be communicating as a client must be identified before the server to server trust can be established. You will make change to the ssl.client.props file and run the **retrieveSigners** command on the server communicating as a client. If both servers will be acting as a client , these steps will be required for both servers.

### About this task

The ssl.client.props file is setup by default to configure Secure Socket Layer (SSL) communication for clients. This makes the default behavior of the **retrieveSigners** command work on the client's trust.p12 file and key.p12 file in the *profile\_root/etc* directory. You can add a signer certificate to a server's trust.p12 file, allowing that server to act as a client communicating to another server. Using the **retrieveSigners** command to add a signer to a server's trust.p12 file requires some changes to the ssl.client.props file.

### Procedure

1. Open the ssl.client.props file. The ssl.client.props file is located in *profile\_root/properties* ditrectory.
2. Uncomment the section of ssl.client.props that starts with com.ibm.ssl.alias=AnotherSSLSettings property.
3. Uncomment the section of ssl.client.props that starts with com.ibm.ssl.trustStoreName=AnotherTrustStore property.
4. Enter the location of the trust store that the signer should be added. If you are using the server trust store for a deployment manager then it is located in *profile\_root/config/cells/cell name/trust.p12*. If using the trust store for an application server, it is located in *profile\_root/config/cells/cell name/nodes/node name/trust.p12*.
5. Update the remaining properties in this section with the values associated with the trust store being used. A description of the properties can be found in ssl.client.props client configuration file.
6. Optional: Uncomment and update section that starts with com.ibm.ssl.trustStoreName=AnotherKeyStore property. Most scenarios only require a signer to be added to the trust store. This example only adds a signer to the trust store, but you can also add a signer to the key store by updating the properties as you did for the trust store in steps 3 through 5.
7. Save the changes made to ssl.client.props.
8. Run the **retrieveSigners** command. For more information see the page about the retrieveSigners command.

```
retrieveSigners NodeDefaultTrustStore AnotherTrustStore -host ademyers.austin.ibm.com -port 8879
```

Example output:

```
CWPKI0308I: Adding signer alias "default_1" to local keystore
 "AnotherTrustStore" with the following SHA digest:
 F4:71:97:79:3E:C1:DC:E7:9F:8F:3D:F0:A0:15:1E:D1:44:73:2C:06
```

## Results

After the steps have been successfully completed, the server acting as a client has the signing certificate of the other server. This allows that server to establish a SSL connection to the other server.

## Example

The example shows the modified section of the `ssl.client.props` file assuming that the server's `trust.p12` file is being used. Any trust store existing trust store can be used if the properties are provided for that trust store.

```
#-----
com.ibm.ssl.alias=AnotherSSLSettings
com.ibm.ssl.protocol=SSL_TLS
com.ibm.ssl.securityLevel=HIGH
com.ibm.ssl.trustManager=IbmX509
com.ibm.ssl.keyManager=IbmX509
com.ibm.ssl.contextProvider=IBMJSSE2
com.ibm.ssl.enableSignerExchangePrompt=true
#com.ibm.ssl.keyStoreClientAlias=default
#com.ibm.ssl.customTrustManagers=
#com.ibm.ssl.customKeyManager=
#com.ibm.ssl.dynamicSelectionInfo=
#com.ibm.ssl.enabledCipherSuites=

KeyStore information
#com.ibm.ssl.keyStoreName=AnotherKeyStore
#com.ibm.ssl.keyStore=${user.root}/etc/key.p12
#com.ibm.ssl.keyStorePassword={xor}CDo9Hgw=
#com.ibm.ssl.keyStoreType=PKCS12
#com.ibm.ssl.keyStoreProvider=IBMJCE
#com.ibm.ssl.keyStoreFileBased=true

TrustStore information
com.ibm.ssl.trustStoreName=AnotherTrustStore
com.ibm.ssl.trustStore=${user.root}/config/cells/localhostCell101/trust.p12
com.ibm.ssl.trustStorePassword={xor}CDo9Hgw=
com.ibm.ssl.trustStoreType=PKCS12
com.ibm.ssl.trustStoreProvider=IBMJCE
com.ibm.ssl.trustStoreFileBased=true
```

## What to do next

After the signer has been added, edit the `ssl.client.props` file to comment out the sections that were used to add the signer certificate.

## Creating a Secure Sockets Layer configuration

Secure Sockets Layer (SSL) configurations contain the attributes that you need to control the behavior of client and server SSL endpoints. You create SSL configurations with unique names within specific management scopes on the inbound and outbound tree in the configuration topology. This task shows you how to define SSL configurations, including quality of protection and trust and key manager settings.

### Before you begin

You must decide at which scope you need to define an SSL configuration, for instance, the cell, node group, node, server, cluster, or endpoint scope, from the least specific to the most specific scope. When you define an SSL configuration at the node scope, for example, only those processes within that node can load the SSL configuration; however, any processes at the endpoint in the cell can use an SSL configuration at the cell scope, which is higher in the topology.

You must also decide which scope to associate with the new SSL configuration, according to the processes that the configuration affects. For example, an SSL configuration for a hardware cryptographic device might require a keystore that is available only on a specific node, or you might need an SSL

configuration for a connection to a particular SSL host and port. For more information, see “Dynamic outbound selection of Secure Sockets Layer configurations” on page 1899.

**gotcha:** The security.xml file is restricted. Therefore, if you need to make changes to the security.xml file, verify that your user ID has administrator role authorization. If you are using a user ID with operator role authorization, you can perform a node synchronization, but any changes that you made to the security.xml file are not synchronized.

## About this task

Complete the following steps in the administrative console:

### Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations**.
2. Select an SSL configuration link on either the Inbound or Outbound tree, depending on the process you are configuring.
  - If the scope is already associated with a configuration and alias, the SSL configuration alias and certificate alias are noted in parentheses.
  - If the parenthetical information is not included, then the scope is not associated. Instead, the scope inherits the configuration properties of the first scope above it that is associated with an SSL configuration and certificate alias.

The cell scope must be associated with an SSL configuration because it is at the top of the topology and represents the default SSL configuration for the inbound or outbound connection.

3. Click **SSL configurations** under Related Items. You can view and select any of the SSL configurations that are configured at this scope. You can also view and select these configuration at every scope that is lower on the topology.
4. Click **New** to display the SSL configuration panel. You cannot select links under Additional Properties until you type a configuration name and click **Apply**.
5. Type an SSL configuration name. This field is required. The configuration name is the SSL configuration alias. Make the alias name unique within the list of SSL configuration aliases that are already created at the selected scope. The new SSL configuration uses this alias for other configuration tasks.
6. Select a truststore name from the drop-down list. A truststore name refers to a specific truststore that holds signer certificates that validate the trust of certificates sent by remote connections during an SSL handshake. If there is no truststore in the list, see “Creating a keystore configuration for a preexisting keystore file” on page 1978 to create a new truststore, which is a keystore whose role is to establish trust during the connection.
7. Select a keystore name from the drop-down list. A keystore contains the personal certificates that represent a signer identity and the private key that WebSphere Application Server uses to encrypt and sign data.
  - If you change the keystore name, click **Get certificate aliases** to refresh the list of certificates from which you can choose a default alias. WebSphere Application Server uses a server alias for inbound connections and a client alias for outbound connections.
  - If there is no keystore in the list, see “Creating a keystore configuration for a preexisting keystore file” on page 1978 to create a new keystore.
8. Choose a default server certificate alias for inbound connections. Select the default only when you have not specified an SSL configuration alias elsewhere and have not selected a certificate alias. A centrally managed SSL configuration tree can override the default alias. For more information, see “Central management of SSL configurations” on page 1900.
9. Choose a default client certificate alias for outbound connections. Select the default only when the server SSL configuration specifies an SSL client authentication.

10. Review the identified management scope for the SSL configuration. Make the management scope in this field identical to the link you selected in Step 2. If you want to change the scope, you must click a different link in the topology tree and continue at Step 3.
11. Click **Apply** if you intend to configure Additional Properties. If not, go to Step 24.
12. Click **Quality of protection (QoP) settings** under Additional Properties. QoP settings define the strength of the SSL encryption, the integrity of the signer, and the authenticity of the certificate.
13. Select a client authentication setting to establish an SSL configuration for inbound connections and for clients to send their certificates, if appropriate.
  - If you select **None**, the server does not request that a client send a certificate during the handshake.
  - If you select **Supported**, the server requests that a client send a certificate. However, if the client does not have a certificate, the handshake might still succeed.
  - If you select **Required**, the server requests that a client send a certificate. However, if the client does not have a certificate, the handshake fails.

**Important:** The signer certificate that represents the client must be in the truststore that you select for the SSL configuration. By default, servers within the same cell trust each other because they use the common truststore, trust.p12, that is located in the cell directory of the configuration repository. However, if you use keystores and truststores that you create, perform a signer exchange before you select either **Supported** or **Required**.

14. Select a protocol for the SSL handshake.
  - The default protocol, SSL\_TLS, supports client protocols TLSv1, SSLv3, and SSLv2.
  - The TLSv1 protocol supports TLS and TLSv1. The SSL server connection must support this protocol for the handshake to proceed.
  - The SSLv3 protocol supports SSL and SSLv3. The SSL server connection must support this protocol for the handshake to proceed.

**Important:** Do not use the SSLv2 protocol for the SSL server connection. Use it only when necessary on the client side.

15. Select one of the following options:
  - A predefined Java Secure Socket Extension (JSSE) provider. The IBMJSSE2 provider is recommended for use on all platforms which support it. It is required for use by the channel framework SSL channel. When Federal Information Processing Standard (FIPS) is enabled, IBMJSSE2 is used in combination with the IBMJCEFIPS crypto provider.
  - A custom JSSE provider. Type a provider name in the **Custom provider** field.
16. Select from among the following cipher suite groups:
  - **Strong:** WebSphere Application Server can perform 128-bit confidentiality algorithms for encryption and support integrity signing algorithms. However, a strong cipher suite can affect the performance of the connection.
  - **Medium:** WebSphere Application Server can perform 40-bit encryption algorithms for encryption and support integrity signing algorithms.
  - **Weak:** WebSphere Application Server can support integrity signing algorithms but not to perform encryption. Select this option with care because passwords and other sensitive information that cross the network are visible to an Internet Protocol (IP) sniffer.
  - **Custom:** you can select specific ciphers. Any time you change the ciphers that are listed from a specific cipher suite group, the group name changes to Custom.
17. Click **Update selected ciphers** to view a list of the available ciphers for each cipher strength.
18. Click **OK** to return to the new SSL configuration panel.
19. Click **Trust and key managers** under Additional Properties.
20. Select a default trust manager for the primary SSL handshake trust decision.

- Choose **IbmPKIX** when you require certificate revocation list (CRL) checking using CRL distribution points in the certificates or the online certificate status protocol (OCSP).
  - Choose **IbmX509** when you do not require CRL checking but do need increased performance. You can configure a custom trust manager to perform CRL checking, if necessary.
21. Define a custom trust manager, if appropriate. You can define a custom trust manager that runs with the default trust manager you select. The custom trust manager must implement the JSSE `javax.net.ssl.X509TrustManager` interface and, optionally, the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface to obtain product-specific information.
    - a. Click **Security > SSL certificate and key management > Manage endpoint security configurations > SSL\_configuration > Trust and key managers > Trust managers > New**.
    - b. Type a unique trust manager name.
    - c. Select the **Custom** option.
    - d. Type a class name.
    - e. Click **OK**. When you return to the Trust and key managers panel, the new custom trust manager displays in the **Additional ordered trust managers** field. Use the left and right list boxes to add and remove custom trust managers.
  22. Select a key manager for the SSL configuration. By default, IbmX509 is the only key manager unless you create a custom key manager.

**Important:** If you choose to implement your own key manager, you can affect the alias selection behavior because the key manager is responsible for selecting the certificate alias from the keystore. The custom key manager might not interpret the SSL configuration as the WebSphere Application Server key manager IbmX509 does. To define a custom key manager, click **Security > Secure communications > SSL configurations > SSL\_configuration > Trust and key managers > Key managers > New**.

23. Click **OK** to save the trust and key manager settings and return to the new SSL configuration panel.
24. Click **Save** to save the new SSL configuration.

## Results

**Important:** You can override the default trust manager when you configure at least one custom trust manager and set the `com.ibm.ssl.skipDefaultTrustManagerWhenCustomDefined` property to `true`. Click **Custom Property** on the SSL configuration panel. However, if you change the default, you leave all the trust decisions to the custom trust manager, which is not recommended for production environments. In test environments, use a dummy trust manager to avoid certificate validation. Remember that these environment are not secure.

## What to do next

In this release of WebSphere Application Server, you can associate SSL configurations with protocols using one of the following methods:

- Set the SSL configuration on the thread programmatically
- Associate the SSL configuration with an outbound protocol, and target host and port. For more information, see “Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint” on page 1956
- Associate the SSL configuration directly using the alias. For more information, see “Selecting an SSL configuration alias directly from an endpoint configuration” on page 1960
- Manage the SSL configurations centrally by associating them with SSL configuration groups or zones that are scoped for endpoints. For more information, see “Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes” on page 1959.

## SSL certificate and key management

Use this page to configure security for Secure Socket Layer (SSL) and key management, certificates, and notifications. The SSL protocol provides secure communications between remote server processes or endpoints. SSL security can be used for establishing communications inbound to and outbound from an endpoint. To establish secure communications, a certificate and an SSL configuration must be specified for the endpoint.

To view this administrative console page, click **Security > SSL certificate and key management**.

### **Configuration settings:**

Specifies the following administrative console tasks:

- Manage endpoint security configurations
- Manage certificate expiration

### **Use Federal Information Processing Standard (FIPS) algorithms:**

Specifies the Federal Information Processing Standard (FIPS)-compliant Java cryptography engine is enabled.

- Does not affect the SSL cryptography that is performed by the application server for z/OS System Secure Sockets Layer (SSSL).
- Does not change the JSSE provider if this cell includes any Application Server versions before the application server for z/OS Version 6.0.x.

When you select the **Use the Federal Information Processing Standard (FIPS)** option, the Lightweight Third Party Authentication (LTPA) implementation uses IBMJCEFIPS. IBMJCEFIPS supports the Federal Information Processing Standard (FIPS)-approved cryptographic algorithms for Data Encryption Standard (DES), Triple DES, and Advanced Encryption Standard (AES). Although the LTPA keys are backwards compatible with prior releases of the application server, the LTPA token is not compatible with prior releases. In prior releases, the application server did not generate the LTPA token using a FIPS-approved algorithm.

The IBMJSSE2 JSSE provider does not perform cryptographic functions directly, and therefore does not need to be FIPS-approved. Instead, the IBMJSSE2 JSSE provider uses the JCE framework for cryptographic functions and uses IBMJCEFIPS when FIPS mode is enabled.

**Default:** Disabled

### **Dynamically update the runtime when SSL configuration changes occur:**

Specifies that all of the SSL-related attributes and LTPA keys that change must be read from the configuration dynamically after they have been saved, then reused for new connections. To avoid customer impact, it is recommended that changes to production servers be made during off-peak periods.

**Default:** Enabled

When this option is selected, the configuration is updated each time you configure an SSL communication.

## SSL configurations for selected scopes

Use this page to display Secure Socket Layer (SSL) configurations for selected scopes, such as a cell, node, server, or cluster. From this page you can navigate to configuration panels for the following: SSL configurations, dynamic inbound and outbound endpoint SSL configurations, key stores, key sets, key set groups, key managers, and trust managers.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**.

**Name:**

Specifies the SSL configuration scope, which is derived from the selected object in the hierarchy.

**Data type:** Text

**Direction:**

Specifies the direction for which the SSLConfig applies. Inbound refers to any listener port. Outbound refers to outbound end point connections.

**Data type:** Text

**SSL configuration:**

Specifies the SSL configuration that is used by requests at this scope.

**Data type:** Text

**Update certificate alias list:**

Specifies the certificate aliases contained in the key store for this SSL configuration can be selected from the **Certificate alias in key store** list. You must update the certificate list after choosing a different SSL configuration alias. If you do not update the list, you will save a certificate alias that is not contained in the SSL configuration.

**Manage certificates:**

Specifies to open the keystore panel for the key store in this SSL configuration, which enables you to manage personal certificates, signers, and certificate requests.

**Certificate alias in key store:**

Specifies the certificate to use in the key store.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the key store, the key manager might not consistently select the same certificate.

**Data type:** Text

## SSL configurations collection

Use this page to define a list of Secure Sockets Layer (SSL) configurations.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **SSL configurations**.

Table 154. SSL configurations buttons. This table lists the SSL configurations buttons.

Button	Resulting action
<b>New JSSE configuration</b>	The Java Secure Socket Extension (JSSE) repertoire is for Java-based SSL communications. You can define a new JSSE configuration that can be used to create an SSLContext, URLStreamHandler, SSLSocketFactory, SSLServerSocketFactory, and so on, using the com.ibm.websphere.ssl.JSSEHelper API.
<b>New SSSL configuration</b>	The System Secure Sockets Layer (SSSL) repertoire is used for HTTPS and Internet InterORB Protocol (IIOP) communication, which are used by the native transports. If you want to use the administrative console after security is enabled, you must define and select a System SSL type repertoire for HTTP. You must define a System SSL repertoire and select if IIOP security requires or supports SSL transport, or if a secure Remote Method Invocation (RMI) connector is selected for administrative requests.
<b>Delete</b>	Deletes an existing JSSE configuration (administrator only). Be careful that any references to the SSL configuration have been removed prior to deleting this SSL configuration.

**Name:**

Specifies the unique name of the SSL configuration in the management scope.

**SSL configuration settings**

Use this page to define Secure Sockets Layer (SSL) configuration properties.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > nodes name**. Under Related items, click **SSL configurations > New**.

**Name:**

Specifies the unique name of the SSL configuration within the management scope in which it resides. For ways to programmatically access the properties that are configured for this SSL configuration, see the com.ibm.websphere.ssl.JSSEHelper application programming interface (API).

**Data type:** Text

**Keyring name:**

Specifies the name of the keyring for the System SSL configuration. This field implies the keystore and trust store.

This field applies to System SSL repertoires only

**Secure Sockets Layer client certificate authentication**

Client software that wants to establish a secure connect to a server by using Secure Socket Layer (SSL) protocol initiates by leveraging SSL protocol or the enhanced protocol called Transport Layer Security (TLS) to perform a SSL handshake with SSL certificates. A personal certificate can represent the server or it can represent a particular client, and is signed by a Certificate Authority (CA) to ensure that the personal certificate is correctly identified.

SSL ensures that the administrator has the CA signer certificate available that is used to sign the personal certificate, and that it is stored in both the client and or the server trusted store. SSL client certificate authentication takes place during the connection handshake by using SSL certificates.

The following events must occur during this process:

- The server side must determine if client authentication is going to take place. The client authentication must be enabled in the SSL configuration of the server and the Common Secure Interoperability version 2 (CSlv2) configuration if Inter-ORB Protocol (IIOP) is used.
- The CSlv2 configuration must take place in global security, not in a security domain.

- The signer certificate of the client must be extracted from the key store of the client and added to the trust store of the server.
- The signer certificate of the server must to be extracted from the key store of the server and added to the trust store of the client.

## Configuring a WebSphere server for client authentication

Client certificate authentication occurs if the server side requests that the client side send a certificate. A Websphere server can be configured for client certificate authentication on the SSL configuration. However, if client authentication is needed for IIOP then it must be configured on the CSiv2 configuration.

To configure client certificate authentication on the SSL configuration using the administrative console:

1. Click **Security > SSL certificate and key management > SSL configurations**.
2. Select a SSL configuration.
3. Under Additional Properties, select **Quality of protection (QoP) settings**.
4. Under Client authentication, select **Required**.
5. Click **OK** to save the changes.

**Note:** You can also use the modifySSLConfig command with the -clientAuthentication flag set to true to enable client authentication. See SSLConfigCommands command group for the AdminTask object for more information about this command.

To configure client certificate authentication on a CSiv2 inbound connection using the administrative console:

1. Click **Security > Global Security**.
2. Under RMI/IIOP security, select **CSiv2 inbound communications**.
3. In the CSiv2 Transport Layer section, and under Client certificate authentication, select **Required**.
4. Click **OK** to save the changes

**Note:** You can also use the configureCSInbound command with the -clientCertAuth flag set to Required to enable client authentication on CSiv2. Read SecurityConfigurationCommands command group for the AdminTask object for more information about this command.

If the client side is set up for client authentication, the signer certificate of the client must be added to the trust store of the server. When you have a certificate from the client in a certificate file it can be added to the trust store of the server.

To add a signer to the trust store of the server using the administrative console:

1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Select the trust store that is configured for client authentication.
3. Under Additional Properties, select **Signer Certificates**.
4. Click **Add**.
5. In the Alias field, type an alias name under which to store the certificate.
6. In the File name box, type the full path to the certificate file.
7. Click **OK** to save the changes

**Note:** You can also use the addSignerCertificate command to add a signer to the trust store of the server. Read SignerCertificateCommands command group for the AdminTask object for more information about this command.

**Note:** If you are using client authentication in a cluster environment, client authentication must be configured for each node that the servers in the cluster are located in.

## Setting up the client side for client authentication

### Clients:

Administrative clients, thin clients or pure clients must have a personal certificate in their key stores. The WebSphere client default key store that is created when WebSphere Application Server is installed already has a personal certificate in it. This key store can be found in the **ssl.client.props** file in the `com.ibm.ssl.keyStore` property. The client key stores are not managed by WebSphere Application Server, so the Key Management utility (iKeyman) or Java keytool utility can be used to extract the certificate to a certificate file.

To extract a certificate using iKeyman:

1. Start iKeyman.
2. Select **Key Database File > open**.
3. Enter the path to the keystore file. You can obtain this from the **ssl.client.props** file.
4. Click **OK**.
5. Enter the password to the key store and click **OK**.
6. Under Personal Certificates, select the client default certificate.
7. Enter a path and file name for the certificate file and click **OK**.

The file that contains the extracted certificate can be used to add the signer to the trust store of the server. Follow the steps in the "Configuring a WebSphere server for client authentication" section to add that signer to the server trust store.

If the communication is over IIOP, the following properties must be set in the **sas.client.props** file.

- Enable SSL:  
`com.ibm.CSI.performTransportAssocSSLTLSSupported=true`  
`com.ibm.CSI.performTransportAssocSSLTLSRequired=false`
- Disable client authentication at the message layer:  
`com.ibm.CSI.performClientAuthenticationRequired=false`  
`com.ibm.CSI.performClientAuthenticationSupported=false`
- Enable client authentication at the transport layer (this is supported, but not required):  
`com.ibm.CSI.performTLClientAuthenticationRequired=false`  
`com.ibm.CSI.performTLClientAuthenticationSupported=true`

Thin clients and pure clients might not use the WebSphere Application Server SSL properties file, **ssl.client.props**. They most likely use the Java system properties to set the client key store and trust store. The signer certificate of the server must be added to the trust store that is specified with the `java.net.ssl.trustStore` system property. Keytool or iKeyman can be used to add the signer certificate. The signer must be extracted from the personal certificate in the key store specified by the `javax.net.ssl.keyStore` system property, and added to the trust store of the server.

For example:

```
javax.net.ssl.keyStore
javax.net.ssl.keyStorePassword
javax.net.ssl.keyStoreType
javax.net.ssl.trustStore
javax.net.ssl.trustStorePassword
javax.net.ssl.trustStoreType
```

### Server acting as a client:

The client can be a WebSphere server acting as a client. If so, determine which SSL configuration is being used as the client side of the communication, extract its certificate's signer and add it to the server side trust store. It is recommended that the root certificate signer be used.

To extract the root certificate using the administrative console:

1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Under the Keystore usages pull-down, select **Root certificate keystore**.
3. Select either **DmgrDefaultRootStore** (for a network deployment server) or **NodeDefaultRootStore** (for an application server).
4. Under Additional Properties, select **Personal certificates**.
5. Select the default root certificate (usually called *root*), and then click **Extract**.
6. In the Certificate file name box, type a full path to the file in which to hold the certificate.
7. Click **OK** to save.

**Note:** You can also use the `extractCertificate` command to extract the root certificate. Read `PersonalCertificateCommands` command group for the `AdminTask` object for more information about this command.

The certificate file that is created can be carried to the server side and added to the trust store of the server.

When a server acts as a client, the client side server requires the signer from the destination server. The signer can be retrieved using the signer certificate **Retrieve from port** option.

To retrieve the signer from the port using the administrative console:

1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Select the trust store of the server from the collection.
3. Under Additional Properties, select **Signer certificates**.
4. Click **Retrieve from port**.
5. Enter a destination host name and a destination port name.
6. Enter an alias name for the certificate.
7. Click **Retrieve signer information**.
8. Click **OK** to save.

You can also use the `retrieveSignerFromPort` command to retrieve the signer from the port. Read `SignerCertificateCommands` command group for the `AdminTask` object for more information about this command.

### **Setting up a browser for client authentication:**

When WebSphere Application Server is configured for client certificate authentication, and an attempt is made to access the server from a browser, the browser must have a certificate for the client certificate authentication. If the default SSL configuration of the server was modified to enable client certificate authentication you are unable to login to the administrative console.

You can create a certificate for the browser by using the administrative console. You must first create a key store and then create a chained certificate. After the certificate is created, use the instructions for your browser to import a certificate. Browsers require that each part of the chain be added to verify the certificate, so the root certificate must be extracted and added to the browser. Follow the instructions in the "Setting up the client side for client authentication" section for information about extracting the root certificate.

To create a key store using the administrative console:

1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Click **New**.
3. Enter a name for the key store.
4. Enter the full path to the key store file.
5. Enter a password for the key store and then confirm.
6. Click **OK** to save.

To create a chained certificate using the administrative console:

1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Select the key store you created previously.
3. Under Additional Properties, click **Personal certificates**.
4. In the pull-down list under the Create button, select **Chained Certificate**.
5. Enter an alias name for the certificate.
6. Provide a common name for the certificate. The name is the "CN=" part of the subject DN.
7. You can enter information in any of the remaining fields to build the subject DN of the chained certificate.
8. Click **OK** to save.

You can also use the `createKeyStore` command to create a key store. Read `KeyStoreCommands` command group for the `AdminTask` object for more information about this command.

You can also use the `createChainedCertificate` command to create a chained certificate. Read `PersonalCertificateCommands` command group for the `AdminTask` object for more information about this command.

**Note:** When client certificate authentication is enabled, web certificate authentication can then be performed as discussed in the next section.

## Web certificate authentication

Certificate base authentication can be performed on Java 2 Platform, Enterprise Edition (J2EE) web modules when the module is configured for client certificate authentication. This enables a user to login to a web module using a certificate to authenticate, and to map that certificate to a user from the registry.

Enabling web certificate authentication requires that the SSL configuration of the server be configured for client certificate authentication on the server where the module is installed.

The server side determines that client authentication is to take place. See the "Configuring a WebSphere server for client authentication" section for information about how to configure client authentication. The client side must have the signer from the server to add to the client truststore. See the "Setting up the client side for client authentication" section for more information.

The **web.xml** file of the web module must have the authentication method set to `CLIENT-AUTH` in the `login-config` section of the **web.xml** file:

```
<login-config>
<auth-method>CLIENT-CERT</auth-method>
</login-config>
```

The certificate must map to a user in the registry or you are unable to login to that web module.

For localOS user registries, the CN value of the certificate subject DN must map to a user in the local OS user registry. For example, if the certificate subject DN is CN=tester,o=ibm,c=us, then tester is the user searched for in the local user registry. If that user does not exist in the local registry then the authentication fails.

The Lightweight Directory Access Protocol (LDAP) user registry provides more options for mapping a certificate to a user identity. The default certificate mapping mode in LDAP is used for an exact DN match between the entry in the LDAP registry and the subject DN in the certificate. For example, if the certificate DN is CN=user1,o=ibm,c=us, then there must be an entry in the LDAP registry with that exact value. The LDAP user registry also has a certificate filter option that can provide a match to a particular part of the certificate subject DN against entries in the LDAP repository. For more detail on LDAP certificate mapping, read "Lightweight Directory Access Protocol repository configuration settings".

A federated repository file-based registry does not support certificate mapping, but the federated repository LDAP registry does. It uses the same mapping rules and properties that the LDAP user registry uses.

Custom user registry can map certificates to a user if the custom registry implemented the mapCertificate() method.

## **Certificate authority (CA) client configuration**

Use this page to create, modify, and configure a certificate authority (CA) client.

To view this administrative console page, click **Security > SSL Configurations and key management** . Under Related Items, click **Certificate Authority (CA) client configurations**. Then click either the **New** button or select an existing CA client by clicking on its <client\_name>.

### ***Name:***

Specifies the unique name of the CA client configuration. This is the name to identify the CA client object. This name needs to be unique to the scope.

**Data type:** String

### ***Implementation class:***

Specifies the name of the module that implements the com.ibm.wsspi.ssl.WSKPIClient interface that is used to act as a client to a CA. This implementation class connects to the CA server and performs a certificate create, revoke, or replace.

**Default:** String

### ***CA server host name:***

Specifies the host name of the CA server, if the implementation requires a host name.

**Data type:** String

### ***Port:***

Specifies the port where the CA server will communicate, if the implementation requires a port.

**Data type:** String

### ***User name:***

Specifies the user Id used to connect to the CA server, if the implementation requires a user to login to the CA.

**Data type:** String

***Password:***

Specifies the password for the connection to the CA server.

**Data type:** String

***Confirm password:***

Confirms the password that is provided in the password field.

**Data type:** String

***Number of times to poll:***

Specifies the number of times to check the CA server to see if the certificate is complete. This poll number applies to the CA that does not return certificates right away.

**Default:** 5

***Polling interval when requesting certificates:***

Specifies the amount of time, in minutes, between checks to the CA server to see if the certificate is complete.

**Default:** 10

***Custom properties:***

Specifies arbitrary name and value pairs of data. The name is a property key, and the value is a string value that can be used to set internal system configuration properties.

**Data type:** string

## **Certificate authority (CA) client configuration collections**

Use this page to define and manage certificate authority (CA) clients or view and modify existing CA clients.

This panel allows you to create a certificate authority (CA) client object in the configuration. You can also view and modify existing CA clients. The information in the CA client object can then be used by the runtime to connect to a CA server to request, revoke, or query a certificate.

To view this administrative console page, click **Security > SSL Configurations and key management > .** Under Related Items, click **Certificate Authority (CA) client configurations.**

Table 155. CA client configuration buttons.

This table describes the CA client configuration buttons.

Button	Resulting action
New	Adds a new CA client object that can be referenced by Secure Sockets Layer (SSL) configurations.
Delete	Deletes an existing CA client object.

**Name:**

Identifies the unique name of the CA client configuration.

**Implementation class:**

Identifies the name of the module that implements the **com.ibm.wsspi.ssl.WSKPIClient** interface that is used to act as a client to a CA.

**Management Scope:**

Identifies the scope where this secure sockets layer (SSL) configuration is visible.

**Writable SAF Keyring settings**

Use this page to manage existing writable System Authorization Facility (SAF) keyrings on the z/OS platform.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related Items, click **Key stores and certificates**. Click an existing keystore. Under Writable SAF Keyrings, click **Control region keyring** to manage the control region keyring information or click **Servant region keyring** to manage the servant region keyring information.

**Note:** Any changes made to this panel are permanent.

**Name:**

Specifies the unique name to identify the writable SAF keyring. The name is the name of the keystore specified on the create command that corresponds to the keyring owned by the RACF ID of the control region process. Or it is the name of the keystore specified on the create command that corresponds to the keyring owned by the RACF ID of the servant region process. The name is **<your\_keystore\_name> -CR** for the control region user and **<your\_keystore\_name> -SR** for the servant region user.

**Data type:** Text

**Description:**

Specifies the description of the writable SAF keyring (either the control region keyring or the servant region keyring).

**Data type:** Text

**Management scope:**

Specifies the management scope associated with the writable SAF keyring. These keystores are created in the same scope as **<your\_keystore\_name>** and can be accessed from the administrative console from the **<your\_keystore\_name>** collection panel.

**Data type:** Text

***Path:***

Specifies the location of the keyring file in the format needed by the keystore type. This file is a URL of the form, **safkeyring:///your\_keyring\_name**.

**Data type:** text

***Change password [existing SAF keyring]:***

Specifies the password used to protect the keystore. For the default keyring (names ending in DefaultKeyStore or DefaultTrustStore) for which this keyring is associated, the password is WebAS. This default password must be changed.

This field can be edited. This password is for the keystore file that you specified in the Path field.

**Data type:** Text

***Type:***

Specifies the implementation for keyring management. This value defines the tool that operates on this keyring type. For a writable SAF keyring, the type is JCERACFKS. For writable SAF keyrings, the tool that operates on this SAF keyring is RACF.

**Data type:** Text

***Read only:***

Specifies whether the writable SAF keyring can be written to or not. If the keyring cannot be written to, certain operations cannot be performed, such as creating or importing certificates.

**Default:** Disabled

***Initialize at startup:***

Specifies whether the writable keyring needs to be initialized before it can be used for cryptographic operations. If enabled, the keyring is initialized at server startup.

**Default:** Disabled

***Enable cryptographic operations on hardware device:***

Specifies whether a hardware cryptographic device is used for cryptographic operations only. Operations that require a login are not supported when using this option.

**Default:** Disabled

## Creating a chained personal certificate in SSL

A chained personal certificate is a personal certificate that is created by using another personal certificate to sign it. This chaining allows a certificate to be signed with a certificate (a root certificate) that has a long life span. Root certificates are stored in the **DmgrDefaultRootStore** or **NodeDefaultRootStore**. The server's default personal certificate is a chained certificate created when the profile is created. Chained certificates can also be created after profile creation

### Before you begin

You use the administrative console to create a chained personal certificate.

### Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Key stores and certificates**.
3. Click a **<keystore name>** to which you want to add the chained personal certificate.
4. Under Additional Properties, click **Personal certificates**.
5. Click the **Create** button and select **Chained Certificate**. The **listCertificates** AdminTask can be used to generate the list of root certificates available to sign the certificate.
6. Fill in the following information to the General Properties section as follows:
  - Supply an alias name.
  - Select Root certificate from the pull down list.
  - Key size
  - Common name
  - Validity period
  - Organization
  - Organization Unit
  - Locality
  - State/Province
  - Zip code
  - Country or region
  -
7. Click **Apply** then **OK**.

### Results

The certificate is created, signed by the root certificate specified, and stored in the keystore. Once a chained personal certificate is created, the certificate can be used by the runtime for SSL communication.

## Recovering deleted certificates in SSL

The SSL configuration contains a keystore created to hold personal certificates that were deleted from other keystores in the configuration. Perform this task to recover deleted certificates.

### Before you begin

The SSL configuration contains a keystore created to hold personal certificates that were deleted from other keystores in the configuration. On a stand alone application server the keystore is called `NodeDefaultDeletedStore` and on a deployment manager the keystore is called `DmgrDefaultDeletedStore`.

When a personal certificate is deleted from a keystore using the administrative console or in a script using the `deleteCertificate` AdminTask, a copy of the certificate is stored in the `DmgrDeletedKeyStore` or

NodeDeletedKeyStore. The personal certificate takes the alias of <keystore>\_<alias> > in the deleted keystore. If the alias name is already used in that deleted keystore a <unique number> is appended to the alias.

A personal certificate can be recovered from the deleted keystore by importing or exporting the personal certificate to a keystore in the configuration. To recover a personal certificate using the administrative console perform the following steps:

### Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Key stores and certificates**.
3. From the Keystore usages drop-down list, select "Deleted certificates keystore".
4. Click **DmgrDefaultDeletedStore** or **NodeDefaultDeletedStore**.
5. Under Additional Properties, click **Personal certificates**.
6. Select a certificate.
7. Select **Export**
8. Click **OK**.
9. Perform the following:
  - Enter the keystore password of the deleted keystore.
  - Enter The alias to be assigned to the certificate (in the key store that will receive the certificate).
  - Select the 'Managed key store' radio button.
  - Select the key store from the drop down list that will receive the certificate.
  - Click **Apply** then **OK**.

### Results

**Note:** To recover a personal certificate you can also use the exportCertToManagedKS AdminTask command.

### Renewing a certificate in SSL

If a personal certificate has been compromised or is about to expire, then it should be renewed. Renewing a certificate recreates the certificate with all the information from the original certificate, but with a new expiration period and public/private key pair. Only self-signed certificates and chained certificates created by WebSphere can be renewed. If the certificate used to sign the chained certificate is not in the root keystore then the default root certificate is used to renew the certificate.

### Before you begin

You use the administrative console to renew the certificate.

### Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Key stores and certificates**.
3. Click the appropriate <keystore name> to which you want to add the new certificate.

**Note:** Only self-signed certificates and chained certificates signed with root certificates from the root keystore can be renewed.

4. Under Additional Properties, click **Personal certificates** to list the personal certificates.
5. Select a personal certificate from the list.
6. Click the **Renew** button.
7. Click **Apply** then **OK**.

## Results

The certificate is renewed in the key store selected in the path to this panel . If the certificate is not a self-signed certificate or a chained certificate signed with a root certificate from the default root store, an error is returned.

**Note:** If this command is used with a CA certificate, an error occurs.

## Revoking a CA certificate in SSL

If a certificate authority (CA) certificate is compromised and the servers cannot trust it anymore that CA certificate can be revoked. To revoke a CA certificate, you perform the following task.

### Before you begin

You use the administrative console to replace or revoke a CA certificate.

### Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Key stores and certificates**.
3. Click a **<keystore name>** to which you want to add the new CA certificate.
4. Under Additional Properties, click **Personal certificates** to list the personal certificates.
5. Select a certificate to revoke (a CA certificate)
6. Click the **Revoke** button.
7. Fill in the following information to the CA certificate section.
  - Revocation password
  - Revocation reason
8. Click **Apply** then **OK**.

## Results

The certificate is revoked in the key store selected in the path. If the certificate selected was not a CA certificate, then an error is returned.

### What to do next

## Using a CA client to create a personal certificate to be used as the default personal certificate

An external certificate authority (CA) certificate can be used as the server default personal certificate. The CA certificate can be created using a CA client.

### Before you begin

What you need to have before you perform this task is as follows:

- A certificate authority (CA) to make the certificate request to.
- A module that implements the **com.ibm.wsspi.ssl.WSPKIClient** interface. This module is needed to connect to the CA server and request a certificate.

You use the administrative console to view or modify a CA client.

### Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Certificate Authority (CA) client configurations**. A panel displaying the existing CA clients appears.

3. Click the **New** button.
4. Enter the CA client information as required.
  - Name of the CA client.
  - The management scope (selected from the drop-down list).
  - Implementation class.
  - CA server host name.
  - User name.
  - Password.
  - Confirm of password.
  - Number of times to poll.
  - Polling interval (in minutes) when requesting certificates.
  - Custom properties.
5. Click **Apply** then **Save**.
6. Navigate to the Server default key store personal certificate. **Security > SSL configuration and certificate management > Key stores and certificates > <server\_default\_keystore>** . Under Additional properties, click **Personal certificates**
7. Click the **Create** button and select **CA-signed certificate**
8. Fill in the following information to the CA certificate section.
  - Revocation password
  - Confirm password.
  - Select the CA client that applies to this CA certificate.

**Note:** You can create a new CA client to apply to this CA authority by clicking the **New** button.

- Fill in the following information to the Request Specification section:
    - Select the radio button for Predefined request alias if you have a predefined alias.
    - If you do not have a predefined alias, fill in the following fields:
      - Type an alias name in the Alias field. The alias identifies the certificate request in the keystore.
      - Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).
      - **Optional:** Type an organization value. This value is the O value in the certificate DN.
      - **Optional:** Select a key size value. The valid key size values are 512, 1024, 2048, 4096, and 8192. The default key size value is 2048 bits.
      - Locality
      - **Optional:** Type the State or Province value. This value is the ST value in the certificate DN.
      - **Optional:** Type a zip code value. The zip code value is the POSTALCODE value in the certificate DN.
      - **Optional:** Type a country or region value from the list. This country value is the C= value in the certificate request DN.
      - Validity period
9. Click **Apply** then **Save**.
  10. Navigate to the Server Default Key store's personal certificates **Security > SSL configuration and certificate management > Key stores and certificates > <server\_default\_keystore>** . Under Additional properties, click **Personal certificates**
  11. Select the server default personal certificate and click the **Replace** button.
  12. Select the CA certificate alias from the list of aliases.
  13. Click **Apply** then **Save**.

## Results

The CA certificate alias replaces the alias of the default certificate in places where it is referenced in the configuration. All signer certificates from the default certificate are replaced with the signer certificate from the CA certificate.

## Creating a CA certificate in SSL

Certificates can be created by a certificate authority (CA) when a CAClient object is configured to connect to the CA to create the certificate. Certificates created by a certificate authority (CA) with a CA client are tracked in the security configuration in an object called CACertificate. The certificate is stored in a keystore and a CACertificate object is added to the configuration to reference the certificate. CA certificates are personal certificates.

## Before you begin

Before you begin, a CA client must be created to connect to the CA server. You then use the administrative console to create a CA certificate.

**Note:** In this release of WebSphere Application Server, the valid key size values are 512, 1024, 2048, 4096, and 8192. The default key size value is 2048 bits.

## Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Key stores and certificates**.
3. Click a **<keystore name>** to which you want to add the new CA certificate.
4. Under Additional Properties, click **Personal certificates** to create a new CA certificate in the configuration.

**Note:** You can also create a CA certificate by using the **requestCACertificate** AdminTask .

5. Click the **Create** button and select **CA-signed Certificate**
  6. Fill in the following information to the CA certificate section.
    - Revocation password
    - Confirm password.
    - Select the CA client from the pull down list.
- Note:** You can create a new CA client to apply to this CA authority by clicking the **New** button.
- Fill in the following information to the Request Specification section:
    - Select the radio button for a predefined request alias if a certificate request is already created.
    - If you do not have a predefined certificate request alias, fill in the following fields:
      - a. Type an alias name in the Alias field. The alias identifies the certificate request in the keystore.
      - b. Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).
      - c. **Optional:** Type an organization value. This value is the O value in the certificate DN.
      - d. **Optional:** Select a key size value. The valid key size values are 512, 1024, 2048, 4096, and 8192. The default key size value is 2048 bits.
      - e. Locality
      - f. **Optional:** Type the State or Province value. This value is the ST value in the certificate DN.
      - g. **Optional:** Type a zip code value. The zip code value is the POSTALCODE value in the certificate DN.

- h. **Optional:** Type a country or region value from the list. This country value is the C= value in the certificate request DN.

7. Click **Apply** then **OK**.

## Results

The certificate is stored in the keystore selected in the path to this panel and a `CACertificate` configuration object is created. Once a CA certificate is created the certificate can be used by the runtime for SSL communication.

An existing certificate request can be used to create the CA certificate or a new certificate request can be created. This panel uses the `requestCAClient AdminTask` to create the CA certificate.

## Developing the WSPKIClient interface for communicating with a certificate authority

Implementing the `WSPKIClient` interface enables WebSphere Application Server security to communicate with a remote certificate authority (CA).

### Procedure

1. Initialize the `WSPKIClient` method, with `init(java.util.HashMap)`.

```
public void init(java.util.HashMap initAttrs) throws WSPKIException;
```

This method is called by WebSphere Application Server runtime to set up connection information to a CA.

2. • Request a certificate with `requestCertificate(byte[], X500Principal, byte[], java.util.HashMap)`.

```
public X509Certificate[] requestCertificate(byte[] certReq,
X500Principal SubjectDN, byte[] revocationPassword,
java.util.HashMap customAttrs) throws WSPKIException;
```

This method is called by WebSphere Application Server runtime to connect to a CA and requests a certificate signed by the authority. A `X509Certificate[]` is returned if the requested certificate is created. If a null is returned then `queryCertificate()` is called to check if the certificate is ready. This method is used when the CA requires manual intervention to process a certificate request.

You can invoke this operation from the administrative console using the “Creating a CA certificate in SSL” on page 1944 task and from a client using the `requestCertificate` script.

3. • Revoke a certificate with `revokeCertificate(X509Certificate[], byte[], String, java.util.HashMap)`.

```
public void revokeCertificate(X509Certificate[] cert, byte[] revocationPassword,
String revocationReason, java.util.HashMap customAttrs) throws WSPKIException;
```

This method called by WebSphere Application Server runtime to submit a request to a CA to revoke a certificate.

You can invoke this operation from the administrative console using the revoke CA certificate task, “Revoking a CA certificate in SSL” on page 1942, or using the `revokeCertificate` script.

4. • Query a certificate with `queryCertificate(X509Certificate[], byte[], java.util.HashMap)`.

```
public X509Certificate[] queryCertificate(byte[] certReq,
java.util.HashMap customAttrs) throws WSPKIException;
```

This method is called by WebSphere Application Server runtime to query if certificate creation is completed on the CA. A `X509Certificate[]` is returned if certificate request is complete. A null is returned if the certificate request is pending.

You perform this operation from the administrative console using the Query (link to `usec_sslperscertreqs.html`) option, see “Personal certificate requests collection” on page 1996 and from a client using the `queryCertificate` script.

## Results

the WSPKIClient interface for communicating with a certificate authority (CA) is implemented.

## Creating a custom trust manager configuration for SSL

You can create a custom trust manager configuration at any management scope and associate the new trust manager with a Secure Sockets Layer (SSL) configuration.

### Before you begin

You must develop, package, and locate a Java Archive JAR file for a custom key manager in the `was.install.root/lib/ext` directory on WebSphere Application Server. For more information, see “Example: Developing a custom trust manager for custom SSL trust decisions” on page 1949.

### About this task

Complete the following steps in the administrative console:

### Procedure

1. Decide whether you want to create the custom trust manager at the cell scope or below the cell scope at the node, server, or cluster, for example.

**Important:** When you create a custom trust manager at a level below the cell scope, you can associate it only with a Secure Sockets Layer (SSL) configuration at the same scope or higher. An SSL configuration at a scope lower than the trust manager does not see the trust manager configuration.

- To create a custom trust manager at the cell scope, click **Security > SSL certificate and key management > Trust managers**. Every SSL configuration in the cell can select the trust manager at the cell scope.
  - To create a custom trust manager at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration > Trust managers**.
2. Click **New** to create a new custom trust manager.
  3. Type a unique trust manager name.
  4. Select the **Custom** implementation setting. The custom setting enables you to define a Java class with an implementation of the `javax.net.ssl.X509TrustManager` Java interface and, optionally, the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` WebSphere Application Server interface.

**Note:** The standard implementation setting applies only when the trust manager is already defined in the Java security provider list as a provider and an algorithm, which is not the case for a custom trust manager.

5. Type a class name, for example, `com.ibm.test.CustomTrustManager`.
6. Select one of the following actions:
  - Click **Apply**, then click **Custom properties** under Additional Properties to add custom properties to the new custom trust manager. When you are finished adding custom properties, click **OK** and **Save**, then go to the next step.
  - Click **OK** and **Save**, then go to the next step.
7. Click **SSL certificate and key management** in the page navigation at the top of the panel.
8. Select one of the following actions:
  - Click **SSL configurations** under Related Items for a cell-scoped SSL configuration.
  - Click **Manage endpoint security configurations** to select an SSL configuration at a lower scope.

9. Click the link for the existing SSL configuration that you want to associate with the new custom trust manager. You can create a new SSL configuration instead of associating the custom trust manager with an existing configuration. For more information, see “Creating a Secure Sockets Layer configuration” on page 1925.
10. Click **Trust and Key managers** under Additional Properties. If the new custom trust manager is not listed in the **Additional ordered trust managers** list, verify that you selected an SSL configuration scope that is at the same level or below the scope that you selected in Step 8.
11. Click **Add**. This action adds the new trust manager to the list of custom trust managers.
12. Click **OK** and **Save**.

## Results

You have created a custom trust manager configuration that references a JAR file in the install directory of WebSphere Application Server and associates it with an SSL configuration during the connection handshake.

## What to do next

You can create a custom trust manager for a pure client. For more information, see the TrustManagerCommands command group for the AdminTask object topic.

### *Trust and key managers settings:*

Use this page to specify trust and key managers for the selected SSL configuration.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under **Related items** click **SSL configurations > SSL\_configuration\_name**. Under **Additional Properties** click **Trust and key managers**.

**Attention:** The application server checks the default trust managers first before checking the additional ordered trust managers in descending order.

### *Default trust manager:*

Specifies the default trust manager. The default trust manager is IbmPKIX, which can be selected when certificate revocation checks must be made using the X509Certificate CRL distribution list. The other default trust manager is IbmX509.

<b>Data type:</b>	Text
<b>Default:</b>	ibmPKIX

### *Additional ordered trust managers:*

Specifies additional trust managers that are used in the order shown for this SSL configuration.

### *Add:*

Specifies to add the selection to the **Additional ordered trust managers** right-hand list.

### *Remove:*

Specifies to remove the selection from the **Additional ordered trust managers** right-hand list.

### *Key manager:*

Specifies the key manager that runs for this SSL configuration.

**Data type:** Text  
**Default:** IbmX509

### ***Trust managers collection:***

Use this page to define the implementation settings for the trust manager. A trust manager is a class that is invoked during a Secure Sockets Layer (SSL) handshake to make trust decisions about the remote end point. A default trust manager is used to validate the signature and expiration of the certificate. Custom trust managers can be plugged in to perform an extended certificate and host name check.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Trust managers**.

*Table 156. Trust managers buttons. This table describes the trust manager buttons.*

Button	Resulting action
New	Adds a new trust manager that can be selected by an SSL configuration. A trust manager is invoked during an SSL handshake and can decide whether the handshake should be accepted based on the information it knows about the remote certificate and host.
Delete	Deletes an existing trust manager. Make sure the trust manager is not referenced by any SSL configuration before you delete it.

### *Name:*

Specifies the name of the trust manager. This name is used as a selection in the SSL configuration panel.

### *Class name:*

Specifies a class that implements the javax.net.ssl.X509TrustManager interface. Optionally, the class can implement the com.ibm.wsspi.ssl.TrustMangerExtendedInfo interface to get extended information about the connection. The class can use the information to verify the host name and so on.

### *Algorithm:*

Specifies the algorithm name of the trust manager that is implemented by the selected provider.

### ***Trust managers settings:***

This page enables you to view and set definitions for trust manager implementation settings. A trust manager is a class that gets invoked during a Secure Sockets Layer (SSL) handshake to make trust decisions about the remote end point. A default trust manager is used to validate the signature and expiration of the certificate. Custom trust managers can be plugged in to perform an extended certificate and hostname check.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items click **Trust managers > New**.

### *Name:*

Specifies the name of the trust manager.

**Data type:** Text  
**Default:** IbmX509TrustManager

*Management scope:*

Specifies the scope where this Secure Sockets Layer (SSL) configuration is visible. For example, if you choose a specific node, then the configuration is only visible on that node and any servers that are part of that node.

This field is not editable and provides information only.

*Standard:*

Specifies that the trust manager selection is available from a Java provider that is installed in the `java.security` file. This provider might be shipped by the Java Secure Sockets Extension (JSSE) or might be a custom provider that implements the `javax.net.ssl.X509TrustManager` interface.

**Default:** Enabled

*Provider:*

Specifies the provider name that has an implementation of the `javax.net.ssl.X509TrustManager` interface. This provider is typically set to `IBMJSSE2`.

Enabled when **Standard** is selected.

**Default** IBMJCE

*Algorithm:*

Specifies the algorithm name of the trust manager implemented by the selected provider.

Enabled when **Standard** is selected.

**Default** ibmX509 or IbmPKIX  
**Range** ibmX509, IbmPKIX

*Custom:*

Specifies that the trust manager selection is based on a custom implementation class that implements the `javax.net.ssl.X509TrustManager` interface and optionally the `com.ibm.wsspi.ssl.TrustManagerExtendedInfo` interface to obtain additional connection information that is not otherwise available.

**Default:** Disabled

*Class name:*

Specifies a class that implements the `javax.net.ssl.X509TrustManager` interface. Optionally, the class can implement the `com.ibm.wsspi.ssl.TrustMangerExtendedInfo` interface to get extended information about the connection. The class can use the information to verify the host name and so on.

Enabled when **Custom** is selected.

**Data type:** Text

***Example: Developing a custom trust manager for custom SSL trust decisions:***

The following example is of a sample custom trust manager. The custom trust manager makes no trust decisions but instead uses the information in the X.509 certificate that it references to make decisions.

After you build and package the custom trust manager, configure it either from the `ssl.client.props` file for a pure client or the `SSLConfiguration TrustManager` link in the administrative console. See “Trust manager control of X.509 certificate trust decisions” on page 1890 for more information about trust managers.

**Note:** This example should only be used as a sample, and is not supported.

```
import java.security.cert.X509Certificate;
import javax.net.ssl.*;
import com.ibm.wsspi.ssl.TrustManagerExtendedInfo;

public final class CustomTrustManager implements X509TrustManager,
TrustManagerExtendedInfo
{
 private static ThreadLocal threadLocStorage = new ThreadLocal();
 private java.util.Properties sslConfig = null;
 private java.util.Properties props = null;

 public CustomTrustManager()
 {
 }

 /**
 * Method called by WebSphere Application Server run time to set the target
 * host information and potentially other connection info in the future.
 * This needs to be set on ThreadLocal since the same trust manager can be
 * used by multiple connections.
 *
 * @param java.util.Map - Contains information about the connection.
 */
 public void setExtendedInfo(java.util.Map info)
 {
 threadLocStorage.set(info);
 }

 /**
 * Method called internally to retrieve information about the connection.
 *
 * @return java.util.Map - Contains information about the connection.
 */
 private java.util.Map getExtendedInfo()
 {
 return (java.util.Map) threadLocStorage.get();
 }

 /**
 * Method called by WebSphere Application Server run time to set the custom
 * properties.
 *
 * @param java.util.Properties - custom props
 */
 public void setCustomProperties(java.util.Properties customProps)
 {
 props = customProps;
 }

 /**
 * Method called internally to the custom properties set in the Trust Manager
 * configuration.
 *
 * @return java.util.Properties - information set in the configuration.
 */
 private java.util.Properties getCustomProperties()
 {
 return props;
 }

 /**
 * Method called by WebSphere Application Server runtime to set the SSL

## Creating a custom key manager for SSL

You can create a custom key manager configuration at any management scope and associate the new key manager with a Secure Sockets Layer (SSL) configuration.

### Before you begin

You must develop, package, and locate a Java Archive (.JAR) file for a custom key manager in the `was.install.root/lib/ext` directory on WebSphere Application Server.

### About this task

Complete the following steps in the administrative console:

#### Procedure

1. Decide whether you want to create the custom key manager at the cell scope or below the cell scope at the node, server, or cluster, for example.

**Important:** When you create a custom key manager at a level below the cell scope, you can associate it only with a Secure Sockets Layer (SSL) configuration at the same scope or higher. An SSL configuration at a scope lower than the key manager does not see the key manager configuration.

- To create a custom key manager at the cell scope, click **Security > SSL certificate and key management > Key managers**. Every SSL configuration in the cell can select the key manager at the cell scope.
  - To create a custom key manager at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL\_configuration > Key managers**.
2. Click **New** to create a new key manager.
  3. Type a unique key manager name.
  4. Select the **Custom** implementation setting. With the custom setting, you can define a Java class that has an implementation on the Java interface `javax.net.ssl.X509KeyManager` and, optionally, the `com.ibm.wsspi.ssl.KeyManagerExtendedInfo` WebSphere Application Server interface. The standard implementation setting applies only when the key manager is already defined in the Java security provider list as a provider and an algorithm, which is not the case for a custom key manager. The typical standard key manager is `algorithm = IbmX509`, `provider = IBMJSSE2`.
  5. Type a class name. For example, `com.ibm.test.CustomKeyManager`.
  6. Select one of the following actions:
    - Click **Apply**, then click **Custom properties** under Additional Properties to add custom properties to the new custom key manager. When you are finished adding custom properties, click **OK** and **Save**, then go to the next step.
    - Click **OK** and **Save**, then go to the next step.
  7. Click **SSL certificate and key management** in the page navigation at the top of the panel.
  8. Select one of the following actions:
    - Click **SSL configurations** under Related Items for a cell-scoped SSL configuration.
    - Click **Manage endpoint security configurations** to select an SSL configuration at a lower scope.
  9. Click the link for the existing SSL configuration that you want to associate with the new custom key manager. You can create a new SSL configuration instead of associating the custom key manager with an existing configuration. For more information, see example below.
  10. Click **Trust and Key managers** under Additional Properties.
  11. Select the new custom key manager in the **Key manager** drop-down list. If the new custom key manager is not listed, verify that you selected an SSL configuration scope that is at the same level or below the scope that you selected in Step 8.
  12. Click **OK** and **Save**.

## Results

You have created a custom key manager configuration that references a JAR file in the installation directory of WebSphere Application Server and associates the custom configuration with an SSL configuration during the connection handshake.

## Example

**Developing a custom key manager for custom Secure Sockets Layer key selection.** The following example is of a sample custom key manager. This simple key manager returns the configured alias if it is set using the alias properties `com.ibm.ssl.keyStoreClientAlias` or `com.ibm.ssl.keyStoreServerAlias`, depending on which side of the connection the key manager is used. The key manager defers to the JSSE default `IbmX509` key manager to select an alias if these properties are not set.

After you build and package a custom key manager, you can configure it from either the `ssl.client.props` file for a pure client or by using the `SSLConfiguration KeyManager` link in the administrative console. See “Key manager control of X.509 certificate identities” on page 1892 for more information about key managers.

Because only one key manager can be configured at a time for any given Secure Sockets Layer (SSL) configuration, the certificate selections on the server side might not work as they would when the default IbmX509 key manager is specified. When a custom key manager is configured, it is up to the owner of that key manager to ensure that the selection of the alias from the SSL configuration supplied is set properly when `chooseClientAlias` or `chooseServerAlias` are called. Look for the `com.ibm.ssl.keyStoreClientAlias` and `com.ibm.ssl.keyStoreServerAlias` SSL properties.

**Note:** This example should only be used as a sample, and is not supported.

```
package com.ibm.test;

import java.security.cert.X509Certificate;

```

## What to do next

You can create a custom key manager for a pure client. For more information, see the `keyManagerCommands` command group for the `AdminTask` object.

## Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint

After you create a Secure Sockets Layer (SSL) configuration, you must associate a secure outbound management scope with the new configuration. In this release, you can associate one SSL configuration with one remote secure endpoint and a different SSL configuration to another remote secure endpoint. Both endpoints can use the same outbound protocol, if appropriate. This task describes how to create the association dynamically.

### Before you begin

Dynamic outbound selection requires that you provide only the outbound protocol name, the target host, and the target port so that WebSphere Application Server can make a connection between the SSL configuration and the outbound protocol or remote secure endpoint. The dynamic outbound selection method takes precedence over other selection methods, such as central management and direct selection, but is second to the programmatic method, that is, setting an SSL configuration on the running thread. For more information about the selection types and precedence rules, see “Secure communications using Secure Sockets Layer (SSL)” on page 1881.

### About this task

Complete the following steps in the administrative console:

#### Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Outbound**.
2. Select the management scope that you want to associate with an SSL configuration on the topology tree.
3. Under Related Items, click **Dynamic outbound endpoint SSL configurations**. The default dynamic outbound configuration name, the target protocol, host, and port connection information, and the SSL configuration name display.
4. Click **New** to create a new dynamic outbound configuration.
5. Type a dynamic outbound configuration name. Use a name that is descriptive of the purpose of the dynamic selection configuration.
6. Optionally, type a dynamic selection configuration description.
7. Type the connection information that you want to associate with the configuration that is displayed in the SSL configuration drop-down list. The connection information must be in the format *protocol name, target host, target port*. You can substitute an asterisk (\*) for any value, as in the following examples, where 443 is a port, `www.mycompany.com` is a host, HTTP is a protocol, and `.hometown.mycompany.com` is a target host. You can add multiple connections, but each additional connection can affect outbound performance.
  - `*,*,443`
  - `*,www.mycompany.com,443`
  - `HTTP,.hometown.mycompany.com,*`
  - `*,*,*`

**gotcha:** Do not use this configuration because it matches all outbound specifications. Therefore, no other SSL configuration is used for outbound connections.

**gotcha:**

- Unless the intention is to set the protocol property through the JSSEHelper API, the protocol filter should be set to \* (as in the first two examples). See "Dynamic Selection" in "Secure communications using Secure Sockets Layer (SSL)" on page 1881 for more information.
  - The connection protocols that are used for dynamic outbound SSL configuration selection, that are illustrated in the preceding examples, which are not corresponding the protocol name of the URL. To use one of these protocols from a user-written application, programmatic SSL configuration selection must be implemented.
8. Click **Add** to add the new connection to the set of SSL configuration connections. To remove a connection, select it and click **Remove**.
  9. Select an SSL configuration from the list.
  10. Click **Get certificate aliases** to refresh the certificate aliases that are contained in the associated key store.
  11. Choose a certificate alias from the list.
  12. Click **OK** and **Save**.

**Results**

WebSphere Application Server is ready to connect one or more SSL configurations to one or more remote secure endpoints.

**What to do next**

You can return to the outbound tree and select another management scope to associate with the same or a new outbound configuration.

***Programmatically specifying an outbound SSL configuration using JSSEHelper API:***

WebSphere Application Server provides a way to specify programmatically which Secure Sockets Layer (SSL) configurations to use prior to making an outbound connection. The `com.ibm.websphere.ssl.JSSEHelper` interface provides a complete set of application programming interfaces (APIs) for handling SSL configurations.

**About this task**

Perform the following steps for your application when using the JSSEHelper API to establish an SSL properties object on the thread for use by the runtime. Some of these APIs have Java 2 Security permission requirements. See the JSSEHelper API documentation for more information about the permissions required by your application.

Select the approach that best fits your connection situation when you specify programmatically which Secure Sockets Layer (SSL) configurations to use prior to making an outbound connection.

**Procedure**

1. Obtain an instance of the JSSEHelper API.  
`com.ibm.websphere.ssl.JSSEHelper jsseHelper = com.ibm.websphere.ssl.JSSEHelper.getInstance();`
2. Obtain SSL properties from the WebSphere Application Server configuration or use those provided by your application. Use one of the following options.
  - By direction selection of an alias name, within the same management scope or higher as in the following example:

```

try
{
String alias = "NodeAServer1SSLSettings";
// As specified in the WebSphere SSL configuration Properties
sslProps = jsseHelper.getProperties(alias);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
e.printStackTrace(); // handle exception
}

```

- By using the `getProperties` API for programmatic, direction, dynamic outbound, or management scope selection (based on precedence rules and inheritance). The SSL runtime uses the `getProperties` API to determine which SSL configuration to use for a particular protocol. This decision is based on both the input (`sslAlias` and `connectionInfo`) and the management scope from which the property is called. The `getProperties` API makes decisions in the following order:
  - a. The API checks the thread to see if properties already exist.
  - b. The API checks for a dynamic outbound configuration that matches the `ENDPOINT_NAME`, `REMOTE_HOST`, and or `REMOTE_PORT`.
  - c. The API checks to see if the optional `sslAlias` property is specified. You can configure any protocol as direct or centrally managed. When a protocol is configured as direct, the `sslAlias` parameter is `null`. When a protocol is configured as centrally managed, the `sslAlias` parameter is also `null`.
  - d. If no selection has been made, the API chooses the dynamic outbound configuration based on the management scope it was called from. If the dynamic outbound configuration is not defined in the same scope, it then searches the hierarchy to locate one.

The last choice is the cell-scoped SSL configuration (in WebSphere Application Server, Network Deployment) or the node-scoped SSL configuration (in Base Application Server). The `com.ibm.websphere.ssl.SSLConfigChangeListener` parameter is notified when the SSL configuration that is chosen by a call to the `getProperties` API changes. The protocol can then call the API again to obtain the new properties as in the following example:

```

try {
String sslAlias = null;
// The sslAlias is not specified directly at this time.
String host = "myhost.austin.ibm.com";
// the target host
String port = "443";
// the target port
HashMap connectionInfo = new HashMap();
connectionInfo.put(JSSEHelper.CONNECTION_INFO_DIRECTION, JSSEHelper.DIRECTION_OUTBOUND);
connectionInfo.put(JSSEHelper.CONNECTION_INFO_REMOTE_HOST, host);
connectionInfo.put(JSSEHelper.CONNECTION_INFO_REMOTE_PORT, Integer.toString(port));
connectionInfo.put(JSSEHelper.CONNECTION_INFO_ENDPOINT_NAME, JSSEHelper.ENDPOINT_I10P);
java.util.Properties props = jsseHelper.getProperties(sslAlias, connectionInfo, null);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
e.printStackTrace(); // handle exception
}

```

- By creating your own SSL properties and then passing them to the runtime, as in the following example:

```

try {
// This is the recommended "minimum" set of SSL properties. The trustStore can
// be the same as the keyStore.
Properties sslProps = new Properties();
sslProps.setProperty("com.ibm.ssl.trustStore", "some value");
sslProps.setProperty("com.ibm.ssl.trustStorePassword", "some value");
sslProps.setProperty("com.ibm.ssl.trustStoreType", "some value");
sslProps.setProperty("com.ibm.ssl.keyStore", "some value");
sslProps.setProperty("com.ibm.ssl.keyStorePassword", "some value");
sslProps.setProperty("com.ibm.ssl.keyStoreType", "some value");
jsseHelper.setSSLPropertiesOnThread(sslProps);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
e.printStackTrace(); // handle exception
}

```

3. Use the `JSSEHelper.setSSLPropertiesOnThread(props)` API to set the `Properties` object on the thread so that the runtime picks it up and uses the same `JSSEHelper.getProperties` API. You can also obtain properties from the thread after they are set with the `jsseHelper.getSSLPropertiesOnThread()` API, as in the following example:

```

try
{
Properties sslProps = jsseHelper.getProperties(null, connectionInfo, null);
jsseHelper.setSSLPropertiesOnThread(sslProps);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
e.printStackTrace(); // handle exception
}

```

4. When the connection is completed, you must clear the SSL properties from the thread by passing the `null` value to the `setPropertiesOnThread` API.

```

try
{
jsseHelper.setSSLPropertiesOnThread(null);
}
catch (com.ibm.websphere.ssl.SSLException e)
{
e.printStackTrace(); // handle exception
}

```

## ***Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes:***

After you create a Secure Sockets Layer (SSL) configuration, you must associate a secure inbound or outbound management scope with the new configuration. You can manage the association centrally so that you can easily make changes that affect all the scopes that are lower on the topology and that are associated with the configuration. Beginning with WebSphere Application Server version 6.1, the recommended and the default configuration method is centrally managed SSL configurations.

### **Before you begin**

You can simplify the number of associations that you need to make for an SSL configuration by associating the configuration with the highest level management scope requiring a unique configuration. SSL configuration associations manifest inheritance behaviors. Because of the inheritance behaviors, all of the scopes that are lower on the topology inherit this SSL configuration. For example, an association you make at the cell level affects nodes, servers, clusters, and endpoints. For more information, see “Central management of SSL configurations” on page 1900.

A precedence rule determines which SSL configuration association is used at a particular scope. The highest precedence is given to endpoints on the topology. If you establish an association at the endpoint, this association overrides any prior association that you made higher up on the management scope topology.

### **About this task**

Complete the following steps in the administrative console:

#### **Procedure**

1. Click **Security > SSL certificate and key management**.
2. Select the **Dynamically update the runtime when SSL configuration changes** check box if you want changes that you make to an existing SSL configuration to occur dynamically. All outbound SSL communications honor the dynamic SSL changes. Protocols that do not use the channel frameworks SSL channel for inbound communications, including Object Request Broker (ORB) and administrative SOAP protocols, do not honor dynamic updates. For more information, see “Dynamic configuration updates in SSL” on page 1918.
3. Click **Manage endpoint security configurations**.
4. Select either the inbound or the outbound tree. After finishing the selected tree, you can return to this step to repeat the following steps for the other tree.
5. Click the link for the selected cell, node, node group, server, cluster, or endpoint on the topology tree. If the scope already has an associated SSL configuration and alias, these objects display in parentheses immediately following the scope name, for example: Node01(NodeDefaultSSLSettings,default). If the deployment manager has federated a node, the node scope SSL configuration overrides the cell scope configuration above it in the topology.
6. Decide whether to override the inherited values that display in the read-only fields. Read-only fields include the management scope name, the direction, and the inherited SSL configuration name and certificate alias.
  - If you are satisfied with these values, do not override them.
  - If you want to override the inherited values, select the **Override inherited values** check box.
7. Select an SSL configuration from the list.
8. Click **Update certificate alias list**. The certificate alias list comes from the key store that is referenced by the new SSL configuration.
9. Click **Manage certificates** if you want to manage the personal certificates that are contained in the key store that is referenced in the SSL configuration.
10. Click **Update certificate alias list** to refresh the list of aliases.

11. Select a certificate alias in the key store to represent the identity of the endpoint.
12. Click **OK** to save your changes.
13. Click **Manage endpoint security configurations and trust zones** to return to the topology tree.
14. Configure the opposite direction on the topology tree using the steps in this task. You can also select additional scopes to associate with the SSL configuration, as needed.

## Results

Each SSL configuration at the selected scope and at scopes beneath it on the topology tree have the same SSL configuration properties. The following SSL configuration methods override the centrally managed configurations that you associate in the tree view:

- Direct selection at the endpoint
- Dynamic outbound SSL configuration associations
- Programmatic specifications

## What to do next

At any management scope, you can configure the following objects: dynamic outbound endpoint SSL configurations, key stores, key sets, key set groups, key managers, and trust managers. Like SSL configurations, these objects are scoped automatically so that they are not visible higher up in the tree nor are they loaded during runtime by processes that are higher up in the tree.

### *Selecting an SSL configuration alias directly from an endpoint configuration:*

You can associate a secure outbound endpoint with a new Secure Sockets Layer (SSL) configuration directly. If you are migrating from a release prior to version 6.1, WebSphere Application Server still supports configurations that were selected directly at an endpoint. Direct selection always overrides centrally managed configurations and preserves migrated configurations.

## About this task

Select an SSL configuration alias directly at the following endpoints:

- **Security > Global security > RMI/IIOP security > CSiv2 outbound transport**
- **Security > Global security > RMI/IIOP security > CSiv2 inbound transport**
- **System administration > Deployment manager > Transport Chain > WCInboundAdminSecure > SSL inbound channel (SSL\_1)**
- **System administration > Deployment manager > Administration Services > JMX connectors > SOAPConnector > Custom Properties > sslConfig**
- **System administration > Node agents > nodeagent > Administration Services > JMX connectors > SOAPConnector > Custom Properties > sslConfig**
- **Servers > Application servers > server1 > Messaging engine inbound transports > InboundSecureMessaging > SSL inbound channel (SIB\_SSL\_JFAP)**
- **Servers > Application servers > server1 > WebSphere MQ link inbound transports > InboundSecureMQLink > SSL inbound channel (SIB\_SSL\_MQFAP)**
- **Servers > Application servers > server1 > SIP Container Settings > SIP container transport chains > SIPInboundDefaultSecure > SSL inbound channel (SSL\_5)**
- **Servers > Application servers > server1 > Web Container Settings > Web container transport chains > WCInboundAdminSecure > SSL inbound channel (SSL\_1)**
- **Servers > Application servers > server1 > Web Container Settings > Web container transport chains > WCInboundDefaultSecure > SSL inbound channel (SSL\_2)**

**Attention:** The central management of SSL configurations can be a more efficient strategy because multiple configurations can be contained within a single SSLConfigGroup. If you need to convert configuration references that are already directly managed to centrally managed configurations, modify each endpoint individually. Use the **AdminConfig.modify** command to set the `sslConfigAlias` value to an empty string (""). Below is an example of doing this:

- Using Jacl:

```
set s1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
set sslChannel [lindex [$AdminConfig list SSLInboundChannel $s1] 0]
$AdminConfig modify $sslChannel [list[list sslConfigAlias ""]]
```

For more information on using this command, see the information about configuring processes using scripting.

For more information on specific wsadmin commands that affect a repertoire as opposed to individual endpoints, see the SSLConfigGroupCommands group for the AdminTask topic.

Complete the following steps in the administrative console:

**Note:** These steps provide an example to follow when you directly select any of the endpoints listed above.

### Procedure

1. Click **Security > Global security > RMI/IIOP security > CSiv2 outbound transport**.
2. Click **Use specific SSL alias**. When you identify a specific SSL alias, you override the centrally managed scope associations.
3. Select an SSL configuration alias from the drop-down list.
4. Click **OK**.
5. Repeat these steps for additional protocols or endpoints, if desired.

### Results

By associating the endpoint directly, you have overridden a centrally managed SSL configuration.

### What to do next

If you decide to use management scopes instead of endpoints to associate an SSL configuration, follow the steps above, but click **Centrally managed** instead of **Use specific SSL alias**, then click **Manage endpoint security configurations**. The console is redirected to **Security > SSL certificate and key management > Manage endpoint security configurations**.

### *Enabling Secure Sockets Layer client authentication for a specific inbound endpoint:*

When you establish a Secure Sockets Layer (SSL) configuration, you can enable client authentication for a specific inbound endpoint.

### Before you begin

The endpoint configuration must already exist in the SSL topology.

### About this task

Complete the following steps in the administrative console:

### Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound > SSL\_configuration**. If you want to enable SSL client authentication for all processes,

define an SSL configuration for the new endpoint at the node or cell level so that it is visible to all processes on the same node or on the entire cell. For more information, see “Creating a Secure Sockets Layer configuration” on page 1925.

2. Select **Override inherited values**. The SSL configuration is used for the current scope and any lower scopes that have not already designated an SSL configuration. This field displays for server and node groups within the object hierarchy and does not display for the top-level node or cell.
3. Select an SSL configuration from the drop-down list.
4. Click **Update certificate alias list**.
5. Select a **Certificate alias** from the drop-down list.
6. Click **OK** to save the configuration.

## Results

You can repeat the previous steps for each endpoint that uses the same SSL configuration to enable client authentication for the inbound endpoints.

## What to do next

### CSlv2 Protocol Exception:

The Common Secure Interoperability Version 2 (CSlv2) secure endpoints, used for Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) security, cannot override inherited values. While the rest of the SSL properties are effective for CSlv2 when they are selected at the centrally-managed Secure Communications panel, the client authentication selection is controlled by the CSlv2 protocol configuration.

To enable SSL client certificate authentication for the CSlv2 protocol, you must use the CSlv2 inbound and outbound authentication panels. For SSL client authentication to occur between two servers, you must enable (support or require) SSL client certificate authentication for both the inbound and the outbound policies.

WebSphere Application Server can either request (support) clients to provide signer certificates for the SSL handshake, or the server can require clients to provide a valid signer certificate for the SSL handshake, which is a more secure method. However, when the server requires certificates, the server must obtain a signer for each client that connects to the server, which involves more server-side management.

The client certificate should not be used for the identity when it is used from server-to-server. However, when a pure client sends the client certificate it is used for the identity unless a message level identity is specified, such as a user ID or a password.

Do the following to enable client certificate authentication for the CSlv2 protocol for server-to-server:

1. Click **Security > Global security**.
2. Expand the **RMI/IIOP** security section.
3. Click **CSlv2 inbound authentication**.
4. Under Client authentication, select either **supported** or **required**. When you select required, only one SSL port is opened (CSV2\_SSL\_MUTUALAUTH\_LISTENER\_ADDRESS). When you select supported, two SSL ports are opened (both CSIV2\_SSL\_MUTUALAUTH\_LISTENER\_ADDRESS and CSIV2\_SSL\_SERVERAUTH\_LISTENER\_ADDRESS).

If there are two ports, the client can select either based on the security configuration policy of the port.

5. Click **OK** to save.
6. If you want server-to-server SSL client authentication, then complete the remaining steps. If you don't complete the remaining steps, only pure clients are enabled to send client certificates.

7. Expand the **RMI/IIOP** security section.
8. Click **CSlv2 outbound authentication**.
9. Under Client authentication, select either **supported** or **required**.

The SSL configuration for the inbound secure endpoints for which you enable SSL client certificate authentication must have the signer certificate from any client that attempts to open a connection to that inbound secure endpoint. You must collect those signers and then add them to the trust store associated with the inbound secure endpoints SSL configuration.

**Manage endpoint security configurations:**

Use this page to select a Secure Socket Layer (SSL) configuration from the Local Topology hierarchy, which includes cells, nodes, node groups, servers, and clusters.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations**.

*Local topology:*

The Local topology represents the hierarchy of nodes, node groups, clusters, servers, and end points within the cell that comprise a centralized SSL configuration.

The topology acts as a hierarchical tree in terms of inheritance. For example, if an SSL configuration has been associated with a specific node, then all servers within that node will inherit that SSL configuration selection, provided the servers are not associated with an SSL configuration at the server scope. Centralized management of SSL is the default configuration; however, it can be overridden at various locations to directly select a specific SSL alias as in previous releases for backwards compatibility.

Scope	Description
Inbound/Outbound	Specifies the topology tree in terms of connection direction. For example, the inbound tree represents all server endpoints that receive connections at the various servers within the cell. The outbound tree represents the client side of connections from the various servers within the cell.
Nodes	Specifies the nodes that are part of the cell. The list of nodes is updated anytime a node gets federated into the cell.
Servers	Specifies the servers that are part of a specific node. You can enable a specific server to have an SSL configuration associated with it so that resources within the same server can use the associated SSL configuration.
Clusters	Specifies the clusters that are part of the cell. When an SSL configuration is associated with a cluster, all servers within the cluster will use the same SSL configuration unless specified at a lower level in the topology.
Nodegroups	Specifies the node groups that are part of the cell. When an SSL configuration is associated with a node group, all nodes within that node group may use the same SSL configuration unless one is specified at a lower scope in the topology or the specific end point has chosen a direct alias reference.

Scope	Description
Secure port and transport	Specifies an endpoint name to associate with an SSL configuration when more specific SSL settings are needed at this level. You could select an alias directly at the endpoint panel; however, when you use <b>Secure port and transport</b> , you can maintain more centralized control of the SSL configuration and make changes more easily.

**Dynamic inbound and outbound endpoint SSL configurations collection:**

Use this page to manage dynamic endpoint Secure Sockets Layer (SSL) configurations, which represent associations between Secure Socket Layer (SSL) configurations and their target protocol, host, and port.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Dynamic outbound endpoint SSL configurations**.

When an outbound connection is attempted, this association is checked ahead of the SSL configuration scope association. Based on the target protocol, host, port, the outbound SSL configuration used can be different from the default specified in the SSL scope configuration.

*Table 157. Dynamic inbound and outbound endpoint SSL configurations buttons. This table lists the dynamic inbound and outbound endpoint SSL configuration buttons.*

Button	Resulting action
<b>New</b>	Adds a new dynamic outbound selection criteria. The outbound connection selects an SSL configuration based upon connection information, including DNS host name and domain, port, and protocol type. When an outbound connection is being made, the dynamic outbound selection criteria are queried for a match, and if found the SSL configuration associated is used.
<b>Delete</b>	Deletes an existing dynamic outbound endpoint SSL configuration.

**Name:**

Specifies the unique name of the dynamic endpoint configuration.

**Connection information:**

Specifies the set of target protocol, host, port for the outbound request in the form *protocol,host,port*.

**SSL Configuration:**

Specifies the SSL configuration that is used by requests at this scope when a match occurs for the given selection criteria.

**Dynamic outbound endpoint SSL configuration settings:**

Use this page to set properties for dynamic outbound endpoint SSL configurations, which represent associations between SSL configurations and their target protocol, host, and port.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Dynamic [inbound | outbound] endpoint SSL configurations**. Then click the **New** button.

When an outbound connection is attempted, this association is checked ahead of the Secure Sockets Layer (SSL) configuration scope association. This means based on the target protocol,host,port, the outbound SSL configuration used can be different than the default specified in the SSL scope configuration.

*Name:*

Specifies the unique name of the dynamic endpoint configuration.

**Data type:** Text

*Description:*

Specifies text that describes the purpose of this dynamic selection criteria.

**Data type:** Text

*Add connection information:*

Specifies select information in the form protocol,host,port for the outbound connection. Multiple selection criteria can be entered. All of the connection information for dynamic outbound selection might not be available, and you may have to adjust the dynamic outbound selection connection filter and fill in an asterisk (\*) for the missing part of the connection information. An asterisk (\*) can be used to mean all protocols, hosts, or ports. You can use an asterisk(\*) for any field.

**Data type:** Text

An example of selection criteria is \*,www.ibm.com,\*, which means that any time the target host is www.ibm.com, you must use the SSL configuration specified here. Another example selection criteria is IIOP,\*,\*, which means that any outbound IIOP request uses the SSL configuration that is specified in the SSL configuration field. When there is a conflict between two selection criteria, the application server uses the first match. The list of valid protocols you can use include: IIOP, HTTP, JMS, LDAP, SIP, ADMIN\_SOAP, ADMIN\_IIOP, or WEBSERVICES\_HTTP.

When user written applications are expecting to take advantage of dynamic outbound selections, know that not all connection information may be available. For example, the openConnection() call on an URL object ultimately calls createSocket(java.net.Socket socket, String host, int port, boolean autoClose). The connection information can be built with the host and port provided, but there is no protocol provided. In this case, a wild card, an asterisk (\*), should be used for the protocol part of the dynamic selection connection information.

*Add:*

Specifies to add the selected information from the **Add select information** menu to the right-hand list.

*Remove:*

Specifies to remove the selection from the right-hand list.

*SSL Configuration:*

Specifies the SSL configuration to be used by requests at this scope when a match occurs for the given selection criteria.

**Data type:** Text

### *Get certificate alias:*

When selected, the keystore within the selected SSL configuration is queried for a list of personal certificates from which to choose.

### *Certificate alias:*

Specifies the certificate alias that is used as the identity for the connection.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the keystore, the key manager might not consistently select the same certificate.

**Data type:** Text  
**Default:** (none)

## **Quality of protection (QoP) settings**

Use this page to specify security level, ciphers, and mutual authentication settings for the Secure Socket Layer (SSL) configuration.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under **Related Items**, click **SSL configurations > {SSL\_configuration\_name}**. Under **Additional Properties**, click **Quality of protection (QoP) settings**.

### *Client authentication:*

Specifies the whether SSL client authentication should be requested if the SSL connection is used for the server side of the connection.

If None is selected, the server does not request that a client certificate be sent during the handshake. If Supported is selected, the server requests that a client certificate be sent. If the client does not have a certificate, the handshake might still succeed. If Required is selected, the server requests that a client certificate be sent. If the client does not have a certificate, the handshake fails.

**Data type:** Text  
**Default:** None

### *Protocol:*

Specifies the Secure Sockets Layer (SSL) handshake protocol. This protocol is typically SSL\_TLS, which supports all handshake protocols except for SSLv2 on the server side. When United States Federal Information Processing standard (FIPS) option is enabled, Transport Layer Security (TLS) is automatically used regardless of this setting.

**Data type:** text  
**Default:** SSL\_TLS

### *Cipher suite groups:*

Specifies the various cipher suite groups that can be chosen depending upon your security needs. The stronger the cipher suite strength, the better the security; however, this can result in performance consequences.

**Data type:** Text  
**Default:** Strong

### ***Update selected ciphers:***

When selected, the cipher suites that are contained within the selected Cipher suite group are added to the list of **Selected ciphers**. Any change to this list changes the Cipher suite group to custom.

### ***Selected ciphers:***

Specifies the ciphers that are effective when the configuration is saved. These ciphers are used to negotiate with the remote side of the connection during the handshake. A common cipher needs to be selected or the handshake fails.

**Data type:** Text

### ***Add:***

Specifies to add the selected cipher to the **Selected ciphers** list.

### ***Remove:***

Specifies to remove the selected cipher from the **Selected ciphers** list.

## **ssl.client.props client configuration file**

Use the `ssl.client.props` file to configure Secure Sockets Layer (SSL) for clients. In previous releases of WebSphere Application Server, SSL properties were specified in the `sas.client.props` or `soap.client.props` files or as system properties. By consolidating the configurations, WebSphere Application Server enables you to manage security in a manner that is comparable to server-side configuration management. You can configure the `ssl.client.props` file with multiple SSL configurations.

## **Setting up the SSL configuration for clients**

Client runtimes are dependent on the WebSphere Application Server `ssl.client.props` configurations.

Use the `setupCmdLine.sh` script on the command line to specify the `com.ibm.SSL.ConfigURL` system property.

The `com.ibm.SSL.ConfigURL` property references a file URL that points to the `ssl.client.props` file. You can reference the `CLIENTSSL` variable on the command line of any script that uses the `setupCmdLine.sh` file.

When you specify the `com.ibm.SSL.ConfigURL` system property, the SSL configuration is available to all protocols that use SSL. SSL configurations, which are referenced in the `ssl.client.props` file, also have aliases that you can reference. In the following sample code from the `sas.client.props` file, all of the SSL properties are replaced with a property that points to an SSL configuration in the `ssl.client.props` file:

```
com.ibm.ssl.alias=DefaultSSLSettings
```

The following sample code shows a property in the `soap.client.props` file that is similar to the `com.ibm.SSL.ConfigURL` property. This property references a different SSL configuration on the client side:

```
com.ibm.ssl.alias=DefaultSSLSettings
```

In the `ssl.client.props` file, you can change the administrative SSL configuration to avoid modifying the `soap.client.props` file.

**Tip:** Support for SSL properties is still specified in the `sas.client.props` and `soap.client.props` files. However, consider moving the SSL configurations to the `ssl.client.props` file, because this file is the new configuration model for client SSL.

When you are configuring a client which does not call `setupCmdLine.sh` to connect to an application server using security, you must ensure that the following system property is defined on the client configuration:

```
-Djava.security.properties=profile_root/properties/java.security
```

## Properties of the `ssl.client.props` file

This section describes the default `ssl.client.props` file properties in detail, by sections within the file. Be aware that if you specify `javax.net.ssl` system properties, these will override the settings in `ssl.client.props` file.

### Global properties

Global SSL properties are process-specific properties that include Federal Information Processing Standard (FIPS) enablement, the default SSL alias, the `user.root` property for specifying the root location of the key and truststore paths, and so on.

*Table 158. Properties of the `ssl.client.props` file. This table describes the properties of the `ssl.client.props` file.*

Property	Default	Description
<code>com.ibm.ssl.defaultAlias</code>	<code>DefaultSSLSettings</code>	Specifies the default alias that is used whenever an alias is not specified by the protocol that calls the <code>JSSEHelper</code> API to retrieve an SSL configuration. This property is the final arbiter on the client side for determining which SSL configuration to use.
<code>com.ibm.ssl.validationEnabled</code>	<code>false</code>	When set to <code>true</code> , this property validates each SSL configuration as it is loaded. Use this property for debug purposes only, to avoid unnecessary performance overhead during production.
<code>com.ibm.ssl.performURLHostNameVerification</code>	<code>false</code>	When set to <code>true</code> , this property enforces URL host name verification. When HTTP URL connections are made to target servers, the common name (CN) from the server certificate must match the target host name. Without a match, the host name verifier rejects the connection. The default value of <code>false</code> omits this check. As a global property, it sets the default host name verifier. Any <code>javax.net.ssl.HttpsURLConnection</code> object can choose to enable host name verification for that specific instance by calling the <code>setHostnameVerifier</code> method with its own <code>HostnameVerifier</code> instance. <b>gotcha:</b> This property does not apply to SSL channels.
<code>com.ibm.security.useFIPS</code>	<code>false</code>	When set to <code>true</code> , FIPS-compliant algorithms are used for SSL and other Java Cryptography Extension (JCE)-specific applications. This property is typically not enabled unless the property is required by the operating environment.
<code>user.root</code>	<code>\${WASROOT}</code>	This property can be used by key and truststore location properties as a single property for specifying the root path to the key and truststores. Typically, this property is the profile root. However, you can modify this property to any root directory on the local machine that has the proper read and potentially write authority to that directory.

### Certificate creation properties

Use certificate creation properties to specify the default self-signed certificate values for the major attributes of a certificate. You can define the distinguished name (DN), expiration date, key size, and alias that are stored in the keystore.

Table 159. Certificate creation properties. This table describes the certificate creation properties.

Property	Default	Description
com.ibm.ssl.defaultCertReqAlias	default_alias	This property specifies the default alias to use to reference the self-signed certificate that is created in the keystore. If the alias already exists with that name, the default alias is appended with <code>_#</code> , where the number sign (#) is an integer that starts with 1 and increments until it finds a unique alias.
com.ibm.ssl.defaultCertReqSubjectDN	cn=\${hostname}, o=IBM,c=US	This property uses the property distinguished name (DN) that you set for the certificate when it is created. The <code>\${hostname}</code> variable is expanded to the host name on which it resides. You can use correctly formed DNs as specified by the X.509 certificate.
com.ibm.ssl.defaultCertReqDays	365	This property specifies the validity period for the certificate and can be as small as 1 day and as large as the maximum number of days that a certificate can be set, which is approximately 15 years.
com.ibm.ssl.defaultCertReqKeySize	1024	This property is the default key size. The valid values depend upon the Java Virtual Machine (JVM) security policy files that are installed. By default, the product JVMs ship with the export policy file that limits the key size to 1024. To get a large key size such as 2048, you can download the restricted policy files from the website.

### Certificate revocation checking

To enable certificate revocation checking, you can set a combination of Online Certificate Status Protocol (OCSP) properties. These properties are not used unless you set the `com.ibm.ssl.trustManager` property to `IbmPKIX`. In addition, to successfully process revocation checking on the client, you must turn off the signer exchange prompt. To turn off the signer exchange prompt, change the `com.ibm.ssl.enableSignerExchangePrompt` property to `false`. For more information, see the related link to the "Enabling certificate revocation checking with the default `IbmPKIX` trust manager" topic.

### SSL configuration properties

Use the SSL configuration properties section to set multiple SSL configurations. For a new SSL configuration specification, set the `com.ibm.ssl.alias` property because the parser starts a new SSL configuration with this alias name. The SSL configuration is referenced by using the alias property from another file, such as `sas.client.props` or `soap.client.props`, through the default alias property. The properties that are specified in the following table enable you to create a `javax.net.ssl.SSLContext`, among other SSL objects.

Table 160. SSL configuration properties. This table lists the SSL configuration properties.

Property	Default	Description
com.ibm.ssl.alias	DefaultSSLSettings	This property is the name of this SSL configuration and must be the first property for an SSL configuration because it references the SSL configuration. If you change the name of this property after it is referenced elsewhere in the configuration, the runtime defaults to the <code>com.ibm.ssl.defaultAlias</code> property whenever the reference is not found. The error trust file is null or key file is null might display when you start an application using an SSL reference that is no longer valid.

Table 160. SSL configuration properties (continued). This table lists the SSL configuration properties.

Property	Default	Description
com.ibm.ssl.protocol	SSL_TLS	This property is the SSL handshake protocol that is used for this SSL configuration. This property attempts Transport Layer Security (TLS) first, but accepts any remote handshake protocol, including SSLv3 and TLS. Valid values for this property include SSLv2 (client side only), SSLv3, SSL, TLS, TLSv1, and SSL_TLS.
com.ibm.ssl.securityLevel	STRONG	This property specifies the cipher group that is used for the SSL handshake. The typical selection is STRONG, which specifies 128-bit or higher ciphers. The MEDIUM selection provides 40-bit ciphers. The WEAK selection provides ciphers that do not perform encryption, but do perform signing for data integrity. If you specify your own cipher list selection, uncomment the property com.ibm.ssl.enabledCipherSuites. <b>Note:</b> The use of javax.net.ssl system properties causes this value to always be HIGH.
com.ibm.ssl.trustManager	IbmX509	This property specifies the default trust manager that you must use to validate the certificate sent by the target server. This trust manager does not perform certificate revocation list (CRL) checking. You can choose to change this value to IbmPKIX for CRL checking using CRL distribution lists in the certificate, which is a standard way to perform CRL checking. When you want to perform custom CRL checking, you must implement a custom trust manager and specify the trust manager in the com.ibm.ssl.customTrustManagers property. The IbmPKIX option might affect performance because this option requires IBM CertPath for trust validation. Use IbmX509 unless CRL checking is necessary. If you are using the Online Certificate Status Protocol (OCSP) properties, set this property value to IbmPKIX.
com.ibm.ssl.keyManager	IbmX509	This property specifies the default key manager to use for choosing the client alias from the specified keystore. This key manager uses the com.ibm.ssl.keyStoreClientAlias property to specify the keystore alias. If this property is not specified, the choice is delegated to Java Secure Socket Extension (JSSE). JSSE typically chooses the first alias that it finds.
com.ibm.ssl.contextProvider	IBMJSSE2	This property is used to choose the JSSE provider for the SSL context creation. It is recommended that you default to IBMJSSE2 when you use a Java virtual machine (JVM). The client plug-in can use the SunJSSE provider when using a Sun JVM.
com.ibm.ssl.enableSignerExchangePrompt	true	This property determines whether to display the signer exchange prompt when a signer is not present in the client truststore. The prompt displays information about the remote certificate so that WebSphere Application Server can decide whether or not to trust the signer. It is very important to validate the certificate signature. This signature is the only reliable information that can guarantee that the certificate has not been modified from the original server certificate. For automated scenarios, disable this property to avoid SSL handshake exceptions. Run the retrieveSigners script, which sets up the SSL signer exchange, to download the signers from the server prior to running the client. If you are using the Online Certificate Status Protocol (OCSP) properties, set this property value to false.
com.ibm.ssl.keyStoreClientAlias	default	This property is used to reference an alias from the specified keystore when the target does not request client authentication. When WebSphere Application Server creates a self-signed certificate for the SSL configuration, this property determines the alias and overrides the global com.ibm.ssl.defaultCertReqAlias property.

Table 160. SSL configuration properties (continued). This table lists the SSL configuration properties.

Property	Default	Description
com.ibm.ssl.customTrustManagers	Commented out by default	This property enables you to specify one or more custom trust managers, which are separated by commas. These trust managers can be in the form of <i>algorithm provider</i> or <i>classname</i> . For example, <code>lbmX509 IBMJSSE2</code> is in the <i>algorithm provider</i> format, and the <code>com.acme.myCustomTrustManager</code> interface is in the <i>classname</i> format. The class must implement the <code>javax.net.ssl.X509TrustManager</code> interface. Optionally, the class can implement the <code>com.ibm.wsspi.ssl.TrustManagerExtendedInfo</code> interface. These trust managers run in addition to the default trust manager that is specified by the <code>com.ibm.ssl.trustManager</code> interface. These trust managers do not replace the default trust manager.
com.ibm.ssl.customKeyManager	Commented out by default	This property enables you to have one, and only one, custom key manager. The key manager replaces the default key manager that is specified in the <code>com.ibm.ssl.keyManager</code> property. The form of the key manager is <i>algorithm provider</i> or <i>classname</i> . See the format examples for the <code>com.ibm.ssl.customTrustManagers</code> property. The class must implement the <code>javax.net.ssl.X509KeyManager</code> interface. Optionally, the class can implement the <code>com.ibm.wsspi.ssl.KeyManagerExtendedInfo</code> interface. This key manager is responsible for alias selection.
com.ibm.ssl.dynamicSelectionInfo	Commented out by default	This property enables dynamic association with the SSL configuration. The syntax for a dynamic association is <i>outbound_protocol</i> , <i>target_host</i> , or <i>target_port</i> . For multiple specifications, use the vertical bar (   ) as the delimiter. You can replace any of these values with an asterisk (*) to indicate a wildcard value. Valid <i>outbound_protocol</i> values include: IIOP, HTTP, LDAP, SIP, BUS_CLIENT, BUS_TO_WEBSPHERE_MQ, BUS_TO_BUS, and ADMIN_SOAP. When you want the dynamic selection criteria to choose the SSL configuration, uncomment the default property, and add the connection information. For example, add the following on one line  <code>com.ibm.ssl.dynamicSelectionInfo=HTTP, .ibm.com,443 HTTP,.ibm.com,9443</code>
com.ibm.ssl.enabledCipherSuites	Commented out by default	This property enables you to specify a custom cipher suite list and override the group selection in the <code>com.ibm.ssl.securityLevel</code> property. The valid list of ciphers varies according to the provider and JVM policy files that are applied. For cipher suites, use a space as the delimiter.
com.ibm.ssl.keyStoreName	ClientDefaultKeyStore	This property references a keystore configuration name. If you have not already defined the keystore, the rest of the keystore properties must follow this property. After you define the keystore, you can specify this property to reference the previously specified keystore configuration. New keystore configurations in the <code>ssl.client.props</code> file have a unique name.
com.ibm.ssl.trustStoreName	ClientDefaultTrustStore	This property references a truststore configuration name. If you have not already defined the truststore, the rest of the truststore properties must follow this property. After you define the truststore, you can specify this property to reference the previously specified truststore configuration. New truststore configurations in the <code>ssl.client.props</code> file should have a unique name.

The default values of keystore and truststore configuration properties depend on the security configuration that you select on the Administrative Security Selection panel of the z/OS Profile Management Tool. The following options are available on the Administrative Security Selection panel:

- If you indicate the **Use a z/OS security product** option, which is the first option, the default values for the keystore and truststore configuration properties point to a keystore with a JCERACFKS type. This

type uses keys and certificates that are stored and managed by a z/OS security product such as RACF. For more information, see the "z/OS keystores" section in the "Keystore configurations" topic.

- If you indicate the **Use WebSphere Application Server security** option, which is the second option, or the **Do not enable security** option, which is the third option, the default values for the keystore and truststore configuration properties point to a keystore with a PKCS12 file. For more information on file-based keystores, see the "IBMJCE file-based keystores (JCEKS, JKS, and PKCS12)" section in the "Keystore configurations" topic.

## Keystore configurations

SSL configurations reference keystore configurations whose purpose is to identify the location of certificates. Certificates represent the identity of clients that use the SSL configuration. You can specify keystore configurations with other SSL configuration properties. However, it is recommended that you specify the keystore configurations in this section of the `ssl.client.props` file after the `com.ibm.ssl.keyStoreName` property identifies the start of a new keystore configuration. After you fully define the keystore configuration, the `com.ibm.ssl.keyStoreName` property can reference the keystore configuration at any other point in the file.

In the following table, the values in the "Default values for a z/OS security product" column correspond to the default values that are used when the **Use a z/OS security product** option is indicated on the Administrative Security Selection panel of the z/OS Profile Management Tool. This option is the first option on the Administrative Security Selection panel. The values in the "Default values for WebSphere Application Server security" column correspond to the default values that are used with the **Use WebSphere Application Server** option is indicated on the Administrative Security Selection panel of the z/OS Profile Management Tool. This option is second option on the Administrative Security Selection panel.

Table 161. Keystore configuration properties. This table lists the keystore configuration properties.

Property	Default values for a z/OS security product	Default values for WebSphere Application Server security	Description
<code>com.ibm.ssl.keyStoreName</code>	ClientDefaultKeyStore	ClientDefaultKeyStore	This property specifies the name of the keystore as it is referenced by the runtime. Other SSL configurations can reference this name further down in the <code>ssl.client.props</code> file to avoid duplication.
<code>com.ibm.ssl.keyStore</code>	<code>safreyring:///your_keyring</code>  This value is set on the SSL Customization panel of the z/OS Profile Management Tool.	<code>\${user.root}/etc/key.p12</code>	This property specifies the location of the keystore in the required format of the <code>com.ibm.ssl.keyStoreType</code> property. Typically, this property references a keystore file name. However, for cryptographic token types, this property references a Dynamic Link Library (DLL) file.

Table 161. Keystore configuration properties (continued). This table lists the keystore configuration properties.

Property	Default values for a z/OS security product	Default values for WebSphere Application Server security	Description
com.ibm.ssl.keyStorePassword	password	WebAS	This property is the default password, which is the cell name for the profile when it is created. The password is typically encoded using an {xor} algorithm. You can use iKeyman to change the password in the keystore, then change this reference. If you do not know the password and if the certificate is created for you, change the password in this property, then delete the keystore from the location where it resides. Restart the client to recreate the keystore by using the new password, but only if the keystore name ends with DefaultKeyStore and if the fileBased property is true. Delete both the keystore and truststore at the same time so that a proper signer exchange can occur when both are recreated together.
com.ibm.ssl.keyStoreType	JCERACFKS	PKCS12	This property is the keystore type. Use the default, PKCS12, because of its interoperability with other applications. You can specify this property as any valid keystore type that is supported by the JVM on the provider list. The type can be JCERACFKS, JCECCARACFKS, or JCECCAJS for cryptographic devices.
com.ibm.ssl.keyStoreProvider	IBMJCE	IBMJCE	The IBM Java Cryptography Extension property is the keystore provider for the keystore type. The provider is typically IBMJCE or IBMPKCS11Impl for cryptographic devices.
com.ibm.ssl.keyStoreFileBased	false	true	This property indicates to the runtime that the keystore is file-based, meaning it is located on the file system.

Table 161. Keystore configuration properties (continued). This table lists the keystore configuration properties.

Property	Default values for a z/OS security product	Default values for WebSphere Application Server security	Description
com.ibm.ssl.keyStoreReadOnly	true	false	This property indicates to the run time for WebSphere Application Server whether the keystore can be modified during the run time. For example, you cannot modify read-only keystores using the Administrative Console or through scripting. SAF Keyrings, which are used by WebSphere Application Server for z/OS, are always read-only.

## Truststore Configurations

SSL configurations reference truststore configurations, whose purpose is to contain the signer certificates for servers that are trusted by this client. You can specify these properties with other SSL configuration properties. However, it is recommended that you specify truststore configurations in this section of the `ssl.client.props` file after the `com.ibm.ssl.trustStoreName` property has identified the start of a new truststore configuration. After you fully define the truststore configuration, the `com.ibm.ssl.trustStoreName` property can reference the configuration at any other point in the file.

A truststore is a keystore that JSSE uses for trust evaluation. A truststore contains the signers that WebSphere Application Server requires before it can trust the remote connection during the handshake. If you configure the `com.ibm.ssl.trustStoreName=ClientDefaultKeyStore` property, you can reference the keystore as the truststore. Further configuration is not required for the truststore because all of the signers that are generated through signer exchanges are imported into the keystore where they are called by the runtime.

In the following table, the values in the "Default values with a z/OS security product" column correspond to the default values that are used when the **Use a z/OS security product option** is indicated on the Administrative Security Selection panel of the z/OS Profile Management Tool. This option is the first option on the Administrative Security Selection panel. The values in the "Default values with WebSphere Application Server security" column correspond to the default values that are used with the **Use WebSphere Application Server** option is indicated on the Administrative Security Selection panel of the z/OS Profile Management Tool. This option is the second option on the Administrative Security Selection panel.

Table 162. Truststore Configuration properties. This table lists the truststore configuration properties.

Property	Default values with a z/OS security product	Default values with WebSphere Application Server security	Description
com.ibm.ssl.trustStoreName	ClientDefaultTrustStore	ClientDefaultTrustStore	This property specifies the name of the truststore as it is referenced by the runtime. Other SSL configurations can reference further down in the <code>ssl.client.props</code> file to avoid duplication.

Table 162. Truststore Configuration properties (continued). This table lists the truststore configuration properties.

Property	Default values with a z/OS security product	Default values with WebSphere Application Server security	Description
com.ibm.ssl.trustStore	safeyring:///your_keyring  This value is set on the SSL Customization panel of the z/OS Profile Management Tool.	\${user.root}/etc/trust.p12	This property specifies the location of the truststore in the format that is required by the truststore type that is referenced by the com.ibm.ssl.trustStoreType property. Typically, this property references a truststore file name. However, for cryptographic token types, this property references a DLL file.
com.ibm.ssl.trustStorePassword	password	WebAS	This property specifies the default password, which is the cell name for the profile when it is created. The password is typically encoded using an {xor} algorithm. You can use iKeyman to change the password in the keystore, then change the reference in this property. If you do not know the password and if the certificate was created for you, change the password in this property, then delete the truststore from the location where it resides. Restart the client to recreate the truststore by using the new password, but only if the keystore name ends with DefaultTrustStore and the fileBased property is true. It is recommended that you delete the keystore and the truststore at the same time so that a proper signer exchange can occur when both are recreated together.
com.ibm.ssl.trustStoreType	JCERACFKS	PKCS12	This property is the truststore type. Use the default PKCS12 type because of its interoperability with other applications. You can specify this property as any valid truststore type that is supported by the JVM functionality on the provider list. The type can be JCERACFKS, JCECCARACFKS, or JCECCAJS for cryptographic devices.
com.ibm.ssl.trustStoreProvider	IBMJCE	IBMJCE	This property is the truststore provider for the truststore type. The provider is typically IBMJCE or IBMPKCS11Impl for cryptographic devices.
com.ibm.ssl.trustStoreFileBased	false	true	This property indicates to the runtime that the truststore is file-based, meaning it is located on the file system.
com.ibm.ssl.trustStoreReadOnly	true	false	This property indicates to the run time for WebSphere Application Server whether the truststore can be modified during the run time. For example, you cannot modify read-only truststores using the Administrative Console or through scripting. SAF Keyrings, which are used by WebSphere Application Server for z/OS, are always read-only.

## Creating a CA client in SSL

A plug point is provided to allow users to connect to a certificate authority (CA) to request, query, and revoke certificates. A security configuration object, called a CAClient, must be created for WebSphere to communicate with the CA. The CAClient object must contain a WSPKIClient() implementation, and it will handle the connection and communicate with the CA server. Users can also create their own implementation.

### Before you begin

The WSPKIClient interface must be implemented and the class name provided as part of the CAClient when it is created.

You use the administrative console to create a new CA client.

### Procedure

1. Click **Security > SSL certificate and key management**.
2. Click **Certificate Authority (CA) client configurations**. A panel of existing CA clients appears.
3. Click **New** to create a new CA client in the configuration.

**Note:** You can also create a CA client by using the **createCAClient** AdminTask .

4. Fill in the following information for the CA client
  - Name of the CA client.
  - The management scope (selected from the drop-down list).
  - WSPKIClient implementation class.
  - CA server host name.
  - User name.
  - Password.
  - Confirm of password.
  - Number of times to poll.
  - Polling interval (in minutes) when requesting certificates.
  - Custom properties.
5. Click **Apply** then **OK**.

### Results

The information in the object can then be used by the runtime to connect to a CA to create, revoke, or replace a certificate.

## Deleting a CA client in SSL

You can delete the CAClient object from the security configuration if a connection to a certificate authority (CA) is no longer needed.

### Before you begin

You use the administrative console to delete a CA client.

### Procedure

1. Click **Security > SSL certificate and key management**.
2. Click **Certificate Authority (CA) client configurations**. A panel displaying the existing CA clients appears.

3. Click the CA client name you want to delete.
4. Click the **Delete** button.

**Note:** You can also use the **deleteAClient** AdminTask to delete the CA client.

## Results

The CA client is deleted from the configuration.

**Note:** When you use the `deleteCAClient` AdminTask to delete the CA client, the CA client cannot be deleted if a CA certificate that exists in the keystore was obtained from the certificate authority and is still referenced by the CA client. For example, when such CA certificate still exists, the user receives the following message:

```
wsadmin>$AdminTask deleteCAClient {-caClientName myca}
WASX7015E: Exception running command:
"$AdminTask deleteCAClient {-caClientName myca}"; exception information:
com.ibm.websphere.management.cmdframework.CommandValidationException:
CWPKI0687E: The Certificate Authority (CA) client myca is still referenced by:
[Certificate alias myca21 in key store CellDefaultKeyStore].
wsadmin>
```

## Viewing or modifying a CA client in SSL

You can view or modify the `CAClient` object settings in the security configuration. The `CAClient` object contains all the information needed to connect and communicate with a certificate authority (CA). A connection to a Certificate Authority is used to request a certificate, query a certificate, or revoke a certificate.

### Before you begin

You use the administrative console to view or modify a CA client.

### Procedure

1. Click **Security > SSL certificate and key management**.
2. Click **Certificate Authority (CA) client configurations**. A panel displaying the existing CA clients appears.
3. Click the CA client name you want to examine and modify.

**Note:** You can also use the **getCAClient** AdminTask to get information about the existing CA client and the **modifyCACleint** AdminTask to make changes to the CA client.

4. Make the changes to the CA client information as required. Modify the following information as required.
  - Name of the CA client.
  - The management scope (selected from the drop-down list).
  - Implementation class.
  - CA server host name.
  - User name.
  - Password.
  - Confirm of password.
  - Number of times to poll.
  - Polling interval (in minutes) when requestin certificates.
  - Custom properties.
5. Click **Apply** then **OK**.

## Results

The information in the object can then be used by the runtime to connect to a CA to create, revoke, or replace a certificate

## What to do next

### Creating a keystore configuration for a preexisting keystore file

A Secure Sockets Layer (SSL) configuration references keystore configurations during WebSphere Application Server runtime. Whether a keystore file was created by another keystore tool or saved from a previous configuration, the file must be referenced by a keystore configuration object to be used by the server. A keystore configuration object can be created to reference a pre-existing keystore object.

## Before you begin

A keystore must already exist.

**Alternative Method:** To create a keystore by using the wsadmin tool, use the **createKeyStore** command of the AdminTask object. For more information, see the KeyStoreCommands command group for the AdminTask object article.

## About this task

Complete the following steps in the administrative console:

### Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound}**.
2. Under Related Items, click **Key stores and certificates**, then click **New**.
3. Type a name in the **Name** field. This name uniquely identifies the keystore in the configuration.
4. Type the location of the keystore file in the **Path** field. The location can be a file name or a file URL to an existing keystore file.
5. Type the Control region Started Task user ID in which the Control region System Authorization Facility (SAF) keyring is to be created in the **Control region user** field. The user ID must match the exact ID being used by the Control region.

**Note:** This option only applies when creating writable SAF keyrings on z/OS.

6. Type the servant region Started Task user ID in which the servant region System Authorization Facility (SAF) keyring is to be created in the **Servant region user** field. The user ID must match the exact ID being used by the Control region.

**Note:** This option only applies when creating writable SAF keyrings on z/OS.

7. Type the keystore password in the **Password** field.  
This password is for the keystore file that you specified in the Path field.  
To be compatible with the JCE keystore in requiring a password, the JCERACFKS password is password. Security for this keystore is not really protected using a password as other keystore types, but rather it is based on the identity of the executing thread for protection with RACF.
8. Type the keystore password again in the **Confirm Password** field to confirm the password.
9. Select a keystore type from the list. The type that you select is for the keystore file that you specified in the **Path** field.
10. Select any of the following optional selections:

- The **Read only selection** creates a keystore configuration object but does not create a keystore file. If this option is selected, the keystore file that you specified in the **Path** field must already exist.
- The **Initialize at startup selection** initializes the keystore during runtime.
- The **Enable cryptographic operations on a hardware device** specifies whether a hardware cryptographic device is used for cryptographic operations only.

**Note:** Operations that require login are not supported when using this option.

11. Click **Apply** and **Save**.

## Results

You have created a keystore configuration object for the keystore file that you specified. This keystore can now be used in an SSL configuration.

**Note:** You also can use this method to add a z/OS keyring file to the configuration. The keyring file must be read only, not file-based.

## What to do next

You can create additional keystore configurations, as needed.

## Managing keystore configurations remotely

You can manage keystores remotely in a WebSphere Application Server, Network Deployment environment on separate machines. A node server can hold the configuration for a keystore, while the actual keystore resides on another system. After you set up a remotely managed configuration, you can perform all of the certificate and keystore operations for the keystore on the remote machine from the server that contains the keystore remote configuration.

## Before you begin

Key stores can be remotely managed only in network deployed environments.

**Alternative Method:** To manage a self-signed certificates by using the wsadmin tool, use the **PersonalCertificateCommands** group commands of the AdminTask object. For more information, see the PersonalCertificateCommands command group for the AdminTask object article.

## About this task

Complete the following steps in the administrative console:

## Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration > Key stores and certificates**.
2. Click **New**.
3. Type a name in the **Name** field. This name uniquely identifies the keystore in the configuration.
4. Type the location of the keystore file in the **Path** field. The location can be a file name or a file Uniform Resource Locator (URL) to an existing keystore file.
5. Type the keystore password in the **Password** field. This password is for the keystore file that you specified in the **Path** field.
6. Type the keystore password again in the **Confirm Password** field to confirm the password.
7. Select a keystore type from the list. The type you select is for the keystore file that you specified in the **Path** field.

8. Select the **Remotely managed** check box, and then fill in one or more hosts names of the systems where the keystore file is to be located. If you provide multiple host names, separate the host names with a pipe (|).
9. Select any of the following optional selections:
  - The **Read only selection** creates a keystore configuration object but does not create a keystore file. If this option is selected, the keystore file that you specified in the **Path** field must already exist.
  - The **Initialize at startup selection** initializes the keystore during run time.
10. Select **Apply** and **Save**.

## Results

A keystore configuration object is created on the server from where the command was run. The keystore file for the configuration will be created on each system that you specified in the host list.

## What to do next

Now, you can perform all certificate management operations on the keystore from the system where the keystore configuration resides. For example, you can perform certificate management operations, such as: creating a self-signed certificate, extracting a certificate, or extracting a signer certificate.

## Keystores and certificates collection

Use this page to manage keystore types, including cryptography, Resource Access Control Facility (RACF), Certificate Management Services (CMS), Java, and all trust store types.

**gotcha:** In most cases, having unused and expired signer certificates in a trust store does not cause problems. However, if you experience a problem because the trust store includes an unused or expired signer certificate, you can safely delete the following expired signer certificates from the dummy keystores files:

- DummyClientKeyFile.jks
- DummyClientTrustFile.jks
- DummyServerKeyFile.jks
- DummyServerTrustFile.jks

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Keystores and certificates**.

*Table 163. Keystores and certificates buttons. This table describes the keystores and certificates buttons.*

Button	Resulting action
<b>New</b>	Adds a new keystore object that can be referenced by Secure Sockets Layer (SSL) configurations or KeySets. The Keystore management scope is based on the part of the topology tree from which it was created.
<b>Delete</b>	Deletes an existing keystore. The keystore should not be referenced by any other parts of the configuration before you delete it.
<b>Change password</b>	Allows for changing a keystore password.
<b>Exchange signers</b>	Refers to exchanging signers in a keystore. You can select two keystores, along with personal certificates or signer certificates from a selected keystore, then add them as a signer to another selected keystore.

**Keystore usages:** Filters the keystore usage types in the keystore collection.

The default value for the keystore usage filter depends on the navigation path that you followed to get to the Keystores and certificates panel. You can change the value of the keystore usage filter by clicking on the drop-down list and selecting a different filter value.

Navigation path	Keystore usage default value
Security > SSL certificate and key management > Keystores and certificates	SSL keystores
Security > SSL certificate and key management > Key sets > CellLTPAKeyPair > Keystores and certificates	Key set keystores
Security > SSL certificate and key management > SSL configurations > CellDefaultSSLSettings > Keystores and certificates	SSL keystores
Security > SSL certificate and key management > Manage endpoint security configurations > <i>node name</i> > Keystores and certificates	SSL keystores

**Name:**

Specifies the unique name that is used to identify the keystore. This name is typically scoped by the ManagementScope scopeName and based upon the location of the keystore. The name must be unique within the existing keystore collection.

This is a user-defined name.

**Description:**

Specifies the description of the keystore.

This is a user-defined description.

**Path:**

Specifies the location of the keystore file in the format needed by the keystore type. This file can be a card-specific configuration file for cryptographic devices or a filename or file URL for file-based keystores. It can be a safkeyring URL for RACF keyrings.

**Key store settings**

Use this page to create all keystore types, including cryptographic, Resource Access Control Facility (RACF), Certificate Management Services (CMS), Java, and all truststore types.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound}**. Under Related Items, click **Key stores and certificates**. Click either **New** or an existing keystore.

Links to Personal certificates, Signer certificates, and Personal certificate requests enable you to manage certificates in a manner similar to iKeyman capabilities. A keystore can be file-based, such as CMS or Java keystore types, or it can be remotely managed.

**Note:** Any changes made to this panel are permanent.

**Name:**

Specifies the unique name to identify the keystore. The keystore is typically scoped by the ManagementScope scopeName based on the location of the keystore. The name must be unique within the existing keystore collection.

**Data type:** Text

**Description:**

Specifies the description of the keystore.

**Data type:** Text

**Management scope:**

Specifies the scope where this Secure Sockets Layer (SSL) configuration is visible. For example, if you choose a specific node, then the configuration is only visible on that node and any servers that are part of that node.

**Data type:** Text

**Path:**

Specifies the location of the keystore file in the format needed by the keystore type. This file can be a dynamic link library (DLL) for cryptographic devices or a filename or file URL for file-based keystores. It can be a safkeyring URL for RACF keyrings.

**Data type:** Text

**Control region user:**

Specifies the Control region Started Task user ID in which the Control region System Authorization Facility (SAF) keyring is created. The user ID must match the exact ID being used by the Control region. Note: This option only applies when creating writable SAF keyrings on z/OS.

**Data type:** Text

**Servant region user:**

Specifies the Servant region Started Task user ID in which the Servant region System Authorization Facility (SAF) keyring is created. The user ID must match the exact ID being used by the Servant region. Note: This option only applies when creating writable SAF keyrings on z/OS.

**Data type:** Text

**Password [new keystore] / Password [existing keystore]:**

Specifies the password used to protect the physical keystore in the operating system. For the default keystore (names ending in DefaultKeyStore or DefaultTrustStore), the password is WebAS. This default password must be changed.

This field can be edited.

**Data type:** Text

**Note:** If you want to push the key store to all nodes, the path should be: `${CONFIG_ROOT}/cells/  
CELLNAME/yourkeystore.kdb`.

**Confirm password:**

Specifies confirmation of the password to open the keystore file or device.

**Data type:** Text

***Type:***

Specifies the implementation for keystore management. This value defines the tool that operates on this keystore type.

The list of options is returned by `java.security.Security.getAlgorithms("KeyStore")`. Some options might be filtered and some might be added based on the `java.security` configuration.

**Data type:** Text  
**Default:** PKCS12

***Read only:***

Specifies whether the keystore can be written to or not. If the keystore cannot be written to, certain operations cannot be performed, such as creating or importing certificates.

**Default:** Disabled

***Remotely managed:***

Specifies whether the key store is remotely managed, which means that a remote MBean call is needed to update the key store based on the host name specified in the host list field. Most hardware cryptographic token devices are remotely managed. If a key store is marked remotely managed, list the host name of the server where the device is installed in the Host list field.

**Default:**

***Initialize at startup:***

Specifies whether the keystore needs to be initialized before it can be used for cryptographic operations. If enabled, the keystore is initialized at server startup.

**Default:** Disabled

***Enable cryptographic operations on hardware device:***

Specifies whether a hardware cryptographic device is used for cryptographic operations only. Operations that require a login are not supported when using this option.

**Default:** Disabled

## **Key managers collection**

Use this page to define the implementation settings for key managers. A key manager is invoked during a Secure Sockets Layer (SSL) handshake to determine which certificate alias is used. The default key manager (`WSX509KeyManager`) performs alias selection. If more advanced function is desired, define a custom key manager on the **Manage endpoint security configurations** panel.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key managers**.

Table 164. Key managers buttons. This table describes the key managers buttons.

Button	Resulting action
New	Adds a new key manager that can be selected by an SSL configuration. A key manager is invoked during an SSL handshake to select a specific certificate alias to use from a key store.
Delete	Deletes an existing key manager. The key manager should not be referenced by any SSL configuration before you can delete it.

**Name:**

Specifies the name of the key manager, which you can select on the SSL configuration panel.

**Class name:**

Specifies the name of the key manager implementation class. This class implements javax.net.ssl.X509KeyManager interface and, optionally, the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface.

**Algorithm:**

Specifies the algorithm name of the key manager that is implemented by the selected provider.

**Key managers settings**

Use this page to define key managers implementation settings. A key manager gets invoked during an Secure Sockets Layer (SSL) handshake to determine the certificate alias to be used. The default key manager (WSX509KeyManager) performs alias selection. If more advanced function is desired, a custom key manager can be specified here and selected in the SSL configuration.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key managers**. On the next panel, click **New**.

**Name:**

Specifies the name of the key manager, which you can select on the SSL configuration panel.

**Data type:** Text

**Management scope:**

Specifies the scope where this Secure Sockets Layer (SSL) configuration is visible. For example, if you choose a specific node, then the configuration is only visible on that node and any servers that are part of that node.

**Data type:** List  
**Range:** Applicable scopes

**Standard:**

Specifies the key manager selection that is available from a Java provider that is installed in the java.security file. This provider might be shipped by Java Secure Sockets Extension (JSSE) or be a custom provider that implements an X509KeyManager interface.

**Default:** Enabled

**Provider:**

Specifies the provider name that has an implementation of an X509KeyManager interface. This provider is typically set to IBMJSSE2.

**Data type:** Text  
**Default:** IBMJCE

**Algorithm:**

Specifies the algorithm name of the trust manager implemented by the selected provider.

**Data type:** Text  
**Default:** IbmX509

**Custom:**

Specifies that the key manager selection is based on a custom implementation class that implements the javax.net.ssl.X509KeyManager interface and optionally the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface to obtain additional connection information not otherwise available.

**Default:** Disabled

**Class name:**

Specifies the name of the key manager implementation class.

**Data type:** Text

## Creating a self-signed certificate

You can create a self-signed certificate. WebSphere Application Server uses the certificate at runtime during the handshake protocol. Self-signed certificates are located in the default keystore.

### Before you begin

You must create a keystore before you can create a self-signed certificate.

**Alternative Method:** To create a self-signed certificate by using the wsadmin tool, use the **createSelfSignedCertificate** command of the AdminTask object. For more information, see the PersonalCertificateCommands command group for the AdminTask object article.

### About this task

Complete the following steps in the administrative console:

#### Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration > Key stores and certificates > [keystore]**.
2. From Additional Properties, click **Personal certificates**.

3. Click **Create a self-signed certificate**.
4. Type a certificate alias name. The alias identifies the certificate request in the keystore.
5. Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).
6. Type the validity period. The default validity period value is 365 days.
7. You can configure one or more of the following optional values:
  - a. Optional: Select a key size value. The default key size value is 2048 bits.
  - b. Optional: Type an organization value. This value is the O value in the certificate DN.
  - c. Optional: Type an organizational unit value. This organizational unit value is the OU value in the certificate DN.
  - d. Optional: Type a locality value. This locality value is the L value in the certificate DN.
  - e. Optional: Type a state or province value. This value is the ST value in the certificate DN.
  - f. Optional: Type a zip code value. This zip code value is the POSTALCODE value in the certificate DN.
  - g. Optional: Select a country value from the list. This country value is the C= value in the certificate request DN.
8. Click **Apply**.

## Results

You have created a self-signed certificate that resides in the keystore. The SSL configuration for the WebSphere Application Server runtime uses this certificate for SSL communication. Extract the signer of the self-signed certificate to add the signer to another keystore.

## Replacing an existing personal certificate

Occasionally, you need to replace an existing personal certificate with a new certificate. This task discusses how to replace the existing personal certificate in the keystore. It searches all keystores for a signer certificate extracted from the original personal certificate, and places the signer of the new personal certificate in its place. It also updates all of the certificate alias references in the security configuration with the new one.

## Before you begin

The current certificate and the certificate replacement must exist in the same keystore before you can replace a certificate.

**Alternative Method:** To replace a self-signed certificate by using the wsadmin tool, use the **replaceCertificate** command of the AdminTask object. For more information, see the PersonalCertificateCommands command group for the AdminTask object article

## About this task

Complete the following steps in the administrative console:

### Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration > Key stores and certificates > [keystore]**.
2. Under Additional Properties, click **Personal certificates**.
3. Select the certificate to be replaced. The alias list must include the certificate to be replaced and the certificate to replace it with.
4. Click **Replace**.
5. Select a replacement certificate alias from the list.

6. You can delete one of the following types of certificates:
  - Select **Delete old certificate** to delete the existing or expired certificate.
  - Select **Delete old signers** to delete the existing signer certificates.
7. Click **Apply**.

## Results

Your results depend on what you selected:

- If you selected **Delete old certificate**, the new certificate alias replaces all of the references to the certificate alias in the configuration.
- If you selected **Delete old signers**, the new signer certificate replaces all of the occurrences of the old signer certificates.
- If the new certificate alias replaces the existing alias, the WebSphere Application Server runtime checks to make sure that:
  - All of the SSL Configurations objects reference the certificate
  - The Dynamic SSL Configuration Selections objects and the SSL Configuration group objects reference the certificate.
- If you selected **Delete old signers**, the existing signer certificates are replaced.
- If you selected **Delete old certificate**, the existing certificate is deleted.

## Creating a new SSL certificate to replace an existing one in a node

When using the `-asExistingNode` option on the `addNode` command, you might be adding an existing node to a different machine. The default Secure Sockets Layer (SSL) certificate of the node does not contain the name of the machine the node is located on. In most scenarios, the subject DN of the default certificate does not make a difference. However, you might want to change the default certificate of the node to contain the hostname of the node.

## Before you begin

To replace the default certificate of a node, you must create a new `NodeDefaultKeyStore` for the certificate and then replace the old certificate with the new one.

The certificate created by default on the WebSphere Application Server subjectDN is of the form `cn=<hostname>, ou=<cell name>, ou=<node name>, o=ibm, c=us`. When creating a new certificate you can also customize the subjectDN.

## About this task

To create a new SSL certificate in the administrative console:

## Procedure

1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Select the `NodeDefaultKeyStore` of the node you want to change.
3. Under Additional Properties, select **Personal certificates**.
4. Under the Create pull-down, select **Chained Certificate**.
5. Enter a certificate and alias name. This can be any name you choose as long as the alias does not already exist. It is just a label to identify the certificate in the keystore.
6. Enter a common name. This is typically the hostname the node is running on.
7. Optional: Fill in any of the other Subject DN related fields. If you want the subject DN to look like the default subjectDN on WebSphere Application Server, then enter:
  - IBM in the Organization field.

- <cell name>,ou=<node name> in the Organization unit field.
  - Under the Country or region pull-down, select **US**.
8. You can use the defaults for Root certificate used to sign the certificate, Key Size, and Validity Period or supply your own values.
  9. Click **Apply**.

**Note:** You can also create a new chained certificate using the createChainedCertificate command. Read PersonalCertificateCommands command group for the AdminTask object for more information.

You must now replace the old certificate with the one you just created. The replace certificate option not only replaces the old default certificate with a new one but also replaces any occurrences of the signer of the old certificate with the signer of the new certificate. The configuration is also checked for references to the alias name of the old certificate and replaces it with the alias name of the new certificate. To replace the old certificate with the new one, complete the remaining steps.

10. Click **Security > SSL certificate and key management > Key stores and certificates**.
11. Select the NodeDefaultKeyStore of the node you want to change.
12. Under Additional Properties, select **Personal certificates**.
13. Select the default certificate of the node, usually called default.
14. Click **Replace**.
15. Select the certificate alias name for the certificate you just created from the **Replace with** pull-down.
16. Click **Delete old Certificate after replacement**.
17. Click **Apply**.

**Note:** You can also create a new chained certificate using the replaceCertificate command. Read PersonalCertificateCommands command group for the AdminTask object for more information.

## What to do next

You can also replace default certificates in an entire cell. Read Creating new SSL certificates to replace existing ones in a cell for more information.

## Creating new SSL certificates to replace existing ones in a cell

To replace default Secure Socket Layer (SSL) certificates in an entire cell, you must create a new self-signed root certificate in the root keystore, DmgrDefaultRootStore, and replace the old root certificate with the new one.

## About this task

For the default certificate of the cell in CellDefaultKeyStore and the default certificate of each node in NodeDefaultKeyStore, create a new chained certificate and replace the old default certificate with the new certificate.

The root certificate is created by default on WebSphere Application Server, and has a subjectDN in the form cn=<hostname>, ou=Root Certificate, ou=<cell name>, ou=<node name>, o=ibm, c=us. When you create a new root certificate you can also customize the subject DN.

To create a new SSL root certificate in the administrative console:

## Procedure

1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Under the Keystore usages pull-down, select **Root certificate keystore**.
3. Select the DmgrDefaultRootStore in the keystore collection.

4. Under Additional Properties, select **Personal certificates**.
5. Under the Create pull-down, select **Self-signed Certificate**.
6. Enter a certificate and alias name. This can be any name you choose as long as the alias does not already exist. It is just a label to identify the certificate in the keystore.
7. Enter a common name. This is typically the hostname the node is running on.
8. Optional: Fill in any of the other Subject DN related fields. If you want the subject DN to look like the default subjectDN on WebSphere Application Server, then enter:
  - IBM in the Organization field.
  - <cell name>,ou=<node name> in the Organization unit field.
  - Under the Country or region pull-down, select **US**.
9. You can use the defaults for Root certificate used to sign the certificate, Key Size, and Validity Period or supply your own values.
10. Click **Apply**.

**Note:** You can also create a self-signed certificate using the `createSelfSignedCertificate` command. Read `PersonalCertificateCommands` command group for the `AdminTask` object for more information.

You must now replace the old root certificate with the one you just created. The `replace certificate` option not only replaces the old default certificate with a new one but also replaces any occurrences of the signer of the old certificate with the signer of the new certificate. The configuration is also checked for references to the alias name of the old certificate and replaces it with the alias name of the new certificate. To replace the old certificate with the new one, complete the remaining steps.

11. Click **Security > SSL certificate and key management > Key stores and certificates**.
12. Select the `CellDefaultKeyStore` of the node you want to change.
13. Under Additional Properties, select **Personal certificates**.
14. Select the default certificate of the node, usually called `default`.
15. Click **Replace**.
16. Select the certificate alias name for the new certificate you just created from the **Replace with** pull-down.
17. Click **Delete old Certificate after replacement**.
18. Click **Apply**.

## What to do next

You can also replace default certificates in a node. Read [Creating a new SSL certificate to replace an existing one in a node](#) for more information

## Creating a certificate authority request

To ensure Secure Sockets Layer (SSL) communication, servers require a personal certificate that is either self-signed, chained or signed by an external certificate authority (CA). You must first create a personal certificate request to obtain a certificate that is signed by a CA.

### Before you begin

The keystore that contains a personal certificate request must already exist.

**Alternative Method:** To create a certificate request by using the `wsadmin` tool, use the `createCertificateRequest` command of the `AdminTask` object. For more information, see the `CertificateRequestCommands` command group of the `AdminTask` object article.

## About this task

Complete the following steps in the administrative console:

### Procedure

1. Click **Security > SSL certificate and key management > Key stores and certificates > keystore**.
2. Click **Personal certificate requests > New**.
3. Type the full path of the certificate request file. The certificate request is created in this location.
4. Type an alias name in the **Key label** field. The alias identifies the certificate request in the keystore.
5. Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).
6. You can configure one or more of the following optional values:
  - a. Optional: Select a key size value. The valid key size values are 512, 1024, 2048, 4096, and 8192. The default key size value is 2048 bits.
  - b. Optional: Type an organization value. This value is the O value in the certificate DN.
  - c. Optional: Type an organizational unit value. This organizational unit value is the OU value in the certificate DN.
  - d. Optional: Type a locality value. This locality value is the L value in the certificate DN.
  - e. Optional: Type a state or providence value. This value is the ST value in the certificate DN.
  - f. Optional: Type a zip code value. The zip code value is the POSTALCODE value in the certificate DN.
  - g. Optional: Select a country value from the list. This country value is the C= value in the certificate request DN.
7. Click **Apply**.

### Results

The certificate request is created in the specified file location in the keystore. The request functions as a temporary placeholder for the signed certificate until you manually receive the certificate in the keystore.

**Note:** Key store tools (such as iKeyman and keyTool) cannot receive signed certificates that are generated by certificate requests from WebSphere Application Server. Similarly, WebSphere Application Server cannot accept certificates that are generated by certificate requests from other keystore utilities.

### What to do next

Now you can receive the CA-signed certificate into the keystore to complete the process of generating a signed certificate for your server.

### Certificate request settings

Use this page to verify the properties of a personal certificate request.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties, click **Personal certificate requests > certificate request**.

#### ***File for certificate request:***

Specifies the fully qualified name of the file that contains the certificate request that can be sent to a certificate authority (CA) server.

**Key label:**

Specifies the certificate alias name for the signer in the key store.

**Key size:**

Specifies the size of the keys that are generated.

**Requested by:**

Specifies the Subject distinguished name (DN) that represents the identity of the certificate request.

**Fingerprint (SHA Digest):**

Specifies the SHA hash of the personal certificate, which can be used to verify that the certificate has not been altered when it is used in a remote connection.

**Signature algorithm:**

Specifies the algorithm used to sign the certificate.

**Personal certificates collection**

Use this page to manage personal certificates.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties, click **Personal certificates**.

The **Personal certificates** page lists all personal certificates in the selected key store. You can do most certificate management operations in this panel, including creating a new self-signed certificate, deleting a certificate, receiving one generated from a CA, replacing a certificate (simultaneous delete and create, replacing references across all key stores), extracting the signer, and importing or exporting a personal certificate.

Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA).

The Key store collection must contain at least two key store files. You must select one file in order to replace, extract, or export a key store,

Table 165. Personal certificates buttons. This table lists the personal certificates buttons.

Button	Resulting action
<b>Create (drop-down list)</b>	<p>Enables the application server to create the following certificates:</p> <ul style="list-style-type: none"> <li>• Self-signed Certificate The create a self-signed certificate function is not available using the administrative console for certificates that are stored in Resource Access Control Facility (RACF), unless the server is configured for writable keyring support. See “Creating writable SAF keyrings” on page 2004 and “Using writable SAF keyrings” on page 2003 for more information on using writable keyring support. Optionally, this function is supported using the RACF administration interfaces.</li> <li>• CA-signed Certificate The create CA signed certificate function is not available using the administrative console for certificates that are stored in RACF, unless the server is configured for writable keyring support. See “Creating writable SAF keyrings” on page 2004 and “Using writable SAF keyrings” on page 2003 for more information on using writable keyring support. Optionally, this function is supported using the RACF administration interfaces.</li> <li>• Chained Certificate The create a chained certificate function is not available using the administrative console for certificates that are stored in RACF, unless the server is configured for writable keyring support. See “Creating writable SAF keyrings” on page 2004 and “Using writable SAF keyrings” on page 2003 for more information on using writable keyring support. Optionally, this function is supported using the RACF administration interfaces.</li> </ul>
<b>Delete</b>	<p>The delete function is not available using the administrative console for certificates that are stored in RACF unless the server is configured for writable keyring support. See “Creating writable SAF keyrings” on page 2004 and “Using writable SAF keyrings” on page 2003 for more information on using writable keyring support. Optionally, this function is supported using the RACF administration interfaces.</p>
<b>Receive a certificate from a certificate authority</b>	<p>Enables the application server to receive a certificate authority (CA)-generated certificate from a file to complete a certificate request.</p> <p>The receive a certificate from a certificate authority function is not available using the administrative console for certificates that are stored in RACF unless the server is configured for writable keyring support. See “Creating writable SAF keyrings” on page 2004 and “Using writable SAF keyrings” on page 2003 for more information on using writable keyring support. Optionally, this function is supported using the RACF administration interfaces.</p>
<b>Replace</b>	<p>Replaces a personal certificate with another personal certificate. All key stores in the configuration looking for signer certificate form the original personal certificate and replaces them with the new personal certificates signer. Any place in the security configuration where the certificate alias is referenced will be replaced with the new certificate alias.</p> <p>The replace function is not available using the administrative console for certificates that are stored in RACF unless the server is configured for writable keyring support. See “Creating writable SAF keyrings” on page 2004 and “Using writable SAF keyrings” on page 2003 for more information on using writable keyring support. Optionally, this function is supported using the RACF administration interfaces.</p>
<b>Extract</b>	<p>Extracts the signer part of personal certificate from the key store and stores it to a file. The file can then be used to add the signer to another key store.</p>
<b>Import</b>	<p>Imports a certificate, including the private key, from a key store file or managed key store.</p> <p>The import function is not available using the administrative console for certificates that are stored in RACF unless the server is configured for writable keyring support. See “Creating writable SAF keyrings” on page 2004 and “Using writable SAF keyrings” on page 2003 for more information on using writable keyring support. Optionally, this function is supported using the RACF administration interfaces.</p>
<b>Export</b>	<p>Exports a certificate, including the private key, to a specified key store file or manage key store.</p> <p>The export function is not available using the administrative console for certificates that are stored in RACF unless the server is configured for writable keyring support. See “Creating writable SAF keyrings” on page 2004 and “Using writable SAF keyrings” on page 2003 for more information on using writable keyring support. Optionally, this function is supported using the RACF administration interfaces.</p>
<b>Revoke</b>	<p>Revokes a CA-signed certificate.</p>
<b>Renew</b>	<p>Renews a self signed or chained certificate.</p>

**Alias:**

Specifies the alias by which the personal certificate is referenced in the key store.

When you select an alias, the View Certificate panel opens.

**Issued by:**

Specifies the distinguished name of the entity by which the certificate was issued. This name is the same as the issued-to distinguished name when the personal certificate is self-signed.

**Issued to:**

Specifies the distinguished name of the entity to which the certificate was issued.

**Serial number:**

Specifies the certificate serial number that is generated by the issuer of the certificate.

**Expiration:**

Specifies the expiration date of the signer certificate for validation purposes.

### Self-signed certificates settings

Use this page to create self-signed certificates.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > keystore**. Under Additional Properties, click **Personal certificates > Create (drop-down list) > Self-signed certificate**.

This same help file is available when you create a new certificate or view an existing certificate. The fields in this help file are described according to how they appear and are used on the administrative console.

**Alias:**

Specifies the alias for the personal certificate in the keystore.

You enter the alias name for the personal certificate in the keystore when you are creating a certificate. *The alias name is read-only when you view an existing certificate.*

**Data type:** Text

**Version:**

Specifies the version of the personal certificate. Valid versions include X509 V3, X509 V2, or X509 V1. It is recommended to use X509 V3 certificates.

*This field is read-only when you create or view a certificate.*

**Data type:** Text  
**Default:** X509 V3  
**Range:**

**Key size:**

Specifies the key size of the private key that is used by the personal certificate.

When you are creating a certificate you can select the key size from the drop-down list. *This field is read-only when you view a certificate.*

**Data type:** Integer  
**Default:** 1024  
**Other valid key sizes:** 512, 2048, 4096

***Common name:***

Specifies the common name portion of the distinguished name (DN). It is recommended that this name be the host name of the machine on which the certificate resides. In some cases, the common name is used to login during Secure Socket Layer (SSL) certificate authentication; therefore, in some cases, this name might be used as a user ID for a local operating system registry.

When you create a new certificate you can enter the common name in this field. *This field does not display when you view an existing certificate.*

**Data type:** Text

***Serial number:***

Identifies the certificate serial number that is generated by the issuer of the certificate. When creating a certificate this field does not appear.

*This field is read-only when you view an existing certificate.*

***Validity period:***

Specifies the length in days during which the certificate is valid. The default is 365 days. You can enter any number of days you wish.

*This field is read-only when you view an existing certificate.* This field displays a validity period as a range of days between two dates. For example, Valid from March 16, 2008 to March 16, 2009.

**Data type:** Text

***Organization:***

You enter the organization portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

**Data type:** Text

***Organization unit:***

Specifies the organization unit portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

**Data type:** Text

***Locality:***

Specifies the locality portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

**Data type:** Text

***State/Province:***

Specifies the state portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

**Data type:** Text

***Zip code:***

Specifies the zip code portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

**Data type:** Integer

***Country or region:***

Select the country portion of the distinguished name from the drop-down list. This field is optional.

This field displays only when you create a new certificate.

**Data type:** Text  
**Default:** (none)

Refer to <http://www.iso.org/iso/en/prods-services/iso3166ma/02iso-3166-code-lists/list-en1.html> for a list of ISO 3166 country codes.

***Validity period:***

Identifies the length, in days, when the certificate is valid. The default is 365 days.

*This field is read-only when you view an existing certificate and shows the start and end dates.*

***Issued to:***

Identifies the distinguished name of the entity to which the certificate was issued.

*This field is read-only when you view an existing certificate.*

***Issued by:***

Identifies the distinguished name of the entity that issued the certificate. When the personal certificate is self-signed, this name is identical to the **Issued to** distinguished name.

*This field is read-only when you view an existing certificate.*

***Fingerprint (SHA Digest):***

Identifies the Secure Hash Algorithm (SHA hash) of the certificate, which can be used to verify the certificate's hash at another location, such as the client side of a connection.

*This field is read-only when you view an existing certificate.*

**Signature algorithm:**

Identifies the algorithm used to sign the certificate.

*This field is read-only when you view an existing certificate.*

## Personal certificate requests collection

Use this page to manage personal certificate requests. Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties, click **Personal certificate requests**.

A private key is generated during the certificate request generation, but only the certificate is sent to the CA. The CA generates a new certificate, signed by the CA. This can be added in the Personal Certificates panel.

*Table 166. Personal certificate requests buttons. This table lists the personal certificate requests buttons.*

Button	Resulting action
New	Creates a personal certificate request that can be given to a certificate authority to complete.
Delete	Deletes a personal certificate request.
Extract	Extracts a personal certificate request. Only one certificate request can be selected at a time.
Query	Queries a personal certificate request. Only one certificate request can be selected at a time.

**Note:** Any changes made to this panel are permanent.

**Key label:**

Specifies the alias that represents the personal certificate request in the key store.

**Requested by:**

Specifies the Subject distinguished name (DN) that represents the identity of the certificate request.

## Personal certificate requests settings

Use this page to create a new certificate request that can be extracted and sent to a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties, click **Personal certificates requests**. Then click the **New** button.

Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA). The private key is generated during the certificate request generation, but only the certificate is sent to the CA. The CA generates a new certificate, signed by the CA.

**Note:** Any changes made to this panel are permanent.

***File for certificate request:***

Specifies the fully qualified file name from which the certificate request is exported. This portion of the certificate request can be given to the certificate authority to generate the real certificate. After the real certificate is generated, you can perform a "Receive a certificate from a certificate authority" from the personal certificate collection view.

**Data type:** String

***Key label:***

Specifies the alias that represents the personal certificate request in the key store.

**Data type:** String

***Key size:***

Specifies the size of the keys that are generated.

**Data type:** Integer  
**Default:** 2048

***Common name:***

Specifies the name of the entity that the certificate represents. This common name can represent a person, company, or machine. For websites, the common name is frequently the DNS host name where the server resides.

**Data type:** String

***Organization:***

Specifies the organization portion of the distinguished name.

**Data type:** String

***Organizational unit:***

Specifies the organization unit portion of the distinguished name. This field is optional.

**Data type:** String

***Locality:***

Specifies the locality portion of the distinguished name. This field is optional.

**Data type:** String

***State or province:***

Specifies the state portion of the distinguished name. This field is optional.

**Data type:** String

***Zip code:***

Specifies the zip code portion of the distinguished name. This field is optional.

**Data type:** Integer

***Country or region:***

Specifies the country portion of the distinguished name.

**Data type:** String

Refer to <http://www.iso.org/iso/en/prods-services/iso3166ma/02iso-3166-code-lists/list-en1.html> for a list of ISO 3166 country codes.

### **Extract certificate request**

Use this page to extract a certificate request to a file so it can be sent to a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties, click **Personal certificate requests > Extract**.

***Key label:***

Specifies the alias that represents the personal certificate request in the key store.

***File for certificate request:***

Specifies the filename where the extracted certificate request is placed.

**Data type:** Text

### **Receiving a certificate issued by a certificate authority**

When a certificate authority (CA) receives a certificate request, it issues a new certificate that functions as a temporary placeholder for a CA-issued certificate. A keystore receives the certificate from the CA and generates a CA-signed personal certificate that WebSphere Application Server can use for Secure Sockets Layer (SSL) security.

### **Before you begin**

The keystore must contain the certificate request that was created and sent to the CA. Also, the keystore must be able to access the certificate that is returned by the CA.

**Note:** To receive a certificate by using the wsadmin tool, use the **receiveCertificate** command of the AdminTask object. For more information, see the PersonalCertificateCommands command group for the AdminTask object article.

## About this task

WebSphere Application Server can receive only those certificates that are generated by a WebSphere Application Server certificate request. It cannot receive certificates that are created with certificate requests from other keystore tools, such as **iKeyman** and **keyTool**.

Complete the following steps in the administrative console:

### Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration > Key stores and certificates > [keystore]**.
2. Under Additional Properties, click **Personal certificates**.
3. Select a personal certificate.
4. Click **Receive a certificate from a certificate authority**.
5. Type the full path and name of the certificate file.
6. Select a data type from the list.
7. Click **Apply** and **Save**.

### Results

The keystore contains a new personal certificate that is issued by a CA. The original certificate request is changed to a personal certificate.

### What to do next

The SSL configuration is ready to use the new CA-signed personal certificate.

#### ***Export certificate to a keystore file or a managed keystore:***

Use this page to specify a personal certificate to export to a keystore file or a managed keystore.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > keystore**. Under Additional Properties, click **Personal certificates**. Select a personal certificate using the check box. Then click the **Export** button.

*Certificate alias to export:*

Displays the name of the certificate that you selected to export on the previous panel.

**Data type:** Text

*Keystore Password:*

Type in the password of the keystore to use for the export.

**Data type:** Text

*Alias:*

Specifies the alias that the personal certificate is referenced by in the destination keystore.

**Data type:** Text

*Managed key store:*

Select this option with the radio button. Then select a keystore from the pull-down list, which is managed by the security configuration, to export the certificate to.

**Data type:** Drop-down list

*Key file name:*

Select this option with the radio button. Then type the keystore file name into which the exported certificate is added. If the keystore file name already exists, the exported certificate is added. If the keystore file name does not already exist, a keystore file name is created, and the exported certificate is added.

**Data type:** Text

*Type:*

Specifies the type of keystore file. The valid types are listed in the drop-down list.

**Data type:** Text  
**Default:** PKCS12

*Key file password:*

Specifies the password that is used to access the keystore file.

**Data type:** Text

***Import certificate from a key file or managed keystore:***

Use this page to specify a personal certificate to import from a keystore or key file.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > keystore**. Under Additional Properties, click **Personal certificates**. Select a personal certificate using the check box. Then click the **Import** button.

*Managed key store:*

Select this option with the radio button. This selection indicates that the keystore that contains the certificate to import is a managed keystore.

**Data type:** radio button

*Key store:*

Select an alias of the keystore from the pull-down list of managed keystores that are managed by the security configuration. The alias you select identifies the keystore that contains the certificate to import.

**Data type:** drop-down list

*Key store password:*

Specifies the password for the keystore to use for import.

**Data type:** Text

*Key store file:*

Select this option with the radio button. This selection indicates a keystore file that contains the certificate to import.

**Data type:** radio button

*Key file name:*

Specifies the fully qualified path to keystore file that contains the certificate to import.

**Data type:** Text

*Type:*

Specify the type of keystore file. Select a valid type from the drop-down list.

**Data type:** Text

*Key file password:*

Type the password that is used to access the keystore file.

**Data type:** Text

*Certificate alias to import:*

Specifies the certificate alias identified as the **Key file name** that you want to import into the current keystore.

**Data type:** Text  
**Default:** (none)

*Imported certificate alias:*

Specifies the new alias that you want the certificate to be named in the current keystore.

**Data type:** Text

**Receive certificate from CA:**

Use this page to import your personal certificate from the certificate authority (CA). The imported certificate replaces the temporary certificate associated with the public/private keys in the certificate request that is stored in the key store.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items click **Key stores and certificates > key store**. Under Additional Properties, click **Personal certificates > Receive certificate from certificate authority**.

*Certificate file name:*

Specifies the filename that contains the certificate generated by the certificate authority (CA).

**Data type:** Text

*Data type:*

Specifies the format of the file that is either Base64 encoded ASCII data or Binary DER data.

**Data type:** Text  
**Default:** Base64-encoded ASCII data

## Replace a certificate

Use this page to specify two certificates: the first selected certificate is replaced by the second selected certificate. The replace function replaces all the old signer certificates in key stores that are managed throughout the cell with the new signer from the new certificate. The same level of trust that was established with the old certificate is maintained. All places the certificate's alias is referenced in the security configuration will be replaced with the certificate's alias. The alias could be referenced on a security object like the SSL configuration, the dynamic outbound endpoint SSL configuration and key set groups.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties click **Personal certificates**. Select a personal certificate, then click the **Replace** button.

*Old certificate:*

Specifies the certificate that you want to replace.

**Data type:** Text

*Replace with:*

Specifies the certificate that you want to replace the old certificate.

**Data type:** Text  
**Default:** (none)

*Delete old certificate after replacement:*

Specifies that you want to delete the old certificate and all associated signer certificates after the new certificate replaces it. If you do not replace the old personal certificate, it might be assigned a new alias name.

**Default:** Disabled

### **Delete old signers:**

Specifies that you want to delete the old signer certificates that are associated with the old certificate after the new signer certificates replace them. If you do not delete the old signer certificates, they might be assigned new alias names.

**Default:** Disabled

## **Using writable SAF keyrings**

WebSphere Application Server provides the function to allow a WebSphere Application Server administrator to perform certificate management operations on System Authorization Facility (SAF) keyrings by utilizing the (Open Cryptographic Services Facility) OCSF Data library functions for SAF keyrings.

### **Before you begin**

You must enable support for writable keyrings using the profile management tool prior to generating the application server profiles. Writable keyring support is only configurable when running z/OS Release 1.9 or at z/OS Release 1.8 with APAR OA22287 - resource access control facility (RACF) (or the APAR for your equivalent security product) and APAR OA22295 – SAF.

### **About this task**

#### **Defining RACF Authority for Clients and Servers**

By default, if writable keyring support is enabled during profile management, the default RACF configuration scripts generate the necessary commands to grant write authority. As an option, when you migrate from an existing installation, you can configure RACF using the procedure below.

**Note:** The control region performs all server certificate management write operations, and the RACF administrator must explicitly grant authority to the RACF ID of the control region to update the control region and servant region keyrings.

The procedure below uses ring-specific profile checking to grant authority. Ring-specific profile checking applies only to a specific keyring and does not allow global access to any keyring.

With ring-specific profile checking, a resource with the format, <ringOwner>.<ringName>.LST is used to provide access control to a specific keyring on the *R\_datalib* READ functions.

A resource with the format <ringOwner>.<ringName>.UPD is used to provide access control to a specific keyring on the UPDATE functions.

The procedure to define RACF authority for clients and servers is as follows:

### **Procedure**

1. Use ring-specific profile checking for the RDATALIB class. You use the following commands:  
SETR CLASSACT(RDATALIB)  
SETR RACLIST(RDATALIB) GENERIC(RDATALIB)
2. Define a ring-specific LST profile for the control region RACF ID and the servant region RACF ID.  
RDEFINE RDATALIB CRRACFID.\*\*.LST UACC(NONE)  
RDEFINE RDATALIB SRRACFID.\*\*.LST UACC(NONE)

3. Give CONTROL access for the **CRRACFID.\*\*.LST** and **SRRACFID.\*\*.LST** profiles in the RACF RDATALIB class to the control region RACF user ID. For example, if the control region RACF user ID is *CRRACFID* and your servant region RACF user ID is *SRRACFID*, issue the following commands:

```
PERMIT CRRACFID.**.LST CLASS(RDATALIB) ID(CRRACFID) ACC(CONTROL)
PERMIT SRRACFID.**.LST CLASS(RDATALIB) ID(CRRACFID) ACC(CONTROL)
PERMIT SRRACFID.**.LST CLASS(RDATALIB) ID(SRRACFID) ACC(CONTROL)
```

Also, give READ access to all IDs in the WASCFFGGROUP for the CRRACFID.\*\*.LST profile.

```
PERMIT CRRACFID.**.LST CLASS(RDATALIB) ID(WASCFFGGROUP) ACC(READ)
```

4. Define a ring-specific UPD profile for the control region RACF ID and the servant region RACF ID.

```
RDEFINE RDATALIB CRRACFID.**.UPD UACC(NONE)
RDEFINE RDATALIB SRRACFID.**.UPD UACC(NONE)
```

5. Give CONTROL access for the **CRRACFID.\*\*.UPD** and **SRRACFID.\*\*.UPD** profiles in the RACF RDATALIB class to the control region RACF user ID. For example, if your control region RACF user ID is *CRRACFID*, issue the following command:

```
PERMIT CRRACFID.**.UPD CLASS(RDATALIB) ID(CRRACFID) ACC(CONTROL)
PERMIT SRRACFID.**.UPD CLASS(RDATALIB) ID(CRRACFID) ACC(CONTROL)
```

6. Grant write access to the WebSphere Application Server administrator ID to permit write operations on WebSphere Application Server client keyrings.

```
RDEFINE RDATALIB ADMINUSERID.**.LST UACC(NONE)
PERMIT ADMINRACFID.**.LST CLASS(RDATALIB) ID(WASCFFGGROUP) ACC(READ)
PERMIT ADMINRACFID.**.LST CLASS(RDATALIB) ID(ADMINRACFID) ACC(CONTROL)
RDEFINE RDATALIB ADMINRACFID.**.UPD UACC(NONE)
PERMIT ADMINUSERID.**.LST CLASS(RDATALIB) ID(ADMINRACFID) ACC(CONTROL)
```

7. Refresh the RDATALIB class.

```
SETR RACLIST(RDATALIB) REFRESH
```

**Note:** If RACF authority is not granted you receive the following message when attempting certificate write operations on a keyring:

```
Error Message: An error occurred creating the key store: R_datalib (IRRSDL00) error: One or more
updates could not be completed. Not RACF authorized to use the requested service.
Function code: (7) Return Codes: (8, 8, 8)
```

**Note:** If you attempt to create a new keyring or perform a specific certificate write operation and do not have native writable support, you receive the following message:

```
R_datalib (IRRSDL00) error: One or more updates could not be completed. Requested Function_code not defined.
Function code: (7) Return Codes: (8, 8, 20)
```

**Remember:** You must be running at z/OS release 1.9 or 1.8 with APAR's OA22287 and OA22295 to use writable keyring support.

You can link to the following documents in the z/OS internet library <http://www-03.ibm.com/servers/eserver/zseries/zos/bkserv/> for more information:

- [Security Server RACF Callable Services \(SA22-7691\)](#) for a complete guide to RACF Callable Services and the R\_Datalib service
- [z/OS Security Server RACF Security Administrator's Guide \(SA22-7683\)](#) for a complete guide to RACF commands

## Creating writable SAF keyrings

WebSphere provides the function to allow a WebSphere administrator to perform certificate management operations on System Authorization Facility (SAF) keyrings by utilizing the (Open Cryptographic Services Facility) OCSF Data library functions for SAF keyrings. This task creates new keystore configurations and their associated keyrings.

## Before you begin

The JCERACFKS keystore is used with the IBMJCE provider or the IBMJCECCA provider. You can use the JCERACFKS keystore for certificates and keys that are managed and stored by resource access control facility (RACF). The uniform resource identifier (URI) path reference for the JCERACFKS keystore is in the form of `safkeyring:///your_keyring_name`.

**Attention:** The JCERACFKS keystore type, is only available on the z/OS platform.

**Important:** You must enable support for writable keyrings using the profile management tool prior to generating the application server profiles. Writable keyring support is only configurable when running at z/OS Release 1.9 or at z/OS Release 1.8 with APAR OA22287 - RACF (or the APAR for your equivalent security product) and APAR OA22295 – SAF.

## About this task

Complete the following steps in the administrative console:

### Procedure

1. Click **Security > SSL certificate and key management** . Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates**. Then click the **New** button.
2. Type a name in the **Name** field. This name uniquely identifies the keystore in the configuration.
3. Type the location of the keystore file in the **Path** field. The URI must contain safkeyring, for example, `safkeyring:///your_keyring_name`.
4. Type the keystore password in the **Password** field as "password". To be compatible with the JCE keystore in requiring a password, the JCERACFKS password is "password". Security for this keystore is not really protected using a password as other keystore types, but rather it is based on the identity of the executing thread for protection with RACF. This password is for the keystore file that you specified in the **Path** field.
5. Select JCERACFKS for the Type and complete the rest of the fields as appropriate.
6. Deselect the **Read only** check box.
7. For the control region user field, specify the control region started task user ID (RACF ID) under which the control region SAF keyring is created. The user ID must match the exact RACF ID being used by the control region.

**Note:** This option only applies when creating writable SAF keyrings on z/OS.

8. For the servant region user field, specify the servant region started task user ID (RACF ID) in which the servant region SAF keyring is created. The user ID must match the exact RACF ID being used by the servant region.

**Note:** This option only applies when creating writable SAF keyrings on z/OS.

9. Click **OK** then click **Save** to apply these changes to the master configuration.

## Results

A keystore is now available to configure SSL connections. Two additional keystore objects are created that may be accessed via the administrative console for performing certificate write operations on the appropriate keyring. The keystore objects are named **your\_keystore\_name -CR** and **your\_keystore\_name -SR**, where *your\_store\_name* is the name of the keystore specified on the create command. **your\_keystore\_name -CR** corresponds to the keyring owned by the RACF ID of the control region process and **your\_keystore\_name -SR** corresponds to the keystore owned by the RACF ID of the servant region process. These keystores are created in the same scope as *your\_keystore\_name* and can be accessed from the administrative console from the *your\_keystore\_name* collection panel.

## What to do next

You can continue securing communication between the client and server using this keystore file when setting up an SSL configuration. Additionally, you are now able to perform certificate management operations from the administrative console or command task framework on the writable keystore configurations generated by this command.

## RACF keyring considerations

### Certificate Deletion

When a certificate is deleted from a RACF keyring, the certificate is not deleted from RACF. It is only disconnected from the keyring. The certificate can be reconnected through RACF if it is accidentally removed from the keyring. If you want the certificate completely deleted from RACF, it must be removed by the RACF administrator.

### Import and Export of Certificates

During the import and export of certificates to and from managed SAF keystores, if the certificate already exists in RACF under a different label, then it will be connected to the keyring with the existing label regardless of the label you assign the certificate on the import or export command.

### Renewing Certificates

Certificates are not physically deleted from RACF. The existing certificate label still exists in RACF and renewing certificates will increment the alias (label) of the certificate by appending `_1`, `_2`, etc., to the existing certificate label.

## Configuring the root certificate keyring

WebSphere Application Server provides the function to allow a WebSphere Application Server administrator to perform certificate management operations on System Authorization Facility (SAF) keyrings by utilizing the (Open Cryptographic Services Facility) OCSF Data library functions for SAF keyrings. This task configures the root certificate keyring.

## Before you begin

You must enable support for writable keyrings using the profile management tool prior to generating the application server profiles. Writable keyring support is only configurable when running z/OS Release 1.9 or at z/OS Release 1.8 with APAR OA22287 - resource access control facility (RACF) (or the APAR for your equivalent security product) and APAR OA22295 – SAF.

## About this task

The root certificate authority (CA) certificate is used to sign other certificates for WebSphere Application Server. By default, during profile management, the default root keyring (**NodeDefaultRootStore** or **DmgrDefaultRootStore** for a deployment manager), and the root CA certificate, are automatically configured. Alternatively, if migrating from a previous WebSphere Application Server installation, you can set up the root keyring for a keystore object using the following steps.

## Procedure

1. Create a keyring for the control region RACF ID for your sever. For example, if your server is running with a RACF user ID called CRRACFID, issue the following command:

```
RACDCERT ADDRING(keyring_name.Root) ID(CRRACFID)
```

*CRRACFID* is the RACF ID for the application server control region. *keyring\_name* is the name of the z/OS keyring that is used by the servers in the cell.

2. To create chained certificates with the root CA certificate, the keyring created in the step (1) must include the public/private key CA certificate generated for your WebSphere Application Server installation. To connect the certificate, you must complete the following step:

Determine the label name of the root CA certificate for your installation and issue the following command:

```
RACDCERT ID(CRRACFID) CONNECT (RING(keyring_name.Root) LABEL('rootcalabel') CERTAUTH USAGE(PERSONAL))
```

*CRRACFID* is the RACF ID for the application server control region. *keyring\_name* is the name of the z/OS keyring that is used by the servers in the cell. *rootcalabel* is the root CA certificate

3. Modify **NodeDefaultRootStore** (**DmgrDefaultRootStore** for deployment manager) to point to the keyring created in step (1).

- a. Click **Security > SSL certificate and key management > Key stores and certificates**
- b. Select **Root Certificates Keystore** under Keystore usages
- c. Select **NodeDefaultRootStore** ( or **DmgrDefaultRootStore** for deployment manager).
- d. Under General Properties

- 1) Modify the Path

```
safkeyring://CRRACFID/keyring_name.Root
```

*CRRACFID* is the RACF ID for the application server control region. *keyring\_name* is the name of the z/OS keyring that is used by the servers in the cell.

- 2) Change the type to JCERACFKS

- 3) Enter the password, *password*.

- e. Click **Apply**.

## Results

After completing these steps, a new z/OS keyring is created that contains the root CA certificate attached with the personal usage.

## What to do next

Verify that the keystore was modified successfully.

1. Under Additional Properties, on the keystore collection panel, click **Personal Certificates**.
2. Verify that the certificate appears in the list.

## Known error conditions

- When attempting to create a new keyring the follow error message can occur:

```
R_datailib (IRRSIDL00) error: One or more updates could not be completed.
Requested Function_code not defined.
Function code: (7) Return Codes: (8, 8, 20)
```

This message indicates that you attempted to create a new keyring and did not have native writable support installed. You must be running at z/OS release 1.9 or 1.8 with APAR's OA22287 and OA22295.

- The following message can occur when attempting to perform write operations on a SAF keyring, operations such as, creating or deleting a certificate:

```
Error Message: An error occurred creating the key store: R_datailib (IRRSIDL00) error: One or more updates could not be completed.
Not RACF authorized to use the requested service. Function code: (7) Return Codes: (8, 8, 8)
```

This message is received if you have not defined the correct RACF authority. See the document [Defining RACF authority for Clients and Servers](http://www-03.ibm.com/servers/eserver/zseries/zos/bkserv/) in the z/OS internet library <http://www-03.ibm.com/servers/eserver/zseries/zos/bkserv/>.

- The following message can occur when performing write operations if the underlying keyring does not exist in RACF.

```
R_datailib (IRRSIDL00) error: profile for ring not found (8, 8, 84)
```

Ensure the keyring exists in RACF prior to performing certificate management write operations.

## Enabling writable SAF keyrings

WebSphere Application Server provides the function to allow a WebSphere Application Server administrator to perform certificate management operations on System Authorization Facility (SAF) keyrings by utilizing the (Open Cryptographic Services Facility) OCSF Data library functions for SAF keyrings. This task migrates existing configurations and enables writable SAF keyrings.

### Before you begin

This task is used for migrating keystore objects that have not been enabled for writable support through profile creation. Writable keyring support is only configurable when running z/OS Release 1.9 or at z/OS Release 1.8 with APAR OA22287 - resource access control facility (RACF) (or the APAR for your equivalent security product) and APAR OA22295 – SAF.

Before starting this task, the wsadmin tool must be running. See the information about starting the wsadmin scripting client.

### About this task

By default, if writable keyring support is enabled during profile management, the default keystore configurations are enabled for writable keyrings. Alternatively, if migrating from a previous WebSphere Application Server installation, you can enable writable keyrings for a keystore object using the following steps.

AdminTask can be used in interactive mode and batch mode. For automation the batch mode options should be used. AdminTask batch mode can be called in a JACL or Jython script. Interactive mode steps you through all the parameters the task needs, required ones are marked with a '\*'. Before the AdminTask runs the task, it echoes the batch mode syntax of the task to the screen. This can be helpful when writing batch mode scripts for automation.

The following attributes are needed to create writable SAF keyring keystore objects:

- keyStoreName
- controlRegionUser
- servantRegionUser

The interactive mode procedure to enable writable SAF keyrings is as follows:

### Procedure

1. Use interactive mode to step through all attributes and use any default values for attributes (if desired).

The default value is in '[' on the prompt line. The actual flag used in batch mode is in '(' on each prompt line. If you are using the default value then the flag will not show up on the batch command line.

- Using JACL:

```
$AdminTask enableWritableKeyrings -interactive
```

- Using Jython:

```
AdminTask.enableWritableKeyings ('[interactive]')
```

2. An example of output from step (1) appears below:

```
*Keystore Name (keyStoreName): NodeDefaultKeyStore
Management Scope Name (scopeName):
*Control region userid for z/OS (SAF) (controlRegionUser): CRRACFID
*Servant region userid for z/OS (SAF) (servantRegionUser): SRRACFID
```

```
Modify keystore for writable SAF support
```

```
F (Finish)
```

```
C (Cancel)
```

Select [F, C]: [F] F

```
WASX7278I: Generated command line: $AdminTask enableWritableKeyrings {-keyStoreName NodeDefaultKeyStore
-controlRegionUser CRRACFID -servantRegionUser SRRACFID })
```

## Results

Two additional keystore objects are created that can be accessed using the administrative console to perform certificate operations on the appropriate keyring. The keystore objects are named **your\_keystore\_name -CR** and **your\_keystore\_name -SR**, where *your\_keystore\_name* is the name of the keystore specified on the create command.

**your\_keystore\_name -CR** corresponds to the keyring owned by the RACF ID of the control region process and **your\_keystore\_name -SR** corresponds to the keystore owned by the RACF ID of the servant region process.

These keystores are created in the same scope as *your\_keystore\_name* and can be accessed using the administrative console from the *your\_keystore\_name* collection panel.

## What to do next

### Accessing writable SAF keyrings

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration > Key stores and certificates > [keystore ]**.
2. Under Writable SAF Keyrings, click either **Control Region Keyring** or **Servant Region Keyring** to display the keystore collection panel for either the control region keyring or servant region keyring, respectively.
3. Under Additional Properties, navigate to the certificate collection panels to perform certificate management operations.

## SAF keyring support for audit signing and encryption

When you enable auditing, logging occurs in both the servant and control regions. When audit uses a certificate for signing and encryption that are stored in SAF keyrings, the certificate and the SAF keyring must be accessible by both the servant and the control region RACF IDs.

## Determining the accessibility of the certificate

You must determine whether a certificate is accessible by both the servant and control region RACF IDs by reviewing the keyring information in RACF. There are multiple methods for determining whether a certificate is accessible. Complete one of the following processes:

- Use the following RACDCERT LISTING commands to list the certificates that are associated with a particular RACF ID for a specific keyring and compare the listings:

```
RACDCERT ID(CRRACFID) LISTRING(keyring_name)
RACDCERT ID(SRRACFID) LISTRING(keyring_name)
```

  - *CRRACFID* is the control region RACF ID
  - *SRRACFID* is the servant region RACF ID
  - *keyring\_name* is the specified key ring
- List information about a certificate in RACF. Use the following RACDCERT LIST command to obtain a list of the keyrings and the RACF IDs that have access to the certificate and determine whether both the servant and control region RACF IDs are listed:

```
RACDCERT LIST (LABEL('certificate_label')) CERTAUTH
```

If the certificate is accessible by one RACF ID and not the other RACF ID, you can use the following RACDCERT CONNECT command to connect the certificate with the other RACF ID:

```
RACDCERT ID(CRRACFID) CONNECT (ID(CRRACFID) LABEL('certificate_label') RING(keyring_name) DEFAULT)
```

For auditing, a keystore object must be associated with a keyring in WebSphere Application Server. If the keystore object and a keyring are not associated, then you can create this association in the administrative console or use the `CreateKeyStore wsadmin` command. For more information, read about the keystore settings or the `KeyStoreCommands` command group.

## Accessing writable SAF keyrings

If you enable writable SAF keyrings and the keyring has a configuration object in WebSphere Application Server, you can use the administrative console or the `wsadmin` task to verify that the certificate is accessible by both the servant and control region RACF IDs. Typically, the following three keystore objects are associated with a writable SAF keyring:

- A read-only view for the keyring
- The servant region view of the keyring
- The control region view of the keyring

If the certificate is seen by both the servant region and the control region keystore objects, you can use the certificate for audit signing and encryption. You can look at the keystore object using the administrative console or using the `listPersonalCertificates` command. For more information, read about certificate management in SSL or the `PersonalCertificateCommands` command group.

If you can see the certificate in one keystore object, but cannot see it in another keystore object, you can import the missing certificate into the other keystore object. For example, you would need to import the certificate into the servant region keystore object if you can see it in the control region keystore object, but cannot see it in the servant region keystore object. You can import the certificate from the control region keystore object to the servant region keystore object using either the administrative console or the `importCertificate` command. For more information, read about importing a certificate or the `PersonalCertificateCommands` command group.

For more information about writable SAF keyrings, read about using, creating, and enabling writable SAF keyrings.

## Using certificates in SAF keyrings for audit

After the certificate is accessible by both the servant and control region RACF IDs of the SAF keyring, you can use the certificate for audit signing and encryption. If you are using writable SAF keyrings, use the read-only keystore object with the audit configuration. For more information about using certificates for audit signing and encryption, read about protecting your security audit data.

## Extracting a signer certificate from a personal certificate

Personal certificates contain a private key and a public key. You can extract the public key, called the *signer certificate*, to a file, then import the certificate into another keystore. The client requires the signer portion of a personal certificate for Security Socket Layer (SSL) communication.

## Before you begin

The keystore that contains a personal certificate must already exist.

**Alternative Method:** To extract a signer certificate from a personal certificate using the `wsadmin` tool, use the `extractCertificate` command of the `AdminTask` object. For more information, see the `PersonalCertificateCommands` command group for the `AdminTask` object article.

## About this task

Complete the following steps in the administrative console:

### Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration > Key stores and certificates > keystore** .
2. Under Additional Properties, click **Personal certificates**.
3. Select a personal certificate.
4. Click **Extract**.
5. Type the full path for the certificate file name. The signer certificate is written to this certificate file.
6. Select a data type from the list.
7. Click **Apply**.

### Results

The signer portion of the personal certificate is stored in the file that is provided.

### What to do next

This signer can now be imported into other keystores.

### Extract certificate

Use this page to extract the signer from the personal certificate and store it in a file. The certificate can be added to a trust store for trust verification. When extracting the signer from a chained personal certificate, the signer at the top level of the chain is extracted.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > key store** . Under Additional Properties, click **Personal certificates > Extract**.

#### ***Certificate alias to extract:***

Displays the name of the certificate that you selected for extraction on the previous panel.

**Data type:** Text

#### ***Certificate file name:***

Specifies the fully qualified path where the certificate file will reside.

**Data type:** Text

#### ***Data type:***

Specifies the format of the file, which is either Base64-encoded ASCII data or Binary DER data.

**Data type:** Text

**Default:** Base64-encoded ASCII data

### Extract signer certificate

Use this page to extract a signer certificate from the keystore to a file so that it can be added elsewhere.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties, click **Signer certificates**. Select a signer certificate, then click the **Extract** button

**File name:**

Specifies the fully qualified file name where the extracted signer certificate is placed.

**Data type:** Text

**Data type:**

Specifies the format of the file, which is either Base64 encoded ASCII data or Binary DER data.

**Data type:** Text

### Retrieving signers using the retrieveSigners utility at the client

The client requires the signer certificates from the server to be able to communicate with WebSphere Application Server. Use the **retrieveSigners** command to get the signer certificate from a server.

#### Before you begin

The retrieveSigners utility is located in one of the following directories, depending on your operating system:

In this release, a Java client that does not have access to a stdin console prompt should use the retrieveSigners utility to download the signers from the remote server key store when signers are needed for a Secure Sockets Layer (SSL) handshake. For example, you might interpret the client as failing to respond if an applet client or Java Web Start Client application cannot access the stdin signer exchange prompt. Thus, you must add the WebSphere Java method call **com.ibm.wsspi.ssl.RetrieveSignersHelper.callRetrieveSigners** to your client application to retrieve the signers and to avoid running the retrieveSigners utility manually.

Use the retrieveSigners utility for situations where you cannot verify whether or not the `com.ibm.ssl.enableSignerExchangePrompt=` property is enabled or disabled when the application makes a request. Set the `com.ibm.ssl.enableSignerExchangePrompt=` property to `false` in the `ssl.client.props` file if you cannot see the console.

Alternatively, you can manually create the server key in the client truststore.

#### About this task

Complete the following steps, as required:

#### Procedure

1. Use the **retrieveSigners** command to get the signer certificate from a server. You can find details about the **retrieveSigners** parameters in “Secure installation for client signer retrieval in SSL” on page 1910.
2. If the client and server are on the same machine, you will need only the *remoteKeyStoreName* and *localKeyStoreName* parameters. The most typical key store to reference on a remote system is `CellDefaultTrustStore` on a network deployed environment and `NodeDefaultTrustStore` on an application server.

- When retrieving signers from a remote server, add these required connection-related parameters: **-host** *host*, **-port** *port*, **-conntype** {*RMI* | *SOAP*}.
- Use the **-autoAcceptBootstrapSigner** parameter if you want to enable automation of the signer retrieval. This parameter automatically adds to the server all the signers that are needed to make the connection.

## Results

After running, the command displays the SHI-1 digest of the signers added. The output looks similar to the following output:

```
C:\WebSphere\AppServer\profiles\AppSrv01\bin\retrieveSigners.bat
CellDefaultTrustStore ClientDefaultTrustStore

CWPKI0308I: Adding signer alias "default_signer" to local keystore
 "ClientDefaultTrustStore" with the following SHA digest:
```

## Example

The following examples illustrate how to call the `retrieveSigners.bat` file.

To retrieve signers on the same system, enter:

```
profile_root\bin\retrieveSigners.bat CellDefaultTrustStore ClientDefaultTrustStore
```

To retrieve signers on a remote system with a SOAP connection, enter:

```
profile_root\bin\retrieveSigners.bat CellDefaultTrustStore ClientDefaultTrustStore
-host myRemoteHost -port 8879 -conntype SOAP -autoAcceptBootstrapSigner
```

To retrieve signers on a remote system with an RMI connection, enter:

```
profile_root\bin\retrieveSigners.bat CellDefaultTrustStore ClientDefaultTrustStore
-host myRemoteHost -port 2809 -conntype RMI -autoAcceptBootstrapSigner
```

To retrieve signers on a remote system that has security enabled, enter:

```
profile_root\bin\retrieveSigners.bat CellDefaultTrustStore ClientDefaultTrustStore
-host myRemoteHost -port 8879 -conntype SOAP -user testuser -password testuserpwd
-autoAcceptBootstrapSigner
```

## Changing the signer auto-exchange prompt at the client

For clients to communicate with WebSphere Application Server, clients must obtain a signer certificate from the server. Clients can use the **retrieveSigners** command to connect to a server to obtain the appropriate signer. A prompt displays that asks whether or not you want to add a signer to the truststore. If the Secure Sockets Layer (SSL) configuration uses an automated script that might hang, use the prompt to obtain the certificate.

### Before you begin

The `com.ibm.ssl.enableSignerExchangePrompt` property in the `profile_home/properties/ssl.client.props` file controls the signer certificate prompt. By default, this property is set to `true`, meaning the prompt is enabled.

### About this task

Complete the following steps to disable or enable the signer-exchange prompt at the client:

#### Procedure

- Open the `profile_home/properties/ssl.client.props` file using an editor.
- Locate the section containing the SSL configuration information for the client that you are working with.
- Change the value of the `com.ibm.ssl.enableSignerExchangePrompt` property to `false` if you do not want the signer-exchange prompt, or set it to `true` if you want to be prompted.

4. Save and close the file.

## Results

When the `com.ibm.ssl.enableSignerExchangePrompt` property is set to `false`, no prompt displays if a signer is not trusted. In this case the SSL handshake fails. Once the proper signer for the connection being made is manually installed in the trust store, the SSL handshake can succeed.

When the `com.ibm.ssl.enableSignerExchangePrompt` property is set to `gui` or `true`, a signer-exchange window is displayed, and you are asked to accept or reject the certificate. If you accept the certificate, it is installed in the trust store automatically and the handshake succeeds. If you reject the certificate, it does not get installed in the trust store and the handshake fails since the certificate is not trusted.

When the `com.ibm.ssl.enableSignerExchangePrompt` property is set to `stdin`, a signer-exchange ASCII prompt is displayed, and you are asked to accept or reject the certificate. If you accept the certificate, it is installed in the trust store automatically and the handshake succeeds. If you reject the certificate, it does not get installed in the trust store and the handshake fails since the certificate is not trusted.

The prompt looks like the following example:

### Example

```
C:\WebSphere\AppServer\profiles\dmgr\bin>serverStatus -all
ADMU0116I: Tool information is being logged in file
 C:\WebSphere\AppServer\profiles\Dmgr\logs\serverStatus.log
ADMU0128I: Starting tool with the dmgr profile
ADMU0503I: Retrieving server status for all servers
ADMU0505I: Servers found in configuration:
ADMU0506I: Server name: dmgr

*** SSL SIGNER EXCHANGE PROMPT ***
SSL signer from target host 192.174.1.5 is not found in truststore
C:/WebSphere/AppServer/profiles/Dmgr/etc/trust.p12.
```

Verify that the digest value matches what is displayed at the server in the following signer information:

```
Subject DN: CN=hostname.austin.ibm.com, O=IBM, C=US
Issuer DN: CN=hostname.austin.ibm.com, O=IBM, C=US
Serial number: 1128544457
Expires: Thu Oct 20 15:34:17 CDT 2006
SHA-1 Digest: 91:A1:A9:2D:F2:7D:70:0F:04:06:73:A3:B4:A4:9C:56:9D:A8:A3:BA
MD5 Digest: 88:72:C5:88:00:1C:A7:FA:D6:EB:04:88:AC:A1:C9:13
```

```
Add signer to the truststore now? (y/n) y
A retry of the request might need to occur.
ADMU0508I: The Application Server "server1" is STARTED.
```

## What to do next

Clients can instigate communications for various processes using signer certificates obtained from WebSphere Application Server.

### Importing a signer certificate from a truststore to a z/OS keyring

You can import a signer certificate, which is also called a certificate authority (CA) certificate, from a truststore on a non-z/OS platform server to a z/OS keyring.

#### Procedure

1. On the non-z/OS platform server, change to the `install_root/bin` directory and start the iKeyman utility, which is called `keyman.bat` (Windows) or `keyman.sh` (UNIX). The `install_root` variable refers to the installation path for WebSphere Application Server.

2. Within the iKeyman utility, open the server truststore. The default server truststore is called the `trust.p12` file. The file is located in the `[/USER_INSTALL_ROOT]/config/cells/<cell_name>/nodes/<node_name>` directory. The default password is WebAS.
3. Extract the signer certificate from the truststore using the **ikeyman** utility. Complete the following steps to extract the signer certificate:
  - a. Select **Signer certificates** from the menu.
  - b. Select **root** from the list.
  - c. Select **Extract**.
  - d. Select the correct data type. The `signer_certificate` can have either a Base64-encoded ASCII data type or a Binary DER data type.
  - e. Specify the fully qualified path and the file name of the certificate.
4. From an FTP prompt on the non-z/OS platform server, type `ascii` to change the file transfer to ascii mode.
5. You can ftp the certificate to the z/OS platform either as a file in the Hierarchical File System (HFS) or as an MVS dataset. To ftp as a dataset: from an FTP prompt on the non-z/OS platform server, type `put 'signer_certificate' mvs.dataset`. The `signer_certificate` variable refers to the name of the signer certificate on the non-z/OS platform server. The `mvs.dataset` variable is the data set name to which the certificate was exported.

To ftp as a file in the HFS from an FTP prompt on the non-z/OS platform server, type `put 'signer_certificate' file_name`. The `signer_certificate` variable refers to the name of the signer certificate on the non-z/OS platform server. The `file_name` variable is the name of the file in the HFS to which the certificate was exported.

The RACDCERT CERTAUTH ADD command in the next step works with a Multiple Virtual Storage (MVS) data set only. You can either turn the certificate file into a binary MVS data set or use the `put` command with an HFS file, and then use the following command to copy the file into a MVS data set:

```
cp -B /u/veser/Cert/W21S01N.p12 "'/VESER.CERT.W21S01N'"
```

6. On the z/OS platform server, go to option 6 in the Interactive System Productivity Facility (ISPF) dialog panels and issue the following commands as a super user to add the signer certificate to the z/OS keyring:
  - a. Type `RACDCERT CERTAUTH ADD ('signer_certificate') WITHLABEL('WebSphere Root Certificate') TRUST .` The `WebSphere Root Certificate` variable refers to the label name for the certificate authority (CA) certificate that you are importing from a non-z/OS platform server. The `keyring_name` variable refers to the name of the z/OS keyring that is used by the servers in the cell.
  - b. Type `RACDCERT ID(ASCR1) CONNECT(CERTAUTH LABEL('WebSphere Root Certificate') RING(keyring_name))`
  - c. Type `RACDCERT ID(DMCR1) CONNECT(CERTAUTH LABEL('WebSphere Root Certificate') RING(keyring_name))`
  - d. Type `RACDCERT ID(DMSR1) CONNECT(CERTAUTH LABEL('WebSphere Root Certificate') RING(keyring_name))` In the previous commands, ASCR1, DMCR1, and DMSR1 are the RACF IDs under which the started tasks for the cell run in WebSphere Application Server for z/OS. The ASCR1 value is the RACF ID for the application server control region. The DMCR1 value is the RACF ID for the deployment manager control region. The DMSR1 value is the RACF ID for the deployment manager server region.

## Results

After completing these steps, the z/OS keyring contains the signer certificates that originated on the non-z/OS platform server.

## What to do next

To verify that the certificates were added, use option 6 on the ISPF dialog panel and type the following command:

```
RACDCERT ID(CBSYMSR1) LISTRING(keyring_name)
```

The CBSYMSR1 value is the RACF ID for the application server region.

**Note:** Although iKeyman is supported for WebSphere Application Server Version 6.1, customers are encouraged to use the administrative console to export signer certificates.

## Exporting a signer certificate from WebSphere Application Server for z/OS to a truststore

You can export a signer certificate, which is also called a certificate authority (CA) certificate, from WebSphere Application Server for z/OS to a truststore.

### Before you begin

WebSphere Application Server, WebSphere Application Server, Network Deployment, or WebSphere Application Server, Express can use the certificate in the truststore.

### Procedure

1. Export the z/OS<sup>®</sup> signer certificate to a data set by issuing the following Resource Access Control Facility (RACF) command as a super user using Time Sharing Option (TSO) option 6:

```
RACDCERT CERTAUTH EXPORT(LABEL('signer_certificate')) DSN('mvs.dataset')FORMAT(CERTDER)
```

The *signer\_certificate* variable is the RACF label name of the certificate that is used by the cell. The *signer\_certificate* can have either a Base64-encoded ASCII data type or a Binary DER data type. The *mvs.dataset* variable is the data set name to which the certificate is exported. You do not need to pre-allocate this data set because it is created by RACF.

2. From a command line on the non-z/OS platform server, type `cd` and change to the following directory:

```
${USER_INSTALL_ROOT}/config/cells/<cell_name>/nodes/<node_name>
```

3. From an FTP prompt on the non-z/OS platform server, type `bin` to change to binary mode.

4. From an FTP prompt on the non-z/OS platform server, type the following command:

```
get 'mvs.dataset' signer_certificate
```

5. On the non-z/OS platform server, change to the *install\_root/bin* directory and start the **iKeyman** utility, which is called `keyman.bat` for Windows or `keyman.sh` for UNIX. Within the iKeyman utility, open the server truststore. The default server truststore is called the `trust.p12` file. The file is located in the `${USER_INSTALL_ROOT}/config/cells/<cell_name>/nodes/<node_name>/` directory. The default password is `WebAS`.
6. Add your exported signer certificate to the server truststore using the iKeyman utility. Complete the following steps to add your exported signer certificate:
  - a. Select **Signer certificates** from the menu.
  - b. Select the correct data type. The signer certificate can have either a Base64-encoded ASCII data type or a Binary DER data type.
  - c. Specify the fully qualified path and file name of the signer certificate.
7. Within the iKeyman utility, open the client truststore. The default client truststore is called the `trust.p12` file. The file is located in the `${USER_INSTALL_ROOT}/etc/` directory. The default password is `WebAS`.
8. Add your exported signer certificate to the client truststore using the iKeyman utility. Complete the following steps to add your exported signer certificate:
  - a. Select **Signer certificates** from the menu.

- b. Select the correct data type. The signer certificate can have either a Base64-encoded ASCII data type or a Binary DER data type.
  - c. Specify the fully qualified path and file name of the signer certificate.
9. Restart the server process to use the new signer certificates.

## What to do next

After completing these steps, you can use the exported signer certificates with the WebSphere Application Server, WebSphere Application Server, Network Deployment, or WebSphere Application Server, Express products.

## Retrieving signers from a remote SSL port

To perform Secure Sockets Layer (SSL) communication with a server, WebSphere Application Server must retrieve a signer certificate from a secure remote SSL port during the handshake. After the signer certificate is retrieved, you can add the signer certificate to a keystore.

## Before you begin

The keystore that is to contain the signer certificate must already exist.

**Alternative Method:** To retrieve a signer certificate from a port using the wsadmin tool, use the **retrieveSignerFromPort** command of the AdminTask object. For more information, see the SignerCertificateCommands command group for the AdminTask object article.

## About this task

Complete the following steps in the administrative console:

### Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > Key stores and certificates > keystore > Signer certificates > Retrieve from port**.
2. Click **Retrieve from port**.
3. Type the host name of the machine on which the signer resides.
4. Type the port location on the host machine on which the signer resides. The port location is not limited to ports on WebSphere Application Server. The ports can include Lightweight Directory Access Protocol (LDAP) ports or ports on any server on which an SSL port is already configured, such as SIB\_ENDPOINT\_SECURE\_ADDRESS.
5. Select an SSL configuration for the outbound connection from the list.
6. Type an alias name for the certificate.
7. Click **Retrieve signer information**. A message window displays information about the retrieved signer certificate, such as: the serial number, issued-to and issued-by identities, SHA hash, and expiration date. If a chained certificate is on the port, information about the root is displayed.
8. Click **Apply**. This action indicates that you accept the credentials of the signer.

## Results

The signer certificate that is retrieved from the remote port is stored in the keystore.

## What to do next

An SSL configuration or client process that requires an SSL connection to the server can use the retrieved and approved signer certificate.

### Retrieve from port

Use this page to retrieve a signer certificate from a remote SSL port. The system connects to the specified remote SSL host and port and receives the signer during the handshake using an SSL configuration.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties, click **Signer certificates**. Then click the **Retrieve from port** button.

To retrieve a signer certificate from a specific port, you enter the host and port, select an SSL configuration from the pull-down list, and enter an alias to identify the signer certificate. Click **Retrieve Signer Information** and information about the signer certificate is displayed, such as the serial number of the certificate, who the certificate is issued to and by, the certificate finger print, and the expiration information for the certificate. If you want the certificate to be stored in the keystore, click **Apply** or **Save**.

#### **Host:**

Specifies the host name to which you connect when attempting to retrieve the signer certificate from the Secure Sockets Layer (SSL) port.

**Data type:** Text

#### **Port:**

Specifies the SSL port to which you connect when attempting to retrieve the signer certificate.

**Note:** In a network deployment environment, you need to specify the correct secure sockets layer (SSL) port number when attempting to retrieve a signer certificate from a remote SSL port.

- Use the port number associated with the port name, **WC\_adminhost\_secure**, when retrieving a signer certificate from the deployment manager.
- Use the port number associated with the port name, **CSIV2\_SSL\_MUTUALAUTH\_LISTENER\_ADDRESS**, when retrieving a signer certificate from a node.

All certificates must be in place prior to retrieving them from the deployment manager or from base servers.

**Data type:** Text

#### **SSL configuration for outbound connection:**

Specifies the SSL configuration that is used to connect to the previously specified SSL port. This configuration is also the SSL configuration that contains the signer after retrieval. This SSL configuration does not need to have the trusted certificate for the SSL port as it is retrieved during validation and presented here.

**Data type:** Text

#### **Alias:**

Specifies the certificate alias name that you want to reference the signer in the key store, which is specified in the SSL configuration.

**Data type:** Text

### ***Retrieved signer information:***

Specifies the signer certificate information if it is retrieved from the remote host and port.

## **Adding a signer certificate to a keystore**

Signer certificates establish the trust relationship in SSL communication. You can extract the signer part of a personal certificate from a keystore, and then you can add the signer certificate to other keystores.

### **Before you begin**

The keystore that you want to add the signer certificate to must already exist.

**Alternative Method:** To add a signer certificate to a keystore by using the wsadmin tool, use the **addSignerCertificate** command of the AdminTask object. For more information, see the SignerCertificateCommands command group for the AdminTask object article.

**Note:** If the security custom property com.ibm.websphere.security.OverwriteAndReplaceOnImport is set to true then import certificate imports a certificate and overwrites an existing certificate. It then perform the certificate replace operation on that certificate. Typically, an existing certificate cannot be overwritten by a certificate that is being imported. The task also replaces all signer certificates from the original certificate and replaces them with the signer certificate from the new certificate that is being imported

### **About this task**

Complete the following steps in the administrative console:

#### **Procedure**

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > ssl\_configuration > Key stores and certificates.**
2. Select a **keystore** from the list of keystores.
3. Click **Signer certificates.**
4. Click **Add.**
5. Enter an alias for the signer certificate in the **Alias** field
6. Enter the full path to the signer certificate file in the **File name** field.
7. Select a data type from the list in the **Data type** field.
8. Click **Apply.**

#### **Results**

When these steps are completed, the signer from the certificate file is stored in the keystore. You can see the signer in the keystore files list of signer certificates. Use the keystore to establish trust relationships for the SSL configurations.

### **Add signer certificate settings**

Use this page to add a signer certificate in a certificate file to the keystore in the security configuration.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration > Key stores and certificates > keystore > Signer certificates > Add.**

**Alias:**

Specifies the alias that is used to identify the signer certificate in the keystore.

**Data type:** String

**File name:**

Specifies the path to the filename where the signer certificate is located.

**Data type:** String

**Data type:**

Specifies the format of the file, which is either Base64 encoded ASCII data or Binary DER data.

**Data type:** String

**Signer certificates collection**

Use this page to manage signer certificates in key stores. Signer certificates are used by Java Secure Socket Extensions (JSSE) to validate certificates sent by the remote side of the connection during a Secure Sockets Layer (SSL) handshake. If a signer does not exist in the trust store that can validate the certificate sent, the handshake fails and generates an "unknown certificate" error.

To view this administrative console page, click **Security > SSL certificate and key management.** Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration.** Under Related items, click **Key stores and certificates > key store.** Under Additional Properties, click **Signer certificates.**

*Table 167. Signer certificates buttons. This table lists the signer certificates buttons.*

Button	Resulting action
<b>Add</b>	Adds a new trusted (signer) certificate.
<b>Delete</b>	Deletes an existing signer certificate.
<b>Extract</b>	Extracts a signer certificate from a personal certificate to a file.
<b>Retrieve from port</b>	Makes a test connection to an SSL port and retrieves the signer from the server during the handshake. The information from the certificate will be displayed so you can decide whether to trust it based upon the MD5 and/or SHA hash.

**Alias:**

Specifies the alias for this signer certificate in the key store.

**Issued to:**

Specifies the distinguished name of the entity that requested the certificate.

**Fingerprint (SHA digest):**

Specifies the Secure Hash Algorithm (SHA hash) of the certificate. This can be used to verify the hash for the certificate at another location, such as the client side of a connection.

**Expiration:**

Specifies the expiration date of the signer certificate for validation purposes.

**Signer certificate settings**

Use this page to verify the general properties of the selected signer certificate.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates > key store**. Under Additional Properties, click **Signer certificates**. Then click on a signer certificate.

**Alias:**

Specifies the alias for this signer certificate in the key store.

**Version:**

Specifies the version of the personal certificate. Valid versions include X509 V3, X509 V2, or X509 V1.

**Key size:**

Specifies the key size of the public key used by the signer certificate.

**Serial number:**

Specifies the certificate serial number that is generated by the issuer of the certificate.

**Validity period:**

Specifies the begin and end dates of the certificate.

**Issued to:**

Specifies the distinguished name of the entity that requested the certificate.

**Issued by:**

Specifies the distinguished name of the entity that issued the certificate. This name is the same as the issued-to distinguished name when the signer certificate is self-signed.

**Fingerprint (SHA Digest):**

Specifies the Secure Hash Algorithm (SHA) hash of the certificate, which can be used to verify the hash for the certificate at another location such as the client side of a connection.

**Signature algorithm:**

Specifies the algorithm that is used to sign the certificate.

**Adding a signer certificate to the default signers keystore**

Signer certificates are added to a keystore on the client side of an SSL communication to establish trust with the server. There is common practice for keystores to have trust established when they are created. The **DmgrDefaultSignersStore** on a deployment manager and the **NodeDefaultSignersStore** on a stand alone application server are created to hold signer certificates used to establish trust by default in newly create keystores.

## Before you begin

The default signers key store is created during profile creation and contains the signer certificate of the server default root certificate. Additional signer certificates can be added to the default signers key store at any time. Anytime a keystore is created using the admin console or by using the **createKeyStore** AdminTask object in scripting, all signer certificates from the default signer store are added to the newly created keystore.

### Alternative Method:

- To add a signer certificate to a default signer keystore by using the wsadmin tool, use the **addSignerCertificate** command of the AdminTask object.
- To create a new keystore by using the wsadmin tool, use the **createKeyStore** command of the AdminTask object.
- To extract the signer from a personal certificate using the wsadmin tool, use the **extractCertificate** of the AdminTask object.
- To exchange a signer certificate using the wsadmin tool, use the **KeyStoreCommands** command group for the AdminTask object.

For more information, see the SignerCertificateCommands command group for the AdminTask object article and the KeyStoreCommands command group for the AdminTask object article.

## Procedure

1. If the certificate is in a certificate file, it can be added to the default signer keystore using the administrative console.
  - a. Click **Security > SSL certificate and key management**.
  - b. Under Related Items, click **Key stores and certificates**.
  - c. Select Default signers keystore under KeyStore Usages. A panel displaying a list of keystores appears.
  - d. Click on **DmgrDefaultSignersStore**.
  - e. Under Additional Properties, click **Signer certificates**.
  - f. Click **Add**.
  - g. Enter an alias in the alias box, a path to the certificate file in the filename box, and an asterisk (\*). Select the format of the certificate file from the pull down list in the “Data type” box.
  - h. Click **Apply** then **Save**.

**Note:** You can also perform this addition using the AdminTask, **addSignerCertificate**.

2. If the signer certificate form of a personal certificate needs to be added to default signers keystore, you can extract the signer from the personal certificate to a certificate file or the signer can be extracted directly to the default signers keystore. To extract a signer certificate from a personal certificate to a certificate file,
  - a. Click **Security > SSL certificate and key management**.
  - b. Under Related Items, click **Key stores and certificates**.
  - c. Select All under Keystore Usages. A panel displaying a list of keystores appears.
  - d. Click on the keystore name
  - e. Under Additional Properties, click **Personal certificates**.
  - f. Select a personal certificate.
  - g. Click **Extract**.
  - h. Enter the path to the certificate file in “Certificate file name” box and select a format type from the pull down list in “Data type” box
  - i. Click **Apply** then **Save**.

j. The signer can be added to the default signers keystore by following step 1.

**Note:** You can also extract the signer from a personal certificate using scripting and the AdminTask `extractCertificate`.

3. To extract a signer certificate to the default signers keystore, an exchange of the signer certificate can be performed from the administrative console.
  - a. Click **Security > SSL certificate and key management**
  - b. Under Related Items, click **Key stores and certificates**.
  - c. Select All under Keystore Usages. A panel displaying a list of keystores appears.
  - d. Click on the default signers keystore and the keystore that contains the personal certificate whose signer certificate is needed.
  - e. Click **Exchange Signers**.
  - f. Select the personal certificate whose signer is needed.
  - g. Click **Add**.
  - h. Click **Apply** then **Save**.

**Note:** You can also perform the exchange using the AdminTask, `exchangeSigner`.

**Note:** A DataPower certificate can be removed from the default signers keystore if it is present. If you are not using the DataPower appliance manager you should remove the DataPower certificate from the default trust store to avoid unintentional trust relationships. However, if you start to use DataPower appliance manager at a later date you must add the DataPower certificate back to the default trust store.

## Results

When these steps are completed, the signer from the certificate file is stored in the default signers keystore. You can see the signer in the keystore files list of signer certificates.

## What to do next

The new keystore will contain the default signers that were added to the default signers keystore.

## Exchanging signer certificates

To establish trust relationships, you can exchange signer certificates between keystores. When you exchange signer certificates, you are extracting a personal certificate from one keystore and adding it to another keystore as a *signer certificate*.

## Before you begin

To exchange signer certificates, there must be two keystores.

## About this task

Complete the following steps in the administrative console:

## Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration > Key stores and certificates**.
2. Select two keystores from the list of keystores.
3. Click **Exchange signers**.

4. Select any of the certificates in the first personal certificates list, and click **Add**. After adding, the signer part of the selected personal certificate appears in the other (second) keystore signers list.
5. Select any of the certificates in the second personal certificates list, and click **Add**. After adding, the signer part of the selected personal certificate appears in the other (first) keystore signers list.
6. Optional: If you need to remove any of the certificates from either of the signers lists, highlight one or more of the certificates, and click **Remove**.
7. Click **Apply** and **Save**.

## Results

The signer certificate appears in the list for each keystore.

## What to do next

The extracted signer certificate is available to both keystores during the connection handshake.

## Keystores and certificates exchange signers

Use this page to extract the signer part of a personal certificate from one keystore and add it to another keystore as a signer certificate. Signer certificates can also be listed, and they will be added to the other keystore as well.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key stores and certificates** then select two key stores to exchange and click the **Exchange signers**.

**Note:** Any changes made to this panel are permanent.

### ***[keystore] personal certificates:***

Specifies the personal certificates and signer certificates that are currently stored in the specified keystore.

Press and hold the **Ctrl** key to select more than one item from the list.

**Data type:** Text

### ***[keystore] signers:***

Specifies the trusted signer certificates that are currently stored in the specified keystore and selected for the exchange.

Press and hold the **Ctrl** key to select more than one item from the list.

**Data type:** Text

### ***Add:***

Specifies to extract the signer from the selected personal certificate in the keystore list on the left and add it to the signers list of the keystore on the right.

After the certificate is added, it no longer displays in the left-hand list. The personal certificate is still in the keystore, but it is no longer selectable

### ***Remove:***

Specifies to remove a selected signer from the signers list of the keystore on the right. The removed certificate displays in the keystore list on the left.

## Configuring certificate expiration monitoring

When certificates expire, they can no longer be used by the system. WebSphere Application Server provides a utility to monitor certificates that are close to expiration or have already expired. You can schedule certificate monitoring, or you can request certificate monitoring on demand. You can also configure options for deleting expired certificates and for recreating certificates.

### Before you begin

**Important:** The Certificate Expiration Monitor does not handle replacing client self-signed certificates and is not capable of sending the new signer certificate needed for trust. If the client is a web server plug-in, it will not be able to securely communicate with the application server after self-signed certificate replacement.

WebSphere Application Server notifies you when a certificate is about to expire. Complete the information required for notification messaging in “Notifications” on page 2028.

### About this task

Complete the following configuration steps in the administrative console:

#### Procedure

1. Click **Security > SSL certificate and key management > Manage certificate expiration**.
2. Type a number for the number of days threshold in the **Expiration notification threshold** field. WebSphere Application Server issues an expiration warning  $n$  number of days before expiration.
3. Select or check one or more of the following options:
  - **Expiration check notification.** Select the method from the list that you want to use to receive your notification.
  - **Automatically replace expiring self-signed certificates.** If you do not want to recreate the self-signed certificate, clear the check box.  
**Attention:** When using writable System Authorization Facility (SAF) keyrings in your configuration, the certificate expiration monitor does not replace expired certificates in the writable SAF keyrings, but only provides a notification of the expiration.
  - **Delete expiring certificates and signers after replacement.** If you do not want to delete the expired certificates and signers, clear the check box.
  - **Enable checking.** If you do not want to have certificate monitoring enabled, clear the check box.
4. Enter the time of day when you want certificate monitoring to take place to schedule the running of the certificate expiration monitor.
5. Select one of the following options:
  - **Check by calendar.** For **Weekday**, enter the day of week that you want to run the certificate expiration monitor. For **Repeat Interval**, specify the frequency to run the certificate monitor.
  - **Check by number of days.** Enter a number for how frequently the monitor runs, in number of days.
6. Type the number of days before the threshold date in which the certificate monitor warns that a certificate is about to be replaced. When a certificate is within the expiration threshold, and automatic replacement is enabled, certificates are replaced. This value specifies the time period before the threshold when warnings are issued by the certificate monitor concerning upcoming replacement dates.
7. Click **Apply**.

## Results

After completing the settings, a certificate expiration monitor object and a schedule are set up in the configuration. The certificate expiration monitor runs according to the configurations options that you configured.

## What to do next

You can generate reports that state which certificates have expired. The reports identify the notifications of certificate replacements and deletions. The report is sent according to the notification option that you specified.

## Manage certificate expiration settings

Use this page to configure the certificate expiration monitor.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage certificate expiration**.

**Attention:** To see the changes to the Expiration checking fields, you must click **Apply**.

### **Start now:**

Specifies to start certificate monitoring. When the monitor runs, it visits all the key stores and checks to see if they are within certificate expiration range. If you set the option to delete or replace expired certificates, you can run these operations immediately by pressing **Start now**.

### **Expiration notification threshold:**

Specifies the period of time that occurs chronologically just before the expiration day of the certificate, within which, if the ExpirationMonitor thread runs, and **Automatically replace expiring self-signed and chained certificates** is enabled, a new self-signed or chained certificate is generated. By default, the replacement period for the certificate is 60 days in length or less as defined in the daysBeforeNotification property.

There is a pre-notification period where the certificate is added to the notification list but not touched for 90 days prior to the 60 days. By default, this pre-notification period is 90 days in length as defined in the com.ibm.ws.security.expirationMonitorNotificationPeriod property.

<b>Data type:</b>	Integer
<b>Default:</b>	60 days or less

### **Enable checking:**

Specifies the certificate monitor is active and will run as scheduled.

### **Scheduled time of day to check for expired certificates:**

Specifies the scheduled time that the system checks for expired certificates.

You can type the scheduled time in hours and minutes, specify either A.M. or P.M., or 24-hour.

<b>Data type</b>	Integer
<b>Default:</b>	0, 0
<b>Range:</b>	1–12, 0–59

### ***Check by calendar:***

Indicates that you want to schedule a specific day of the week on which the expiration monitor runs. For example, it might run on Sunday.

**Default:** Enabled

### ***Weekday:***

Specifies the day of the week on which the expiration monitor runs if **Check on a specific day** is selected.

**Default:** Sunday

**Range:** Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday

### ***Repeat interval:***

Specifies the period of time between each schedule time to check for expired certificates or the interval between schedule checks.

**Default:** Daily

**Range:** Daily, Weekly

### ***Check by number of days:***

Specifies that you want to schedule a specific number of days between each run of the expiration monitor. The day of the week on which this occurs is not counted. For example, if you set the interval to check for expired certificates every seven days, the expiration monitor runs on day eight.

**Default:** Disabled

### ***Next start date:***

Specifies the date for the next scheduled check. This allows the deployment manager to be stopped and restarted without resetting the date.

### ***Expiration check notification:***

Specifies the notification type (either email, or an entry in the system log) when an expiration monitor runs.

**Default:**

### ***Automatically replace expiring self-signed certificates and chained certificates:***

Specifies a new self-signed certificate or chained certificate be generated using the same certificate information if the expiration notification threshold is reached. The old certificate is replaced and uses the same alias. All old signers are managed by the key store configuration are also replaced. The system only replaces self-signed certificates.

**Note:** This checkbox is only applicable when using file based keystores.

**Default:** Enabled

### **Delete expiring certificates and signers after replacement:**

Specifies whether to completely remove old, self-signed certificates from the key store during a replace operation or leave them there under a renamed alias. If an old certificate is not deleted, the system renames the alias so that the new certificate can use the old alias, which might be referenced elsewhere in the configuration.

**Note:** This checkbox is only applicable when using file based keystores.

**Default:** Enabled

## **Notifications**

Use this page to specify the generic notification definitions that are used in certificate expiration monitors.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage certificate expiration**. Under Related items, click **Notifications**.

Table 168. Notifications buttons. This table lists the notifications buttons.

Button	Resulting action
New	Adds a notification. The notification configures how the expiration monitor notifies the administrator of certificates that will expire within the specified threshold.
Delete	Deletes an existing notification.

### **Notification name:**

Specifies the notification name.

### **Message log:**

Specifies that this configuration intends to log certificate expiration information to the message log file.

### **Send Email:**

Specifies that this configuration intends to send certificate expiration information to the list of users in the email list.

### **List of email addresses:**

Specifies the email addresses that are sent notifications when certificates fall within the expiration threshold. You must specify the SMTP server for each email address. If an email address is not specified, by default the application server assumes that the SMTP server is "smtp-server." For example, if you type *name@domain*, the SMTP server will be smtp-server.domain.

## **Notifications settings**

Use this page to set properties for new notifications used in certificate expiration monitors or for security audit subsystem failures.

To view this administrative console page perform one of the following:

- Click **Security > SSL certificate and key management > Manage certificate expiration > Notifications > New**.
- Click **Security > Security auditing > Audit monitor > New**

### **Notification name:**

Specifies the name of the notification configuration.

**Data type:** Text

***Message log:***

Specifies that this configuration will log the notification to a message log file.

**Default:** Disabled

***Email sent to notification list:***

Specifies that this configuration send a notification as an email to the email list.

**Default:** Disabled

***Email address to add:***

Specifies the email addresses that are sent notifications. You must specify the SMTP server for each email address. If an email address is not specified, by default the application server assumes that the SMTP server is "smtp-server." For example, if you type *name@domain*, the SMTP server will be smtp-server.domain.

**Data type:** Text (format as valid Internet mail address)

***Add:***

Adds the email address to the right-hand list.

***Remove:***

Removes the email address from the right-hand list.

***Outgoing mail (SMTP) server:***

Specifies the SMTP server to be used with the email address. If none is specified, the email realm will be used.

## **Key management for cryptographic uses**

WebSphere Application Server provides a framework for managing keys (secret keys or key pairs) that applications use to perform cryptographic operations on data. The key management framework provides an application programming interface (API) for retrieving these keys. Keys are managed in keystores so the keystore type can be supported by WebSphere Application Server, provided that the keystores can store the referenced key type. You can configure keys and scope keystores so that they are visible only to particular processes, nodes, clusters, and so on.

The key management infrastructure is based on two key configuration object types: key sets and key set groups. WebSphere Application Server uses a key set to manage instances of keys of the same type. You can configure a key set to generate a single key or a key pair, depending on the key or key pair generator class. A key set group manages one or more key sets and enables you to configure and generate different key types at the same time. For example, if your application needs both a secret key and key pair for cryptographic operations, you can configure two key sets, one for the key pair and one for the secret key that the key set group manages. The key set group controls the auto-generation characteristics of the

keys, including the schedule. The framework can automatically generate keys on a scheduled basis, such as on a particular day of the week and time of day, so that key generation is done during off-peak hours.

Figure 1 shows an example of a key set group that is configured to manage two key sets: key set 1 and key set 2.

Figure 36.

Key set 1 generates key pairs. Key set 2 generates secret keys. The application needs both types of keys for its cryptographic operations, signing and encryption, on data. The keys for each key set need to be generated in tandem. The application stores the key set group name with the encrypted data. The key set group generates a new set of keys every Sunday night at 11 P.M.. The application maintains key generation data for two weeks.

## Creating a key set configuration

You can use key sets to manage multiple instances of cryptographic keys. WebSphere Application Server uses keys to encrypt or sign outbound data, and decrypt or verify inbound data during cryptographic operations.

### Before you begin

You must have write-access to the keystore that will contain the keys after you generate them from a key set. However, if you want to generate keys outside of WebSphere Application Server, you can reference the keys from a read-only keystore that contains a secret key that you can access when you generate the keys. If you are creating a key pair using an X509Certificate and a PrivateKey object, see “Example: Developing a key or key pair generation class for automated key generation” on page 2037.

### About this task

Complete the following steps in the administrative console:

#### Procedure

1. Decide whether you want to create the key set at the cell scope or below the cell scope at the node, server, or cluster, for example:
  - To create a key set at the cell scope, click **Security > SSL certificate and key management > Key sets**.
  - To create a key set at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration > Key sets**.
2. Click **New** to create a new key set.
3. Type a key set name. For example, CellmyKey.
4. Type a key alias prefix name. For example, myKey. This field specifies the prefix for the key alias when the new key is generated and stored in the keystore. Following the prefix is the key reference version number, for example, 2, so that the full key alias name would be myKey\_2. If the key reference already has a specified alias for a key that exists in the keystore, then WebSphere Application Server ignores this field.
5. Type a key password. The key password protects the key in the keystore. This password is ignored by WebSphere Application Server if you already specified a password for the key alias reference. To check for a key reference password, click **Active key history** under Additional Properties. The key reference password protects keys that are generated by a key generator class.
6. Type the password again to confirm it.

7. Optional: Type the key generator class name. For example, `com.ibm.ws.security.ltpa.LTPAKeyGenerator`. The class name generates keys. If the class implements `com.ibm.websphere.crypto.KeyGenerator`, then a `getKey` method returns a `java.security.Key` object that is set in the keystore using the `setKey` method without a certificate chain. If the class implements `com.ibm.websphere.crypto.KeyPairGenerator`, then a `getKeyPair` method returns a `com.ibm.websphere.crypto.KeyPair` object that contains either a `java.security.PublicKey` and `java.security.PrivateKey` or a `java.security.cert.Certificate` and a `java.security.PrivateKey` object. The key generator class and the `KeySetHelper` API specify the details of the keys that are generated.
8. Optional: Select **Delete key references that are beyond the maximum number of keys** if you do not want old keys saved in the keystore after WebSphere Application Server removes their references from the Active key history listing. The Active key history lists the keys that the `KeySetHelper` API is currently tracking. The number of keys in the list is equal to the number of keys that you specify in **Maximum number of keys referenced**.
9. Type a numeric value for the maximum number of keys referenced. For example, if you type 3 and select **Delete key references that are beyond the maximum number of keys**, the fourth key version generation automatically triggers WebSphere Application Server to delete the first key version from the keystore. If you choose not to delete the old keys, they do not display in the Active key history list but instead remain in the keystore where you can remove them manually.
10. Select a keystore from the drop-down list.
  - Select a JCEKS keystore if you are storing a secret key.
  - Select any keystore if you are storing a key pair with an `X509Certificate` and `PrivateKey` object.
11. Optional: Select **Generates key pair** if your key generator class name implements the `com.ibm.websphere.crypto.KeyPairGenerator` interface instead of the `com.ibm.websphere.crypto.KeyGenerator` interface. This option designates that the key references a key pair instead of a single key. A key pair contains both a public key and a private key. The WebSphere Application Server run time determines whether or not key pairs are stored and loaded differently than single keys.
12. Optional: Click **Apply** if you want to select **Active key history** under Additional Properties to add alias references or generate more keys.
  - a. Click **Active key history**.
  - b. Click **Add key alias reference** if you are not using the key generator class name to add key alias references to the keys that already exist in the keystore. Use this option to retrieve the keys from a read-only keystore without the key set generating them.
  - c. Type an alias reference.
  - d. Click **Generate key** if you want to generate a key using the class name that you defined in the key sets panel. Each new key increments numerically, for example, `myAlias_2`.
  - e. Click **Apply**.
13. Click the key set name in the navigation path at the top of the panel.
14. Click **OK** and **Save**.

## Results

You have created a key set that you can manage using the **Active key history** link. You can generate keys manually to associate them with specified key sets.

## What to do next

After you generate new keys from a key set, you can access them programmatically using the `com.ibm.websphere.crypto.KeySetHelper` API. You must have Java 2 Security permissions, if enabled, to access keys in key sets. Specify the key set name within the fine-grained permissions, as in the following code sample: `WebSphereRuntimePermission "getKeySets.keySetName".` For more information, see “Example: Retrieving the generated keys from a key set group” on page 2036. To generate multiple key

types at the same time or to schedule the key generation on a specific schedule, see “Creating a key set group configuration” on page 2035.

## Active key history collection

Use this page to manage key alias references.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration > Key Sets > key set > Active key history**.

Table 169. Active key history buttons. This table lists the active key history buttons.

Button	Resulting action
<b>Add key alias reference</b>	Adds a reference to a key that already exists in a key store. If a key generation class is configured, the references are added automatically during generation and do not need to be added manually.
<b>Delete</b>	Deletes an existing key reference. This action does not delete the key in the keystore.
<b>Generate key</b>	Generates a key. The button is displayed only if a generator class name is specified for the key set, and the selected key store is editable.

### **Alias reference:**

Specifies the name of the alias as it appears in the keystore.

## Add key alias reference settings

Use this page to access key alias reference information.

To view this administrative console page, Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key Sets > key set**. Under Additional Properties, click **Active key history** then click the **Add key alias reference** button.

### **Alias reference:**

Specifies the name of the alias as it appears in the key store.

**Data type:** Text

### **Password:**

Specifies the key password to get access to the key. This password is enforced by the keystore for that specific key. If the key does not have a password, this field can be left blank.

**Data type:** Text

### **Confirm password:**

Confirms the password entered in the previous field.

**Data type:** Text

## Key sets collection

Use this page to manage key sets, which control a set of key instances of the same type for use in cryptographic operations. The keys can either be generated using a custom class or reference keys that already exist in a keystore.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key sets**.

Table 170. Key set buttons. This table lists the key set buttons.

Button	Resulting action
New	Adds a new key set.
Delete	Deletes an existing key set. Make sure the key set is not referenced by a key set group before deleting it.

**Key set name:**

Specifies the key set name that is used to select the key set from a key set group and from runtime application programming interfaces (API).

**Key store:**

Specifies the key store that contains the keys for storage, retrieval, or both.

**Key alias prefix name:**

Specifies the prefix for the key alias when a new key is generated and stored in a key store. The rest of the key alias comes from the key reference version number.

For example, if the alias prefix is mykey and the key reference version is 2, the keystore references the key using alias mykey\_2. If the key reference already has a specified alias for a key already existing in the keystore, this field is ignored.

**Key sets settings**

Use this page to set the properties for a new key set.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key sets > New**.

**Key set name:**

Specifies the key set name that is used to select the key set from a key set group and from runtime application programming interfaces (API).

**Data type:** Text

**Management scope:**

Specifies the scope where this Secure Sockets Layer (SSL) configuration is visible. For example, if you choose a specific node, then the configuration is only visible on that node and any servers that are part of that node.

**Data type:** List  
**Range:** Applicable scopes

**Key alias prefix name:**

Specifies the prefix for the key alias when a new key is generated and stored in a keystore. The rest of the key alias comes from the key reference version number. For example, if the alias prefix is mykey and

the key reference version is 2, the keystore references the key using alias mykey\_2. If the key reference already has a specified alias for a key already existing in the keystore, this field is ignored.

**Data type:** Text

***Key password:***

Specifies the password used to protect the key in the keystore. If a password is specified in the key reference as well, this password is ignored. This password is used for keys that get generated by a key generator class.

**Data type:** Text

***Confirm password:***

Specifies the same password again to confirm it was entered correctly the first time.

**Data type:** Text

***Key generator class name:***

Specifies the class name that generates keys. If the class implements com.ibm.websphere.crypto.KeyGenerator, then a getKey() method should return a java.security.Key object that is set in the key store using the setKey method without a certificate chain. The key store type associated with the key set must support storing keys without certificates, such as JCEKS.

**Data type:** Text

If the class implements com.ibm.websphere.crypto.KeyPairGenerator, then a getKeyPair() method should return a com.ibm.websphere.crypto.KeyPair object containing either a java.security.PublicKey and java.security.PrivateKey, or a java.security.cert.Certificate[] and a java.security.PrivateKey. The key generator class and the caller of the KeySetHelper API should know the details of the keys that are generated. This framework does not need to understand the key algorithms and lengths.

*Delete key references that are beyond the maximum number of keys:*

Specifies that the keys are deleted from the keystore at the same time that the key reference is deleted. The server deletes the older key references as the Maximum number of keys referenced value is exceeded.

***Maximum number of keys referenced:***

Specifies the maximum number of key instances that are returned when keys from this key set are requested. The oldest key reference gets removed whenever a new key reference gets generated after the maximum has been reached.

**Data type:** Integer

**Default:** 3

***Key store:***

Specifies the key store that contains the keys for storage, retrieval, or both.

Data type:

Text

### ***Generates key pair:***

Specifies that a key references a key pair instead of a key. The key pair contains both a public key and a private key.

## **Creating a key set group configuration**

A key set group manages one or more key sets. WebSphere Application Server uses key set groups to automatically generate cryptographic keys or multiple synchronized key sets.

### **About this task**

Complete the following steps in the administrative console:

### **Procedure**

1. Decide whether you want to create the key set group at the cell scope or below the cell scope at the node, server, or cluster, for example.
  - To create a key set group at the cell scope, click **Security > SSL certificate and key management > Key set groups**.
  - To create a key set group at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > SSL\_configuration > Key set groups**.
2. You can choose to generate a key for an existing key set group, delete an existing key set group, or create a new key set group.
  - To generate a key for an existing key set group, select a key set group from the list of existing key set groups, and click **Generate keys**. You have generated a new key for each key set in the selected group.
  - To delete an existing key set group, select a key set group from the list of existing key set groups, and click **Delete**. You have deleted the key set group.
  - To create a new key set group, go to step 3.

#### **CAUTION:**

**Do not delete the cell or node LTPAKeySetGroup, which is used by the Lightweight Third Party Authentication (LPTA) mechanism.**

3. Click **New** to create a new key set group.
4. Type a key set group name. You can reference this name by using the `com.ibm.websphere.crypto.KeySetHelper` API to retrieve the managed keys from an application.
5. Select one or more key sets from the Key sets list.

**Note:** If the key set(s) you want is not listed, make sure that it was created at the same scope or a higher scope than where you are creating the new key set group.

6. Click **Add** to add the selected key set(s) to the new key set group.
7. Select **Automatically generate keys** to generate the new keys on a schedule. If you decide to generate keys automatically, then you must specify a scheduled time of day.
8. Specify the scheduled time to generate keys automatically in hours and minutes, A.M. or P.M., or every 24 hours.
9. You can choose to generate new keys on a specific day or at an interval.
  - Select **Generate on a specific day**. Select a day of the week from the drop-down list, and type a repeat interval number for the number of days between each key generation. This choice enables you to schedule key generation when your systems are least busy.

- Select **Generate at an interval**. Type a repeat interval number for the number of days between each key generation. This choice enables you to schedule key generation more frequently than once a week.

**Note:** The **Next start date** is a read-only field that specifies the date for the next scheduled generation. You can stop and restart the deployment manager or base application server without resetting this date. If you do not see the next start date appear after changing the configuration, click **OK** to save it, then check that the next start date displays.

10. Click **Save**.

## Results

You have created a new key set group to manage key sets and key generation on a schedule.

## What to do next

After you generate new keys from a key set, you can access them programmatically using the `com.ibm.websphere.crypto.KeySetHelper` API. You must have Java 2 Security permissions, if enabled, to access keys in key sets. Specify the key set name within the fine-grained permissions, as in the following code sample: `WebSphereRuntimePermission "getKeySets.keySetName".` For more information, see “Example: Retrieving the generated keys from a key set group.”

### Example: Retrieving the generated keys from a key set group

This example shows how applications can use the `com.ibm.websphere.crypto.KeySetHelper` API to retrieve managed keys from the `KeySet` or `KeySetGroup` configurations. Use the `com.ibm.websphere.crypto.KeySetHelper` API to get either the latest set of keys or all the keys in the `KeySet` or `KeySetGroup` object.

Use the latest keys when performing any new cryptographic operations. All of the other keys that are defined in the `KeySet` or `KeySetGroup` object are for the validation of previously performed cryptographic operations.

The following example uses a method that an application might use to initialize the keys in the associated `KeySetGroup` object. The application might want to store the keys in two separate maps, one for generation and one for validation. Refer to the API documentation for `KeySetHelper` API to determine which Java 2 Security requirements are required.

```
/**
 * Initializes the primary and secondary Maps used for initializing the keys.
 */
public void initializeKeySetGroupKeys() throws com.ibm.websphere.crypto.KeyException
{
 java.util.Map generationKeys = null;
 java.util.Map validationKeys = null;

 PublicKey tempPublicKey = null;
 PrivateKey tempPrivateKey = null;
 byte[] tempSharedKey = null;

 keySetGroupName = "ApplicationKeySetGroup";
 com.ibm.websphere.crypto.KeySetHelper ksh = com.ibm.websphere.crypto.KeySetHelper.getInstance();
 generationKeys = ksh.getLatestKeysForKeySetGroup(keySetGroupName);

 /**
 * Latest keys: {
 * KeyPair_3=com.ibm.websphere.crypto.KeyPair@64ec64ec,
 * Secret_3=javax.crypto.spec.SecretKeySpec@fffe8aa7
 * }
 */
 /**
 */

 if (generationKeys != null)
 {
 Iterator iKeySet = generationKeys.keySet().iterator();

 while (iKeySet.hasNext())
 {
 String keyAlias = (String)iKeySet.next();
 }
 }
}
```

```

 Object key = generationKeys.get(keyAlias);

 if (key instanceof java.security.Key)
 {
 tempSharedKey = ((java.security.Key)key).getEncoded();
 }
 else if (key instanceof com.ibm.websphere.crypto.KeyPair)
 {
 java.security.Key publicKeyAsSecret =
 ((com.ibm.websphere.crypto.KeyPair)key).getPublicKey();
 tempPublicKey = new PublicKey(publicKeyAsSecret.getEncoded());
 java.security.Key privateKeyAsSecret =
 ((com.ibm.websphere.crypto.KeyPair)key).getPrivateKey();
 tempPrivateKey = new PrivateKey(privateKeyAsSecret.getEncoded());
 }
 }

 // save these for use later, if necessary
 validationKeys = ksh.getAllKeysForKeySetGroup(keySetGroupName);

 /**
 * All keys: {
 * version_1=
 * {Secret_1=javacx.crypto.spec.SecretKeySpec@178cf,
 * KeyPair_1=com.ibm.websphere.crypto.KeyPair@1c121c12},
 * version_2=
 * {Secret_2=javacx.crypto.spec.SecretKeySpec@17a77,
 * KeyPair_2=com.ibm.websphere.crypto.KeyPair@182e182e},
 * version_3=
 * {Secret_3=javacx.crypto.spec.SecretKeySpec@fffe8aa7,
 * KeyPair_3=com.ibm.websphere.crypto.KeyPair@4da04da0}
 * }
 */
 }
 else
 {
 throw new com.ibm.websphere.crypto.KeyException("Could not generateKeys.");
 }
}

```

## Example: Developing a key or key pair generation class for automated key generation

A class that generates keys for cryptographic operations can be created automatically. With this capability, the key management infrastructure can maintain a list of keys for a predefined key set, and applications can access these keys.

You can schedule new key generation at predefined frequencies. Remember that key generation frequency affects the security of your data. For example, for persistent data, you might schedule key generation less frequently than for real time communications, which require that the keys be generated more often as old keys expire.

When you develop a key generation class, decide if you are creating a shared key or a key pair because this decision determines the interface you must use.

If you are developing shared keys, refer to the following example, which uses the KeyGenerator class to implement the com.ibm.websphere.crypto.KeyGenerator interface. The interface returns a java.security.Key key, which is stored as a SecretKey in a JCEKS keystore type. You can use any other keystore type that supports storing secret keys.

```

package com.ibm.test;

import java.util.*;
import com.ibm.ws.ssl.core.*;
import com.ibm.ws.ssl.config.*;
import com.ibm.websphere.crypto.KeyException;

public class KeyGenerator implements com.ibm.websphere.crypto.KeyGenerator
{
 private java.util.Properties customProperties = null;
 private java.security.Key secretKey = null;

 public KeyGenerator()
 {
 }

 /**
 * This method is called to pass any custom properties configured with
 * the KeySet to the implementation of this interface.
 */
}

```

```

 *
 * @param java.util.Properties
 **/
public void init (java.util.Properties customProps)
{
 customProperties = customProps;
}

/**
 * This method is called whenever a key needs to be generated either
 * from the schedule or manually requested. The key is stored in the
 * KeyStore referenced by the configured KeySet that contains the
 * keyGenerationClass implementing this interface. The implementation of
 * this interface manages the key type. The user of the KeySet
 * must know the type that is returned by this keyGenerationClass.
 *
 * @return java.security.Key
 * @throws com.ibm.websphere.crypto.KeyException
 **/
public java.security.Key generateKey () throws KeyException
{
 try
 {
 // Assume generate3DESKey is there to create the key.
 byte[] tripleDESKey = generate3DESKey();
 secretKey = new javax.crypto.spec.SecretKeySpec(tripleDESKey, 0, 24, "3DES");

 if (secretKey != null)
 {
 return secretKey;
 }
 else
 {
 throw new com.ibm.websphere.crypto.KeyException ("Key could not be generated.");
 }
 }
 catch (Exception e)
 {
 e.printStackTrace(); // handle exception
 }
}
}

```

If you are developing a key pair, refer to the following example, which uses the KeyPairGenerator class to implement the com.ibm.websphere.crypto.KeyPairGenerator interface.

```

package com.ibm.test;

import java.util.*;
import javax.crypto.spec.SecretKeySpec;
import com.ibm.websphere.crypto.KeyException;

/**
 * This implementation defines the method to generate a java.security.KeyPair.
 * When a keyGeneration class implements this method, the generateKeyPair method
 * is called and a KeyPair is stored in the keystore. The isKeyPair
 * attribute is ignored since the KeyGenerationClass is an
 * implementation of KeyPairGenerator. The isKeyPair attributes is for when
 * the keys already exist in a KeyStore, and are just read (not
 * generating them).
 *
 * @author IBM Corporation
 * @version WebSphere Application Server 6.1
 * @since WebSphere Application Server 6.1
 **/
public class KeyPairGenerator implements com.ibm.websphere.crypto.KeyPairGenerator
{
 private java.util.Properties customProperties = null;

 public KeyPairGenerator()
 {
 }

 /**
 * This method is called to pass any custom properties configured with
 * the KeySet to the implementation of this interface.
 *
 * @param java.util.Properties
 **/
 public void init (java.util.Properties customProps)
 {
 customProperties = customProps;
 }

 /**
 * This method is called whenever a key needs to be generated either
 * from the schedule or manually requested and isKeyPair=true in the KeySet
 * configuration. The key is stored in the KeyStore referenced by
 * the configured KeySet which contains the keyGenerationClass implementing

```

```

* this interface. The implementation of this interface manages the
* type of the key. The user of the KeySet must know the type that
* is returned by this keyGenerationClass.
*
* @return com.ibm.websphere.crypto.KeyPair
* @throws com.ibm.websphere.crypto.KeyException
**/
public com.ibm.websphere.crypto.KeyPair generateKeyPair () throws KeyException
{
 try
 {
 java.security.KeyPair keyPair = generateKeyPair();

 // Store as SecretKeySpec
 if (keyPair != null)
 {
 java.security.PrivateKey privKey = keyPair.getPrivate();
 java.security.PublicKey pubKey = keyPair.getPublic();

 SecretKeySpec publicKeyAsSecretKey = new SecretKeySpec
 (pubKey.getEncoded(), "RSA_PUBLIC");
 SecretKeySpec privateKeyAsSecretKey = new SecretKeySpec
 (privKey.getEncoded(), "RSA_PRIVATE");

 com.ibm.websphere.crypto.KeyPair pair = new
 com.ibm.websphere.crypto.KeyPair(publicKeyAsSecretKey, privateKeyAsSecretKey);
 return pair;
 }
 else
 {
 throw new com.ibm.websphere.crypto.KeyException ("Key pair could
 not be generated.");
 }
 }
 catch (Exception e)
 {
 e.printStackTrace(); // handle exception
 }
}
}

```

This interface returns a `com.ibm.websphere.crypto.KeyPair` key pair, which can contain either a `X509Certificate` and `PrivateKey` object or `PublicKey` and `PrivateKey` objects. If the `com.ibm.websphere.crypto.KeyPair` interface contains a `X509Certificate` and `PrivateKey` object, the certificate and private key are stored in the keystore. Consequently, they can use any `KeyStore` type.

If the `com.ibm.websphere.crypto.KeyPair` interface contains `PublicKey` and `PrivateKey` objects, you must convert the encoded values to the `SecretKeySpec` object in order to store them. The WebSphere Application Server runtime stores and retrieves the key pair as secret keys. The runtime converts the key pair back to `PublicKey` and `PrivateKey` objects when the server retrieves the pair during the handshake.

Use the following constructors to develop the `com.ibm.websphere.crypto.KeyPair` interface:

- Public and private constructor

```
public KeyPair(java.security.Key publicKey, java.security.Key privateKey)
```

- Certificate and private constructor.

```
public KeyPair(java.security.cert.Certificate[] certChain,
java.security.Key privateKey)
```

The previous example code shows the `KeyPairGenerator` class using the public and private constructor. Each call to this class generates a new and unique key pair, and this class is invoked by a `KeySet` to create a new key pair when `isKeyPair=true`. The version number in the key set increments each time it is called.

## Key set groups collection

Use this page to manage groups of public, private, and shared keys. These key groups enable the application server to control multiple sets of Lightweight Third Party Authentication (LTPA) keys.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl\_configuration***. Under Related items, click **Key set groups**.

Table 171. Key set groups buttons. This table lists the key set groups buttons.

Button	Resulting action
<b>New</b>	Adds a key set group. A key set group combines one or more key sets together as a single key set group. It allows the generation of multiple different types of keys to occur at the same time. A single key set represents one type of key, so a key set group allows you to group the different types.
<b>Delete</b>	Deletes an existing key set group. You must be sure that there are no other references to this key set group before you delete it.
<b>Generate keys</b>	Generates keys for key set group. The system generates keys for each key set within the key set group so that the keys remain synchronized with each other in terms of version. You must configure a valid key generation class and a key store that is writable. See the <code>com.ibm.websphere.crypto.KeySetHelper</code> application programming interfaces (APIs) to enable the use of keys that are managed by a <code>KeySetGroup</code> or <code>KeySet</code> .

**Key set group name:**

Specifies the name of the key set group used to reference it.

**Automatically generate keys:**

Specifies that the keys are to be generated automatically on a schedule.

**Key set groups settings**

Use this page to create new key set groups.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > ssl\_configuration**. Under Related items, click **Key set groups > New**.

**Key set group name:**

Specifies the name of key set group used. This name can be referenced using the `com.ibm.websphere.crypto.KeySetHelper` API to retrieve the managed keys from an application.

**Data type:** Text

**Management scope:**

Specifies the scope where this Secure Sockets Layer (SSL) configuration is visible. For example, if you choose a specific node, then the configuration is only visible on that node and any servers that are part of that node.

**Data type** List  
**Range:** Applicable scopes

**Key sets:**

Specifies a set of key instances of the same type for use in cryptographic operations.

This setting has the following options:

**Add** Specifies to add the selected key set part of this key set group.

**Remove**  
 Specifies to remove the selection from the **Key sets** list.

**Automatically generate keys:**

Specifies that the keys are generated automatically on a schedule. When a new key is generated, the `security.xml` is updated and saved by the runtime to track the key reference version. This can cause save conflicts when updating the same file from admin applications.

**gotcha:** Starting with Versions 6.1.0.23 and 7.0.0.3, the default value for this property is Disabled.

If you try to enable this property, and automatic synchronization is off in any node, the following administrative console message displays:

Warning: At least one node in the cell was unreachable or is not configured to automatically synchronize. It is strongly recommended that you verify your node settings, and do not enable automatic generation of LTPA keys while automatic synchronization is disabled on any node.

<b>Default for Versions 7.0, and 7.0.0.1:</b>	Enabled
<b>Default for Versions 7.0.0.3 and higher:</b>	Disabled

### ***Scheduled time for generation:***

Specifies the scheduled time when the system generates selected key set group or groups. You can specify the scheduled time in hours and minutes; specify either A.M. or P.M., or specify 24-hour. You can also specify the day of the week you want the scheduled event to occur. It is recommended that you set this event to occur during a low peak time, especially for keys that are used by runtime for token validation.

<b>Data type</b>	Integer
<b>Default:</b>	8, 0 A.M.
<b>Range:</b>	1–12, with a A.M. or P.M. setting 0–59, with a 24-hour setting

### ***Generate on a specific day:***

Specifies whether to have the generation occur on a specific day of the week. It is best to auto-generate keys during a low peak day.

This setting has the following options:

#### **Weekday**

Specifies the day of the week on which the expiration monitor will run if the Check on a specific day option is selected.

<b>Default:</b>	Sunday
<b>Range:</b>	Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday

#### **Repeat interval**

Specifies the period of time, in weeks, between each schedule time to check for expired certificates or the interval between schedule checks.

<b>Default:</b>	4 weeks
-----------------	---------

### ***Generate at an interval:***

Specifies to generate keys at the specified frequency regardless of the day of the week on which generation occurs.

<b>Default:</b>	Disabled
-----------------	----------

This setting has the following options:

**Repeat interval**

Specifies the period of time, in days, between each schedule time to check for expired certificates or the interval between schedule checks.

**Default:** 7 days

**Next start date:**

Specifies the date for the next scheduled check. This allows the deployment manager to be stopped and restarted without resetting the date.

---

## Auditing the security infrastructure

You can use the Auditing Facility to report and track auditable events to ensure the integrity of your system.

### Before you begin

Before enabling the security auditing subsystem, you must enable global security in your environment.

### About this task

**Note:** The security auditing subsystem has been introduced as part of the security infrastructure. The primary responsibility of the security infrastructure is to prevent unauthorized access and usage of resources. Utilizing security auditing has two primary goals:

- Confirming the effectiveness and integrity of the existing security configuration.
- Identifying areas where improvement to the security configuration might be needed.

Security auditing achieves these goals by providing the infrastructure that allows you to implement your code to capture and store supported auditable security events. During run time, all code other than the Java EE 5 application code is considered to be trusted. Each time a Java EE 5 application accesses a secured resource, any internal application server process with an audit point included can be recorded as an auditable event.

The security auditing subsystem has the ability to capture the following types of auditable events:

- Authentication
- Authorization
- Principal/Credential Mapping
- Audit policy management
- Delegation

**Restriction:** Audit instrumentation has not been included in the web services client run time.

These types of events can be recorded into audit log files. Each audit log has the option to be signed and encrypted to ensure data integrity. These audit log files can be analyzed to discover breaches over the existing security mechanisms and to discover potential weaknesses in the current security infrastructure. Security event audit records are also useful for providing evidence of accountability and nonrepudiation as well as vulnerability analysis. The security auditing configuration provides four default filters, a default audit service provider, and a default event factory. The default implementation write to a binary text-file based log. Use this topic to customize your security auditing subsystem.

## Procedure

1. “Enabling the security auditing subsystem” on page 2044

Security auditing will not be performed unless the audit security subsystem has been enabled. Global security must be enabled for the security audit subsystem to function, as no security auditing occurs if global security is not also enabled.

2. Assign the auditor role to a user

A user with the auditor role is required to enable and configure the security auditing subsystem. It is important to require strict access control for security policy management. The auditor role has been created providing granularity to allow for separation of the auditing role from the authority of the administrator. When Security Auditing is initially enabled, the cell administrator has auditor privileges. If the environment requires separation of privileges, then changes will need to be made to the default role assignments.

3. “Creating security auditing event type filters” on page 2049

You can configure event type filters to only record a specific subset of auditable event types in your audit logs. Filtering the event types that are recorded makes for easier analysis of your audit records by ensuring only those records important to your environment are archived.

4. Configuring the audit service provider.

The audit service provider is used to format the audit data object that was passed to it before outputting the data to a repository. A default audit service provider implementation is included. See “Configuring the default audit service providers for security auditing” on page 2060 for more details on the default implementation. A third party implementation can also be coded and used. See “Configuring a third party audit service providers for security auditing” on page 2064 for more details on this implementation.

An implementation for SMF is also available. See “Configuring the SMF audit service providers for security auditing” on page 2065 for more details on this implementation.

5. “Configuring audit event factories for security auditing” on page 2066

The audit event factory gathers the data associated with the auditable events and creates an audit data object. The audit data object is then sent to the audit service provider to be formatted and recorded to the repository.

6. “Protecting your security audit data” on page 2070

It is important to secure and ensure the data integrity of the recorded audit data. To ensure that access to the data is restricted and tamper proof, you can encrypt and sign your audit data.

7. “Configuring security audit subsystem failure notifications” on page 2057

Notifications can be enabled to generate alerts when the security auditing subsystem experiences a failure. Notifications can be configured to record an alert in the System logs or can be configured to send an alert through email to a specified list of recipients.

## Results

After successfully completing this task, you audit data will be recorded for the selected auditable events that were specified in the configuration.

## What to do next

After configuring security auditing, you can analyze your audit data for potential weaknesses in the current security infrastructure and to discover security breaches that may have occurred over the existing security mechanisms. You can also use the security auditing subsystem to provide data for problem determination. If the default audit service provider was selected, the resulting binary audit log file can be read using the Audit Reader.

## Enabling the security auditing subsystem

Security auditing will not be performed unless the audit security subsystem has been enabled. Global security must be enabled for the security audit subsystem to function, as no security auditing occurs if global security is not also enabled.

### Before you begin

Before enabling security auditing subsystem, enable global security in your environment.

### About this task

The recording of auditable security events is achieved by enabled the security auditing subsystem. Follow these steps to enable the security auditing subsystem.

### Procedure

1. Click **Security > Security auditing**.
2. Select Enable security auditing. The Enable security auditing check box is not selected by default. This check box must be selected to allow security auditing to be performed with the configurations that have been specified in the `audit.xml` file.

**Note:** The `audit.xml` file is used to store the audit subsystem configurations. Changes to the security auditing subsystem should be made with the user interface or the `wsadmin` utility. This file should not be edited manually.

3. Select the action from the Audit subsystem failure action dropdown menu to be perform when an audit subsystem failure occurs. Notifications configured to warn of a security auditing subsystem failure will not be posted if the No Warning option is selected for this field. If you select either the Log warning or the Terminate server option, then you must also configure a notification for the action to be performed.
4. Select the Auditor ID from the dropdown menu. The auditor role is needed to make changed to the security auditing configurations. By default, when auditing is first enabled, the primary administrator is also given the auditor role. The primary administrator can then add the auditor role to other users. After the auditor role is added to other users, the auditor role can be removed from the administrator to create a separation of authority between the auditor and the administrator. The Auditor ID is the user considered to be the primary auditor.
5. Optional: Select Enable verbose auditing. When an auditable event is recorded, a default set of audit data is included in the audit data object and recorded to the repository. An additional set of audit data is made available by enabling verbose auditing.
6. Click **Apply**.
7. Restart the application server. The application server must be restarted before the changes go into effect.

### Results

The successful completion of these steps results in the security auditing subsystem being enabled.

### What to do next

After enabling the security auditing subsystem, refinements can be made to the configuration. You might want to modify the access control of the audit subsystem to separate the authority of the administrator from the authority of the auditor. If no changes to your access control are needed, then you can configure the types of auditable security events should be recorded. To configure the types of events that are recorded, click **Event type filters**.

## Security Auditing detail

The Security auditing subsystem can be enabled and configured from this panel, by users assigned the auditor role.

To view this administrative console page, click **Security > Security Auditing**. If Enable security auditing is not selected, then all of the other fields on this panel will be disabled.

### ***Enable security auditing:***

The Enable security auditing check box allows users to enable or disable Security Auditing. By default, Security Auditing will not be enabled. This field corresponds with the `auditEnabled` field in the `audit.xml` file.

### ***Audit subsystem failure action:***

The Audit subsystem failure action setting describes the behavior of the application server in the event of a failure in the auditing subsystem. Audit Notifications must be configured in order for notifications of a failure in the audit subsystem to be logged. If security auditing is not enabled, then these actions will not be performed. Failures can include an error in the interface or in the event processing. By default, the audit subsystem failure action setting is set to No warning.

The Audit subsystem failure action dropdown menu has the following options:

- No warning  
The No warning action specifies that the auditor will not be notified of a failure in the audit subsystem. The product will continue processing but audit reporting will be disabled.
- Log warning  
The Log warning action specifies that the auditor will be notified of a failure in the audit subsystem. The product will continue processing but audit reporting will be disabled.
- Terminate server  
The Terminate server action specifies the application server to gracefully quiesce when an unrecoverable error occurs in the auditing subsystem. If email notifications are configured, the auditor will be sent a notification that an error has occurred. If logging to the system log is configured, the notification of the failure will be logged to the system file.

### ***Primary auditor user name:***

The Primary auditor user name dropdown menu defines a valid user which exists in the current user registry and for whom the auditor role has been given. By default, this field is blank and is a required field.

### ***Enable verbose auditing:***

The Enable verbose auditing option determines the amount of audit data that is reported in an audit record. Verbose mode captures all the auditable data points, whereas not enabling verbose mode captures only a subset of the available data. This option is disabled by default.

## Context object fields

Each auditable event has an associated set of information that is available for logging. This information is grouped into specific context objects. The context objects that are available for logging a specific event are specified by the event type. This topic details the information that exists for each context object and specifies whether the information is logged by default or is only logged when the verbose logging option is enabled.

## The SessionContextObj object

Table 172. SessionContextObj fields. This table lists the SessionContextObj fields.

Field	Type	Description	Default or Verbose logging
sessionId	String	An identifier for the user session	Default
remoteAddr	String	The IP address for the remote host	Default
remotePort	String	The port of the remote host	Default
remoteHost	String	The host name of the remote host	Default

## The PropagationContextObj object

Table 173. PropagationContextObj fields. This table lists the PropagationContextObj fields.

Field	Type	Description	Default or Verbose logging
firstCaller	String	The identity of the first user in the caller list	Default
callerList	String array	A list of names representing the identities of the users	Verbose

## The RegistryContextObj object

Table 174. RegistryContextObj fields. This table lists the RegistryContextObj fields.

Field	Type	Description	Default or Verbose logging
type	String	The type of user registry being used, such as LDAP or AIX	Default

## The ProcessContextObj object

Table 175. ProcessContextObj fields. This table lists the ProcessContextObj fields.

Field	Type	Description	Default or Verbose logging
domain	String	The domain to which the user belongs	Verbose
realm	String	The registry partition to which the user belongs	Default

## The EventContextObj object

Table 176. EventContextObj fields. This table lists the EventContextObj fields.

Field	Type	Description	Default or Verbose logging
lastEventTrailId	String	The last ID associated with a given transaction	Verbose
eventTrailId	String array	An array of IDs that allow events that belong to a given transaction to be correlated	Default
creationTime	Date	The date an event was created	Default
globalInstanceId	Long	The unique identifier of this event	Default

## The DelegationContextObj object

Table 177. DelegationContextObj fields. This table lists the DelegationContextObj fields.

Field	Type	Description	Default or Verbose logging
delegationType	String	no delegation, simple delegation, method delegation or switch user delegation	Default
roleName	String	The Run as role being used: runAsClient, runAsSpecified, runAsSystem, own ID	Default
identityName	String	Information about the mapped user	Default

## The AuthnContextObj object

Table 178. AuthnContextObj fields. This table lists the AuthnContextObj fields.

Field	Type	Description	Default or Verbose logging
authnType	String	The type of authentication used	Default

## The ProviderContextObj object

Table 179. ProviderContextObj fields. This table lists the ProviderContextObj fields.

Field	Type	Description	Default or Verbose logging
provider	String	The provider of the authentication or authorization service	Default
providerStatus	String	Status of whether the authentication or authorization event processed successfully by the provider	Default

## The AuthnMappingContextObj object

Table 180. AuthnMappingContextObj fields. This table lists the AuthnMappingContextObj fields.

Field	Type	Description	Default or Verbose logging
mappedSecurityDomain	String	The security domain after mapping has occurred	Default
mappedRealm	String	The realm after mapping has occurred	Default
mappedUserName	String	The user name after mapping has occurred	Default

## The AuthnTermContextObj object

Table 181. AuthnTermContextObj fields. This table lists the AuthnTermContextObj fields.

Field	Type	Description	Default or Verbose logging
terminateReason	String	The reason authentication ended	Default

## The AccessContextObj object

Table 182. AccessContextObj fields. This table lists the AccessContextObj fields.

Field	Type	Description	Default or Verbose logging
progName	String	The name of the program that was involved in the event	Default
action	String	The action being performed.	Default
registryUserName	String	The name of the user in the registry	Default
appUserName	String	The name of the user within an application	Default
accessDecision	String	The decision of the authorization call	Default
resourceName	String	The name of the resource in the context of the application	Default
resourceType	String	The type of resource	Default
resourceUniqueld	Long	The unique identifier of the resource	Default
permissionsChecked	String array	The permissions that were checked during the authorization call	Default
permissionsGranted	String array	The permissions that were granted during the authorization call	Default
rolesChecked	String array	The roles that were checked during the authorization call	Default

Table 182. *AccessContextObj* fields (continued). This table lists the *AccessContextObj* fields.

Field	Type	Description	Default or Verbose logging
rolesGranted	String array	The roles that were granted during the authorization call	Default

## The PolicyContextObj object

Table 183. *PolicyContextObj* fields. This table lists the *PolicyContextObj* fields.

Field	Type	Description	Default or Verbose logging
policyName	String	The name of the policy	Default
policyType	String	The type of policy	Default

## The KeyContextObj object

Table 184. *KeyContextObj* fields. This table lists the *KeyContextObj* fields.

Field	Type	Description	Default or Verbose logging
keyLabel	String	The key or certificate label	Default
keyLocation	String	The physical location of the key database	Default
certLifetime	Date	The date when a certificate expires	Default

## The CipherContextObj object

Table 185. *CipherContextObj* fields. This table lists the *CipherContextObj* fields.

Field	Type	Description	Default or Verbose logging
cipherData	Byte array	The cipher data that is captured	Verbose

## The MgmtContextObj object

Table 186. *MgmtContextObj* fields. This table lists the *MgmtContextObj* fields.

Field	Type	Description	Default or Verbose logging
mgmtType	String	The type of management operation	Default
mgmtCommand	String	The application-specific command that was performed	Default
targetInfoAttributes	Target Attribute array	Information about one or more secondary objects involved in this operation	Verbose

## The ResponseContextObj object

Table 187. *ResponseContextObj* fields. This table lists the *ResponseContextObj* fields.

Field	Type	Description	Default or Verbose logging
url	String	The URL of the HTTP request	Default
httpRequestHeaders	Attributes array	The HTTP request headers provided by the client	Verbose
httpResponseHeaders	Attributes array	The HTTP response headers returned by the server	Verbose

## The CustomPropertyContextObj object

Table 188. *CustomPropertyContextObj* fields. This table lists the *CustomPropertyContextObj* fields.

Field	Type	Description	Default or Verbose logging
key	String	The label representing the custom property key name	Verbose

Table 188. CustomPropertyContextObj fields (continued). This table lists the CustomPropertyContextObj fields.

Field	Type	Description	Default or Verbose logging
value	Object	The object value of the custom property	Verbose

## Creating security auditing event type filters

Event type filters are used to specify the types of auditable security events that are audited. Default event type filters are included with the product, but you can also configure new event type filters to specify a subset of auditable event types to be recorded by the security auditing subsystem.

### Before you begin

Before configuring security auditing filters and the rest of the security auditing subsystem, enable global security in your environment. You must be assigned the auditor role to complete this task. Event type filters are used to specify what events are audited. The amount of data that is recorded for each event is specified with the **Enable verbose auditing** check box on the same panel used to enable the auditing subsystem. Navigate to **Security > Security auditing** to enable security auditing and determine the data recorded for each event.

### About this task

Table 189. Commonly used event type filters by default in the audit.xml template file. The application server provides the following commonly used event type filters by default in the audit.xml template file:

Name	Event name	Outcome of event
DefaultAuditSpecification_1	SECURITY_AUTHN	SUCCESS
DefaultAuditSpecification_2	SECURITY_AUTHN	DENIED
DefaultAuditSpecification_3	SECURITY_RESOURCE_ACCESS	SUCCESS
DefaultAuditSpecification_4	SECURITY_AUTHN	REDIRECT

New event type filters can be created, or the existing default filters can be extended, to capture more event types and outcomes. Use this task to create new event type filters.

### Procedure

1. Click **Security > Security Auditing > Event type filters > New**.
2. Enter the unique name that should be associated with this event type filter configuration in the Name field.
3. Specify the events that should be recorded when this filter is applied:
  - a. Select the events that you want to be audited from the Selectable events list.
  - b. Click **Add >>** to add the selected events to the Enabled events list.
  - c. Select the outcomes that you want to be audited from the Selectable event outcomes list.
  - d. Click **Add >>** to add the selected outcomes to the Enabled event outcomes lists.
4. Click **OK**.

### Results

The successful completion of this task results in the creation of an event type filter that can be selected by the audit service providers and audit event factories to gather and record a specific set of auditable security events.

## What to do next

After creating an event type filter, the filter must be specified in the audit service provider and the audit event factory to be used to gather or report audit data. The next step in configuring the security auditing subsystem is you should configure an audit service provider to define where the audit data will be archived.

## Auditable security events

Auditable security events are security events that have audit instrumentation added to the security run time code to enable them to be recorded. Event filters are configured to specify which auditable security events are recorded to the audit log files.

The following list describes each valid auditable event that you can specify as an enabled event type when creating an event filter:

*Table 190. Event types. Valid auditable events can be specified as an enabled event type when creating an event filter:*

Event name	Description
SECURITY_AUTHN	Audits all authentication events
SECURITY_AUTHN_MAPPING	Audits events that record mapping of credentials where two user identities are involved
SECURITY_AUTHN_TERMINATE	Audits authentication termination events such as a timeout, terminated session, or user-initiated logging out
SECURITY_AUTHZ	Audits events related to authorization checks when the system enforces access control policies
SECURITY_RUNTIME	Audits runtime events such as the starting and the stopping of security servers. This event type is not meant for administrative operations performed by a system administrator as such operations need to use the other SECURITY_MGMT_* event types.
SECURITY_MGMT_AUDIT	Audits events that record operations related to the audit subsystem such as starting audit, stopping audit, turning audit on or off, changing configuration of audit filters or level, archiving audit data, purging audit data, and so on.
SECURITY_RESOURCE_ACCESS	Audits events that record all accesses to a resource. Examples are all accesses to a file, all HTTP requests and responses to a given web page, and all accesses to a critical database table
SECURITY_SIGNING	Audits events that record signing such as signing operations used to validate parts of a SOAP Message for web services
SECURITY_ENCRYPTION	Audits events that record encryption information such as encryption for web services
SECURITY_AUTHN_DELEGATION	Audits events that record delegation, including identity assertion, RunAs, and low assertion. Used when the client identity is propagated or when delegation involves the use of a special identity. This event type is also used when switching user identities within a given session.
SECURITY_AUTHN_CREDS_MODIFY	Audits events to modify credentials for a given user identity

For each audit event type, you must specify an outcome. Valid outcomes include SUCCESS, FAILURE, REDIRECT, ERROR, DENIED, WARNING, and INFO. Not all outcomes are applicable with all event types.

**Note:** Support for the SECURITY\_RUNTIME auditing event type has been fully implemented for this release of WebSphere Application Server. It audits runtime events such as the starting and the stopping of security servers.

*Table 191. Event Type SMF Codes. The following tables map the Security auditing event types and event outcomes to the SMF interpretations.*

Event name	SMF Code	SMF Unload Keyword
SECURITY_AUTHN	1	*WASAUTN
SECURITY_AUTHN_MAPPING	3	*WASAUTM
SECURITY_AUTHN_TERMINATE	2	*WASAUTT
SECURITY_AUTHZ	4	*WASAUTZ
SECURITY_MGMT_CONFIG	8	*WASCONF
SECURITY_MGMT_POLICY	5	*WASPOLM
SECURITY_MGMT_PROVISIONING	9	*WASPROV
SECURITY_MGMT_RESOURCE	10	*WASRESM
SECURITY_RUNTIME	7	*WASRUNT

Table 191. Event Type SMF Codes (continued). The following tables map the Security auditing event types and event outcomes to the SMF interpretations.

Event name	SMF Code	SMF Unload Keyword
SECURITY_RUNTIME_KEY	11	*WASKEYR
SECURITY_MGMT_KEY	12	*WASKEYM
SECURITY_MGMT_AUDIT	13	*WASAUDI
SECURITY_MGMT_REGISTRY	6	*WASREGM
SECURITY_RESOURCE_ACCESS	14	*WASACCE
SECURITY_SIGNING	15	*WASSIGN
SECURITY_ENCRYPTION	16	*WASCRYP
SECURITY_AUTHN_DELEGATION	17	*WASDELE
SECURITY_AUTHN_CREDS_MODIFY	18	*WASCRED

Table 192. Event Outcome SMF Qualifier. The following table lists the event outcome SMF Qualifier.

Event Outcome	SMF Qualifier	SMF Unload Keyword
SUCCESSFUL	0	SUCCESS
INFO	1	INFO
WARNING	2	WARNING
FAILURE	3	FAILURE
REDIRECT	4	REDIRECT
DENIED	5	DENIED

## Event type filter settings

The Event type filter settings panel is used by an auditor to manage and create event type filters. Default event type filters have been included, this panel allows additional event type filters to be added. Existing event type filters are also managed using this panel.

To view this administrative console page, click one of the following paths:

- **Security > Security Auditing > Event type filters > *event\_type\_filter\_name*.**
- **Security > Security Auditing > Event type filters > New .**

### **Name:**

The Name field specifies the unique name of the event type filter.

### **Enabled:**

The state of enablement of the filter is defined by the Enable check box. This field is represented as a boolean value. A value of true specifies that the enable field associated with the audit specification in the `audit.xml` is set to true. It does not imply that all configured event factories and service providers will be using this filter.

Filters still need to be configured for each event factory and service provider. Filters are enabled by default during configuration. However, if a filter has the enabled checkbox set to false, the filter will not gather or report data for the events and outcomes defined in that filter.

### **Events to associate with an audit filter:**

The Events to associate with an audit filter field specifies the auditable security events to be associated with this filter.

- **Selectable events:**

The Selectable events list displays the available auditable security events. To enable an event for this filter, select the event from the Selectable event outcomes list and then click **Add**.

- Enabled events:

The Enabled events list displays the audit security events that are currently enabled for this filter. To disable an event for this filter, select the event from the Enabled events list and then click **Remove**.

#### ***Event outcomes to associate with an audit filter:***

The Event outcomes to associate with an audit filter field specifies the auditable security event outcomes to be associated with this filter.

- Selectable event outcomes:

The Selectable event outcomes list displays the available auditable security event outcomes. To enable an event outcome for this filter, select the event outcome from the Selectable event outcomes list and then click **Add**.

- Enabled event outcomes:

The Enabled event outcomes list displays the audit security event outcomes that are currently enabled for this filter. To disable an event outcome for this filter, select the event outcome from the Enabled event outcomes list and then click **Remove**.

### **Event type filters collection**

The Event type filters panel displays a listing of all configured audit specifications with their unique names, the state of their enablement, and the event types and event outcomes that are specified for each configuration.

To view this administrative console page, click **Security > Security Auditing > Event type filters**.

#### ***Name:***

The Name field displays the unique name of the event type filter that is being represented.

#### ***Enable:***

The Enable check box species the state of enablement for the filter. This field is represented as a boolean value. A value of true specifies that the enable field associated with the audit specification in the `audit.xml` is set to true. It does not imply that all configured event factories and service providers will be using this filter. Filters are enabled by default when they are created. Even though it is enabled by default when it is created, the event type filter must be specified for the event factory and the audit service provider before it is actually used,

Filters still need to be configured for each event factory and service provider. A filter that is configured for an event factory or a service provider that has Enabled set to false, will not gather or report data for the events and outcomes defined in that filter.

#### ***Events and outcomes:***

The event types and the event outcomes that are specified by this filter. The specifications are listed in the form `event_type:event_outcome` and separated by commas if multiple combinations are specified by the event type filter.

### **Example: Generic Event Interface**

This interface is used for processing generic audit events. Other interfaces can be defined which extend this interface to process specific audit event groupings, such as security events, transaction events, or other custom groupings. For WebSphere Application Server version 7.0, only security types of events are supported.

## Generic Event Interface

Specific implementations might be developed to handle the data in a particular internal format. When the `buildEvent()` method is called, the implementation must then build the specified base event type using the internal information it has stored. After the information has been stored into a `GenericEvent` instance, the `GenericEvent` interface provides a generic way of handling the event.

```
public interface GenericEvent {

 /**
 * Property name used to specify the base event type to the
 * {@link GenericEvent#buildEvent} method.
 */
 public static final String BASE_EVENT_TYPE = GenericEvent.class.getName() + ".baseEventType";

 /**
 * Returns the eventType of the event. The eventType distinguishes between these
 * related events.
 * The eventType depends on the particular implementation
 * of the GenericEvent. For example, the Security Event implementation has
 * eventTypes such as SECURITY_AUTHN and SECURITY_AUTHZ.
 * @return eventType - the eventType of the event
 */

 public String getEventType();

 /**
 * Returns the creationTime, the creation time of the event.
 * @return creationTime - the creation time of the event
 */
 public Date getCreationTime(); /**
 * Returns the version, the version of the event.
 * @return version - the version of the event
 */

 public String getVersion (Properties props) throws GenericEventConfigurationException;

 /**
 * Returns the globalInstanceId, which is a globally unique instance
 * identifier for the event.
 * @return globalInstanceId - a globally unique instance identifier for the event
 */

 public Long getGlobalInstanceId();

 /**
 * Verifies whether the event is valid; which depends on the particular
 * implementation of the GenericEvent. If the event is not valid, an
 * GenericEventValidationException error occurs.
 */

 public void validate() throws GenericEventValidationException;

 /**
 * Returns the internally wrapped base event instance after
 * completing and validating the current instance of the GenericEvent.
 * An GenericEvent implementation can maintain its information
 * in any undisclosed internal format. The buildEvent()
 * method that specifies that a specific base event type be built
 * using the internal information. This allows GenericEvent implementations
 * to support multiple base event formats. Thus the GenericEvent implementation
 * provides a layer of abstraction higher than the base event type.
 * @param properties The value of the property BASE_EVENT_TYPE
 * defines the type of the base event * @return the internally wrapped base event instance
 * @throws GenericEventConfigurationException if the base event type is invalid
 * or the JAR files to support that event type are not available.
 * @throws GenericEventCompletionException if event completion has failed.
 * @throws GenericEventValidationException if the validation has failed. This is
 * validation as is performed by the validate() method.
 */

 public Object buildEvent(Properties properties)
 throws GenericEventConfigurationException,
 GenericEventValidationException,
 GenericEventCompletionException;

 /**
 * Returns the wrapped base event instance as a string after
 * completing and validating the current instance of the GenericEvent.
 * An GenericEvent implementation can maintain its information
 * in any undisclosed internal format. It is the buildEventString()
 * method that specifies that a specific base event type be built
 * using the internal information. This allows GenericEvent implementations
 * to support multiple base event formats. Thus the GenericEvent implementation
 * provides a layer of abstraction higher than the base event type.
 * @param properties The value of the property BASE_EVENT_TYPE
 * defines the type of the base event
 * @return the wrapped base event instance as a String
 * @throws GenericEventConfigurationException if the base event type is invalid
 * or the JAR files to support that event type are not available.
 * @throws GenericEventCompletionException if event completion has failed.
 * @throws GenericEventValidationException if the validation has failed. This is
 * validation as is performed by the validate() method.
 */
}
```

```

public String buildEventString(Properties properties)
 throws GenericEventConfigurationException,
 GenericEventValidationException,
 GenericEventCompletionException;
}

```

## Context objects for security auditing

Each event has an associated set of information that is available for logging. This information is grouped into specific context objects. The context objects that are available for logging a specific event are specified by the event type. All event types have the `sessionContextObj`, `eventContextObj`, `accessContextObj`, `propagationContextObj`, `processContextObj` and `registryContextObj` objects. This topic specifies which additional context objects are available for each event type.

*Table 193. Context objects associated with event types. The following table describes the context objects associated with event types.*

Event Type	Additional Context Objects
SECURITY_AUTHN	authnContextObj, providerContextObj
SECURITY_AUTHN_DELEGATION	delegationContextObj
SECURITY_AUTHN_MAPPING	authnMappingContextObj, providerContextObj
SECURITY_AUTHZ	providerContextObj, policyContextObj
SECURITY_ENCRYPTION	keyContextObj
SECURITY_MGMT_AUDIT	mgmtContextObj
SECURITY_RESOURCE_ACCESS	responseContextObj

For more details on the auditable data that is gather for each of these context objects, see the information for context object fields.

## Context object fields

Each auditable event has an associated set of information that is available for logging. This information is grouped into specific context objects. The context objects that are available for logging a specific event are specified by the event type. This topic details the information that exists for each context object and specifies whether the information is logged by default or is only logged when the verbose logging option is enabled.

### The SessionContextObj object

*Table 194. SessionContextObj fields. This table lists the SessionContextObj fields.*

Field	Type	Description	Default or Verbose logging
sessionId	String	An identifier for the user session	Default
remoteAddr	String	The IP address for the remote host	Default
remotePort	String	The port of the remote host	Default
remoteHost	String	The host name of the remote host	Default

### The PropagationContextObj object

*Table 195. PropagationContextObj fields. This table lists the PropagationContextObj fields.*

Field	Type	Description	Default or Verbose logging
firstCaller	String	The identity of the first user in the caller list	Default
callerList	String array	A list of names representing the identities of the users	Verbose

### The RegistryContextObj object

*Table 196. RegistryContextObj fields. This table lists the RegistryContextObj fields.*

Field	Type	Description	Default or Verbose logging
type	String	The type of user registry being used, such as LDAP or AIX	Default

## The ProcessContextObj object

Table 197. ProcessContextObj fields. This table lists the ProcessContextObj fields.

Field	Type	Description	Default or Verbose logging
domain	String	The domain to which the user belongs	Verbose
realm	String	The registry partition to which the user belongs	Default

## The EventContextObj object

Table 198. EventContextObj fields. This table lists the EventContextObj fields.

Field	Type	Description	Default or Verbose logging
lastEventTrailId	String	The last ID associated with a given transaction	Verbose
eventTrailId	String array	An array of IDs that allow events that belong to a given transaction to be correlated	Default
creationTime	Date	The date an event was created	Default
globalInstanceId	Long	The unique identifier of this event	Default

## The DelegationContextObj object

Table 199. DelegationContextObj fields. This table lists the DelegationContextObj fields.

Field	Type	Description	Default or Verbose logging
delegationType	String	no delegation, simple delegation, method delegation or switch user delegation	Default
roleName	String	The Run as role being used: runAsClient, runAsSpecified, runAsSystem, own ID	Default
identityName	String	Information about the mapped user	Default

## The AuthnContextObj object

Table 200. AuthnContextObj fields. This table lists the AuthnContextObj fields.

Field	Type	Description	Default or Verbose logging
authnType	String	The type of authentication used	Default

## The ProviderContextObj object

Table 201. ProviderContextObj fields. This table lists the ProviderContextObj fields.

Field	Type	Description	Default or Verbose logging
provider	String	The provider of the authentication or authorization service	Default
providerStatus	String	Status of whether the authentication or authorization event processed successfully by the provider	Default

## The AuthnMappingContextObj object

Table 202. AuthnMappingContextObj fields. This table lists the AuthnMappingContextObj fields.

Field	Type	Description	Default or Verbose logging
mappedSecurityDomain	String	The security domain after mapping has occurred	Default
mappedRealm	String	The realm after mapping has occurred	Default

Table 202. AuthnMappingContextObj fields (continued). This table lists the AuthnMappingContextObj fields.

Field	Type	Description	Default or Verbose logging
mappedUserName	String	The user name after mapping has occurred	Default

## The AuthnTermContextObj object

Table 203. AuthnTermContextObj fields. This table lists the AuthnTermContextObj fields.

Field	Type	Description	Default or Verbose logging
terminateReason	String	The reason authentication ended	Default

## The AccessContextObj object

Table 204. AccessContextObj fields. This table lists the AccessContextObj fields.

Field	Type	Description	Default or Verbose logging
progName	String	The name of the program that was involved in the event	Default
action	String	The action being performed.	Default
registryUserName	String	The name of the user in the registry	Default
appUserName	String	The name of the user within an application	Default
accessDecision	String	The decision of the authorization call	Default
resourceName	String	The name of the resource in the context of the application	Default
resourceType	String	The type of resource	Default
resourceUniqueld	Long	The unique identifier of the resource	Default
permissionsChecked	String array	The permissions that were checked during the authorization call	Default
permissionsGranted	String array	The permissions that were granted during the authorization call	Default
rolesChecked	String array	The roles that were checked during the authorization call	Default
rolesGranted	String array	The roles that were granted during the authorization call	Default

## The PolicyContextObj object

Table 205. PolicyContextObj fields. This table lists the PolicyContextObj fields.

Field	Type	Description	Default or Verbose logging
policyName	String	The name of the policy	Default
policyType	String	The type of policy	Default

## The KeyContextObj object

Table 206. KeyContextObj fields. This table lists the KeyContextObj fields.

Field	Type	Description	Default or Verbose logging
keyLabel	String	The key or certificate label	Default
keyLocation	String	The physical location of the key database	Default
certLifetime	Date	The date when a certificate expires	Default

## The CipherContextObj object

Table 207. CipherContextObj fields. This table lists the CipherContextObj fields.

Field	Type	Description	Default or Verbose logging
cipherData	Byte array	The cipher data that is captured	Verbose

## The MgmtContextObj object

Table 208. MgmtContextObj fields. This table lists the MgmtContextObj fields.

Field	Type	Description	Default or Verbose logging
mgmtType	String	The type of management operation	Default
mgmtCommand	String	The application-specific command that was performed	Default
targetInfoAttributes	Target Attribute array	Information about one or more secondary objects involved in this operation	Verbose

## The ResponseContextObj object

Table 209. ResponseContextObj fields. This table lists the ResponseContextObj fields.

Field	Type	Description	Default or Verbose logging
url	String	The URL of the HTTP request	Default
httpRequestHeaders	Attributes array	The HTTP request headers provided by the client	Verbose
httpResponseHeaders	Attributes array	The HTTP response headers returned by the server	Verbose

## The CustomPropertyContextObj object

Table 210. CustomPropertyContextObj fields. This table lists the CustomPropertyContextObj fields.

Field	Type	Description	Default or Verbose logging
key	String	The label representing the custom property key name	Verbose
value	Object	The object value of the custom property	Verbose

## Configuring security audit subsystem failure notifications

Notifications can be generated by a failure of the security audit subsystem. The security audit subsystem notifications can alert auditors that the security audit system is no longer recording auditable security events. Notifications are generated by a failure of the auditing subsystem, they are not related to any auditable security events or event outcome that has occurred. Notifications triggered by an event or an event outcome are not supported.

### Before you begin

Before configuring notifications, enable global security and the security audit subsystem in your environment. You must be assigned the auditor role to complete this task.

### About this task

If a problem is experienced with the security audit subsystem, then a notification can be generated. This is an alert that security events are no longer being audited. Notification can be written to the system log file or can be sent to a specified group of users as an email. You are able to configure notifications to alert the auditor of a problem using both of these methods simultaneously. Notifications are only generated when the Audit subsystem failure action field is set to Log warning or Terminate server.

## Procedure

1. Optional: Click **Security > Security Auditing**.
2. Optional: Confirm the Audit subsystem failure action field is set to Log warning or Terminate server. If the Audit subsystem failure action field is set to No warning, then notifications will not be generated.
3. Click **Security > Security Auditing > Audit monitor** .
4. Under Notifications, Click **New**
5. Enter the name that should be associated with this notification configuration in the Notification name field.
6. Select the Message log check box to specify the failure notifications are recorded in the audit log.
7. Select the email sent to notification list check box to specify that failure notification email should be sent to the addresses listed in the notification list.
8. Enter an email address in the email address to add field This step is not needed if email notifications are not going to be sent.
9. Enter the mail server address in the Outgoing mail (STMP) server address. This step is not needed if email notifications are not going to be sent.
10. Click **Add >>** to add the email address and associated mail server to the email notification list.
11. Repeat steps 5 through 7 for each email address you want to specify in the email notification list.
12. Click **OK**.
13. Select the Enable monitoring check box to turn on audit failure notifications.
14. Select the notification configuration to be used from the Monitor notification dropdown menu.
15. Click **OK**.

## Results

After completing this task, a notification will be generated if the security auditing subsystem experiences an unrecoverable error resulting in security events no longer being audited.

## What to do next

After configuring notifications, you can analyze your audit data for potential weaknesses in the current security infrastructure and to discover possible security breaches that might have occurred.

Audit notifications cannot be removed using the administrative console. To remove an audit notification you first must run the `deleteAuditNotificationMonitorByRef` or the `deleteAuditNotificationMonitorByName` command. After running one of those commands, remove the audit notification by running the `deleteAuditNotification` command.

## Audit monitor collection

Use this page to configure audit subsystem failure notifications. The Auditor monitor panel lists the existing notification configurations and is the gateway for creating new notification configurations and for managing the existing notification configurations.

To view this administrative console page, click **Security > Security Auditing > Audit monitor**.

### ***Enable monitoring:***

Specifies whether to enable or disable notifications. If the check box is selected, then monitoring is enabled. If the check box is not selected, then monitoring is disabled. This check box is disabled by default.

### ***Monitor notification:***

Specifies the notification configuration that will be used for reporting audit subsystem failures.

***Notification name:***

Specifies a string that uniquely identifies a notification configuration.

***Message log:***

Specifies if the configuration will send failure notifications to the message log file. If the value is true, then failure notifications will be sent to the message log file. If the value is false, then failure notifications will be not be sent to the message log file. When creating a notification, this field is in the form of a check box and is not selected by default.

***Send Email:***

Specifies whether an email notification is sent to the addresses listed in the List of email addresses column.

***List of email addresses:***

Specifies the email addresses listed as recipients for email notification in the event of an audit subsystem failure. No email addresses are listed by default. Email addresses will appear in this column if they are listed in the notification list in the notification, this applies even when the Email sent to notification list check box is not selected in the notification.

## **Audit notification settings**

Use this page to create and manage notification configurations that define how auditors are made aware of audit subsystem failures.

To view this administrative console page, click **Security > Security Auditing > Audit monitor > New**.

***Notification name:***

Specifies a string that uniquely identifies a notification configuration.

***Message log:***

Specifies if the configuration will send failure notifications to the message log file. If the check box is selected, then failure notifications will be sent to the message log file. If the check box is not selected, then failure notifications will be not be sent to the message log file. This check box is not selected by default.

***Send secure emails:***

***Email sent to the notification list:***

Specifies whether the configuration will send a failure notification to the recipients listed in the notification list. If the check box is selected, then failure notifications will be sent to the recipients in the notification list. If the check box is not selected, then failure notifications will not be sent to the recipients in the notification list. This check box is not selected by default.

***Email address to add:***

Specifies the email address to be added to the notification list to received failure notification emails. To add a recipient to the notification list, this field and the Outgoing mail (SMTP) server field must both be completed before you click the **Add**.

### **Outgoing mail (SMTP) server:**

Specifies the SMTP server to be used with this email address. If no server is specified, then the email realm will be used.

## **Configuring the default audit service providers for security auditing**

The audit service provider is used to format the audit data object that was sent by the audit event factory. After being formatted, the audit data is recorded to the repository defined in the audit service provider configuration.

### **Before you begin**

Before configuring the audit service provider, enable global security in your environment.

### **About this task**

This task configures the audit service provider used to record generated audit records.

### **Procedure**

1. Click **Security > Security Auditing > Audit service provider**.
2. Click **New** and then select **Binary file based emitter**.
3. Enter the unique name that should be associated with this audit service provider in the Name field.
4. Enter the file location of the binary log file in the Audit log file location field.
5. Optional: Enter the maximum size allowed for a single binary log file in the Audit log file size field.  
This field is specified in megabytes. After the maximum audit file size is reached, a new audit file will be created or an existing audit file will be overwritten. If the maximum number of audit log files has not been set, the default maximum file value used is 10 megabytes. There is no audit archiving utility included with the product. You are responsible for the archiving of your audit data.
6. Optional: In the Maximum number of audit log files field, enter the maximum number of audit logs to be stored before the oldest is overwritten.

The default value for this field is 100. The value of 100 is also used if the field is empty.

**Note:** The maximum number of logs does not include the current binary log that is being written to. It is a reference to the maximum number of archived (timestamped) logs. The total number of binary logs that can exist for a server process is the maximum number of archived logs plus the current log.

Also under this field, there are additional options to select the behavior when the maximum number of logs is reached. The choices are:

**oldest** If you select this option, when the maximum audit logs are reached, the oldest audit log is rewritten; notification is not sent to the auditor.

#### **stop server**

This option does not rewrite over the oldest audit log. It stops the audit service, sends a notification to the SystemOut.log, and quiesces the application server.

#### **stop logging**

This option does not rewrite over the oldest audit log. It also stops the audit service, but does allow the WebSphere process to continue. Notifications are not posted in the SystemOut.log.

7. Select the filters to be used by this audit service provider. The Selectable filter list consists of a list of the configured filters that have been configured and are currently enabled.
  - a. Select the filters that should be audited from the Selectable filter list.
  - b. Click **Add >>** to add the selected filters to the Enabled filter list.
8. Click **Apply**.

## Results

After completing these steps, your audit data will be sent to the specified repository in the format required by that repository.

## What to do next

After creating an audit service provider, the audit service provider must be associated with an audit event factory provide the audit data objects to the audit service provider. Next you should configure an audit event factory.

### Audit service provider collection

The Audit service provider panel displays a listing of all configured audit service provider implementations. Using this panel, a user can define a new audit service provider implementation, delete an existing implementation, and display or modify the fields associated with an existing implementation.

To view this administrative console page, click **Security > Security Auditing > Audit service provider**.

By default, the `audit.xml` will contain the IBM audit service provider implementation which emits audit records to a binary file-based text file. This implementation is used for Binary file-based audit service provider configurations. For each existing audit service provider in the list on this panel, the unique name, type and event formatting class associated with the audit service provider will be displayed.

#### **Name:**

The Name field is the unique name associated with the audit service provider implementation.

#### **Type:**

The Type field specifies if the implementation is a binary file-based implementation, SMF implementation or a third party implementation.

#### **Event formatting module class name:**

The event formatting class is a class used to format the generic event data object into a format that is specific to the audit service provider implementation. For example, a third party audit service provider implementation might have an event formatting class that takes the generic event and translates it into XML data. There is no Event formatting module class for binary file-based implementations nor for SMF implementations.

### Audit service provider settings

Use this page to define the implementation details of the audit service provider. There are three types of audit service providers: binary file-based, third party and SMF.

To view this administrative console page, click one of the following paths:

- **Security > Security auditing > Audit service provider > *audit\_service\_provider\_name*.**
- **Security > Security auditing > Audit service provider > New > Binary File-based emitter.**
- **Security > Security auditing > Audit service provider > New > Third party emitter.**
- **Security > Security auditing > Audit service provider > New > SMF emitter.**

#### **Name:**

Specifies the unique name associated with the audit service provider.

#### **Third party emitter class name:**

Specifies the name of the class for this implementation. This field is only present for Third party emitter implementations.

***Audit file location:***

Specifies the path to the binary log file.

***Audit file size:***

Specifies the maximum size of a single binary log file. This value is defined in megabytes.

***Maximum number of audit log files:***

Specifies the maximum number of binary log files to create before the oldest is replaced.

**Note:** The maximum number of logs does not include the current binary log that is being written to. It is a reference to the maximum number of archived (timestamped) logs. The total number of binary logs that can exist for a server process is the maximum number of archived logs plus the current log.

***Audit log wrapping:***

Specifies the wrapping behavior of the binary audit log when the maximum number of binary audit log files is reached.

**Note:** In this release of WebSphere Application Server, there are new customizable options available when specifying the default audit log wrapping behavior. This is only applicable to the Binary Audit Log implementation.

Choose from one of the following options:

**WRAP**

If you select this option, when the maximum audit logs are reached, the oldest audit log is rewritten; notification is not sent to the auditor. This is the default option, and mimics the default behavior in WebSphere Application Server Version 7.0.

**NOWRAP**

This option does not rewrite over the oldest audit log. It stops the audit service, sends a notification to the SystemOut.log, and quiesces the application server.

**SILENT\_FAIL**

This option does not rewrite over the oldest audit log. It also stops the audit service, but does allow the WebSphere process to continue. Notifications are not posted in the SystemOut.log.

**Note:** If audit notification of failures in the audit subsystem is configured, and SILENT\_FAIL is selected, the auditor is not notified of the audit subsystem failure. The SILENT\_FAIL option takes precedence

**Note:** If you use the NOWRAP or SILENT\_FAIL options, when the server is stopped as a result of the logs being maxed-out, a stopserver is performed, or because the server abends in some way, you must archive the binary audit logs before you restart the server.

**Note:** This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log, SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using

HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

### ***Event formatting module class name:***

Specifies a class used to format the generic event into a format that is specific to the audit service provider implementation. For example, a third party audit service provider implementation might have an event formatting class that takes the generic event and translates it into XML data.

### ***Selectable filters:***

Specifies the available event filters. To enable a filter for an implementation, select the filter from the Selectable event filters list and then click >.

### ***Enabled filters:***

Specifies the event filters that are currently enabled for an implementation. To disable a filter for an implementation, select the filter from the Enabled filters list and then click <.

### ***Custom properties:***

Specifies any custom properties that might be used to add properties to a third party implementation. Custom properties are not available for binary file-based implementations or SMF implementations.

- Name
- Value

## **Example: Base Generic Emitter Interface**

The Base Generic Emitter interface defines how audit events are emitted. Other interfaces can exist to extend this interface and to process specific audit events groupings, such as security events, transactional events, or some other custom grouping. Use this interface to create a custom implementation of the emitter.

### **Base Generic Emitter Interface**

```
/**
 * This is the interface for the event emitter. Event sources use this interface
 * to send events to an event service.
 */
public interface BaseGenericEmitter {
 /**
 * Sends an event to the configured GenericEmitter implementation.
 *
 * @param event The event to be sent to the event service.
 * This value cannot be null.
 * @return The global instance ID of the event that was built.
 * @exception GenericEmitterException If an error occurs during emitter processing.
 * @exception IllegalArgumentException If the event parameter is null.
 */
 public String sendEvent(GenericEvent event) throws
 GenericEventException;
 /**
 * Sends an array of events to the configured GenericEmitter implementation.
 *
 * @param events The event array to be sent to the event service.
 * This value cannot be null.
 * @return The global instance IDs of the events that were built.
 * @exception GenericEmitterException If an error occurs during emitter processing.
 * @exception IllegalArgumentException If the events parameter is null.
 */
 public String[] sendEvents(GenericEvent events[]) throws
 GenericEventException;
 /**
 * Causes the emitter to release all resources that are owned by this
 * object and its dependents.
 * Subsequent calls to this method have no effect.
 *
 * @throws GenericEmitterException If the emitter does release the
 * held resources.
 * resources.
 * @throws GenericEventException If any other error occurs when releasing resources.
 */
}
```

```
*/
public void close() throws
 GenericEventException;
}
```

## Configuring a third party audit service providers for security auditing

The audit service provider is used to format the audit data object that was sent by the audit event factory. In addition to the default audit service provider, you may use a third party implementation as your audit service provider.

### Before you begin

Before configuring the audit service provider, enable global security in your environment.

### About this task

This task configures the audit service provider used to record generated audit records.

### Procedure

1. Click **Security > Security Auditing > Audit service provider**.
2. Click **New** and then select **Third party emitter**.
3. Enter the unique name that should be associated with this audit service provider in the Name field.
4. Enter the Third party emitter class name.
5. Enter the Event formatting module class name. This field specifies the class used to format the generic event into a format that is specific to the audit service provider implementation. For example, your implementation might have an event formatting class that takes the generic event and translates it into XML data.
6. Select the filters to be used by this audit service provider. The Selectable filter list consists of a list of the configured filters that have been configured and are currently enabled.
  - a. Select the filters that should be audited from the Selectable filter list.
  - b. Click **Add >>** to add the selected filters to the Enabled filter list.
7. Optional: Enter any custom properties that you included in your third party emitter code.
8. Click **Apply**.

### Results

After completing these steps, your audit data will be sent to the specified repository in the format required by that repository.

### What to do next

After creating an audit service provider, the audit service provider must be associated with an audit event factory provide the audit data objects to the audit service provider. Next you should configure an audit event factory.

### Example: Base Generic Emitter Interface

The Base Generic Emitter interface defines how audit events are emitted. Other interfaces can exist to extend this interface and to process specific audit events groupings, such as security events, transactional events, or some other custom grouping. Use this interface to create a custom implementation of the emitter.

### Base Generic Emitter Interface

```
/**
 * This is the interface for the event emitter. Event sources use this interface
 * to send events to an event service.
 */
```

```

*/
public interface BaseGenericEmitter {
/**
 * Sends an event to the configured GenericEmitter implementation.
 *
 * @param event The event to be sent to the event service.
 * This value cannot be null.
 * @return The global instance ID of the event that was built.
 * @exception GenericEmitterException If an error occurs during emitter processing.
 * @exception IllegalArgumentException If the event parameter is null.
 */
public String sendEvent(GenericEvent event) throws
 GenericEventException;
/** * Sends an array of events to the configured GenericEmitter implementation.
 * @param events The event array to be sent to the event service.
 * This value cannot be null.
 * @return The global instance IDs of the events that were built.
 * @exception GenericEmitterException If an error occurs during emitter processing.
 * @exception IllegalArgumentException If the events parameter is null.
 */
public String[] sendEvents(GenericEvent events[]) throws
 GenericEventException;
/**
 * Causes the emitter to release all resources that are owned by this
 * object and its dependents.
 * Subsequent calls to this method have no effect.
 *
 * @throws GenericEmitterException If the emitter does release the
 * held resources.
 * resources.
 * @throws GenericEventException If any other error occurs when releasing resources.
 */
public void close() throws
 GenericEventException;
}

```

## Configuring the SMF audit service providers for security auditing

The audit service provider is used to format the audit data object that was sent by the audit event factory. For z/OS systems you can choose to use the SMF emitter implementation to output audit records to the Service Management Framework (SMF) as SMF Type 83 Subtype 5 Relocates.

### Before you begin

Before configuring the audit service provider, enable global security in your environment. SMF recording must be enabled at the operating system level before configuring the SMF audit service provider to be used. If SMF recording is off and a SMF audit service provider implementation is used, then audit records are not logged to SMF and no warning is presented to alert you that the records are not being recorded.

### About this task

This task configures the audit service provider used to record generated audit records.

### Procedure

1. Click **Security > Security Auditing > Audit service provider**.
2. Click **New** and then select **SMF emitter**.
3. Enter the unique name that should be associated with this audit service provider in the Name field.
4. Select the filters to be used by this audit service provider. The Selectable filter list consists of a list of the configured filters that have been configured and are currently enabled.
  - a. Select the filters that should be audited from the Selectable filter list.
  - b. Click **Add >>** to add the selected event type filters to the Enabled filter list.
5. Click **Apply**.

### Results

After completing these steps, your audit data will be sent to the specified repository in the format required by that repository when an audit event factory is associated with this audit service provider

## What to do next

After creating an audit service provider, the audit service provider must be associated with an audit event factory that will provide the audit data objects to the audit service provider. Next you should configure an audit event factory.

Audit records emitted to SMF may be read using the SMF Unload utility. See the z/OS Internet Library for more information about the SMF Unload utility.

You can specify the `com.ibm.audit.field.length.limit` custom property to set the length at which variable-length audit data is truncated. For more information, see the documentation about the security custom properties.

## Example: Base Generic Emitter Interface

The Base Generic Emitter interface defines how audit events are emitted. Other interfaces can exist to extend this interface and to process specific audit events groupings, such as security events, transactional events, or some other custom grouping. Use this interface to create a custom implementation of the emitter.

### Base Generic Emitter Interface

```
/**
 * This is the interface for the event emitter. Event sources use this interface
 * to send events to an event service.
 */
public interface BaseGenericEmitter {
 /**
 * Sends an event to the configured GenericEmitter implementation.
 *
 * @param event The event to be sent to the event service.
 * This value cannot be null.
 * @return The global instance ID of the event that was built.
 * @exception GenericEmitterException If an error occurs during emitter processing.
 * @exception IllegalArgumentException If the event parameter is null.
 */
 public String sendEvent(GenericEvent event) throws
 GenericEventException;
 /**
 * Sends an array of events to the configured GenericEmitter implementation.
 * @param events The event array to be sent to the event service.
 * This value cannot be null.
 * @return The global instance IDs of the events that were built.
 * @exception GenericEmitterException If an error occurs during emitter processing.
 * @exception IllegalArgumentException If the events parameter is null.
 */
 public String[] sendEvents(GenericEvent events[]) throws
 GenericEventException;
 /**
 * Causes the emitter to release all resources that are owned by this
 * object and its dependents.
 * Subsequent calls to this method have no effect.
 *
 * @throws GenericEmitterException If the emitter does release the
 * held resources.
 * resources.
 * @throws GenericEventException If any other error occurs when releasing resources.
 */
 public void close() throws
 GenericEventException;
}
```

## Configuring audit event factories for security auditing

The audit event factory collects the data associated with the auditable security events and builds the audit data object. The object is then sent to the audit service provider to be formatted and recorded to a specified repository.

### Before you begin

Before configuring an event factory, enable global security in your environment. An event type filter and an audit service provider need to be created before completing these steps

## About this task

### Procedure

1. Click **Security > Security Auditing > Audit event factory configurations > New**.
2. Enter the unique name that should be associated with this Audit event factory configuration in the Name field.
3. Select either **IBM audit event factory** or **Third party event factory**.
  - a. Enter the Third party audit event factory class name. This step is only required if a Third party event factory is being created.
4. Select the appropriate audit service provider implementation from the Audit service provider dropdown menu,
5. Select the event type filter configuration to be used by this audit event factory. The Filters list consists of a list of the event type filter configurations that have been created and are currently enabled.
  - a. Select the event type filters that should be used from the Selectable filter list.
  - b. Click **Add >>** to add the selected event type filter configurations to the Enabled filter lists.
6. Enter any Custom properties that need to be included with this audit event factory configuration. Custom properties are only available for Third party event factory implementations.
7. Click **Apply**.

### Results

After successful completion of these steps, you will have an event factory that can be used to gather auditable event data.

### What to do next

After configuring an audit event factory, you can optionally protect your data by configuring the security auditing subsystem to sign and encrypt your audit logs.

### Audit event factory configuration collection

The Audit event factory configuration panel displays a list of all currently configured audit event factory implementations. This panel allows a user with the auditor role to manage their configured audit event factories. This includes the ability to configure a new implementation, which is done using the **New** button on this panel.

To view this administrative console page, click **Security > Security Auditing > Audit event factory configuration**.

#### **Name:**

The Name field specifies the unique name associated with the audit event factory configuration.

#### **Type:**

The Type field specifies this audit event factory configuration as either an IBM audit event factory or a Third party audit event factory.

#### **Class name:**

The Class name field specifies the class that is being implemented in an audit event factory configuration.

The class name is `com.ibm.ws.security.audit.AuditEventFactoryImpl` for an IBM event factory. For a Third party audit event factory, the class name is the class specified in the Third party audit event factory class name field.

## Audit event factory settings

The Audit event factory settings panel displays the details of a specific audit event factory. The auditor uses this panel to manage and create audit event factory configurations.

To view this administrative console page, click on one of the following paths:

- **Security > Security Auditing > Audit event factory configuration > *audit\_event\_factory\_configuration\_name*.**
- **Security > Security Auditing > Audit event factory configuration > New.**

### **Name:**

Specifies the unique name associated with the audit event factory configuration.

### **Type:**

Specifies this audit event factory configuration as either an IBM audit event factory or a Third party audit event factory. This field does not appear on the panel during the creation of a new audit event factory. It is included when viewing or modifying an existing audit event factory.

### **IBM audit event factory:**

Specifies that the Type field of this audit event factory is IBM audit event factory. This check box only appears on the panel during the creation of a new audit event factory. This check box is selected by default when creating a new audit event factory.

### **Third party audit event factory:**

Specifies that the Type field of this audit event factory is Third party audit event factory. This check box only appears on the panel during the creation of a new audit event factory. This check box is not selected by default when creating a new audit event factory.

- The Third party audit event factory class name field is active when the Third party audit event factory check box is selected. This field represents the class name of the third-party implementation of the Audit Event Factory interface

### **Class name:**

Specifies the class that is being implemented in a audit event factory configuration.

Although not specified during creation, the class name is `com.ibm.ws.security.audit.AuditEventFactoryImp` for an IBM event factory.

### **Audit service provider:**

Specifies where the audit data objects gathered by this audit event factory will be sent.

### **Selectable filters:**

Specifies the filters that are currently available to be used for an implementation. To enable a filter for an implementation, select the filter from the Selectable filter list and then click >.

### **Enabled filters:**

Specifies the filters that are currently enabled for an implementation. To disable a filter for an implementation, select the filter from the Enabled filter list and then click <.

### **Custom properties:**

Specifies properties that the auditor can define to configure the Audit Event Factory implementation. This might be used by third party implementation of the audit event factory interface. Custom properties are not used for the IBM audit event factory implementation.

Each custom property has the following fields:

- Name
- Value

## Example: Generic Event Factory Interface

This interface is used for processing generic audit events. Other interfaces can be defined which extend this interface to process specific audit event groupings, such as security events, transaction events, or some other custom grouping.

### Generic Event Factory Interface

```
/**
 * GenericEventFactory is the interface that is used to generate audit events.
 * This interface may be extended to generate application specific audit events.
 *
 * One or more GenericEventFactory implementations each with a unique name can be defined in the
 * security configuration and be used by WebSphere Application Server security auditing service.
 * @author IBM Corporation
 * @version WAS 7.0
 * @since WAS 7.0
 */
public interface GenericEventFactory {
 /**
 * The init method allows a GenericEventFactory implementation to
 * initialize its internal auditing configuration using the properties and context object.
 *
 * The properties and context objects are treated as read-only and must not be modified by the
 * GenericEventFactory implementation.
 *
 * @param A String object represents the name of this GenericEventFactory.
 * @param A Map properties object that contains the custom properties that can be defined in the
 * the admin console or by using wsadmin scripting tool.
 * @param A Map object that contains the context that includes cell name, node name, and server name.
 * @exception ProviderFailureException might occur if the audit factory does not initialize
 */
 public void init(String name, Map properties, Map context) throws ProviderFailureException;
 /**
 *
 * The terminate method gracefully quiesces the event factory implementation.
 */
 public void terminate();
 /**
 *
 * The refresh method allows a GenericEventFactory implementation to
 * update its internal auditing configuration using the properties object.
 *
 * The properties object is treated as read-only and must not be modified by the
 * GenericEventFactory implementation.
 *
 * @param A Map object that contains the custom properties
 * @exception ProviderFailureException might occur if the factory does not refresh
 */
 public void refresh(java.util.Map properties) throws ProviderFailureException;
 /**
 *
 * The getName method returns the name of this GenericEventFactory.
 *
 * @param None
 * @return a String object represents the name of the GenericEventFactory.
 */
 public String getName();
 /**
 *
 * The sendEvent method determines whether the specified audit event is generated by this
 * GenericEventFactory.
 *
 * @param a String object represents an audit event
 * @param a OutcomeType object represents the audit outcome value
 * @exception ProviderFailureException might occur if the audit factory does not initialize
 * @return a boolean success/failure
 * @exception ProviderFailureException might occur if the audit factory does not send the event.
 */
 public boolean sendEvent(String auditEventType, OutcomeType auditOutcome) throws
 ProviderFailureException;
}
```

## Protecting your security audit data

The security auditing subsystem allows for protection of your security audit data by increasing the assurance that the audit data has not been tampered or modified outside of the auditing facility. This option also protects the confidentiality of the data. The audit data is protected by encrypting and signing the recording data.

### Before you begin

**Restriction:** Signing and encrypting your audit data is only available for data created using the default binary log audit service provider. If you are using the SMF emitter or a 3rd party emitter you will not be able to sign or encrypt your data.

Before configuring protection for your security audit data, enable global security and security auditing in your environment. You must be assigned the auditor role to complete the task of protecting your audit data. You will also need the administrator role to configure your audit data to be signed.

### About this task

The practice of auditing requires assurances that your audit data is accurate and uncompromised. Your audit data has the option to be encrypted, signed, or encrypted and signed. You can protect your audit data using these options to provide assurances that your data is only viewed by authorized users and can not untraceably be modified. To protect the validity of your security auditing functionality, complete the following steps:

### Procedure

1. "Encrypting your security audit records" Audit logs can be encrypted to ensure your audit data is protected. The audit logs will be encrypted using a certificate that is saved to a keystore in the `audit.xml` file. By encrypting your audit records, only users with the password to the keystore will be able to view or update the audit logs.
2. "Signing your security audit records" on page 2071 Audit logs can be signed to ensure the integrity of your audit data. By signing your audit records, you ensure any modifications of the audit logs can be traced.

### Results

After completing these steps your data will be signed, encrypted or signed and encrypted to provide assurances that the data is accurate and confidential.

### What to do next

After protecting your data, you can configure notifications to ensure you are notified if a problem with the security auditing subsystems occurs that prevents security events from being recorded.

### Encrypting your security audit records

Audit logs can be encrypted to ensure your audit data is protected. By encrypting your audit records, only users with access to the encrypting certificate will be able to view the audit logs.

### Before you begin

**Restriction:** Encrypting audit data is only available for data created using the default audit service provider. If you are using the SMF emitter or a 3rd party emitter you will not be able to encrypt your data.

Before configuring your security audit records to be encrypted, enable global security and security auditing in your environment. You must be assigned the auditor role to encrypt your security auditing records. If you

are using a certificate stored in the `security.xml` file, you also require the administrator role to complete this task.

## About this task

### Procedure

1. Click **Security > Security Auditing > Audit record encryption configuration**.
2. Select the Enable encryption check box to specify that your audit records should be encrypted. All other fields on this panel will be unavailable until this check box has been selected.
3. Select the keystore that contains the encrypting certificate from the dropdown menu or click **New** to create a new certificate in an existing keystore. Use the following steps if you are creating a new certificate:
  - a. Enter the name of the keystore in the Name field.
  - b. Enter the path to the keystore file in the Path field.
  - c. Enter the password to be associated with the keystore in the Password field.
  - d. Confirm the password associated with the keystore by retyping the password in the Confirm password field.
  - e. Select the keystore type from the Type dropdown list. The default value of the Type dropdown list is PKCS12.
4. If you are using an existing certificate to encrypt your audit records, ensure **Certificate in keystore** is selected and specify the intended certificate in the Certificate alias dropdown menu.
5. If you are generating a new certificate to encrypt your audit records, select **Create a new certificate in the selected keystore** and follow these steps:
  - a. Enter the name of your new certificate in the Certificate alias field.
  - b. Select either Automatically generate certificate or Import a certificate. The certificate used to encrypt the data in the audit log files can either be created or imported. If you selected to generate a certificate, then skip to the last step on this page. If you selected to import a certificate, then continue on with step c.
  - c. Enter the name of the keystore file in the Key file name field.
  - d. Enter the path to the keystore file in the Path field.
  - e. Select the keystore type from the Type dropdown list. The default value of the Type dropdown list is PKCS12.
  - f. Enter the password associated with the keystore in the Key File password field.
  - g. Click **Get key file aliases** to populate the Certificate alias to import dropdown menu.
  - h. Select the certificate to be imported from the Certificate alias to import dropdown menu.
6. Click **OK**.

### Results

After completing these steps, your audit logs will be encrypted to ensure only authorized users can view the content of your audit log files.

### What to do next

After you have finished configuring your audit logs to be encrypted, you can ensure the data integrity of your audit logs by configuring the audit subsystem to sign your audit records.

### Signing your security audit records

Audit logs can be signed to ensure the integrity of your audit data. By signing your audit records, modifications of the audit logs can be traced.

## Before you begin

**Restriction:** Signing audit data is only available for data created using the default audit service provider. If you are using the SMF emitter or a 3rd party emitter you will not be able to sign your data.

Before configuring your security audit records to be signed, enable global security and security auditing in your environment. You must be assigned the auditor role and the administrator role to configure audit record signing.

## About this task

### Procedure

1. Click **Security > Security Auditing > Audit record signing configuration**.
2. Select the Enable signing check box to specify that your audit records should be signed. All other fields on this panel will be unavailable until this check box has been selected.
3. Select the keystore that contains the signing certificate from the Managed keystore containing the signing certificate dropdown menu.
4. If you are using an existing certificate to sign your audit records, ensure Certificate in keystore is selected and specify the intended certificate in the Certificate alias dropdown menu.
5. If you are generating a new certificate to sign your audit records, select Create a new certificate in the selected keystore and follow these steps:
  - a. Enter the name of your new certificate in the Certificate alias field.
  - b. Select one of the following options: Import the encryption certificate, Automatically generate certificate or Import a certificate. The certificate used to encrypt the data in the audit log files can either be created or imported.
    - If you selected Import the encryption certificate, then you will use the encryption certificate to also sign your audit records. Skip to the last step on this page to complete this configuration.
    - If you selected to generate a certificate, then skip to the last step on this page to complete this configuration.
    - If you selected to import a certificate from an existing keystore, then continue on with step c.
  - c. Enter the name of the keystore file in the Key file name field.
  - d. Enter the path to the keystore file in the Path field.
  - e. Select the keystore type from the Type dropdown list. The default value of the Type dropdown list is PKCS12.
  - f. Enter the password associated with the keystore in the Key File password field.
  - g. Click **Get key file aliases** to populate the Certificate alias to import dropdown menu.
  - h. Select the certificate to be imported from the Certificate alias to import dropdown menu.
6. Click **OK**.

### Results

After you have completed these steps, your audit logs will be digitally signed to ensure the integrity of the data.

### What to do next

After you have finished configuring your audit logs to be signed, you can ensure the confidentiality of your audit logs by configuring the audit subsystem to encrypt your audit records.

## Audit encryption keystores and certificates collection

The Audit encryption keystores and certificates panel allows the auditor to manage the keystores and certificates used for audit encryption.

To view this administrative console page, click **Security > Security Auditing > Audit encryption keystores and certificates**.

**Name:**

Specifies the unique name of the keystores used for storing the encryption certificate.

**Path:**

Specifies the path to the listed keystore file.

The path to the keystore file can be listed using environment variables, `${PROFILE_ROOT}`, or with a fully qualified path.

### **Audit record encryption configuration settings**

Use this page to enable encryption for your audit records. Encrypting your audit records ensures only a user given access to the certificate used for encryption is allowed to view the audit records.

To view this administrative console page, click **Security > Security auditing > Audit record encryption configuration**. If **Enable encryption** is not selected, then all of the other fields on this panel will be disabled. Encryption is not enabled by default.

**Enable encryption:**

Specifies whether your audit records will be encrypted. This check box is not selected by default.

**Audit keystore containing the encryption certificate:**

Specifies the audit keystore specified to store the encryption certificate.

A new keystore can be created by clicking on the **New...** button.

**Certificate in keystore:**

Specifies an existing certificate will be used from the keystore specified in the Audit keystore containing the encryption certificate field. This field is selected by default. If a keystore in the `security.xml` file is used, the administrator role is required.

- Certificate alias

When the **Certificate in keystore** field is selected, the certificate alias dropdown menu displays a list of certificate aliases contained in the keystore defined by the **Audit keystore containing the encryption certificate** field. Select the certificate from the dropdown menu to be used to encrypt your audit records.

**Create a new certificate in the selected keystore:**

Specifies that a new certificate will be created in the keystore defined by the **Audit keystore containing the encryption certificate** field.

- Certificate alias

When the **Create a new certificate in the selected keystore** is selected, the **Certificate alias** field is used to define the name of the certificate to be created in the keystore defined by the **Audit keystore containing the encryption certificate** field.

- Automatically generate certificate

When selected, the **Automatically generate certificate** field specifies that the application server will automatically generate the certificate. This field is selected by default when the **Create a new certificate in the selected keystore** field is selected.

- Import a certificate

When selected, the **Import a certificate** field specifies that an existing self-signed certificate will be imported by the auditor into the keystore and used to encrypt your audit records. This field is not selected by default when the **Create a new certificate in the selected keystore** field is selected. The following fields need to be defined to import an existing certificate.

- The **Key file name** field specifies the keystore filename that contains the certificate to be imported.
- The **Path** field specifies the path to the keystore file that contains the certificate to be imported.
- The **Type** field specifies the type of the keystore file that contains the certificate to be imported.
- The **Key file password** field specifies the password used to access the keystore file that contains the certificate to be imported.
- **Certificate alias to import** field specifies the alias of the certificate to be imported.

## Audit record signing configuration settings

Use this page to enable signing for your audit records. Signing audit records ensures tamper-proof recording of the auditable events. Both the auditor and administrator roles are required to configure the signing of your audit data.

To view this administrative console page, click **Security > Security auditing > Audit record signing configuration**. If **Enable signing** is not selected, then all of the other fields on this panel will be disabled.

### **Enable signing:**

Specifies whether your audit records will be encrypted. This check box is not selected by default.

### **Managed keystore containing the signing certificate:**

Specifies the keystore used to store the signing certificate.

### **Certificate in keystore:**

Specifies an existing certificate will be used from the keystore specified in the **Managed keystore containing the signing certificate** field. This field is selected by default.

- Certificate alias

When the **Certificate in keystore** field is selected, the **Certificate alias** dropdown menu displays a list of certificate aliases contained in the keystore defined by the **Managed keystore containing the signing certificate** field. Select the certificate from the dropdown menu to be used to sign your audit records.

### **Create a new certificate in the selected keystore:**

Specifies that a new certificate will be created in the keystore defined by the **Managed keystore containing the signing certificate** field.

- Certificate alias

When the **Create a new certificate in the selected keystore** is selected, the **Certificate alias** field is used to define the name of the certificate to be created in the keystore defined by the **Audit keystore containing the encryption certificate** field.

- Import the encryption certificate

Specifies the certificate used for encryption will be imported into the signing keystore file and used for signing.

- Automatically generate certificate

Specifies the application server will automatically generate the certificate. This field is selected by default when the **Create a new certificate in the selected keystore** field is selected.

- Import a certificate

Specifies an existing self-signed certificate will be imported by the auditor into the keystore and used to encrypt your audit records. This field is not selected by default when the **Create a new certificate in the selected keystore** field is selected. The following fields need to be defined to import an existing certificate.

- The **Key file name** field specifies the keystore filename that contains the certificate to be imported.
- The **Path** field specifies the path to the keystore file that contains the certificate to be imported.
- The **Type** field specifies the type of the keystore file that contains the certificate to be imported.
- The **Key file password** field specifies the password used to access the keystore file that contains the certificate to be imported.
- **Certificate alias to import** field specifies the alias of the certificate to be imported.

### **Audit record keystore settings**

The Audit record keystore panel is used by an auditor to define the keystores used for storing the encryption certificate used to encrypt the audit records. Keystores used for auditing are managed outside of other keystores being used on the system to facilitate separation of the authority of the auditor for the authority of the administrator.

To view this administrative console page, click one of the following paths:

- **Security > Security Auditing > Audit encryption keystores and certificates > *keystore\_name*.**
- **Security > Security Auditing > Audit encryption keystores and certificates > New.**
- **Security > Security Auditing > Audit record encryption configuration > New**

#### ***Name:***

The Name field specifies the unique name for the keystore. This is a required field.

#### ***Path:***

Specifies the path where the keystore file is located. This is a required field.

#### ***Password:***

Specifies the password to be used for this keystore. This is a required field.

#### ***Confirm Password:***

Specifies confirmation of the value provided in the Password field. This is a required field.

#### ***Type:***

The Type field specifies the type of the keystore. The Type dropdown menu has the following options for defining the keystore type:

- JCEKS
- CMSKS
- PKCS12 - The default value for the Type field is PKCS12.
- Cryptographic Token Device (PKCS11)
- JKS
- PKCS12JarSigner

## Using the audit reader

The audit reader is a utility that can be used to read the binary audit logs generated by the default binary emitter implementation. The audit reader parses the audit log to generate an HTML report. The audit reader is invoked using wsadmin commands and is not accessible using the administrative console.

### Before you begin

The audit reader can only be used to parse log files that are created by the default audit service provider. Logs created by a third-party emitter can not be parsed by the audit reader.

### About this task

Your audit logs might be encrypted, signed, encrypted and signed or neither encrypted nor signed. The audit reader is able to parse any of these combinations to generate an HTML report. If the audit log file is encrypted, the password of the keystore storing the certificate used to encrypt the log must be provided. The showAuditLogEncryptionInfo wsadmin command can be used to get information to determine which keystore was used to sign the audit log.

Depending on the selections you made in your audit service provider configuration, the size of the audit logs can become large enough to make them cumbersome to review. What data has been recorded into your log is dependant on the event type filters you are using and whether you specified to use verbose logging. Options are provided for you to further limit the data included in the HTML report that is generated by the audit reader to a subset that you specify. The audit reader can be used to parse the same data multiple times to generate separate reports for your different requirements.

By default, all event types, outcome types, timestamps, and sequence numbers will be gathered from the Binary Audit log and generated into a report. The ability to specify only specific event types, only specific sequence numbers, only records with specific timestamps, as well as specific outcome types is provided. A sequence number is a unique identifier assigned to each audit record. Options exist to limit which events, outcomes, and sequence numbers are included in the report.

The report type controls what data is reported for each audit record in the log file. The default report type includes the follow data for each audit record:

- creationTime
- action
- progName
- registryType
- domain
- realm
- remoteAddr
- remotePort
- remoteHost
- resourceName
- resourceType
- resourceUniqueld

The complete report type generates a report based on all the data that was logged for the selected audit records. The complete report type includes all the data that is included by the default report type and all the additional datapoints that were logged for these audit records. The additional available datapoints for an audit record varies depending on the event type it represents.

A custom report type is also included. Use the custom report type to specify only the datapoints that you want generated in the report. A report may be generated based on the following criteria:

- all or specific event types
- all or specific outcome types
- all or a specific sequence number range
- all or a specific timestamp range

## Procedure

Run the binaryAuditLogReader wsadmin command to use the audit reader to generate a log report. See the AuditReaderCommands command group for the AdminTask object article for more information.

## Results

After you complete these steps, you will generated an HTML report containing the data specific to your requirement.

## Example

### Audit Event Outcome Codes

In a binary audit log or the output of the audit reader tool, audit event outcomes are expressed with a numeric code. Use this table to associate the audit event outcome code in the binary audit logs to a generic error messages.

*Table 211. Event Outcome Codes. This table lists the event outcome codes.*

Outcome Reason Code	Description
0	An error occurred while parsing the certificate.
1	The security context does not exist for the thread.
2	There is conflicting session evidence.
3	The session has been rejected.
4	The token has expired.
5	Successful authentication has occurred.
6	Successful authentication for accessing a resource has occurred.
7	Successful authentication occurred while mapping a user.
8	Successful authorization has occurred.
9	Login termination was successful.
10	Invalid evidence exists.
11	There was a GSS formatting error.
12	Credentials were unauthenticated.
13	Authentication failed.
14	An invalid resource was accessed.
15	Authentication was denied.
16	Authorization was denied.
17	Access was denied because of an authentication failure.
18	Authorization was excluded.
19	Authorization was excluded because of access without proper security role.
20	An unsupported authentication mechanism was used.
21	An authentication redirect occurred.
22	The context does not exist.
23	A TAI challenge occurred.
24	A TAI validation was not successful.
25	A TAI mapping was not successful.
26	A provider failure occurred.
27	A SSO token validation was not successful.

Table 211. Event Outcome Codes (continued). This table lists the event outcome codes.

28	An invalid user id or password was provided.
29	A send login form
30	An invalid configuration exists.
31	An user id or password is missing.
32	Failure occurred for an unknown reason.
33	The account was disabled because of retry violations.
34	The account was locked out because of retry violations.
35	The account was locked out because the maximum number of unsuccessful login attempts has occurred.
36	The account is disabled.
37	The account has expired.
38	The account is unlocked.
39	The maximum inactive time permitted for the account has elapsed.
40	The password has expired.
41	The minimum interval for a password change has unexpired.
42	The maximum interval permitted before a password must be changes has elapsed.
43	An authentication failure has occurred.
44	An invalid user name was provided.
45	A pin is required.
46	This outcome code is not used in this release.
47	A user mapping did not occur successfully.
48	A certificate failure occurred.
49	A policy violation has occurred.
50	A policy violation has occurred because of the time of day.
51	The policy allows access.
52	A policy violation has occurred because the maximum number of unsuccessful login attempts has been reached.
53	A user name mismatch has occurred.
54	An invalid user password was provided.
55	A token signature violation has occurred.
56	The token is not yet valid.
57	The token is not supported.
58	The token is not in a valid format.
59	A credential mapping failure occurred.
60	The delegate is not authorized.
61	Access to a resource is unauthorized because of an authorization.
62	Access to a resource is unauthorized because of a time of day policy.
63	Access to a resource is unauthorized.
64	Access to a resource is unauthorized because of quality of protection.
65	Access to a resource is unauthorized because of an authorization level.
66	Access to a resource is unauthorized because reauthentication is required.
67	A password error has occurred because it does not meet password standards: minimum alphabetic characters required.
68	A password error has occurred because it does not meet password standards: minimum alphanumeric characters required.
69	A password error has occurred because it does not meet password standards: minimum numeric characters required.
70	A password error has occurred because it does not meet password standards: minimum alphabetic low case characters required.
71	A password error has occurred because it does not meet password standards: minimum alphabetic upper case characters required.
72	A password error has occurred because it does not meet password standards: minimum special characters required.

Table 211. Event Outcome Codes (continued). This table lists the event outcome codes.

73	A password error has occurred because it does not meet password standards: maximum repeated characters exceeded.
74	A password error has occurred because it does not meet password standards: contains user name
75	A password error has occurred because it does not meet password standards: reused password.
76	A password error has occurred because it does not meet password standards: contains previous password.
77	A password error has occurred because it does not meet password standards: violations in number of characters.
78	A password error has occurred because it does not meet password standards: first or last characters are numeric.
79	An illegal form login configuration exists.
80	Access is denied because of a incorrect URI.
81	Start was successful
82	Stop was successful.
83	The audit subsystem has been stopped.
84	The audit subsystem has successfully been enabled.
85	The audit subsystem has had a successful policy change.
86	Delegation was successful.
87	Delegation was not successful.
88	The audit subsystem has successfully been disabled.
89	An audit subsystem has occurred because a security header is missing.
90	An audit timestamp has been confirmed.
91	A bad audit timestamp has occurred.
92	Audit confidentially has been confirmed
93	Audit confidentially cannot be confirmed.
94	An audit decryption error has occurred.
103	A login attempt has been made by a user who has already logged in successfully.

---

## Chapter 23. Administering Service integration

This page provides a starting point for finding information about service integration.

Service integration provides asynchronous messaging services. In asynchronous messaging, producing applications do not send messages directly to consuming applications. Instead, they send messages to destinations. Consuming applications receive messages from these destinations. A producing application can send a message and then continue processing without waiting until a consuming application receives the message. If necessary, the destination stores the message until the consuming application is ready to receive it.

---

### Enabling or disabling service integration notification events

You can monitor your service integration environment by using notification events.

#### About this task

Service integration notification events allow you to monitor the activity of your service integration configuration by using your own system management application. For more details see Service integration notification events.

You can enable or disable service integration notification events at either the bus or the messaging engine level. The following table illustrates the effect of the two setting levels on the enablement of notifications:

*Table 212. Notification settings. The first and second columns of the table list the combinations of the bus-level and messaging engine level notification settings. The third column indicates if the notification is enabled or not based on the combination of the two notification settings.*

Bus-level notification setting	ME-level notification setting	Are notifications enabled
Not set	Not set	Disabled
Not set	Enabled	Enabled
Not set	Disabled	Disabled
Disabled	Not set	Disabled
Disabled	Enabled	Disabled
Disabled	Disabled	Disabled
Enabled	Not set	Enabled
Enabled	Enabled	Enabled
Enabled	Disabled	Disabled

#### Procedure

1. By using the administrative console, open the **Custom properties** page for either the bus or the messaging engine for which you want to set notification events:
  - Click **Service integration -> Buses -> bus\_name -> [Additional Properties] Custom properties** to display the custom properties for a bus.
  - Click **Service integration -> Buses -> bus\_name -> [Topology] Messaging engines -> engine\_name -> [Additional Properties] Custom properties** to display the custom properties for a messaging engine.
2. Click **New** to create a new custom property.
3. Enter sib.event.notification as the name of the custom property. Set the value of the custom property to either “enabled” or “disabled” as required.
4. Optional: Enter a description for the custom property.
5. Click **OK** and save your changes to the master configuration.

---

## Administering service integration buses

Application servers or clusters of application servers in a WebSphere Application Server cell can cooperate to provide asynchronous messaging services. Service integration provides asynchronous messaging services, and a group of servers or clusters that cooperate in this way is called a service integration bus. Each of the cooperating servers or clusters is made a member of the bus. In the simplest case, a service integration bus consists of a single bus member, which is one application server.

### Procedure

- Service integration technologies
- Bus configurations
- “Configuring buses”
- “Operating buses” on page 2151

## Configuring buses

You can configure service integration buses in a variety of ways; for example you can create and apply security to a bus and you can then add servers or server clusters to that bus.

### Creating a bus

When you create a service integration bus, you add a new bus in the administrative console, and then add one or more servers or server clusters as bus members. Thereafter, you administer the bus, and its constituent bus members, as a single unit.

### Before you begin

- Plan your bus topology. For more information, see [Bus configurations](#).
- Plan your security strategy. For more information, see [Service integration security planning](#).

### About this task

You can create a bus by using the administrative console. Wizards are provided to help you add a secured bus, and add a member to the bus. A messaging engine is created for most types of bus member, and you are prompted to specify a data store. The exception is WebSphere MQ server where, because a messaging engine is not created, a message store is not required.

### Procedure

1. Add a secured bus or an unsecured bus. For the steps, see “Adding buses” on page 2083.
2. Add a member to the bus. Choose one of the following approaches:
  - “Adding a server as a new bus member” on page 2088. This creates a messaging engine with default properties.
  - “Adding a cluster as a member of a bus” on page 2089. This creates at least one messaging engine for the cluster, with default properties.
3. Optional: Configure the messaging engine, if required. See “Configuring messaging engine properties” on page 2103.
4. Optional: Configure the message store for the messaging engine, if required. Choose one of the following approaches:
  - For a messaging engine in an application server, you can change the data store configuration. You might do this, for example, if you want to use DB2 rather than Apache Derby as the database system. For more information about changing the data store configuration, see “Configuring a JDBC data source for a messaging engine” on page 2174.
  - For a messaging engine in a server cluster, configure the data store. For more information about configuring the data store for a messaging engine in a cluster, see “Configuring a data source for a messaging engine running in a cluster” on page 2177.

You can also change the file store configuration. Refer to “Modifying file store configuration” on page 2167.

5. Restart the server or, if the member you added was a cluster, restart the eligible servers in the cluster. The messaging engine starts when the server starts.

## Results

A new bus is created.

## What to do next

You can now change the configuration of the bus; for example, by adding additional members, by creating bus destinations, and by creating links to WebSphere MQ networks. You can create other buses and, if required, connect them together.

## Adding buses

You can add a new service integration bus by using the administrative console. If messaging security is enabled, security settings are configured for the bus by default. You can add a unsecured bus if you disable messaging security.

### *Adding a secured bus:*

In this task you add a new service integration bus that is secured by default. The security settings for the bus are stored in a security domain. When you add a new bus, you can assign it to the default global security domain, the cell-level domain, or specify a custom domain that contains a set of settings that are unique to the bus, or shared with another resource.

## Before you begin

- Plan the security requirements for the bus. For more information about security planning, see Service integration security planning. For more information about security domains, see Messaging security and multiple security domains.
- Stop all servers that have the SIB Service enabled. This ensures that the bus security configuration is applied consistently when the servers are restarted. For more information, see Stopping an application server.

## About this task

This task uses an administrative console security wizard to add a new bus. If the wizard detects that administrative security is disabled, it prompts you to configure a user repository, and enable administrative security.

By default, connecting clients are required to use SSL protected transports to ensure data confidentiality and integrity. If you do not want clients to use SSL protected transports, you can specify that you do not require this option.

The type of security domain you can specify for the bus depends on the versions of the bus members you intend to add to the bus:

- You must specify the global domain if you want to add one or more WebSphere Application Server Version 6 bus members.
- You can specify the global, cell-level, or custom domain if you want to add WebSphere Application Server Version 7.0 or later bus members only.

## Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of buses is displayed.
2. Click **New**.
3. Type a name for the new bus. You must choose bus names that are compatible with the WebSphere MQ queue manager naming restrictions. You cannot change a bus name after the bus is created, which means that you can only interoperate with WebSphere MQ in the future if you use compatible names. See the topic about WebSphere MQ naming restrictions in the related links.
4. Ensure that the **Bus security** check box is selected.
5. Click **Next**. The Bus Security Configuration wizard is started.
6. Read the Introduction panel, and click **Next**.
7. If the wizard detects that administrative security is disabled, follow the prompts to select, and configure the appropriate user repository.
8. Click **Next**. A summary of the administrative security settings for the bus is displayed.
9. Review the summary, and click **Finish**. Administrative security for the cell is now enabled.
10. If you do not want clients to use SSL protected transports, clear the check box **Require clients use SSL protected transports**.
11. Select a security domain for the bus.
12. If you have selected to use a custom security domain, follow the prompts to specify a user realm.
13. Review the summary of your choices, and click **Finish**.
14. Save your changes to the master configuration.

## Results

You have created a new bus secured with your chosen security settings.

## What to do next

- You must propagate the bus security configuration to all the affected nodes, and restart the servers. For more information, see Synchronizing nodes using the wsadmin scripting tool and Starting an application server.
- You can add bus members to the bus.
- Groups of users in the user repository require explicit authority to access the bus. For more information, see Administering authorization permissions.

## *Adding an unsecured bus:*

By default, bus security is enabled and you add buses with security configured. However, you can add a new service integration bus without any security settings. If you want to secure the bus at a later date, you can do so by configuring the security settings for the bus.

## About this task

To add a bus, use the administrative console to complete the following steps:

## Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of buses is displayed.
2. In the content pane, click **New**.
3. Type a name for the new bus. You must choose bus names that are compatible with the WebSphere MQ queue manager naming restrictions. You cannot change a bus name after the bus is created, which means that you can only interoperate with WebSphere MQ in the future if you use compatible names. See the topic about WebSphere MQ naming restrictions in the related links.
4. Clear the **Bus security** check box to disable bus security.

5. Click **Next**.
6. Review the summary of the settings for the new bus, then click **Finish**.
7. Save your changes to the master configuration.

## Results

Bus security is disabled, and you have added a new unsecured service integration bus.

## What to do next

You can now add servers or server clusters to the bus.

## Configuring bus properties

You can configure how many messages the bus can handle, when to discard messages, and which messaging engines the bus can communicate with. You can also specify changes that can be made to the bus that do not require a restart of the messaging engines.

## About this task

You configure bus properties after you have created a bus. To configure the properties of a bus, use the administrative console to complete the following steps:

## Procedure

1. Click **Service integration -> Buses -> *bus\_name***.
2. Specify the following properties for the bus:

### Description

A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

### Inter-engine transport chain

The transport chain used for communication between messaging engines in this bus.

The transport chain must correspond to one of the transport chains defined in the *Messaging engine inbound transports* settings for the server. All servers automatically have a number of transport chains defined to them, and it is also possible to create new transport chains.

When you specify the name of a transport chain, that chain must be defined to all servers hosting messaging engines in the bus. Otherwise, some messaging engines might not be able to communicate with their peers in the bus.

When the use of permitted chains is enforced and a protocol is not specified for intra-bus communications then InboundSecureMessaging is assumed instead of InboundBasicMessaging. This can be overridden by setting the protocol attribute in the bus configuration. If InboundSecureMessaging is not a permitted chain then an error occurs.

### Discard messages

Whether messages on a deleted message point should be retained at a system exception destination or can be discarded. Select this option to indicate that after a queue has been deleted, any messages left in the data store for that queue should be discarded.

### Configuration reload enabled

Select this option to enable automatic update of configuration information on all the messaging engines on the bus.

Changes to bus destinations or mediations are applied when destinations or mediations are added to or removed from the bus.

Changes to the modifiable configuration information for any foreign bus connections are also updated automatically. The time when these changes take effect varies:

**Foreign Bus Connection properties**

Immediately

**WebSphere MQ link properties**

On channel restart, except Description (immediately), and Initial State (on messaging engine restart)

**MQ sender channel properties**

On channel restart, except Initial State (on messaging engine restart or sender channel creation)

**MQ receiver channel properties**

On channel restart, except Initial State (on messaging engine restart or receiver channel creation)

**Publish/subscribe broker profile (0 to n) properties**

Immediately

**Service integration bus link properties**

On link restart, except Description (immediately), and Initial State (on messaging engine restart or link creation)

To ensure that dynamic configuration updates are made on an application server, click **Servers -> Server Types -> WebSphere application servers -> server\_name -> [Server messaging] SIB service** then select **Configuration reload enabled**.

To ensure that dynamic configuration updates are made to each node, click **System administration -> Console Preferences** to display the Console Preferences window then select **Synchronize changes with nodes**.

**Default messaging engine high message threshold**

A threshold above which the messaging system will take action to limit the addition of more messages to a message point. When a messaging engine is created on the bus, the value of this property is used to set the default high message threshold for the messaging engine.

3. Specify topology, destination resources, web services and additional properties for the bus, as required. To restrict the number of audit messages, add a custom property called `audit.bus.authentication` with one of the following values:
  - `all` (audit all attempts to authenticate to the bus)
  - `failure` (audit only failure to authenticate to the bus)
  - `none` (do not audit any attempts to authenticate to the bus)
4. Click **OK**.
5. Save your changes to the master configuration.

**Listing the buses**

You can view the list of the service integration buses that currently exist. You can decide which buses you want to change, for example, to add a server or a server cluster to a bus.

**About this task**

To list the buses, use the administrative console to complete the following step. After you list the service integration buses, you can add or delete a bus. Also, you can select a bus to view its details, add a member to the bus, create a foreign bus connection, or apply security to the bus.

**Procedure**

In the navigation pane, click **Service integration -> Buses**.

## Results

A list of buses is displayed in the content pane.

## What to do next

You can now add or delete buses, or click on a bus name to display or configure its properties.

## Displaying the topology of a service integration bus

You can display a tree view of the members of a bus, and the messaging engines used by a selected bus, in the administrative console. You can also view the runtime status for each messaging engine.

## About this task

Use this task to display a *local topology* view of the bus members and messaging engines in a service integration bus. You can use this view to add servers and server clusters as members of the bus, and to add messaging engines to cluster bus members.

To display the local topology view of a service integration bus, use the administrative console to complete the following steps:

## Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of buses is displayed in the content pane.
2. In the content pane, click the name of the bus. For example, `SCA.SYSTEM.localhostCell101.Bus`
3. Click the tab **Local Topology**

## Results

The topology of the bus is displayed as an expandable tree.

## What to do next

You can expand nodes of the tree to display the bus members and their messaging engines.

You can add servers and server clusters as members of the bus, and add messaging engines to cluster bus members.

## Deleting a bus

You can delete a service integration bus, for example if it is no longer in use.

## Before you begin

**Attention:** When you delete a bus, each messaging engine on the bus is also deleted and any associated messages are discarded. If you subsequently create a new bus with the same name as the deleted bus, the new bus will not have the same universal unique identifier (UUID) as the deleted bus.

## About this task

To delete a bus, use the administrative console to complete the following steps.

## Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of buses is displayed in the content pane.
2. In the content pane, select the bus that you want to delete.

3. Click **Delete**.
4. Click **OK**.
5. Save your changes to the master configuration.

## What to do next

You must disable the SIB Service at server startup.

When the SIB Service is enabled on z/OS, a flag is set to start the control region adjunct process when the server starts up. When you delete a bus, disable the SIB Service to prevent an adjunct space from starting when the server starts up.

## Configuring the members of a bus

Use the administrative console to add, remove, and list the members of a bus.

### ***Adding a server as a new bus member:***

The members of a service integration bus are the application servers and clusters within which messaging engines for that bus can run. When you add a new bus member, you configure its message store, which is either a file store or a data store.

### **About this task**

If you add a server as a member of a bus, WebSphere Application Server creates a messaging engine for the server. By default, the messaging engine is configured to use a file store. If you choose a data store, you have the choice of using the default JDBC data source and Derby JDBC Provider for its data store. If you do not want to use the default data source configuration, you can choose to use a different data source or you can configure the data store to use a different JDBC provider.

If you subsequently delete a bus member and then recreate it, you should make sure that you understand the life cycle of the file store or a data store. Refer to Data store life cycle and “Removing a messaging engine from a bus” on page 2103 for details.

If you are working in a mixed-version cell, a service integration bus running in this version of the product can only include WebSphere Application Server Version 6 bus members that are running in the following versions of the product:

- 6.0.2 (Fix Pack 23 or later)
- 6.1.0 (Fix Pack 13 or later)

If security is enabled, and the bus has mixed-version bus members, the bus members establish trust by using an inter-engine authentication alias. If you add a server as a bus member at WebSphere Application Server Version 6, and it is the first bus member at this level, you must select or create an authentication alias during this task. This action sets the inter-engine authentication alias.

### **Procedure**

1. In the navigation pane, click **Service integration -> Buses -> bus\_name -> [Topology] Bus members**. A list of members in the bus is displayed.
2. Click **Add**.
3. Select scope of the new bus member: this is one of *Server*, *Cluster* or *WebSphere MQ server*. **Server** is selected by default. Only select the **Cluster** scope in WebSphere Application Server environments that support server clusters.
4. Make your selection and click **Next**.
5. Select the type of message store: it is either a file store or a data store. For more information, see File stores and Data stores. **File store** is selected by default.

6. Click **Next**.

**Optional:** If you use a file store and want to change the default values, you can change them here. For more information refer to “Modifying file store configuration” on page 2167.

**Optional:** If you use a data store and want the messaging engine in the bus member to use a non-default data source, select **Use existing data source** and enter the JNDI name of an existing data source, and the name of the schema and authentication alias to be used. For more information, see “Configuring a messaging engine to use a data store” on page 2171. If there are multiple messaging engines, you must configure each messaging engine to use a unique schema, otherwise FFDC error messages stating that Connection cannot be provided as Datasource has been disabled! might appear. This applies to DB2 in particular.

7. Click **Next**.

8. If security is enabled, and adding this server creates a mixed-version bus, the wizard prompts for an authentication alias. Do one of the following:

- Select an existing authentication alias.
- Create a new authentication alias. Specify a unique alias name and password.

This action sets the inter-engine authentication alias.

9. Click **Finish** to confirm the creation of the bus member.

10. Save your changes to the master configuration. You must restart the server for the changes to take effect.

## Results

The member is added to the bus and a messaging engine is created for that member.

## What to do next

Next, you can configure the messaging engine. For more information about configuring messaging engines and their message stores, see the related tasks.

### *Adding a cluster as a member of a bus:*

You can add a server cluster as a member of a service integration bus so that it can use the bus to communicate. When a cluster is added to the bus, all servers in the cluster are added to it, and at least one messaging engine is created. The members of a service integration bus are the application servers and clusters within which messaging engines for that bus can run.

## Before you begin

To add a cluster to a bus, the following resources must be defined:

- A service integration bus.
- A cluster. For a high availability configuration, the cluster should contain at least two nodes, each with a server on, that is, at least two physical machines.
- A location for the message store for the messaging engine. Each messaging engine uses a message store to preserve operating and recovery information.
  - To use a file store, you need a file location.
  - To use a data store, you need a suitable data source, such as a relational database, that is accessed through a JDBC data source.

You can use the default JDBC data source and Derby JDBC Provider for its data store. If you do not want to use the default data source configuration, you can use a different data source or you can configure the data store to use a different JDBC provider.

If you want any of the messaging engines in the cluster to fail over to another server, all servers that might host each messaging engine need access to the message store for that messaging engine.

### **About this task**

When you add a server cluster as a member of a bus, consider the following points:

- If you use messaging engine policy assistance, one or more messaging engines are created and configured, according to the messaging engine policy type you select. You can choose one of the predefined messaging engine policy types, which are designed to support frequently-used configurations, or choose a custom messaging engine policy type, where some configuration settings are created automatically but you can customize them.
- If you do not use messaging engine policy assistance, one messaging engine is created. This messaging engine has default properties and uses the default core group policy for service integration, “Default SIBus Policy”. After adding the bus member, you can create more messaging engines and can configure one or more new core group policies to customize the way that the messaging engines are managed. It is advisable to create a new, separate, core group policy for each new messaging engine, including the first one. It is not advisable to alter the default policy for service integration. Use this procedure if you are already familiar with it. Otherwise, use messaging engine policy assistance.
- If you are working in a mixed-version cell, a service integration bus running in this version of the product can only include WebSphere Application Server Version 6 bus members that are running in the following versions of the product:
  - 6.0.2 (Fix Pack 23 or later)
  - 6.1.0 (Fix Pack 13 or later)
- If security is enabled, and the bus has mixed-version bus members, the bus members establish trust by using an inter-engine authentication alias. If you add a server cluster as a bus member at WebSphere Application Server Version 6, and it is the first bus member at this level, you must select or create an authentication alias during this task. This action sets the inter-engine authentication alias.
- If you subsequently delete a bus member and then re-create it, you must manually delete the old data source to ensure that the messaging engines will restart after the bus member has been created. Refer to Data store life cycle and “Removing a messaging engine from a bus” on page 2103 for details.

*Adding a cluster to a bus for high availability or scalability:*

You can add a cluster as a member of a bus and use messaging engine policy assistance and a predefined messaging engine policy that provides high availability, scalability, or scalability with high availability. Messaging engine policy assistance helps you to create and configure the messaging engines in a cluster to provide the required messaging engine behavior.

### **Before you begin**

Ensure that you have defined the resources listed in “Adding a cluster as a member of a bus” on page 2089.

### **About this task**

The following predefined messaging engine policies are available:

- High availability. Use the high availability policy when you want to ensure that there is always a messaging engine running in that cluster, so that messages are always transmitted.

The high availability messaging engine policy creates a single messaging engine for the cluster. The messaging engine is configured to fail over to any of the other servers in the cluster. The order in which the servers are used for failover depends on their order in the preferred servers list. The earlier the server in the preferred servers list, the stronger the preference for that server. The messaging engine does not fail back, that is, if a more preferred server becomes available again, the messaging engine does not move back to that server.

- **Scalability.** Use the scalability policy for a system where you want to add more servers to a cluster and maintain the performance.

The scalability messaging engine policy creates a single messaging engine for each server in the cluster. Each messaging engine can run only on the server that it is assigned to, and it cannot fail over to another server. If a server fails, the messaging engine that is running on it also fails, and is not available until the server recovers. You can add new servers to the cluster without affecting existing messaging engines in the cluster.

- **Scalability with high availability.** Use the scalability with high availability policy for a system where you want to add more servers to a cluster and maintain the performance, but you also want to ensure that messaging is always available.

The scalability with high availability messaging engine policy creates a single messaging engine for each server in the cluster. Each messaging engine can fail over to one other specified server in the cluster. Each server can host up to two messaging engines, such that there is an ordered circular relationship between the servers. Each messaging engine can fail back, that is, if a messaging engine fails over to another server, and then the original server becomes available again, the messaging engine automatically moves back to that server.

If you are working in a mixed-version cell, a service integration bus running in this version of the product can only include WebSphere Application Server Version 6 bus members that are running in the following versions of the product:

- 6.0.2 (Fix Pack 23 or later)
- 6.1.0 (Fix Pack 13 or later)

If security is enabled, and the bus has mixed-version bus members, the bus members establish trust by using an inter-engine authentication alias. If you add a server cluster as a bus member at WebSphere Application Server Version 6, and it is the first bus member at this level, you must select or create an authentication alias during this task. This action sets the inter-engine authentication alias.

### Procedure

1. In the navigation pane, click **Service integration -> Buses -> *bus\_name* -> [Topology] Bus members.**
2. Click **Add** to start the Add a new bus member wizard.
3. In the first pane, select **Cluster**, and, from the drop-down list, select the cluster that you want to make a member of the bus.
4. In the Messaging engine policy assistance settings pane, ensure that the **Enable messaging engine policy assistance** check box is selected. Select one of the following options, depending on the messaging engine policy that you require:
  - **High availability**
  - **Scalability**
  - **Scalability with high availability**

If the value of the “Is further configuration required” column for the selected messaging engine policy is No, continue with the procedure. Otherwise, examine the messages displayed and decide whether to go back and change the cluster configuration, or to continue. A diagram of the selected cluster and the eventual outcome of the selected messaging engine policy is displayed.

5. Select the type of message store that you have already defined.
6. In the Configure messaging engines pane, for each messaging engine listed, click the messaging engine name and enter details for its message store.
  - If you use a file store, specify the directory paths for the log files, the permanent file store, and the temporary file store. Do not use the default path, and ensure that you use a unique path for each messaging engine.

- If you use a data store, specify the JNDI name of the data source that provides access to the database that holds the data store.
7. If security is enabled, and adding this cluster bus member creates a mixed-version bus, the wizard prompts for an authentication alias. Do one of the following:
- Select an existing authentication alias.
  - Create a new authentication alias. Specify a unique alias name and password.
- This action sets the inter-engine authentication alias.
8. When the Add a new bus member wizard is finished, save your changes to the master configuration.

## Results

You have created a cluster bus member.

- For the high availability messaging engine policy, there is a single messaging engine, named *cluster\_name.nnn-bus\_name*, which can fail over to any of the servers in the cluster.
- For the scalability messaging engine policy, there is one messaging engine for each server in the cluster, named *cluster\_name.nnn-bus\_name*. Each messaging engine in the cluster is restricted to running on one server.
- For the scalability with high availability messaging engine policy, there is one messaging engine for each application server in the cluster, named *cluster\_name.nnn-bus\_name*. Each messaging engine in the cluster can fail over to one other specified server in the cluster, and can fail back to its preferred server if that server becomes available again.

For each messaging engine, there is a core group policy named *messaging\_engine\_name-numberPolicy*. This core group policy is configured with the behavior you chose for the messaging engine policy, and is associated with the messaging engine through its match criteria.

*Adding a cluster to a bus with a custom configuration:*

You can add a cluster as a member of a bus and use messaging engine policy assistance and the custom messaging engine policy. In this situation, messaging engine policy assistance helps you to create and configure messaging engines in a cluster that is a member of a bus when the predefined messaging engine policy types do not meet your needs. You can configure the messaging engine behavior, and the appropriate messaging engine policies are created automatically.

## Before you begin

Ensure that you have defined the resources listed in “Adding a cluster as a member of a bus” on page 2089.

## About this task

When you use the custom messaging engine policy, you can create any number of messaging engines for the cluster. For each messaging engine, you must specify the behavior that you require, such as whether it can fail over and whether it uses preferred servers. The core group policies and match criteria for each messaging engine are automatically created. Use this option when the other options of High availability, Scalability, or Scalability with high availability do not provide the messaging engine behavior you require, and you are familiar with creating messaging engines and configuring messaging engine policy settings.

If you are working in a mixed-version cell, a service integration bus running in this version of the product can only include WebSphere Application Server Version 6 bus members that are running in the following versions of the product:

- 6.0.2 (Fix Pack 23 or later)
- 6.1.0 (Fix Pack 13 or later)

If security is enabled, and the bus has mixed-version bus members, the bus members establish trust by using an inter-engine authentication alias. If you add a server cluster as a bus member at WebSphere Application Server Version 6, and it is the first bus member at this level, you must select or create an authentication alias during this task. This action sets the inter-engine authentication alias.

## Procedure

1. In the navigation pane, click **Service integration -> Buses -> bus\_name -> [Topology] Bus members**.
2. Click **Add** to start the Add a new bus member wizard.
3. In the first pane, select **Cluster**, and, from the drop-down list, select the cluster that you want to make a member of the bus.
4. In the Messaging engine policy assistance settings pane, ensure that the **Enable messaging engine policy assistance** check box is selected, and select **Custom**.
5. Select the type of message store that you have already defined.
6. In the Configure messaging engines pane, click **Add** to add and configure at least one messaging engine.
7. In the Configure the messaging engine policy pane, use the options and the preferred servers list to set the messaging engine behavior you require. The messaging engine name is automatically generated, in the format *cluster\_name.nnn-bus\_name*.
8. Enter details for the message store.
  - If you use a file store, specify the directory paths for the log files, the permanent file store, and the temporary file store. Do not use the default path, and ensure that you use a unique path for each messaging engine.
  - If you use a data store, specify the JNDI name of the data source that provides access to the database that holds the data store.
9. If security is enabled, and adding this cluster bus member creates a mixed-version bus, the wizard prompts for an authentication alias. Do one of the following:
  - Select an existing authentication alias.
  - Create a new authentication alias. Specify a unique alias name and password.

This action sets the inter-engine authentication alias.
10. Optional: Repeat the steps to add and configure further messaging engines for the cluster.
11. When the Add a new bus member wizard is finished, save your changes to the master configuration.

## Results

You have created a cluster bus member and at least one messaging engine, named *cluster\_name.nnn-bus\_name*. For each messaging engine, there is a core group policy named *messaging\_engine\_name-numberPolicy*. This core group policy is configured with the behavior you chose for the messaging engine policy, and is associated with the messaging engine through its match criteria.

## What to do next

To see a diagram of the cluster and the messaging engine configuration you have created, click the bus member name in the Bus members collection pane.

*Adding a cluster to a bus without using messaging engine policy assistance:*

You can add a cluster as a member of a service integration bus without using messaging engine policy assistance. One messaging engine with default properties is created for the cluster. After you add the cluster, you can create more messaging engines and you can create and configure new core group policies to customize the way that the messaging engines are managed.

## Before you begin

Ensure that you have defined the resources listed in “Adding a cluster as a member of a bus” on page 2089.

## About this task

When you add a server cluster as a member of a bus without using messaging engine policy assistance, one messaging engine is created for the cluster. The messaging engine uses the default SIBus core group policy with default properties, such that the messaging engine can fail over to any server in the cluster.

After you add the cluster, you can customize the configuration. You can create more messaging engines and you can create and configure new core group policies to customize the way that the messaging engines are managed. To do this, you must know how to create and configure a core group policy for messaging engines, and know how to use match criteria to associate a messaging engine with a core group policy.

Use the following procedure if you are already familiar with this procedure. Otherwise, use messaging engine policy assistance.

If you are working in a mixed-version cell, a service integration bus running in this version of the product can only include WebSphere Application Server Version 6 bus members that are running in the following versions of the product:

- 6.0.2 (Fix Pack 23 or later)
- 6.1.0 (Fix Pack 13 or later)

If security is enabled, and the bus has mixed-version bus members, the bus members establish trust by using an inter-engine authentication alias. If you add a server cluster as a bus member at WebSphere Application Server Version 6, and it is the first bus member at this level, you must select or create an authentication alias during this task. This action sets the inter-engine authentication alias.

## Procedure

1. In the navigation pane, click **Service integration -> Buses -> bus\_name -> [Topology] Bus members**.
2. Click **Add** to start the Add a new bus member wizard.
3. In the first pane, select **Cluster** and, from the drop-down list, select the cluster that you want to make a member of the bus.
4. In the Messaging engine policy assistance settings pane, ensure that the **Enable messaging engine policy assistance** check box is not selected.
5. Select the type of message store that you have already defined.
  - If you use a file store, specify the directory paths for the log files, the permanent file store, and the temporary file store. Do not use the default path, and ensure that you use a unique path for each messaging engine.
  - If you use a data store, specify the JNDI name of the data source that provides access to the database that holds the data store.
6. If security is enabled, and adding this cluster bus member creates a mixed-version bus, the wizard prompts for an authentication alias. Do one of the following:
  - Select an existing authentication alias.
  - Create a new authentication alias. Specify a unique alias name and password.

This action sets the inter-engine authentication alias.

7. When the Add a new bus member wizard is finished, save your changes to the master configuration.

## Results

The cluster is now a member of the bus and has a single messaging engine, named *cluster\_name.nnn-bus\_name*. The messaging engine uses the default SIBus core group policy with default properties (One of N with no preferred servers), such that the messaging engine can fail over to any server in the cluster. This cluster configuration provides a highly available messaging engine.

## What to do next

If you require high availability, you might want to do further configuration, for example to specify preferred servers for the messaging engine, or enable the messaging engine to fail back. If you require scalability or workload sharing, add as many messaging engines as you require to the cluster. To customize the messaging engine behavior, create and configure a new core group policy for the messaging engines and use match criteria to associate the messaging engines with the core group policy. It is advisable to create a new, separate, core group policy for each new messaging engine, including the first one. It is not advisable to alter the default SIBus core group policy. For more information, see the related tasks.

### ***Modifying the messaging engine policy for a cluster bus member:***

You can change the messaging engine policy for a cluster bus member that is already configured, and change the number of messaging engines and their behavior so that they conform with the new messaging engine policy.

## Before you begin

If you modify the messaging engine policy to provide a high availability configuration, the cluster should contain at least two nodes, each with a server on, that is, at least two physical machines.

## About this task

Use this procedure when you have already added a server cluster as a member of a bus and configured its messaging engines, and you now want to change the configuration. For example, if a cluster is configured for high availability, there is one messaging engine for the cluster and it is set to fail over to any other server in the cluster. To change the cluster to provide scalability, you need one messaging engine for each server, set so that each messaging engine cannot fail over. Messaging engine policy assistance guides you through this process by providing messages about the changes required to achieve the required configuration.

## Procedure

1. In the navigation pane, click **Service integration -> Buses -> bus\_name -> [Topology] Bus members -> bus\_member\_name**. If messaging engine policy assistance is enabled, the Bus member detail pane is displayed. If messaging engine policy assistance is not enabled, the Messaging engine collection pane is displayed.
2. If messaging engine policy assistance is not enabled, click **Enable policy assistance** and follow the instructions on the wizard.
3. From the Bus member detail pane, select one of the following messaging engine policy types, then click **Apply**:
  - **High availability**
  - **Scalability**
  - **Scalability with high availability**

If these policy types do not satisfy your requirements, is possible to select **Custom** and create your own configuration. If you do this, the system cannot generate any advice or warning messages.

4. Examine the resulting diagram and the messages for the selected messaging engine policy type. Act on the messages as follows:

- To add a server or a node, go back and change the cluster topology before you continue with the current procedure.
- To add or remove messaging engines, under **Additional Properties**, click **Messaging engines** and use the options on the resulting pane.
- To correct messaging engine policies, under **Additional Properties**, click **Messaging engine policy maintenance** and use the options on the resulting pane.

At each stage, save your changes to the master configuration. If the Bus members collection pane is displayed, click the cluster name to return to the Bus member detail pane.

When the “Is further configuration required” column for the selected messaging engine policy type displays No, the configuration is complete.

5. If necessary, save your changes to the master configuration.

## Results

The cluster has the number of messaging engines that are required to conform to your selected messaging engine policy type. Any changes to the core group policies associated with the messaging engines are made automatically.

### *Adding a WebSphere MQ server as a member of a bus:*

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. A WebSphere MQ server bus member is used as a bus member for assigning queue points and mediation points to WebSphere MQ queues.

## Before you begin

Get details of the client connection from your WebSphere MQ administrator.

Ensure that the WebSphere MQ server has been configured, that the bus has been defined and that the server is not already a member of the bus.

Decide which method to use to configure these resources. You can add the WebSphere MQ server as a bus member by using the administrative console as described in this task, or by using the “addSIBusMember command” on page 2485.

## About this task

When you add a WebSphere MQ server to one or more buses, messaging engines on these buses can access queues on the target WebSphere MQ installation. When you make the server a bus member, you can override the server connection settings with settings that are specific to the new bus member. This can be useful in a multiple bus topology.

## Procedure

1. Start the administrative console.
2. Navigate to the list of bus members for the bus to which you are adding the WebSphere MQ server.  
Click **Service integration -> Buses -> bus\_name -> [Topology] Bus members**.
3. Click **Add**. The “Add a new bus member” wizard is displayed.
4. Select the WebSphere MQ server to add to the bus:
  - a. Select **WebSphere MQ server**.
  - b. From the drop-down list, select the server to add.
  - c. Click **Next**.
5. Specify the virtual queue manager name.

When sending messages to WebSphere MQ, the WebSphere MQ gateway queue manager sees the bus as a remote queue manager. The virtual queue manager name is the name that is passed to WebSphere MQ as the name of this remote queue manager. The default value is the name of the bus. If this value is not a valid name for a WebSphere MQ queue manager, or if another WebSphere MQ queue manager already exists that has the same name, then replace the default value with another value that is a valid and unique name for a WebSphere MQ queue manager. To be valid, the name must meet the following criteria:

- It must contain between 1 and 48 characters.
  - It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).
6. Optional: To override the server connection settings, select the **Override WebSphere MQ server connection properties** check box.  
When you select this option, the connection properties for the server are made available so that you can change them to settings that are specific to this bus member. For more information about these connection properties, see “WebSphere MQ server bus member [Settings]” on page 2467.
  7. Optional: If you have changed the server connection settings, you can click **Test connection** to test the connection to the associated WebSphere MQ network.
  8. Click **Next**.
  9. Click **Finish** to confirm.
  10. Save your changes to the master configuration.

### What to do next

You are now ready to create a WebSphere MQ queue-type destination for the new bus member.

### *Listing the members of a bus:*

You can display a list of servers, server clusters, and WebSphere MQ servers that have been added as members of a bus.

### About this task

You can list the members of a bus, then you can add, remove, or edit the bus members. To list the members of a bus, use the administrative console to complete the following steps.

### Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of buses is displayed in the content pane.
2. In the content pane, select the bus whose members you want to list.
3. In the content pane, under **Topology**, click **Bus members**. A list of members of the bus is displayed.

### *Removing a member from a bus:*

You can remove an application server, or a server cluster, from a bus so that it is no longer used to process messages.

## Before you begin

### Attention:

- When you remove a member from a bus, all messaging engines on that bus member are also deleted and their associated messages are discarded. If you add the same bus member again, first you must manually delete the old data source for the messaging engines to ensure that once the new messaging engines are created, they can restart.
- If you remove a member from a bus, and it is the only member for that server, you must also disable the SIB Service at server start up.  
On z/OS, disabling the SIB Service prevents an adjunct address space from starting when the server starts up.

### About this task

To remove a member from a bus, use the administrative console to complete the following steps:

### Procedure

1. In the navigation pane, click **Service integration** -> **Buses**. A list of buses is displayed in the content pane.
2. In the content pane, select the bus from which you want to remove the member.
3. In the content pane, under **Topology**, click **Bus members**. A list of members in the bus is displayed.
4. Select the bus member that you want to remove.
5. Click **Remove**.
6. Save your changes to the master configuration.

### Results

The member is removed from the bus. All the messaging engines on that bus member and the core group policies that are associated with those messaging engines are deleted.

### What to do next

If you have removed the only bus member for a server, you must now disable the SIB Service at server start up.

### *Disabling the service integration service:*

The SIB Service, which provides messaging capability, is enabled automatically when you add a server to a service integration bus. If required, you can disable service integration bus functions when the application server starts.

### About this task

You can choose to disable the SIB Service, for example if you have removed the only bus member for a server.

Enabling or disabling the SIB Service has the same effect as enabling or disabling the Control Region Adjunct (CRA).

You can use the administrative console to disable the SIB Service, or wsadmin scripting. The following example shows a Jython script for disabling the SIB Service:

```
server = AdminConfig.getid('/Server:server1/')
sibService = AdminConfig.list('SIBService', server)
AdminConfig.modify(sibService, [["enable", "false"]])
```

To use the administrative console to disable the SIB Service, complete the following steps.

### Procedure

1. Click **Servers -> Server Types -> WebSphere application servers -> *server\_name* -> [Server messaging] SIB service** to display the SIB service settings pane.
2. Click the Configuration tab to display configuration properties for the service integration service.
3. Clear the Enable service at server startup check box.
4. Save your changes to the master configuration.

### Results

You have disabled the SIB Service. Service integration bus functions are not available when the application server starts up.

## Administering bootstrap members for a bus

A service integration bus can have bootstrap members. These are bus members, cell members for which the Service Integration Bus Service is enabled, or nominated cell members that can service requests to bootstrap into the bus, depending on the bootstrap policy configured for the bus.

### Before you begin

**Note:** If the bus is in a mixed-version cell, the deployment manager must be at a Version 7.0 or later level.

### About this task

You can configure the bootstrap member policy for a bus, nominate, list and delete bootstrap members for a selected bus as follows:

#### *Configuring a bootstrap member policy for a bus:*

By configuring a bootstrap member policy for a selected service integration bus, you control which servers and clusters respond to bootstrap requests from client applications.

### Before you begin

**Note:** If the bus is in a mixed-version cell, the deployment manager must be at a Version 7.0 or later level.

### About this task

A bus can use bootstrap members to service connection requests from client applications. In this task, you define a bootstrap member policy for a selected bus that defines which servers and clusters can bootstrap into the bus. The default bootstrap member policy is all cell members that have the Service Integration Bus Service enabled. You can restrict bootstrap membership to bus members only, or to bus members, and nominated bootstrap members. These are servers and clusters that are not bus members, but have been nominated as bootstrap members.

### Procedure

1. Log onto the administrative console.
2. Click **Service integration -> Buses -> *bus\_name***. The configuration panel for the selected bus is displayed.
3. Choose one of the following bootstrap members policies for the bus:

### **All members of the cell with the Service Integration Bus Service enabled**

This is the default option. All the servers and clusters in the cell that have the Service Integration Bus Service enabled are bootstrap members.

### **Bus members and nominated bootstrap members**

Bootstrap membership is restricted to servers and clusters that are bus members, or have been nominated as bootstrap members.

### **Bus members only**

Bootstrap membership is restricted to servers and clusters that are bus members.

4. Click **Apply**.
5. Save your changes to the master configuration.

## **Results**

Requests from client applications to connect to the bus are serviced by the servers and clusters in the cell that meet the criteria set by the bootstrap member policy you have configured for the bus.

## **What to do next**

Use the administrative console to list, nominate or delete bootstrap members for the selected bus.

### ***Listing the bootstrap members for a bus:***

Use this task to find out which servers and clusters in the cell are available to service requests from clients to connect to a particular service integration bus. The list of available servers and clusters is restricted by the bootstrap member policy configured for the bus.

## **Before you begin**

You must ensure that the appropriate bootstrap member policy has been configured for the bus. For more information, see “Configuring a bootstrap member policy for a bus” on page 2099.

## **About this task**

In this task, you use the administrative console to list the bootstrap members for a selected bus. The list of bootstrap members depends on which of the following bootstrap member policies is configured for the bus:

### **All members of the cell with the Service Integration Bus Service enabled**

This is the default policy. The list includes all the WebSphere Application ServerVersion 7.0 or later servers and clusters in the cell that have the Service Integration Bus Service enabled.

### **Bus members and nominated bootstrap members**

The list includes all the servers and clusters that are bus members, or have been nominated as bootstrap members.

### **Bus members only**

The list includes only servers and clusters that are members of the bus.

## **Procedure**

1. Log into the administrative console.
2. Click **Service integration -> Buses -> bus\_name -> [Topology] Bootstrap members**.

## **Results**

A list of the bootstrap members for the selected bus is displayed.

## What to do next

You can use the administrative console to nominate or remove bootstrap members, or configure a different bootstrap member policy for the bus.

### *Nominating bootstrap members for a bus:*

You can nominate one or more servers and clusters on cell nodes as bootstrap members for a selected bus. When the Bus members and nominated bootstrap members policy is configured for the bus, the nominated bootstrap members can service requests from client applications to connect to the bus.

## Before you begin

**Note:** You must ensure that the following requirements are met:

- If the bus is in a mixed-version cell, the deployment manager must be at a Version 7.0 or later level.
- The servers and clusters that you want to nominate as bootstrap members must be on Version 7.0 or later cell nodes.

## About this task

In this task, you use an administrative console wizard to configure the **Bus members and nominated bootstrap members** policy, and nominate bootstrap members for a selected bus.

## Procedure

1. Log onto the administrative console.
2. Click **Service integration -> Buses -> bus\_name -> [Topology] Bootstrap members**. The Bootstrap members panel displays all the bus members, servers and clusters in the cell that have the Service Integration Bus Service enabled.
3. Select the policy **Bus members and nominated bootstrap members**.
4. Click **Apply**. A list of current bus members, and nominated bootstrap members is displayed.
5. Click **New**. The Nominate a bootstrap server wizard is started.
6. Type the name of the server or cluster that you want to add in the **Name** field. The first match in the list of available servers and clusters is highlighted. Click **Add** to add the named server or cluster to the list of servers and clusters to add.
7. When you have listed all the servers and clusters that you want to add, click **Next**.
8. Review the summary of the servers and clusters that you have chosen to add.
9. If you want to change your selections:
  - a. Click **Previous** to return to the first step of the wizard.
  - b. Make the changes you require, and click **Next**.
10. Click **Finish** to add the new bootstrap members to the local configuration.
11. Save your changes to the master configuration. An updated list of bus members and nominated bootstrap members is displayed.

## Results

The nominated servers and clusters can service requests from client applications to bootstrap into the bus.

### *Deleting nominated bootstrap members from a bus:*

Deleting a nominated bootstrap member from a selected service integration bus prevents the server or cluster from servicing requests from client applications to bootstrap into the bus.

## Before you begin

You must configure the **Bus members and nominated bootstrap members** policy for the selected bus. For more information, refer to “Configuring a bootstrap member policy for a bus” on page 2099.

## About this task

In this task, you use the administrative console to list all the bootstrap members for a selected bus, and then delete the nominated bootstrap members that you no longer want to use to bootstrap into the bus. Note that you can delete only nominated bootstrap members.

## Procedure

1. Log onto the administrative console.
2. Click **Service integration -> Buses -> bus\_name -> [Topology] Bootstrap members**. All the nominated bootstrap members for the bus are listed.
3. Select the nominated bootstrap members that you no longer want to use to bootstrap into the bus, and click **Delete**. The Bootstrap members panel displays an updated list of bootstrap members.
4. Save your changes to the master configuration.

## Results

You cannot use the deleted nominated bootstrap members to bootstrap into the selected bus.

## Configuring messaging engines

You can configure messaging engines in a variety of ways. For example, you can create and apply security to a messaging engine, then use this engine to send and receive messages. When you add a server cluster to a service integration bus, at least one messaging engine is created automatically. If you also use messaging engine policy assistance, some configuration properties are set automatically.

### *Adding additional messaging engines to a cluster bus member:*

You can add extra messaging engines to a cluster bus member, for example to provide high availability or scalability in a cluster.

## About this task

When you add a server or cluster as a member of a bus, at least one messaging engine is created automatically. Each server bus member has only one messaging engine. However, cluster bus members can support additional messaging engines.

You can add multiple messaging engines at the time you create the cluster bus member, or you can add extra messaging engines at a later time.

When you add an extra messaging engine to an existing cluster bus member, the flow of messages through existing messaging engines is not disrupted. Also, if dynamic reloading is enabled (by selecting the **Configuration reload enabled** property for the cluster bus member), the existing messaging engines do not have to be restarted to become aware of the new messaging engine.

For more information about configuring bus properties, see “Configuring bus properties” on page 2085.

## Procedure

1. Add an extra messaging engine to an existing cluster bus member by completing one of the following steps:

- Add one or more messaging engines when you create a new cluster bus member. Use messaging engine policy assistance, which guides you through the creation and configuration of the messaging engines. See “Adding a cluster as a member of a bus” on page 2089.
  - Add an extra messaging engine to an existing cluster bus member. Either use the administrative console as described in “Adding a messaging engine to a cluster” on page 2105, or use the createSIBEngine command.
2. Optional: Enable dynamic reloading for the cluster bus member:
    - a. In the administrative console, navigate to **Servers -> Server Types -> WebSphere application servers -> server\_name -> [Server messaging] SIB service**.
    - b. Select **Configuration reload enabled**.
    - c. Click **OK**.
  3. Save your changes to the master configuration.

### ***Configuring messaging engine properties:***

You can configure the properties of a messaging engine in the administrative console. For example you can select whether the messaging engine is started automatically when its associated application server is started, how many messages it can process, and target groups that the engine can join.

### **About this task**

In most cases, you can configure the properties of a messaging engine without interrupting the processing of messages by the messaging engine.

### **Procedure**

1. Start the administrative console.
2. Navigate to **Service integration -> Buses -> bus\_name -> [Topology] Messaging engines -> engine\_name**.
3. Configure the messaging engine properties. For information about the properties that you can configure, see the property descriptions in “Messaging engines [Settings]” on page 2340
4. Click **OK**.
5. Save your changes to the master configuration.

### ***Listing the messaging engines in a bus:***

You can view the list of existing messaging engines in a bus by using the administrative console. You can decide which messaging engines you want to change, for example which buses they are associated with.

### **About this task**

To list the messaging engines in a bus, use the administrative console to complete the following steps.

### **Procedure**

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Topology**, click **Messaging engines**. The list of messaging engines in the bus is displayed.

### ***Removing a messaging engine from a bus:***

You can remove a messaging engine from a service integration bus if you no longer require it to send and receive messages on the bus.

## Before you begin

You should be wary of deleting and recreating messaging engines on bus members for which WS-Notification-administered subscribers have been configured, because in some cases this can leave the remote web service subscription active (and passing notification messages to the local server) even though there is no longer any record of it. For more information, see the WS-Notification troubleshooting tip *Problems can occur when deleting administered subscribers and messaging engines*.

## Procedure

1. Stop the messaging engine. You can stop either in **Immediate** or **Force** mode, as described in “Stopping a messaging engine” on page 2165.
2. Use the wsadmin command `deleteSIBEngine` to delete the messaging engine. All service integration bus links, MQ links, and custom properties that are owned by the engine are deleted.

**Note:** When you remove a messaging engine, WebSphere Application Server does not delete the data store tables automatically. You must remove them manually, or delete all the rows in all the tables. If you do this, a new messaging engine might fail to start if it attempts to use an orphaned data store. Refer to the documentation for your chosen relational database management system for information about deleting tables.

Alternatively, for Apache Derby, you can delete the database directory, which is located in `profile_root/databases/com.ibm.ws.sib`, where `profile_root` is the directory in which profile-specific information is stored. However, do this only if the messaging engine is the sole user of the database.

For more information, see *Data store life cycle*.

Similarly, the file store files are not automatically deleted when you delete the messaging engine. You might want to delete the file store files to reclaim disk space.

### ***Listing the messaging engines defined for a server bus member:***

You can display a list of messaging engines defined for a server bus member by using the administrative console. You can decide which messaging engines you want to change, for example, which buses they are associated with.

## About this task

To display the list of messaging engines, use the administrative console to complete the following steps:

## Procedure

1. In the navigation pane, click either **Service integration -> Buses -> bus\_name -> [Topology] Messaging engines** or **Servers -> Server Types -> WebSphere application servers -> server\_name -> [Server messaging] Messaging engines**. A list of messaging engines is displayed in the content pane.
2. Optional: Select one or more messaging engines to work with, for example to change the properties of the messaging engine.

### ***Listing the messaging engines for a cluster bus member:***

You can display the messaging engines for a cluster bus member in the administrative console. You can decide which messaging engines you want to change, for example, to change the properties of the messaging engine.

## About this task

To display the list of messaging engines for a cluster bus member, use the administrative console to complete the following steps:

### Procedure

1. In the navigation pane, click **Service integration -> Buses -> *bus\_name* -> [Topology] Bus members**.
2. Click the name of the cluster bus member. The Bus member detail panel is displayed.
3. In the content pane, under **Additional properties**, click **Messaging engines**.

### Results

A list of messaging engines is displayed in the content pane.

### What to do next

You can now add a messaging engine to the cluster bus member. You can remove, start, or stop selected messaging engines. You can click a messaging engine name and change the properties of the messaging engine.

#### *Adding a messaging engine to a cluster:*

You can add a messaging engine to a cluster bus member to provide additional asynchronous messaging services to the servers that are members of the cluster. Typically, you do this to provide workload sharing or scalability in the cluster.

### Before you begin

Ensure that you have defined a location for the message store for the messaging engine. Each messaging engine uses a message store to preserve operating and recovery information.

- To use a file store, you need a file location.
- To use a data store, you need a suitable data source, such as a relational database, that is accessed through a JDBC data source. You can use the default JDBC data source and Derby JDBC Provider for its data store. If you do not want to use the default data source configuration, you can use a different data source or you can configure the data store to use a different JDBC provider.

If you want any of the messaging engines in the cluster to fail over to another server, all servers that might host each messaging engine need access to the message store for that messaging engine.

## About this task

Use this procedure when you want to add a messaging engine to an existing cluster bus member.

Alternatively, you can add one or messaging engines when you add a cluster as a member of a bus. You can use messaging engine policy assistance, which guides you through the creation and configuration of the messaging engines.

### Procedure

1. In the navigation pane, click **Service integration -> Buses -> *bus\_name* -> [Topology] Bus members**.
2. In the content pane, click the name of the cluster to which you want to add a messaging engine. The Bus member detail pane is displayed.

3. In the content pane, under **Additional properties**, click **Messaging engines**. A list of messaging engines for the cluster is displayed.
4. In the content pane, click **Add messaging engine**.
5. Select the type of message store that you have already defined.
6. Enter details for the message store.
  - If you use a file store, specify the directory paths for the log files, the permanent file store, and the temporary file store. Do not use the default path, and ensure that you use a unique path for each messaging engine.
  - If you use a data store, specify the JNDI name of the data source that provides access to the database that holds the data store.
7. When the wizard is finished, save your changes to the master configuration.

## Results

A messaging engine is added to the cluster. You can now configure the messaging engine if required.

### ***Removing a messaging engine from a cluster:***

You can reduce the number of messaging engines configured for a cluster bus member by removing a messaging engine.

### **Before you begin**

Before you remove a messaging engine from a cluster, drain it of messages and prevent further messages being sent to it. Otherwise, when a messaging engine is removed, all messages currently stored on that messaging engine are deleted. Any messages that are in transit to the removed messaging engine might remain on the sending messaging engine on a remote queue point and require manual cleanup.

When you remove messaging engines from a cluster, remove them in numerical order from highest to lowest so as to avoid a situation where, for example, there are messaging engines numbered 001 and 002 and not 000. This is to avoid problems if you use WS-Notification, which attaches special significance to the first-created messaging engine in a cluster. For more information, see the WS-Notification troubleshooting tip Problems can occur when deleting administered subscribers and messaging engines.

When you remove a messaging engine from a cluster, all message points and their messages are deleted, so if the cluster has a queue destination configured, some of the messages stored for that queue might be lost.

### **About this task**

To remove a messaging engine from a cluster:

#### **Procedure**

1. In the navigation pane, click **Service integration -> Buses -> bus\_name -> [Topology] Bus members**.
2. In the content pane, click the cluster from which you want to remove a messaging engine. The Bus member detail panel is displayed.
3. In the content pane, under **Additional properties**, click **Messaging engines**. A list of messaging engines for the cluster is displayed.
4. In the content pane, select the messaging engine that you want to remove.
5. Click **Remove messaging engine**.
6. Save your changes to the master configuration.

## Results

The messaging engine is removed from the cluster.

You can also use the **deleteSIBEngine** command to remove a messaging engine from a cluster.

## What to do next

**Remember:** When you remove a messaging engine, WebSphere Application Server (base) does *not* delete the data store tables or the file store files automatically.

- For a data store, if you want to recreate the same messaging engine, you must first delete the previous set of tables. If you create a messaging engine and use existing tables, the tables must be empty so that the messaging engine can function correctly. Refer to the documentation for your chosen relational database management system (RDBMS) for information about how to delete tables. However, if you created a data store with default settings, you do not need to delete previous tables.
- For a file store, you might want to delete the file store files to reclaim disk space.

### ***Correcting the messaging engine policy:***

You can change the messaging engine policy for a messaging engine in a cluster so that it conforms to one of the predefined messaging engine policy types that are available when you use messaging engine policy assistance.

## About this task

Use this procedure when you are creating or maintaining a cluster bus member and messaging engine policy assistance is enabled, but there are warning messages that the messaging engine policy should be corrected. For example, you create and configure a cluster for scalability, where each messaging engine cannot fail over. If you want to change the cluster to provide scalability and high availability, the messaging engine policies must be corrected so that the messaging engines can fail over, and the preferred servers list must be corrected so that there is a preferred server and a failover server for each messaging engine.

This procedure does not add or remove messaging engines. If there are warning messages to add or remove messaging engines to conform to the selected messaging engine policy type, use the procedures in the related tasks.

## Procedure

1. In the navigation pane, click **Service integration -> Buses -> bus\_name -> [Topology] Bus members -> bus\_member\_name**. If messaging engine policy assistance is enabled, the Bus member detail panel is displayed. If messaging engine policy assistance is not enabled, the messaging engine collection panel is displayed.
2. If messaging engine policy assistance is not enabled, click **Enable policy assistance** and follow the instructions on the wizard.
3. From the Bus member detail panel, in the content pane, under **Additional properties**, click **Messaging engine policy maintenance**. A list of messaging engines for the cluster, and details of their current messaging engine policy settings, is displayed. Messages in the details column indicate whether the current settings conform to the selected messaging engine policy type.
4. Select the policies you want to correct, then click **Correct messaging engine policy**.
5. Save your changes to the master configuration.

## Results

The selected messaging engine policies are corrected and the new policy settings are displayed in the panel. The core group policies and match criteria for the messaging engines are automatically corrected.

### ***Deleting a redundant core group policy:***

If there is a core group policy that is associated with a cluster, but that is not associated with any messaging engine in the cluster, and you are using messaging engine policy assistance, you can identify and delete that policy.

### **About this task**

Use this procedure when you are creating or maintaining a cluster bus member and messaging engine policy assistance is enabled, but there are warning messages that a core group policy is redundant. This message indicates that the core group policy is associated with a cluster through its match criteria, but it is not associated with any messaging engine that is currently in the cluster.

When you use messaging engine policy assistance, the required associations are created automatically and you do not have to create or manage core group policies directly. A redundant core group policy might occur if messaging engine policy assistance is disabled and you remove a messaging engine without deleting its associated core group policy, or create a core group policy that is not associated with a messaging engine.

### **Procedure**

1. In the navigation pane, click **Service integration -> Buses -> bus\_name -> [Topology] Bus members -> bus\_member\_name**. If messaging engine policy assistance is enabled, the bus member detail panel is displayed. If messaging engine policy assistance is not enabled, the messaging engine collection panel is displayed.
2. If messaging engine policy assistance is not enabled, click **Enable policy assistance** and follow the instructions on the wizard.
3. In the content pane, under **Additional properties**, click **Redundant core group policies**. A list of redundant core group policies and details of the current core group policy settings is displayed.
4. Select the policies you want to delete, then click **Delete**.

## Results

The selected core group policies are deleted.

### ***Creating the database, schema and user ID for a messaging engine:***

Before the data store for a messaging engine can be set up, you must first create the database, the schema and the database user ID that the messaging engine needs to access the data store tables.

### **Before you begin**

Before you start this task, review the information in Configuration planning for a messaging engine to use a data store, and ensure that you have taken any appropriate action.

### **About this task**

To create the database, schema and user ID for a messaging engine, complete the following steps.

**Note:** For detailed set up instructions for z/OS see the IBM Redbooks publication Architecting High Availability Using WebSphere V6 on z/OS.

## Procedure

1. Create the database for the data store.
2. Create users and schemas in the database. Ensure that the user ID has sufficient privilege to allow the messaging engine to access the data store tables. For more information about the privileges that are required for the selected database, see “Database privileges” on page 2181.
3. If required, create the data store tables by using the data definition language (DDL) statements generated by using the sibDDLGenerator command.

*Configuring a messaging engine data store to use a data source:*

After configuring a JDBC data source, you can configure a messaging engine data store to use the data source.

## Before you begin

To complete this task, you must have chosen or created a bus and a messaging engine, and the messaging engine must specify data store as its message store type.

You must also have configured a data source, as described in “Creating the database, schema and user ID for a messaging engine” on page 2108.

## About this task

A messaging engine uses an instance of a JDBC data source to interact with the database that contains the data store for that messaging engine.

Use the WebSphere Application Server administrative console to set the data store configuration parameters.

## Procedure

1. In the navigation pane, click **Service integration -> Buses -> bus\_name -> [Topology] Messaging engines -> engine\_name**.
2. Check that the **Message store type** is *Data store*.
3. Click **[Additional Properties] Message store**. The data store configuration detail panel is displayed.
4. Specify the following data store configuration details:

### Data source JNDI name

Type the JNDI name of the data source that provides access to database that holds the data store.

### Schema name

Type the name of the database schema that contains the tables used by the data store.

**General tip:** The schema name is usually the same as the user ID that is declared in the authentication alias. With some databases, for example DB2, you can provide an alternative schema name. For more information about the relationship between users and schema, refer to the documentation for your chosen RDBMS.

**Informix tip:** When you configure your messaging engine to use an Informix database, you must specify the schema name in lowercase letters.

When it is starting, a messaging engine that uses a data store checks to see if its data store exists. If the **Create tables** option is selected for the configuration, the messaging engine creates the tables in its chosen schema.

The **Schema name** field is optional. If you require a schema name, consider the following:

- The default schema name is IBMWSSIB.
- If you delete the text so that field is blank, the messaging engine takes the user id defined in the authentication alias to be the schema name.
- If you define a schema name explicitly, that schema name is used by the messaging engine.
- If there are multiple messaging engines, you must configure each messaging engine to use a unique schema, otherwise FFDC error messages stating that Connection cannot be provided as Datasource has been disabled! might appear. This applies to DB2 in particular.

#### **Authentication alias**

Select the authentication alias that enables access to the data source.

#### **Create tables**

Select the check box if you want WebSphere Application Server to create the database tables automatically.

**Note:** The user ID that the messaging engine uses to connect to the data source must have sufficient authority to create the database tables and indexes.

**DB2 for z/OS restriction:** Do not select **Create tables** if you are using DB2 for z/OS, otherwise an exception will be thrown when WebSphere Application Server attempts to create the tables.

#### **Number of tables for permanent objects**

Permanent tables contain persistent objects for the data store.

**Note:** You can only increase the number of permanent tables, not decrease them.

#### **Number of tables for temporary objects**

Temporary tables contain nonpersistent objects that have been saved to the data store to reduce the messaging engine memory requirement.

**Note:** You can only increase the number of temporary tables, not decrease them.

#### ***Configuring service integration bus links:***

You can configure service integration bus links on messaging engines in a variety of ways. For example, you can start, stop, or remove links.

#### **About this task**

When you create a foreign bus connection to connect two service integration buses, a service integration bus link is created automatically. The foreign bus connection contains a routing definition, which is a virtual link, and the service integration bus link is the corresponding physical link on the messaging engine.

#### ***Configuring foreign bus connections:***

You can configure a bus to connect to, and exchange messages with, other messaging networks. To do this, you must configure a foreign bus connection. A foreign bus connection encapsulates information related to the remote messaging network, such as the type of the foreign bus and whether messaging applications are allowed to send messages to the foreign bus.

#### **About this task**

A foreign bus connection is associated with a service integration bus. The bus with which the foreign bus connection is associated is known as the local bus. The foreign bus connection represents another service

integration bus, either in the same cell as the local bus or in a different cell, or it represents a WebSphere MQ queue manager. From the local bus, every other bus is regarded as a foreign bus, even if it is a bus in the same cell.

Messages route to a foreign bus either directly through a link between the local bus and the foreign bus, or indirectly through one or more intermediate buses.

If, when you configure the local bus, you select **Configuration reload enabled**, future changes to the configuration information for any foreign bus connections are updated automatically. The time when these changes take effect varies:

**Foreign Bus Connection properties**

Immediately

**WebSphere MQ link properties**

On channel restart, except Description (immediately), and Initial State (on messaging engine restart)

**MQ sender channel properties**

On channel restart, except Initial State (on messaging engine restart or sender channel creation)

**MQ receiver channel properties**

On channel restart, except Initial State (on messaging engine restart or receiver channel creation)

**Publish/subscribe broker profile (0 to n) properties**

Immediately

**Service integration bus link properties**

On link restart, except Description (immediately), and Initial State (on messaging engine restart or link creation)

To ensure that dynamic configuration updates are made to each node, click **System administration -> Console Preferences** to display the Console Preferences window, then select **Synchronize changes with nodes**.

*Configuring the properties of a service integration bus link:*

After establishing a service integration bus link you might want to configure the properties of a service integration bus link such as the name of the service integration bus link, or authentication alias used by foreign bus that the link connects to.

**About this task**

To configure the properties of a service integration bus link, use the administrative console to complete the following steps:

**Procedure**

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to configure the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to configure.
5. Specify the following properties for the service integration bus link:

**Name** The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

**Description**

An optional description for the service integration bus link, for administrative purposes.

**UUID** The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

**Foreign messaging engine**

The messaging engine on the foreign bus to which this link connects.

**Note:** This foreign bus name must not be altered after it has been configured. If you alter it, any messaging engines that already hold state information on the link will not be able to use the link unless the foreign bus name is reset to its original value.

**Target inbound transport chain**

The type of transport chain used for communication with the foreign bus. The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

**Bootstrap endpoints**

The comma-separated list of endpoints used to connect to a bootstrap server. This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see the steps relating to setting bootstrap endpoints in “Configuring a connection to a non-default bootstrap server” on page 610.

**Note:** Service integration bus links over `BootstrapTunneledMessaging` and `BootstrapTunneledSecureMessaging` transport chains only work directly between application server instances. Bus links over `TunneledMessaging` transport chains do not work if an HTTP server is placed in front of either application server instance.

**Authentication alias**

The name of the authentication alias, used to authenticate access to the foreign bus. The alias must be known to the foreign bus.

**Initial state**

Whether the link is started automatically when the messaging engine is started. Until started, the gateway link is unavailable. If this property is set to **Started** the service integration bus link is started when the messaging engine is started.

6. Click **OK**.
7. Save your changes to the master configuration.

*Listing the service integration bus links:*

You can list all the service integration bus links that are linked to a messaging engine.

**About this task**

To list the service integration bus links for a messaging engine, use the administrative console to complete the following steps:

**Procedure**

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Additional properties**, click **Messaging engines**. The list of messaging engines in the bus is displayed.
4. In the content pane, select the messaging engine for which you want to list the service integration bus links.

- In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.

### Example

The following combinations of **Status** and **Activity** values are possible:

*Table 213. Results of possible status and activity values. The first and second columns of the table provide the possible combinations of status and activity values, and the third column explains the possible connection status of the local and foreign buses.*

Status	Activity	Meaning
started	inactive	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to successfully activate a connection between the buses.
started	active	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
stopped	inactive	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
unknown	inactive	An error might have occurred in setting up the link, such that the object that is used to report the current state is not available. The deployment manager cannot contact a remote server to determine the status.

### What to do next

You can now add or remove a service integration bus link or select a service integration bus link to start, stop, or configure.

#### *Starting a service integration bus link:*

When a service integration bus link has been started, it can be used for communicating with its associated messaging engines.

### About this task

To start a service integration bus link, use the administrative console to complete the following steps:

#### Procedure

- Display the list of messaging engines.
- In the content pane, select the messaging engine for which you want to start the service integration bus link.
- In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
- Select the service integration bus link that you want to start.
- Click **Start**.

#### *Stopping a service integration bus link:*

When a service integration bus link has been stopped, it cannot be used for communication until it is restarted.

## About this task

To stop a service integration bus link, use the administrative console to complete the following steps:

### Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine to which the service integration bus link that you want to stop belongs.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to stop.
5. Click **Stop**.

### *Removing a service integration bus link:*

When a service integration bus link to a messaging engine has been removed, it cannot be used for communication until it is recreated.

## Before you begin

Before you remove the service integration bus link you must stop the link.

When you remove a service integration bus link, all traffic that uses the link needs to be dealt with in a similar way to when you remove a destination. For further details, see “Deleting a non-topic space bus destination” on page 2210. Note that express Quality of Service (QoS) messages are discarded.

## About this task

To remove a service integration bus link from a messaging engine, use the administrative console to complete the following steps:

### Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine that is associated with the service integration bus link that you want to remove.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to remove.
5. Click **Delete**.
6. Save your changes to the master configuration.

## What to do next

When you remove a service integration bus link, all traffic that uses the link must be diverted by alternative routes or held pending further administrative action. Express QoS messages are discarded.

## Configuring bus destinations

Use the following tasks to configure permanent bus destinations on service integration buses.

## About this task

The steps involved in configuring a bus destination depend on the intended usage of the destination.

For example, the following figure shows a basic scenario based on an application using a JMS queue for point-to-point messaging. A producing application sends messages to a JMS queue from which a consuming application retrieves the messages. The JMS queue is assigned to a queue destination and its associated queue point, where messages are stored.

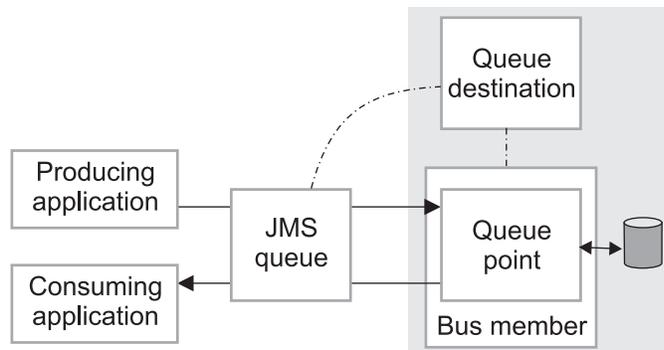

Figure 37. Application use of destinations - basic case

To enable the JMS applications to use a queue destination, you configure the following administrative destination objects:

1. A queue destination on a service integration bus. This configures the properties of the queue, such as the name, and associates the queue with one bus member (an application server or server cluster). This also automatically configures, on the bus member, a queue point where messages for the queue are held and processed.
2. A JMS queue, which configures the name that applications can use to look up the queue in JNDI. The JMS queue encapsulates the name of the queue destination, as defined in the queue destination above, together with other properties to be used by applications.

After you have created a queue destination, you can optionally configure the queue point to override some properties configured on the queue destination. You can also undertake other configuration tasks on the destination and its queue point, and can act on the runtime view.

Each messaging engine has a default exception destination, named `_SYSTEM.Exception.Destination.messaging_engine_name`. This exception destination can be used to handle messages that cannot be delivered for all bus destinations that are localized to the messaging engine. Each bus destination can be configured with a non-default exception destination.

For more information about configuring bus destinations, see the following topics:

- Listing bus destinations
- Creating a bus destination
- Configuring qualities of service for a destination
- Deleting a non-topic space bus destination
- Deleting a topic space

## Connecting buses

You can connect several service integration buses in a network directly, or indirectly, by creating and configuring foreign bus connections. You can connect a service integration bus and a WebSphere MQ queue manager or queue-sharing group in a similar way. You can enable point-to-point or publish/subscribe messaging across multiple buses.

## About this task

For a conceptual overview of connecting different service integration buses, including security issues, see [Interconnected buses](#). You can configure a bus to connect to, and exchange messages with, other messaging networks. To do this, you must configure a foreign bus connection. A foreign bus connection encapsulates information related to the remote messaging network, such as the type of the foreign bus and whether messaging applications are allowed to send messages to the foreign bus. Messages route to a foreign bus either directly through a link between the local bus and the foreign bus, or indirectly through one or more intermediate buses.

### **Configuring foreign bus connections:**

You can configure a bus to connect to, and exchange messages with, other messaging networks. To do this, you must configure a foreign bus connection. A foreign bus connection encapsulates information related to the remote messaging network, such as the type of the foreign bus and whether messaging applications are allowed to send messages to the foreign bus.

## About this task

A foreign bus connection is associated with a service integration bus. The bus with which the foreign bus connection is associated is known as the local bus. The foreign bus connection represents another service integration bus, either in the same cell as the local bus or in a different cell, or it represents a WebSphere MQ queue manager. From the local bus, every other bus is regarded as a foreign bus, even if it is a bus in the same cell.

Messages route to a foreign bus either directly through a link between the local bus and the foreign bus, or indirectly through one or more intermediate buses.

If, when you configure the local bus, you select **Configuration reload enabled**, future changes to the configuration information for any foreign bus connections are updated automatically. The time when these changes take effect varies:

### **Foreign Bus Connection properties**

Immediately

### **WebSphere MQ link properties**

On channel restart, except Description (immediately), and Initial State (on messaging engine restart)

### **MQ sender channel properties**

On channel restart, except Initial State (on messaging engine restart or sender channel creation)

### **MQ receiver channel properties**

On channel restart, except Initial State (on messaging engine restart or receiver channel creation)

### **Publish/subscribe broker profile (0 to n) properties**

Immediately

### **Service integration bus link properties**

On link restart, except Description (immediately), and Initial State (on messaging engine restart or link creation)

To ensure that dynamic configuration updates are made to each node, click **System administration -> Console Preferences** to display the Console Preferences window, then select **Synchronize changes with nodes**.

*Connecting a bus and a WebSphere MQ gateway queue manager to use point-to-point messaging:*

You can connect a service integration bus to a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue sharing group to send or receive messages by using point-to-point messaging. One way to do this is to create a foreign bus connection, where the WebSphere MQ queue manager or queue-sharing group is configured as a foreign bus.

### Before you begin

To connect a service integration bus and a WebSphere MQ queue manager or queue-sharing group to use point-to-point messaging, the following resources must be defined in WebSphere Application Server:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.

The following resources must be defined in WebSphere MQ:

- A queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network.
- A listener that is configured and running.
- A sender channel (to receive messages on the local bus), a receiver channel (to send messages from the local bus), or both.

### About this task

In point-to-point messaging, the sending application specifies the target destination for the message. To receive the message, the receiving application specifies the same destination when it communicates with the messaging provider. Therefore, there is a one-to-one mapping between the sender and receiver of a message.

This task describes one way to achieve point-to-point messaging between WebSphere MQ queue manager or queue-sharing group. For further information about interoperation with a WebSphere MQ network, see the related tasks.

### Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.
6. In the Foreign bus type pane, select **WebSphere MQ**.
7. In the Local bus details pane, select the messaging engine that you want to use and enter the name of the virtual queue manager, that is, the name by which the virtual queue manager of the service integration bus is known to the WebSphere MQ network.
8. In the WebSphere MQ details pane, enter a name for the foreign bus, that is, the bus that represents the WebSphere MQ queue manager. Enter a name for the WebSphere MQ link that connects to the foreign bus. Ensure that these two names are not the same.
9. Ensure that the **Configure publish-subscribe messaging for this connection** check box is clear.
10. To send messages from the local bus to the WebSphere MQ queue manager, complete the following details:
  - a. Ensure that **Enable Service integration bus to WebSphere MQ message flow** is selected.
  - b. Enter the WebSphere MQ receiver channel name, host name and communication port.
  - c. If the WebSphere MQ queue manager requires a secure connection, select the **Is the WebSphere MQ receiver channel secure?** check box. When this option is selected, the WebSphere MQ receiver channel accepts only connections that have secure sockets layer (SSL)

based encryption. The connection is successful only if a set of suitably compatible SSL credentials are associated with the service integration bus outbound channel and the WebSphere MQ receiver channel that it connects to.

11. To receive messages on the local bus from the WebSphere MQ queue manager, complete the following details:
  - a. Ensure that **Enable WebSphere MQ to Service integration bus message flow** is selected.
  - b. Enter the WebSphere MQ sender channel name.
  - c. Optionally, enter the service integration bus inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:
    - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
    - You want local control of access to inbound messages to the local bus.

If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.

12. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

## Results

You have created a connection between a service integration bus and a WebSphere MQ queue manager to use point-to-point messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a WebSphere MQ link on the messaging engine for the local bus, is created automatically.

## What to do next

You can test the connection.

*Connecting a bus and a WebSphere MQ network to use publish/subscribe messaging:*

You can connect a service integration bus and a WebSphere MQ network to send and receive messages by using publish/subscribe messaging. To do this, you create a foreign bus connection, where the WebSphere MQ network is viewed as a foreign bus.

## Before you begin

To connect a service integration bus and a WebSphere MQ network to use publish/subscribe messaging, the following resources must be defined in WebSphere Application Server:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.

The following resources must be defined in WebSphere MQ:

- A queue manager or (for WebSphere MQ for z/OS) queue-sharing group, which acts as the gateway to the WebSphere MQ network.
- A listener that is configured and running.
- A topic and input queue for broker publish/subscribe flow configured in WebSphere MQ.
- A sender channel (to receive messages on the local bus), a receiver channel (to send messages from the local bus), or both.

## About this task

In publish/subscribe messaging, the sending application publishes messages to an intermediate broker destination. Multiple receiving applications can subscribe to this destination to receive a copy of any messages that are published. When a message arrives at a destination, the messaging provider distributes a copy of the message to all the receiving applications that subscribe to the destination. There can be a one-to-many relationship between the sender and receiver of a message, depending on how many receiving applications are subscribed to a destination when a message arrives.

## Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.
6. In the Foreign bus type pane, select **WebSphere MQ**.
7. In the Local bus details pane, select the messaging engine that you want to use and enter the name of the virtual queue manager, that is, the name by which the virtual queue manager of the service integration bus is known to the WebSphere MQ network.
8. In the WebSphere MQ details pane, complete the following details:
  - a. Enter a name for the foreign bus, that is, the bus that represents the WebSphere MQ network.
  - b. Enter a name for the WebSphere MQ link that connects to the foreign bus. Ensure that the Foreign bus name and MQ link name are different.
  - c. Select the **Configure publish-subscribe messaging for this connection** check box.
9. To send messages from the local bus to the WebSphere MQ network, complete the following details:
  - a. Ensure that **Enable Service integration bus to WebSphere MQ message flow** is selected.
  - b. Enter the WebSphere MQ receiver channel name, host name and communication port.
  - c. If the WebSphere MQ gateway queue manager or queue-sharing group requires a secure connection, select the **Is the WebSphere MQ receiver channel secure?** check box. When this option is selected, the WebSphere MQ receiver channel accepts only connections that have secure sockets layer (SSL) based encryption. The connection is successful only if a set of suitably compatible SSL credentials are associated with the service integration bus outbound channel and the WebSphere MQ receiver channel that it connects to.
10. To receive messages on the local bus from the WebSphere MQ network, complete the following details:
  - a. Ensure that **Enable WebSphere MQ to Service integration bus message flow** is selected.
  - b. Enter the WebSphere MQ sender channel name.
  - c. Optionally, enter the service integration bus inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:
    - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
    - You want local control of access to inbound messages to the local bus.

If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.

11. From the Publish-subscribe details pane, repeat the following steps for each topic mapping you want to create:
  - a. Enter the name of the topic on the local bus.
  - b. Select the name of the topic space on the local bus that will map to the topic space on the foreign bus.
  - c. Enter the name of the gateway queue manager or queue sharing group for the WebSphere MQ broker configured for broker publish/subscribe flow.
  - d. To send messages from the local bus to the WebSphere MQ gateway queue manager or queue-sharing group, enter the name of the queue for the WebSphere MQ broker destination.
  - e. To receive messages on the local bus from the WebSphere MQ gateway queue manager or queue-sharing group, enter the name of the subscription point that will receive messages.
  - f. Select the direction of message flow for the publish/subscribe topic mapping. The options available depend on whether you completed details on the WebSphere MQ details pane to send messages, receive messages, or both, on the local bus.
  - g. Click **Add**.
12. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

## Results

You have created a connection between a service integration bus and a WebSphere MQ network to use publish/subscribe messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a WebSphere MQ link on the messaging engine for the local bus, is created automatically.

## What to do next

You can test the connection.

*Connecting service integration buses to use point-to-point messaging:*

You can connect a service integration bus to another service integration bus to send and receive messages by using point-to-point messaging. To do this, you create a foreign bus connection.

## Before you begin

To connect a service integration bus to another service integration bus to use point-to-point messaging, the following resources must be defined:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.
- A service integration bus that you want to connect to, known as the foreign bus. The bus must have at least one bus member.
- Optionally, to configure a secure connection, an authentication alias.

The buses that you connect must have unique names, because the connection will fail if the buses have the same name.

## About this task

In point-to-point messaging, the sending application specifies the target destination for the message. To receive the message, the receiving application specifies the same destination when it communicates with the messaging provider. Therefore, there is a one-to-one mapping between the sender and receiver of a message.

## Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.
6. In the Foreign bus type pane, ensure that **Service integration bus** is selected.
7. In the Local bus details pane, select from the drop-down list the messaging engine that you want to use.
8. Optionally, enter a name for the inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:
  - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
  - You want local control of access to inbound messages to the local bus.

If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.

9. In the Foreign bus details pane, complete the details as appropriate:
  - If the service integration bus you want to connect to is in a different cell from the local bus, complete the following details:
    - a. Ensure that **Configure a foreign bus in a remote cell** is selected.
    - b. Enter the name of the service integration bus to connect to, that is, the foreign bus. Enter the exact name of the existing service integration bus.
    - c. Enter the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.
    - d. Ensure that the **Configure publish-subscribe messaging for this connection** check box is clear.
    - e. Enter the name of the service integration bus link.
    - f. Enter one or more bootstrap endpoints, that is, the host, port location, and transport chain for the messaging engine on the foreign bus that the local service integration bus connects to. The port is the SIB\_ENDPOINT\_ADDRESS (or SIB\_ENDPOINT\_SECURE\_ADDRESS if security is enabled) of the messaging engine. Use the format *hostName:portNumber.chainName*, separating each bootstrap endpoint by a comma. For more information, see the steps relating to setting bootstrap endpoints in “Configuring a connection to a non-default bootstrap server” on page 610.
  - If the service integration bus you want to connect to is in the same cell as the local bus, complete the following details:
    - a. Ensure that **Configure a foreign bus in a local cell** is selected.
    - b. Select the name of the service integration bus to connect to, that is, the foreign bus.
    - c. Select the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.
    - d. Ensure that the **Configure publish-subscribe messaging for this connection** check box is clear.
    - e. Enter the name of the service integration bus link.
10. Optionally, to secure the connection, in the Foreign bus details pane, complete the following details:

- a. Select the **Secure connection** check box.
  - b. Select the type of transport chain to use to communicate with the messaging engine in the foreign bus. Select one of the following:
    - InboundBasicMessaging. InboundBasicMessaging is a predefined transport chain where communication uses the TCP protocol.
    - InboundSecureMessaging. InboundSecureMessaging is a predefined transport chain where communication is secured by using the secure sockets layer (SSL) based encryption protocol over a TCP network. For successful connection, a set of suitably compatible SSL credentials must be associated with the local bus inbound channel and the foreign bus outbound channel.
    - Other, please specify. Select this option to specify your own transport chain and enter the details in the field that appears.
  - c. Select the name of the authentication alias to use to authenticate access to the foreign bus. The alias must be known to the foreign bus.
11. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

## Results

You have created a connection from a local service integration bus to a foreign service integration bus to use point-to-point messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a service integration bus link on the messaging engine for the local bus, is created automatically.

## What to do next

You must create a connection in the opposite direction between the two buses. To do this, repeat the procedure, using the bus you have just connected to as the local bus, and the bus you have just connected from as the foreign bus. Ensure that you use exactly the same name for the service integration bus link. After you create a foreign bus connection for each service integration bus, you can test the connection.

*Connecting service integration buses to use publish/subscribe messaging:*

You can connect a service integration bus to another service integration bus to send and receive messages by using publish/subscribe messaging. To do this, you create a foreign bus connection.

## Before you begin

To connect a service integration bus to another service integration bus to use publish/subscribe messaging, the following resources must exist:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.
- A service integration bus that you want to connect to, known as the foreign bus. The bus must have at least one bus member.
- A topic space on both service integration buses. If the foreign bus is in a remote cell, you must know the topic space name.
- Optionally, to configure a secure connection, an authentication alias.

The buses that you connect must have unique names, because the connection will fail if the buses have the same name.

## About this task

In publish/subscribe messaging, the sending application publishes messages to an intermediate broker destination. Multiple receiving applications can subscribe to this destination to receive a copy of any

messages that are published. When a message arrives at a destination, the messaging provider distributes a copy of the message to all the receiving applications that subscribe to the destination. There can be a one-to-many relationship between the sender and receiver of a message, depending on how many receiving applications are subscribed to a destination when a message arrives.

## Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.
6. In the Foreign bus type pane, ensure that **Service integration bus** is selected.
7. In the Local bus details pane, select from the drop-down list the messaging engine that you want to use.
8. Optionally, enter a name for the inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:
  - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
  - You want local control of access to inbound messages to the local bus.

If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.

9. In the Foreign bus details pane, complete the details as appropriate:
  - If the service integration bus you want to connect to is in a different cell from the local bus, complete the following details:
    - a. Ensure that **Configure a foreign bus in a remote cell** is selected.
    - b. Enter the name of the service integration bus to connect to, that is, the foreign bus. Enter the exact name of the existing service integration bus.
    - c. Enter the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.
    - d. Select the **Configure publish-subscribe messaging for this connection** check box.
    - e. Enter the name of the service integration bus link.
    - f. Enter one or more bootstrap endpoints, that is, the host, port location, and transport chain for the messaging engine on the foreign bus that the local service integration bus connects to. The port is the SIB\_ENDPOINT\_ADDRESS (or SIB\_ENDPOINT\_SECURE\_ADDRESS if security is enabled) of the messaging engine. Use the format *hostName:portNumber.chainName*, separating each bootstrap endpoint by a comma. For more information, see the steps relating to setting bootstrap endpoints in “Configuring a connection to a non-default bootstrap server” on page 610.
  - If the service integration bus you want to connect to is in the same cell as the local bus, complete the following details:
    - a. Ensure that **Configure a foreign bus in a local cell** is selected.
    - b. Select the name of the service integration bus to connect to, that is, the foreign bus.
    - c. Select the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.
    - d. Select the **Configure publish-subscribe messaging for this connection** check box.

- e. Enter the name of the service integration bus link.
10. Optionally, to secure the connection, in the Foreign bus details pane, complete the following details:
  - a. Select the **Secure connection** check box.
  - b. Select the type of transport chain to use to communicate with the messaging engine in the foreign bus. Select one of the following:
    - InboundBasicMessaging. InboundBasicMessaging is a predefined transport chain where communication uses the TCP protocol.
    - InboundSecureMessaging. InboundSecureMessaging is a predefined transport chain where communication is secured by using the secure sockets layer (SSL) based encryption protocol over a TCP network. For successful connection, a set of suitably compatible SSL credentials must be associated with the local bus inbound channel and the foreign bus outbound channel.
    - Other, please specify. Select this option to specify your own transport chain and enter the details in the field that appears.
  - c. Select the name of the authentication alias to use to authenticate access to the foreign bus. The alias must be known to the foreign bus.
11. In the Publish-subscribe details pane, repeat the following steps for each topic mapping you want to create:
  - a. Select the name of the topic space on the local bus that will map to the topic space on the foreign bus.
  - b. Enter the name of the topic space on the foreign bus. If the foreign bus is in the same cell as the local bus, you can select this name from a drop-down list.
  - c. Click **Add**.
12. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

## Results

You have created a connection from a local service integration bus to a foreign service integration bus to use publish/subscribe messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a service integration bus link on the messaging engine for the local bus, is created automatically.

## What to do next

You must create a connection in the opposite direction between the two buses. To do this, repeat the procedure, using the bus you have just connected to as the local bus, and the bus you have just connected from as the foreign bus. Ensure that you use exactly the same name for the service integration bus link. After you create a foreign bus connection for each service integration bus, you can test the connection.

*Connecting buses by using an indirect connection:*

You can connect a service integration bus to another service integration bus or a WebSphere MQ queue manager or queue-sharing group (known as the “gateway queue manager”) through one or more intermediate foreign buses. To do this, you create an indirect foreign bus connection.

## Before you begin

To create an indirect foreign bus connection, the following resources must be defined:

- A service integration bus that you want to connect from, known as the local bus.
- A direct foreign bus connection from the local bus to the bus you want to use as the intermediate bus.
- A service integration bus or a gateway queue manager that you want to connect to indirectly, known as the target foreign bus.

## About this task

To connect two buses indirectly, you create a indirect foreign bus connection on the local bus that specifies a suitable intermediate bus and the required target bus. There must be a connection, either direct or indirect, between the intermediate bus and the target foreign bus, that is, the service integration bus or a gateway queue manager that you want to connect to.

To connect one bus to another bus through an intermediate bus, or a chain of buses, if the connection between the intermediate bus or the chain of buses and the target bus already exists, you do not require any new physical links. Instead, each foreign bus connection identifies a neighboring bus on the route to the final target bus as the "next hop" in the chain. Each bus in the chain must know about the next hop in the chain to reach the target bus. The local bus uses a foreign bus connection to identify the next bus in the chain to the target bus, and uses its direct physical link to flow messages to that bus. Then, each intermediate bus uses its locally defined foreign bus connection to identify the next bus in the chain until the target bus is reached.

## Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, select **Indirect, using another bus**.
6. In the Indirect connection details pane, complete the following details:
  - a. Enter the name of the target foreign bus that you want to connect to indirectly.
  - b. Select the name of the existing, directly connected foreign bus that will be the intermediate bus to the target bus.
7. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

## Results

You have created a connection from the local bus to the target bus by way of the intermediate bus. You have created an indirect foreign bus connection, which contains a routing definition, or virtual link.

## What to do next

Check whether there are connections between the intermediate bus you specified and the target bus. If necessary, repeat the procedure to create the "next hop" in the chain.

### *Testing foreign bus connections:*

After you define a direct foreign bus connection between a service integration bus and either another service integration bus or a WebSphere MQ queue manager, you can test the connection to check that it can be used to exchange messages.

## Before you begin

To test a foreign bus connection, a service integration bus, known as the local bus, with a direct foreign bus connection to a service integration bus, or a WebSphere MQ queue manager must be defined.

## About this task

You might want to test a foreign bus connection before you send messages that use that connection, or if you have difficulty sending and receiving messages that use that connection. You can test only direct foreign bus connections. You cannot test indirect foreign bus connections, because it might not be possible to reach the target destination bus.

If a connection name list is provided in the WebSphere MQ link sender channel properties, the connections are tried in the order in which they are specified in the connection list until a connection is successful. If no connection is successful an error message is logged.

## Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the Buses pane, click the bus that has the connection you want to test.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**. A list of foreign bus connections is displayed.
4. Select the check box for the connection you want to test.
5. Click **Test Connection**. A message is displayed at the top of the pane that shows the result of the test.

## Results

You have tested a bus connection.

*Listing the foreign bus connections:*

You can list the foreign bus connections that are associated with a local bus to see which foreign buses are currently configured.

## Before you begin

To list foreign bus connections, the following resources must be defined:

- A service integration bus with one or more foreign bus connections between it and another service integration bus or a WebSphere MQ queue manager.

## About this task

You can list foreign bus connections by using the administrative console, as described in this topic, or by using the wsadmin tool and the listSIBForeignBuses command.

To list the foreign bus connections that are associated with the local bus, complete the following steps.

## Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses**.
3. In the service integration buses pane, select the bus for which you want to list the connections.
4. In the configuration tab, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.

## Results

You have listed the foreign bus connections that are associated with the local bus.

*Removing a foreign bus connection from a bus:*

You can remove a foreign bus connection from a bus so that the connection can no longer be used for sending and receiving messages.

### **Before you begin**

When a foreign bus connection is deleted from the configuration, the next time the hosting messaging engine for a link transmitter is started, the messaging engine moves the messages to the exception destination. To avoid this situation, drain the messages from the link transmitter queue as far as is possible and then, before deleting the link configuration, either move any remaining messages from the transmission queues to an exception destination, or delete them. For more details, refer to the subtopics that follow.

### **About this task**

Removing a foreign bus connection from a bus removes the resources associated with the connection. The bus will no longer service the deleted link.

### **Procedure**

1. In the navigation pane, click **Service integration -> Buses**.
2. In the Buses pane, select the bus from which you want to remove the foreign connection.
3. In the configuration tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
4. Select the check box that corresponds to the connection that you want to remove.
5. Click **Delete**.
6. Save your changes to the master configuration.

### **Results**

You have now deleted the foreign bus connection from a bus. This connection can no longer be used for communication.

*Preparing to remove a foreign bus connection between two service integration buses:*

Before you remove a foreign bus connection between two service integration buses, drain as many messages as you can from the link transmitter queue, then manually move or delete any remaining messages.

### **Before you begin**

You must know which foreign bus connection is being prepared for deletion.

### **About this task**

When a foreign bus connection and its service integration bus link is deleted from the configuration, the next time the hosting messaging engine for a link transmitter is started, the messaging engine deletes all its messages or moves them to the exception destination. To avoid messages being unintentionally deleted or moved to the exception destination, drain the messages from the link transmitter queue as much as possible and then, before deleting the link configuration, either move any remaining messages to an exception destination or delete them.

### **Procedure**

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses** to display a list of buses.
3. Select the bus from which you want to remove the foreign bus connection.

4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections**. A list of connections for this bus is displayed.
5. From the list of foreign bus connections, click the name of the foreign bus connection to display its details.
6. Under **General properties**, clear the **Send Allowed** check box to prevent new messages from being produced for this service integration bus link.
7. Click **Apply** to save the configuration.
8. To determine when there are no more messages queued on this link, under **Related Items** click **Service integration bus links** to display the details of the service integration bus links.
9. Click the **Refresh** icon of **Status** to refresh the view of the current outbound messages.
10. When there are no current outbound messages, select the check box next to the appropriate link and then click **Stop** to stop the link to the foreign bus. When the status of the link turns to red, the link to the foreign bus has no remaining messages and is stopped.
11. Repeat steps 2 to 10 for the foreign bus, because the foreign bus can continue to produce messages after the foreign bus connection on the local bus has been deleted.
12. Save your changes to the master configuration.

## Results

You have drained the messages from the link transmitter queue as much as possible, and either moved any remaining messages from the transmission queues to an exception destination or deleted them. You are now ready to remove the foreign bus connection.

*Preparing to remove a foreign bus connection between a service integration bus and a WebSphere MQ network:*

Before you remove a foreign bus connection between a service integration bus and a WebSphere MQ network, drain as many messages as you can from the link transmitter queue, then manually move or delete any remaining messages.

## Before you begin

You must know which foreign bus connection is being prepared for deletion. You should also inform the WebSphere MQ administrator that the foreign bus connection is about to be deleted and therefore no longer paired with its WebSphere MQ gateway queue manager or message broker in the WebSphere MQ network.

## About this task

When a foreign bus connection is deleted from the configuration, the next time the hosting messaging engine for a link transmitter is started, it deletes all its messages or moves them to the exception destination. To avoid messages being unintentionally deleted or moved to the exception destination, drain as many messages as possible from the link transmitter queue. Then, before you delete the link configuration, either move any remaining messages to an exception destination or delete them.

If there are publish/subscribe broker profiles defined, you should remove the subscriptions.

## Procedure

1. Start the administrative console.
2. Optional: If there are publish/subscribe broker profiles defined on any of the links for this foreign bus connection, remove the subscriptions.

Complete the following substeps for each broker profile:

- a. Navigate to **Service integration -> Buses -> bus\_name -> [Topology] Foreign bus connections -> foreign\_bus\_name -> [Related Items] WebSphere MQ links -> link\_name -> [Additional Properties] Publish/subscribe broker profiles -> profile\_name**
- b. Click the **Runtime** tab.
- c. Click **Subscriptions**.
- d. Click **Unsubscribe** to remove all the subscriptions listed.

When an unsubscribe command is sent to the message broker in the WebSphere MQ network, the relevant topic mapping is put into an indoubt state until the unsubscribe is confirmed when the topic mapping is deleted. After the unsubscribe is confirmed, the topic mapping is no longer shown in the runtime view. You might have to refresh the runtime view for all subscriptions to be shown as removed.

3. Prevent new messages from being produced for this foreign bus connection.
  - a. Navigate to **Service integration -> Buses -> bus\_name -> [Topology] Foreign bus connections -> foreign\_bus\_name**
  - b. Under **General properties**, clear the **Send Allowed** check box.
  - c. Click **Apply** to save the configuration.
4. Determine when there are no more messages queued, then stop the link to the foreign bus in a controlled manner.
  - a. Under **Related Items**, click **WebSphere MQ links** to display the list of links for this bus.
  - b. Click the **Refresh** icon of **Status** to refresh the view of the current outbound messages.
  - c. When there are no current outbound messages, select the check box next to the appropriate link and then select a **Stop mode** of "Quiesce".
  - d. Select a **Target state** of "Stopped" so that the link can only be started again by administrator action.
  - e. When the status of the link turns to red, the link to the foreign bus has no remaining messages and is stopped.
5. The foreign bus can continue to produce messages after the foreign bus connection on the local bus has been deleted. Because the foreign bus is a WebSphere MQ network, refer to the WebSphere MQ Intercommunication guide for details about the safe deletion of channels at Managing WebSphere MQ channels.
6. Save your changes to the master configuration.

## Results

You have removed the subscriptions from any publish/subscribe brokers on the link. You have drained as many messages as possible from the link transmitter queue, and either moved any remaining messages from the transmission queues to an exception destination or deleted them.

## What to do next

You are now ready to remove the foreign bus connection.

*Configuring destination defaults for a foreign bus connection:*

You can configure default values to apply when applications use destinations on a foreign bus and these properties are not explicitly defined elsewhere. You configure the destination defaults for the foreign bus connection, which represents either a service integration bus or a WebSphere MQ queue manager or queue-sharing group (known as a "gateway queue manager").

## Before you begin

To configure destination defaults for a foreign bus, at least one foreign bus connection that represents that foreign bus must be defined.

## About this task

Destination defaults are default values for the destination attributes, such as the default priority. They are used when an application produces messages that are destined for a destination on a foreign bus, but the properties are not defined elsewhere:

- The application has not explicitly set certain attributes on the message.
- A foreign destination is not defined on the local bus, so cannot be a source of destination defaults.
- An alias destination is not defined on the local bus, so cannot be a source of destination defaults.

You configure destination defaults for a foreign bus connection to apply to all applicable destinations on the corresponding foreign bus. In contrast, the destination defaults of an alias destination or foreign destination apply to an individual destination on a foreign bus.

## Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the service integration buses pane, select the bus that you want to configure.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**. A list of foreign bus connections is displayed.
4. Select the foreign bus connection that you want to configure.
5. In the content pane, under **Additional properties**, click **Destination defaults**.
6. Specify the following properties for the destination defaults:

### Default priority

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

### Default reliability

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

### Maximum reliability

The maximum reliability of messages accepted by this destination.

### Send allowed

Clear this option (setting it to false) to stop producers from being able to send messages to destinations on this foreign bus.

### Enable producers to override default reliability

Select this option to enable producers to override the default reliability that is set on the destination.

### Include an RFH2 message header when sending messages to WebSphere MQ.

If selected, messages sent to WebSphere MQ include an RFH2 header. The RFH2 header stores additional information to that which is stored in the WebSphere MQ message header.

7. Click **OK**.
8. Save your changes to the master configuration.

## Results

You have configured destination defaults for a foreign bus connection.

### ***Managing messages that use foreign bus connections:***

You can manage messages that use a foreign bus connection.

## Before you begin

You must know whether the foreign bus connection represents a connection from a service integration bus to another service integration bus, or to a WebSphere MQ network, because this determines the points where you can manage messages.

### About this task

For a foreign bus connection from a service integration bus to another service integration bus, you can manage messages that are queued for link transmitters and link receivers.

For a foreign bus connection from a service integration bus to a WebSphere MQ network, you can manage messages that are queued for link transmitters, known link transmitters, and the sender channel transmitter.

A link can have multiple link transmitters; one for each messaging engine that sends messages on the link to the foreign bus, and one for each topic space destination that is mapped to a topic space in the foreign bus.

For a foreign bus connection to a WebSphere MQ network, there is one known link transmitter for each link transmitter, and one sender channel transmitter for the WebSphere MQ link that sends messages to a gateway queue manager on the WebSphere MQ network.

Complete this task when you want to view, delete, or move messages on a transmitter.

### Procedure

Select the appropriate task from the following topics.

*Configuring exception destination processing for a link to a foreign bus:*

You can configure the exception destination processing for a link from a service integration bus to another service integration bus or to a WebSphere MQ network. You can configure whether any undeliverable messages that the link handles are rerouted to an exception destination, and whether to use a system default exception destination or configure a specific exception destination.

## Before you begin

To configure the exception destination processing for a service integration bus link or WebSphere MQ link, you must know the name of the foreign bus connection that is associated with that link. A foreign bus connection represents either a connection between two service integration buses or a connection between a service integration bus and a WebSphere MQ network.

To configure a specific exception destination for the link, the exception destination must exist. An exception destination must be a queue destination, and can be on the local bus or a foreign bus. See “Creating a queue for point-to-point messaging” on page 2185.

### About this task

An exception destination for a link is the destination for an inbound message when the service integration bus link or WebSphere MQ link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

You can configure an exception destination for a link as one of the following:

- **None.** The link does not use an exception destination and undeliverable messages are not rerouted to an exception destination. For a service integration bus link, such messages can block the processing of other messages waiting for delivery to the same destination. For a WebSphere MQ link, such messages can block the processing of other messages waiting for delivery through that link to the same bus.
- **System.** The link uses the default exception destination. Messages that cannot be delivered to the bus destination are rerouted to the system default exception destination for the messaging engine that this link is assigned to: `_SYSTEM.Exception.Destination.messaging_engine_name`. This is the default option.
- **Specify.** The link uses the specified exception destination. If the link cannot use this exception destination, it uses the system exception destination.

Note that best-effort messages are always discarded if they cannot be delivered to their target destination, that is, they never use an exception destination.

Any report options that are set in the properties of a message also affect exception destination processing. Depending on the report options, a message might be discarded if it is not delivered.

### Procedure

1. In the navigation pane of the administrative console, click **Service integration -> Buses** to display a list of buses.
2. Select the bus that has the link for which you want to configure exception destination processing.
3. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
4. Select the name of the foreign bus connection that is associated with the link for which you want to configure exception destination processing.
5. For a link to another service integration bus, under **Related Items**, click **Service integration bus links**. For a link to a WebSphere MQ network, under **Related Items**, click **WebSphere MQ links**.
6. Select the name of the link you require from the list. The details of that link are displayed.
7. In the **Configuration** tab, under **General properties**, in the Exception destination section, use the radio buttons to configure the exception destination processing that this link uses:
  - Select **None** to specify that the link does not use an exception destination.
  - Select **System** to use the default exception destination.
  - Select **Specify** and enter an exception destination to configure the exception destination you require.
8. Save your changes to the master configuration.

### Results

You have configured the exception destination processing for undeliverable messages that are handled by the link.

### What to do next

You can also configure exception destination processing for a bus destination.

*Managing messages in a link transmission queue for a connection between two buses:*

You can manage messages in a link transmission queue that is associated with a foreign bus connection from one service integration bus to another service integration bus.

### Before you begin

You must know the link transmitter on which messages are to be managed.

## About this task

A service integration bus link can have multiple link transmitters. For applications that use point-to-point messaging, there is one link transmitter for each messaging engine in the sending bus. For applications that use publish/subscribe messaging, there is one link transmitter for each topic space destination that is mapped to a topic space in the foreign bus.

Complete this task when you want to view, delete, or move messages that are queued for a link transmitter.

## Procedure

1. From the navigation pane of the administrative console, click **Service integration -> Buses** to display a list of buses.
2. Select the bus whose link transmission queue you want to manage.
3. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
4. From the list of foreign bus connections, select the name of a foreign bus connection to display its details.
5. Under **Related Items**, click **Service integration bus links**, then select the check box for a link.
6. In the **Runtime** tab, click **Link transmitters** to display the list of link transmitters for messaging engines that are sending messages to the foreign bus.
7. Optional: To manage all messages that are queued for a link transmitter, select the link transmitter and complete your required task:
  - Click **Delete all messages** to delete all the available messages that are queued for a selected link transmitter.
  - Click **Move all messages** to move all the available messages that are queued for a selected link transmitter to the configured exception destination. If the exception destination is configured as **None**, or if the link transmitter is a publish/subscribe link transmitter, the messages are discarded. If it is configured as **System**, the messages are sent to the system default exception destination. If a specified destination is configured, the messages are sent to the exception destination specified for this link.
8. Optional: To manage selected messages that are queued for a link transmitter, click the name of the messaging engine from the list of link transmitters, and then click **View messages** to view the messages on an outbound stream from this link transmitter to the foreign bus.
9. Select one or more messages and complete your required task:
  - Click **Delete** to delete the selected messages.
  - Click **Move** to move the selected messages to the local exception destination. If the exception destination is configured as **None**, or if the link transmitter is a publish/subscribe link transmitter, the messages are discarded.
  - Click **Refresh** to view the current messages that are queued for a selected link transmitter.

**Note:** Only messages up to the specified maximum displayed messages are displayed.

## Results

You have managed the messages that are queued for a specified link transmitter for a specified foreign bus connection.

*Viewing messages in a link receiver queue for a connection between two buses:*

You can view messages in a link receiver queue that is associated with a foreign bus connection from one service integration bus to another service integration bus.

## Before you begin

You must know the link receiver on which messages are to be viewed.

## About this task

A service integration bus link can have multiple link receivers. For applications that use point-to-point messaging, there is one link receiver for each messaging engine in the foreign bus, that is, the bus that sends messages through the link. For applications that use publish/subscribe messaging, there is one link receiver for each topic space in the foreign bus.

In this situation, the bus with the link receiver is the local bus. The bus that the applications that produce messages are connected to is the foreign bus.

Complete this task when you want to view messages on a link receiver.

## Procedure

1. From the navigation pane of the administrative console, click **Service integration -> Buses** to display a list of buses.
2. Select the bus that has the link receiver queue you want to view.
3. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
4. From the list of foreign bus connections, select the name of the foreign bus connection to display its details.
5. Under **Related links** click **Service integration bus links**, then select the check box for a link.
6. In the **Runtime** tab, click **Link receivers** to display the list of link receivers for messaging engines on the foreign bus that are sending messages to this bus.
7. To view the messages on the link receiver, select the name of the messaging engine from the list of link receivers, then click **View messages** to view the messages on an inbound stream from the messaging engine on the foreign bus. Click **Refresh** to view the current messages on the selected link receiver.

## Results

You have viewed the messages on a specified link receiver queue for a specified foreign bus connection.

*Managing messages in a link transmission queue for a connection to a WebSphere MQ network:*

You can manage messages in a link transmission queue that is associated with a foreign bus connection from a service integration bus to a WebSphere MQ network.

## Before you begin

You must know the foreign bus connection and the link transmitter for which you want to manage messages.

## About this task

A link can have multiple link transmitters; one for each messaging engine that sends messages on the link to the foreign bus, and one for each topic space destination that is mapped to a topic space in the foreign bus.

Complete this task when you want to view, delete, or move messages that are queued for a link transmitter.

## Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses** to display a list of buses.
3. Select the bus whose link transmission queue you want to manage.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
5. Select the name of the foreign bus connection to display its details.
6. Under **Related Items**, click **WebSphere MQ links**, then select the name of the link.
7. In the **Runtime** tab, click **Sender channel** to display the sender channels that are sending messages to the foreign bus.
8. Optional: To manage all messages that are queued for a link transmitter, select the link transmitter and complete your required task:
  - Click **Delete all messages** to delete all the available messages that are queued for the selected link transmitter.
  - Click **Move all messages** to move all the available messages that are queued for the selected link transmitter to the configured exception destination. If the exception destination is configured as **None**, or if the link transmitter is a publish/subscribe link transmitter, the messages are discarded. If it is configured as **System**, the messages are sent to the system default exception destination. If a specified destination is configured, the messages are sent to the exception destination specified for this link.
9. Optional: To manage selected messages that are queued for a link transmitter, click the name of the messaging engine from the list of link transmitters and then click **View messages** to view the messages on an outbound stream from this link transmitter to the foreign bus.
10. Select one or more messages and complete one of the following tasks:
  - Click **Delete** to delete the selected messages.
  - Click **Move** to move the selected messages to the local exception destination. If the exception destination is configured as **None**, or if the link transmitter is a publish/subscribe link transmitter, the messages are discarded.
  - Click **Refresh** to view the current messages that are queued for the selected link transmitter.

**Note:** Only messages up to the specified **Maximum displayed messages** are displayed.

## Results

You have managed the messages that are queued for a specified link transmitter for a specified foreign bus connection.

*Managing messages in a known link transmission queue for connection to a WebSphere MQ network:*

You can manage messages in a known link transmission queue that is associated with a foreign bus connection from a service integration bus to a WebSphere MQ network.

## Before you begin

You must know the foreign bus connection and the known link transmitter for which you want to manage messages.

## About this task

A link can have multiple known link transmitters; one for each messaging engine in the bus that has sent messages through the link to the foreign bus, and one for each topic space destination that is mapped to a topic space in the foreign bus.

Complete this task when you want to view, delete, or move messages that are queued for a known link transmitter.

## Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses** to display a list of buses.
3. Select the bus whose known link transmission queue you want to manage.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
5. Select the name of the foreign bus connection to display its details.
6. Under **Related Items** click **WebSphere MQ links**, then select the name of the link.
7. In the **Configuration** tab, under **Additional Properties**, click **Sender channel** to display the sender channels for all messaging engines that are sending messages to this bus. The sender channel sends messages to the gateway queue manager.
8. From the list of sender channels, select the check box of a **Sender MQ channel name** and click **View known link transmitters** to display a list the remote messaging engines producing messages for this WebSphere MQ link.
9. Click **Refresh** to view the current messages on the message engines.
10. Optional: To manage all messages that are queued for a known link transmitter, select a known link transmitter and complete your required task:
  - Click **Delete all messages** to remove the messages from the known link transmission queue.
  - Click **Move all messages** to move all the available messages that are queued for a selected known link transmitter to the configured exception destination. If the exception destination is configured as **None**, or if the known link transmitter is a publish/subscribe known link transmitter, the messages are discarded. If it is configured as **System default** the messages are sent to the system default exception destination. If a **Specified destination** is configured, the messages are sent to the exception destination specified for this link.
11. Optional: To manage selected messages that are queued for a known link transmitter, select a known link transmitter then click **View messages** to view the messages.
12. Select one or more messages and complete your required task:
  - Click **Delete** to remove the selected messages from the known link transmission queue.
  - Click **Move** to move the selected messages to the configured exception destination. If the exception destination is configured as **None**, or if the known link transmitter is a publish/subscribe known link transmitter, the messages are discarded. If the exception destination is configured as **System default**, the messages are sent to the system default exception destination. If a **Specified destination** is configured, the messages are sent to the exception destination specified for this link.

## Results

You have managed the messages in a known link transmission queue for a specified foreign bus connection between a service integration bus and a WebSphere MQ network.

*Managing messages in a sender channel transmission queue for a connection to a WebSphere MQ network:*

You can manage messages in a sender channel transmission queue that is associated with a foreign bus connection between a service integration bus and a WebSphere MQ network.

## Before you begin

You must know the foreign bus connection and the sender channel transmitter for which you want to manage messages.

## About this task

There is one sender channel transmitter on the WebSphere MQ link that sends messages to a gateway queue manager on the WebSphere MQ network (the foreign bus).

Complete this task when you want to view, delete, or move messages that are queued for the sender channel transmitter.

## Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration** -> **Buses** to display a list of buses.
3. Select the bus whose sender channel transmission queue you want to manage.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
5. Select the name of the foreign bus connection to display its details.
6. In the **Configuration** tab, under **Related Items** click **WebSphere MQ links**, then select the check box for a link.
7. Click **Sender channel transmitter** under **Current outbound messages**, or click **Sender channel transmitter** under **Messages sent**, to see the relevant message details for this sender channel transmitter.
8. Select the check box of the sender channel transmitter and complete your required task:
  - Click **Delete all messages** to remove the messages from the sender channel transmission queue.
  - Click **Move all messages** to move all the available messages on the sender channel transmitter to the configured exception destination. If the exception destination is configured as **None**, the messages are discarded. If it is configured as **System**, the messages are sent to the system default exception destination. If a specified destination is configured, the messages are sent to the exception destination specified for this link.

## Results

You have managed the messages on a sender channel transmitter that sends messages to a gateway queue manager on the WebSphere MQ network.

### *Managing pending acknowledgement messages on a deleted WebSphere MQ link:*

If a foreign bus link to a WebSphere MQ network is deleted from the WebSphere Application Server configuration before being drained of messages, a batch of messages pending acknowledgement remains stored in the WebSphere MQ link sender channel transmitter. You can use the administrative console to resolve these messages.

## Before you begin

You must know the name of the WebSphere MQ link that has been deleted.

## About this task

To resolve pending acknowledgement messages on a deleted WebSphere MQ link, use the administrative console to complete the following steps.

## Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses** to display a list of buses.
3. Select the bus whose link transmission queue you want to manage.
4. In the **Configuration** tab, under **Topology**, click **Foreign Bus Connections** to display a list of connections for this bus.
5. From the list of foreign bus connections, select the name of a foreign bus connection to display its details.
6. Under **Related Items** click **Service integration bus links** to display the details of the service integration bus links.
7. Select the MQ network foreign bus that has a connection that is active, but a configuration status that is **Deleted**. If clicking **Link transmitters** displays an empty list, no messaging engines are producing messages to this link and all the link transmitters have been deleted because they were drained of messages. The **Sender channel transmitter** link displays the status of the sender channel as stopped but **Current outbound messages** shows remaining messages on the sender channel transmitter.
8. Click a WebSphere MQ link **Sender channel** link to display the messages that are queued on the WebSphere MQ link sender channel transmitter for transmission to the WebSphere MQ network.
9. If the Status of a batch of messages is "Commit pending batch", the batch has arrived safely at the MQ network. Select the batch and click **Commit pending batch** to remove the messages from the transmission queue.
10. If the Status of a batch of messages is "Pending batch acknowledgement", the batch did not arrive at the MQ network. Select the batch and click **Rollback pending acknowledge batch** to roll back the transaction and restore the messages to the channel in an available state. These messages are either automatically deleted or moved to the exception destination. When the channel transmitter is empty, the link is automatically deleted from the runtime environment.

## Results

You have resolved any pending acknowledgement messages on a WebSphere MQ link that has been deleted from a foreign bus connecting to a service integration bus.

### *Modifying a routing definition:*

You can view or change the routing definition of an existing foreign bus connection between a local bus and a foreign bus. The routing definition defines the virtual link between two buses that enables them to exchange messages. The routing definition can define properties for a virtual service integration bus link, a virtual WebSphere MQ link, or an indirect foreign bus connection.

## About this task

You create a routing definition when you create a foreign bus connection. For a direct foreign bus connection, the routing definition, or virtual link, has a corresponding physical link on a messaging engine.

To change the properties of the routing definition, use the administrative console to complete the following steps:

## Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that is connected to another bus, that is, the local bus you require.

3. In the content pane, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.
4. Select the required foreign bus.
5. In the content pane, under **Additional properties**, click the routing properties option. The routing properties option depends on the type of routing definition and is one of the following:
  - **Service integration bus link routing properties**
  - **WebSphere MQ link routing properties**
  - **Indirect routing properties**
6. Specify the new routing properties:
  - For a virtual service integration bus link or a virtual WebSphere MQ link, specify properties as follows:

#### **Inbound user ID**

The user name used to authenticate inbound message flows from the foreign bus.

When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:

- The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
- You want local control of access to inbound messages to the local bus.

If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.

#### **Outbound user ID**

The user name used to authenticate outbound message flows to the foreign bus.

The outbound user ID replaces the user ID that identifies the message source in every message sent to the foreign bus. Where it is defined, the outbound user ID replaces the user ID in messages sent by the local bus to the foreign bus. If the local bus and the foreign bus are both secure, and the foreign bus has not overridden the user ID with its own inbound user ID, the foreign bus also uses the outbound user ID to authorize the message to its destination.

- For an indirect foreign bus connection, select the name of the next foreign bus you require in the chain of intermediate buses. For a bus to be available for selection, it must already have a direct foreign bus connection from the local bus.
7. Click **OK**.
  8. Save your changes to the master configuration.

#### ***Configuring service integration bus links:***

You can configure service integration bus links on messaging engines in a variety of ways. For example, you can start, stop, or remove links.

#### **About this task**

When you create a foreign bus connection to connect two service integration buses, a service integration bus link is created automatically. The foreign bus connection contains a routing definition, which is a virtual link, and the service integration bus link is the corresponding physical link on the messaging engine.

*Configuring the properties of a service integration bus link:*

After establishing a service integration bus link you might want to configure the properties of a service integration bus link such as the name of the service integration bus link, or authentication alias used by foreign bus that the link connects to.

### About this task

To configure the properties of a service integration bus link, use the administrative console to complete the following steps:

### Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to configure the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to configure.
5. Specify the following properties for the service integration bus link:

**Name** The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

### Description

An optional description for the service integration bus link, for administrative purposes.

**UUID** The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

### Foreign messaging engine

The messaging engine on the foreign bus to which this link connects.

**Note:** This foreign bus name must not be altered after it has been configured. If you alter it, any messaging engines that already hold state information on the link will not be able to use the link unless the foreign bus name is reset to its original value.

### Target inbound transport chain

The type of transport chain used for communication with the foreign bus. The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

### Bootstrap endpoints

The comma-separated list of endpoints used to connect to a bootstrap server. This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see the steps relating to setting bootstrap endpoints in “Configuring a connection to a non-default bootstrap server” on page 610.

**Note:** Service integration bus links over `BootstrapTunneledMessaging` and `BootstrapTunneledSecureMessaging` transport chains only work directly between application server instances. Bus links over `TunneledMessaging` transport chains do not work if an HTTP server is placed in front of either application server instance.

### Authentication alias

The name of the authentication alias, used to authenticate access to the foreign bus. The alias must be known to the foreign bus.

### Initial state

Whether the link is started automatically when the messaging engine is started. Until started, the gateway link is unavailable. If this property is set to **Started** the service integration bus link is started when the messaging engine is started.

6. Click **OK**.
7. Save your changes to the master configuration.

*Listing the service integration bus links:*

You can list all the service integration bus links that are linked to a messaging engine.

### About this task

To list the service integration bus links for a messaging engine, use the administrative console to complete the following steps:

### Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Additional properties**, click **Messaging engines**. The list of messaging engines in the bus is displayed.
4. In the content pane, select the messaging engine for which you want to list the service integration bus links.
5. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.

### Example

The following combinations of **Status** and **Activity** values are possible:

*Table 214. Results of possible status and activity values. The first and second columns of the table provide the possible combinations of status and activity values, and the third column explains the possible connection status of the local and foreign buses.*

Status	Activity	Meaning
started	inactive	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to successfully activate of a connection between the buses.
started	active	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
stopped	inactive	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
unknown	inactive	An error might have occurred in setting up the link, such that the object that is used to report the current state is not available. The deployment manager cannot contact a remote server to determine the status.

### What to do next

You can now add or remove a service integration bus link or select a service integration bus link to start, stop, or configure.

*Starting a service integration bus link:*

When a service integration bus link has been started, it can be used for communicating with its associated messaging engines.

## About this task

To start a service integration bus link, use the administrative console to complete the following steps:

### Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to start the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to start.
5. Click **Start**.

*Stopping a service integration bus link:*

When a service integration bus link has been stopped, it cannot be used for communication until it is restarted.

## About this task

To stop a service integration bus link, use the administrative console to complete the following steps:

### Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine to which the service integration bus link that you want to stop belongs.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to stop.
5. Click **Stop**.

*Removing a service integration bus link:*

When a service integration bus link to a messaging engine has been removed, it cannot be used for communication until it is recreated.

## Before you begin

Before you remove the service integration bus link you must stop the link.

When you remove a service integration bus link, all traffic that uses the link needs to be dealt with in a similar way to when you remove a destination. For further details, see “Deleting a non-topic space bus destination” on page 2210. Note that express Quality of Service (QoS) messages are discarded.

## About this task

To remove a service integration bus link from a messaging engine, use the administrative console to complete the following steps:

### Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine that is associated with the service integration bus link that you want to remove.

3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to remove.
5. Click **Delete**.
6. Save your changes to the master configuration.

### **What to do next**

When you remove a service integration bus link, all traffic that uses the link must be diverted by alternative routes or held pending further administrative action. Express QoS messages are discarded.

### ***Configuring topic space mappings between service integration buses:***

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. You can configure topic space mappings between a local service integration bus and a foreign service integration bus.

### **About this task**

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus, an equivalent topic space mapping is required by the foreign bus.

If you want to publish messages from a local bus to a foreign bus that is linked indirectly through a third bus, you must configure topic space mappings between the local bus and the intermediate bus, and between the intermediate bus and the foreign bus. The messages can be for publication to the foreign bus only, or to all three buses. If you want to publish messages only to the local and foreign buses, these two buses must be connected directly.

If you want to publish messages from a local service integration bus to a foreign bus that represents a WebSphere MQ network, you must define topic mappings on the broker profile associated with the WebSphere MQ link.

For more details about the foreign bus and publish/subscribe messaging between buses, see Foreign buses.

### ***Creating topic space mappings:***

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. You can create topic space mappings between two service integration buses.

### **About this task**

You can create topic space mappings as part of the procedure to create a foreign bus connection, or you can create them separately, as described in this topic.

Note that for publishing and subscribing between a service integration bus and a foreign bus that represents a WebSphere MQ network, you must define topic mappings on the broker profile associated with the WebSphere MQ link.

To map a topic space on a local service integration bus to a topic space on a foreign service integration bus, use the administrative console to complete the following steps.

## Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that is connected to another bus, that is, the local bus you require.
3. In the content pane, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.
4. Select the required foreign bus.
5. In the content pane, under **Additional properties**, click **Service integration bus link routing properties**.
6. In the content pane, under **Additional properties**, click **Topic space map entries**.
7. Click **New**.
8. Specify the mappings as follows:

### Local topic space

The name of the topic space on this (local) bus that is mapped to the remote topic space on the foreign bus.

### Remote topic space

The name of the topic space on the foreign bus that is mapped to the local topic space.

**Note:** The names of the local and foreign topic space do not have to match, but the names of the topics must match in both local and foreign buses.

9. Click **OK**.
10. Save your changes to the master configuration.

## Results

The remote topic space is mapped to the local topic space.

### *Deleting topic space mappings:*

You can delete topic space mappings so that subscribers on the local topic space cannot receive messages that are published in the foreign topic space.

## About this task

To delete topic space mappings, use the administrative console to complete the following steps:

## Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that is connected to another bus, that is, the local bus you require.
3. In the content pane, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.
4. Select the required foreign bus.
5. In the content pane, under **Additional properties**, click **Service integration bus link routing properties**.
6. In the content pane, under **Additional properties**, click **Topic space map entries**. A list of topic space map entries is displayed.
7. Select the topic space map entry that you want to remove.
8. Click **Delete**.

9. Save your changes to the master configuration.

*Listing topic space map entries:*
