For more information, see section 121.5 “Bean Manager” and section 121.6 “Service Manager” of the OSGi Service Platform Release 4 Version 4.2 Enterprise Specification.

e. Save and close the file.

Note: You might get an exception message (visible in the Problems pane) saying that there is no `bin.include` entry for `OSGI-INF` in the build properties file. If you see this message, use the **quick-fix** option to add the entry (right-click the problem, then select **quick-fix**).

Results

You have created two bundles, `com.ibm.ws.eba.helloWorld.api` and `com.ibm.ws.eba.helloWorld.service`. The `com.ibm.ws.eba.helloWorld.service` service implements the HelloWorldEBA interface that is declared in the `com.ibm.ws.eba.helloWorld.api` bundle, and contains the business logic and metadata needed to export the `com.ibm.ws.eba.helloWorld.service` service.

What to do next

You can now create the client bundle that uses the `com.ibm.ws.eba.helloWorld.service` service.

Creating a client bundle

For the simple hello-world OSGi application, the client bundle consumes the HelloWorldService service, and uses it to produce the message “OSGi Service: Hello World!”.

Before you begin

This task assumes that you have already created the HelloWorldService service, as described in “Creating a service bundle” on page 661.

About this task

A bundle, the modular unit in the OSGi model, is a JAR file that includes the OSGi application metadata. This metadata is defined in the manifest file of the JAR file, `META-INF/MANIFEST.MF`.

IBM Rational Application Developer Version 8 provides graphical support for creating and packaging bundles. The sample procedure that follows uses this tool. You can also use other tools, and the steps are adaptable to other tools.

This sample procedure builds a bundle called `com.ibm.ws.eba.helloWorld.client`. This bundle uses the HelloWorldService service that is exported by the bundle `com.ibm.ws.eba.helloWorld.service`, as described in “Creating a service bundle” on page 661.

Procedure

1. Create an OSGi bundle project.
   a. Click **File** > **New** > **OSGi Bundle Project**. The OSGi Bundle Project panel is displayed.
   b. Configure the project.
      - For **Project name**, enter `com.ibm.ws.eba.helloWorld.client`.
      - Clear the **Add bundle to application** check box. If you leave this check box selected, a new OSGi application project is created automatically, and the bundle is added to it. Here, however, the application project will be created manually in a separate task, “Creating an OSGi application” on page 668.
      - Leave the other options as the default values.
   c. Click **Next**. The Java Configuration panel is displayed. Accept the default values for all the options on this panel.
   d. Click **Next**. The OSGi bundle settings panel is displayed. Accept the default values for all the options on this panel.
   e. Click **Finish**.

   You have created your OSGi project.
2. Make the HelloWorldEBA interface available to the client implementation bundle.

   Edit the client bundle manifest to make classes inside the `com.ibm.ws.eba.helloWorld.api` package available to the client implementation bundle. The `com.ibm.ws.eba.helloWorld.api` package is part of the `com.ibm.ws.eba.helloWorld.api` bundle.
   a. Expand the `com.ibm.ws.eba.helloWorld.client` project
   b. Open the bundle `MANIFEST.MF` file with the manifest editor. This file is in the `BundleContent/META-INF` directory.
   c. Click the **Dependencies** tab.
   d. In the Imported Packages pane, click **Add**.

e. In the Package Selection dialog, enter com.ibm.ws.eba, select com.ibm.ws.eba.helloWorld.api (1.0.0) from the Exported Packages list, then click **OK**. The package is added to the Imported Packages list.

f. In the Imported Packages list, select the com.ibm.ws.eba.helloWorld.api package then click **Properties**.

g. In the **Properties** dialog, set the **minimum version** to 1.0.0 Inclusive, and set the **maximum version** to 2.0.0 Exclusive, then click **OK**. The entry for this package in the Imported Packages list is updated to com.ibm.ws.eba.helloWorld.api [1.0.0,2.0.0).

This version syntax means "exported packages with versions between 1.0.0 inclusive and 2.0.0 exclusive will match this import". For more information on the version syntax, see section 3.2.6 "Version Ranges" of the OSGi Service Platform Release 4 Version 4.2 Core Specification.

This version range has been specified to ensure that the client bundle uses an updated version of the package if it differs in the value of the minor version or the micro version, but not the major version, because only a binary incompatible change, such as the deletion of a public method, can cause the client bundle to cease functioning correctly.

h. Save and close the file.

3. Create a class HelloWorldClient.

a. In the project source folder src, create a package called com.ibm.ws.eba.helloWorld.client. In the package, create a class called HelloWorldClient with the following contents:

```
package com.ibm.ws.eba.helloWorld.client;

import com.ibm.ws.eba.helloWorld.api.HelloWorldEBA;

public class HelloWorldClient {
    private HelloWorldEBA helloWorldEBAService = null; //a reference to the service

    public void refHello() {
        System.out.println("Client: Start...");
        helloWorldEBAService.hello();
        System.out.println("Client: End...");
    }

    public HelloWorldEBA getHelloWorldEBAService() {
        return helloWorldEBAService;
    }

    public void setHelloWorldEBAService(HelloWorldEBA helloWorldEBAService) {
        this.helloWorldEBAService = helloWorldEBAService;
    }
}
```

In the previous code block:

- The line HelloWorldEBA helloWorldEBAService = null; defines the service dependency.
- The line helloWorldEBAService.hello(); demonstrates that a service has been injected for the helloWorldEBAService dependency.

b. Save and close the file.

4. Create a Blueprint configuration.

A Blueprint configuration contains the bundle component assembly and configuration information. It also describes how components are registered in the OSGi service registry, or how they look up services from the OSGi service registry. This information is used at run time to instantiate and configure the required components when the bundle is started.

a. In the project com.ibm.ws.eba.helloWorld.client, create a Blueprint XML file:

1) Right-click the com.ibm.ws.eba.helloWorld.client project, and select **New** > **Blueprint File**.

2) (Optional) Specify the file name. This can be any name provided it is an XML file. For example, helloWorldRef.xml.

3) Leave the other options as the default values.

4) Click **Finish**.

b. Add a reference element to the Blueprint XML file.
   1) In the **Design** tab, click **Add** in the Overview pane.
   2) Select **Reference**, and click **OK**.
   3) Click **Browse** alongside the **Reference Interface** field.
   4) Enter `Hello`, select `HelloWorldEBA` from the **Matching items** list, and click **OK**.
   5) In the **Reference ID** field, enter `helloEBARef`, then click **OK** to add the reference element.

c. Add a bean element to the Blueprint XML file.
   1) Select **Blueprint** in the Overview pane, and click **Add**.
   2) Select **Bean**, and click **OK**.
   3) Click **Browse**, select `HelloWorldClient`, and click **OK**.
   4) Click **OK** to add the bean element.
   5) In the Method References pane, click **Browse** alongside the **Initialization method** field.
   6) Select **refHello()** and click **OK**

d. Add a property to the bean.
   1) Select **HelloWorldClientBean** in the Overview pane, and click **Add**.
   2) Select **Property**, and click **OK**.
   3) In the Details pane, enter `helloWorldEBAService` in the **Name** field.
   4) Click **Browse** alongside the **Reference** field.
   5) Select **helloEBARef** and click **OK**.

e. Examine the Blueprint XML source code. This Blueprint file specifies the internal wiring of the components.

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0">
  <reference id="helloEBARef"
    interface="com.ibm.ws.eba.helloWorld.api.HelloWorldEBA"/>
  <bean id="HelloWorldClientBean"
    class="com.ibm.ws.eba.helloWorld.client.HelloWorldClient"
    init-method="refHello">
    <property name="helloWorldEBAService" ref="helloEBARef"/>
  </bean>
</blueprint>
```

   In the previous code block:

   - The `init-method refHello` is called when the `com.ibm.ws.eba.helloWorld.client.HelloWorldClient` bean is created.
   - The `property` element specifies how a dependency is injected.
     - The property `helloWorldEBAService` is set by invoking the property setter `public void setHelloWorldEBAService(HelloWorldEBA helloWorldEBAService)`. You can use setter injection for bean properties that are defined in accordance with Java bean conventions.
     - The attribute `ref` specifies the Blueprint element ID of the component to be injected. The `ref` attribute must match a top-level element in this file. In this case, it matches the `reference` element.
   - The `reference` element defines a dependency of this Blueprint module on an OSGi service with interface `com.ibm.ws.eba.helloWorld.api.HelloWorldEBA`. When the Blueprint Container starts this module, it must match the name of the interface attribute with an available service in the OSGi service registry. If this cannot be done, the Blueprint module is not started. In this case, the service is defined in the service element of the Blueprint XML of the service bundle.

   For more information, see section 121.5 “Bean Manager” and section 121.7 “Service Reference Managers” of the OSGi Service Platform Release 4 Version 4.2 Enterprise Specification.

f. Save and close the file.

Results

You have created a bundle called com.ibm.ws.eba.helloWorld.client. This bundle consumes the HelloWorldService service, and uses it to produce the message “OSGi Service: Hello World!”.

What to do next

You can now create an OSGi application, in which multiple bundles are packaged together.

Creating an OSGi application

For the simple hello-world OSGi application, the bundle that defines the service, and the bundle that uses the service, are packaged together in an OSGi application.

Before you begin

This topic assumes that you have already completed the following tasks:

- “Creating a service bundle” on page 661 com.ibm.ws.eba.helloWorld.service.
- “Creating a client bundle” on page 665 com.ibm.ws.eba.helloWorld.client.

You can create your application as described in this topic, in which case the application manifest file is created for you by the tooling, or you can create your application using Apache Ant.

About this task

OSGi bundles are packaged as Java archive (.jar) files. A single OSGi application is packaged in an enterprise bundle archive (.eba) file, just as an enterprise application is packaged in an enterprise archive (.ear) file. In this example application, the bundles are packaged directly in the .eba file. However the .eba file does not have to contain the bundles; they can be pulled in at run time. For an OSGi application deployed to WebSphere Application Server, a bundle can be located in the .eba file, or in the WebSphere Application Server internal bundle repository, or in an external bundle repository. Every .eba file contains an application manifest (APPLICATION.MF) file, which contains the metadata that defines the application. It lists the bundles that the application uses, and says where each bundle is located.

IBM Rational Application Developer Version 8 provides graphical support for creating and packaging bundles. The sample procedure that follows uses this tool. You can also use other tools, and the steps are adaptable to other tools.

This sample procedure creates a simple hello-world OSGi application called com.ibm.ws.eba.helloWorldApp, in which the three bundles com.ibm.ws.eba.helloWorld.api, com.ibm.ws.eba.helloWorld.service and com.ibm.ws.eba.helloWorld.client are packaged together in an .eba file.

When you deploy and start this application, it prints the greeting message “OSGi Service: Hello World!” to the system output log.

Procedure

1. Create an OSGi application project.
   a. Click **File** > **New** > **OSGi Application Project**. The OSGi Application Project panel is displayed.
   b. Configure the project.
      - For **Project name**, enter com.ibm.ws.eba.helloWorldApp.
      - Ensure that **Use default location** is selected.
      - Ensure that **Add project to working sets** is cleared.
   c. Click **Next**.

d. In the Contained Bundles list, select `com.ibm.ws.eba.helloWorld.api 1.0.0`, `com.ibm.ws.eba.helloWorld.client1.0.0` and `com.ibm.ws.eba.helloWorld.service1.0.0`.

   For more information about these bundles, see “Creating a service bundle” on page 661 and “Creating a client bundle” on page 665.

e. Click **Finish**.

2. Optional: Deploy and test the OSGi application project on a server running inside IBM Rational Application Developer.

   If you are using IBM Rational Application Developer Version 8, you can deploy to a local machine without first exporting the OSGi application as an EBA file. This is typically how you would test your application. If you are using another tool, omit this step.

   a. Right-click the `com.ibm.ws.eba.helloWorldApp` project, then select **Run As** > **Run on Server**. The Run On Server panel is displayed. If you have already configured a WebSphere Application Server in your IBM Rational Application Developer workspace, you can select **Choose an existing server**, and then select that server, otherwise manually define a new server by completing the remaining steps.

   b. Configure the Run On Server panel:

      1) For server type, select **IBM** > **WebSphere Application Server v8.0**.
      2) For server host name, enter a valid TCP/IP host name. For example, enter the TCP/IP hostname for your computer or enter `localhost`.
      3) For server name, enter the name by which you want to refer to the server within IBM Rational Application Developer.
      4) For server runtime environment, select **WebSphere Application Server v8.0**. If this option is not available in the list, complete the following steps:
         a) Click **Add**.
         b) Navigate to the *app_server_root* directory for your installation of WebSphere Application Server; for more information on the *app_server_root* directory, see *app_server_root*.
         c) Click **Finish**.
      5) Click **Next**.

      The WebSphere Application Server Settings panel is displayed.

   c. Configure the WebSphere Application Server Settings panel:

      1) For the profile name, select the profile that you use with OSGi Applications.
      2) For the application server name, verify that the application server name for your profile is displayed. By default, the first application server for a profile is called `server1`.
      3) If security is enabled on your application server, enter a user ID and password.
      4) Click **Next**.

      The list of configured OSGi application projects is displayed.

   d. Check that your OSGi application project is in the list of configured projects.

   e. Click **Finish**. The server starts automatically, your application is published and started, and the following output is displayed on the **Console** tab:

```
[4/15/10 14:07:33:295 GMT] 00000023 SystemOut O Client: Start...
[4/15/10 14:07:33:581 GMT] 00000023 SystemOut O OSGi Service: Hello World!
[4/15/10 14:07:33:581 GMT] 00000023 SystemOut O Client: End...
```

3. Export the project as an EBA file.

   a. Right-click the project name, then select **Export** > **OSGi** > **OSGi Application EBA**.

   b. Enter a location for the exported file, then name the file `com.ibm.ws.eba.helloWorldApp.eba`.

   c. Click **Finish**.

Results

You have completed the detailed instructions for developing a simple OSGi application. In this application, a client bundle that uses a service that is defined in a service bundle to produce the message “OSGi Service: Hello World!”. Your application uses the OSGi service registry to share the hello service between the defining bundle and the client bundle. All interactions with the service registry are handled through Blueprint.

What to do next

You are now ready to deploy and start your OSGi application outside of IBM Rational Application Developer, by completing the following steps:

1. Deploy your OSGi application as a business-level application.
2. Start your business-level application.
3. Check the system output log for the greeting message “OSGi Service: Hello World!”.

You can use the administrative console or wsadmin commands to deploy and start an OSGi application in WebSphere Application Server. For information about how to do this for any OSGi application, see “Deploying an OSGi application as a business-level application” on page 2091 and Starting your business-level application. When you check the system output log, you should see the following message:

```
[4/15/10 14:07:33:295 GMT] 00000023 SystemOut O Client: Start...
[4/15/10 14:07:33:581 GMT] 00000023 SystemOut O OSGi Service: Hello World!
[4/15/10 14:07:33:581 GMT] 00000023 SystemOut O Client: End...
```

Creating an OSGi application using Apache Ant

You can use the Apache Ant (Ant) command-line tool to package bundles together into an OSGi application.

Before you begin

This topic assumes that you understand how to use the Ant build tooling, and that you have already created the bundles and the application manifest file that you want to package together as an OSGi application.

For a detailed overview of creating an OSGi application, and instructions on how to do this using IBM Rational Application Developer Version 8 or similar tooling, see “Creating an OSGi application” on page 668.

About this task

The code example in this topic shows the syntax for using the Ant **zip** task to package a set of bundles and an application manifest (`APPLICATION.MF`) file into an enterprise bundle archive (`.eba`) file.

Example

```
<zip destfile="${output.dir}/myExample.eba" basedir="${basedir}">
    <filename name="META-INF/APPLICATION.MF"/>
    <fileset dir="${basedir}">
        <include name="*.jar"/>
    </fileset>
</zip>
```

This example packages the `META-INF/APPLICATION.MF`file into the EBA file, and also includes all files ending in “`.jar`” (that is, the bundles).

`${output.dir}` and `${basedir}` refer to the following Ant properties:

- **output.dir** is user-defined, and specifies the output directory for your build.

- **basedir** is predefined, and specifies the directory that contains the Ant `build.xml` file.

What to do next

You can use the administrative console or wsadmin commands to deploy and start an OSGi application in WebSphere Application Server. See “Deploying an OSGi application as a business-level application” on page 2091 and Starting your business-level application.

Developing a composite bundle

A composite bundle groups shared bundles together into aggregates. It provides one or more packages at specific versions to an OSGi application. You can also extend a deployed application by adding one or more composite bundles to the composition unit for the application. You can use OSGi application tooling to develop a composite bundle.

About this task

When you want to ensure consistent behavior from a set of shared bundles in an OSGi application, you use a composite bundle to provide that set of bundles to the application. If a required package or service is available at the same version from both a bundle and a composite bundle, the provisioning process selects the package or service from the composite bundle.

When you want to extend a deployed business-level application that contains an OSGi application, and you do not want to stop the application or modify the underlying EBA asset, you add one or more composite bundles to the composition unit.

A composite bundle is packaged as a composite bundle archive (CBA) file. This file is a compressed archive file with a `.cba` file extension. If the composite bundle is part of an enterprise OSGi application, the CBA file can be directly contained within the enterprise bundle archive (EBA) file for the application, or pulled in by reference from the internal bundle repository or from an external repository that can process composite bundles. A composite bundle can directly contain bundles in its CBA file. It can also include by reference bundles that are hosted alongside the CBA file within the same EBA file, or bundles that are installed in the same bundle repository.

A composite bundle is described in a composite bundle manifest file, `META-INF/COMPOSITEBUNDLE.MF`. This manifest file lists the OSGi bundles that are directly contained in the composite bundle, and the reference bundles that are hosted alongside the composite bundle in the same EBA file, or in the same bundle repository.

If you want to use your composite bundle to extend a deployed application, you must install the CBA file in the internal bundle repository or in an external repository that can process composite bundles. If you install a composite bundle in a bundle repository, and the composite bundle includes bundles by reference, you must ensure that the referenced bundles are also available in the same repository. If you use the internal bundle repository, and the composite bundle directly contains bundles, the contained bundles are not listed separately and are only available as part of the composite bundle. For more information, see Composite bundles.

IBM Rational Application Developer Version 8 provides graphical support for creating and packaging composite bundles. You can also use other tools.

Procedure

1. Develop the bundles.

   See “Creating a service bundle” on page 661 and “Creating a client bundle” on page 665. You might also want to explore the sample OSGi applications.
2. Create the composite bundle manifest.

Most OSGi application tooling, including IBM Rational Application Developer Version 8, helps you create the composite bundle manifest. See also Example: OSGi composite bundle manifest file.

3. Package the directly-contained bundles and the composite bundle manifest as a compressed file with a `.cba` file extension.

   Note: The file extension must be `.cba`, but the composite bundle name need not include "cba".

4. Check that all referenced bundles are available in the EBA file (if the composite bundle is part of an enterprise OSGi application), or in a bundle repository that can process composite bundles (such as the internal bundle repository).

   See Administering bundles in the internal bundle repository or Administering bundles in the internal bundle repository using wsadmin commands.

5. Add the CBA file to the EBA file or to the bundle repository.

What to do next

- If you have configured an enterprise OSGi application to use your composite bundle, you can now import the application as an asset. See "Deploying an OSGi application as a business-level application" on page 2091.
- If you want to use your composite bundle to extend a composition unit, see Adding or removing extensions for an OSGi composition unit.

Converting existing applications to OSGi applications

You can convert an enterprise application or a Spring application to an OSGi application.

Procedure

- Convert an enterprise application to an OSGi application.
- Convert a Spring application to an OSGi application.

Converting an enterprise application to an OSGi application

You convert an enterprise application to an OSGi application by completing manual tasks that convert the enterprise archive (EAR) file to an enterprise bundle archive (EBA) file.

To convert your enterprise application to an OSGi application, you must separately convert each of the components in the EAR file.

Complete the following tasks:

1. Change the file extension from `.ear` to `.eba`.
2. Convert any web application archive (WAR) files to OSGi web application bundles.
3. Convert any enterprise bean (EJB) Java archive (JAR) files to OSGi EJB bundles.
4. Convert any utility JAR files to OSGi bundles.
5. Convert any persistence archive files to OSGi persistence bundles.
6. Convert Java 2 security settings to OSGi.

These tasks are described in detail in the following subtopics:

Converting a web application archive file to an OSGi web application bundle

When converting an enterprise archive (EAR) file to an enterprise bundle archive (EBA) file, you complete manual tasks to convert any web application archive (WAR) files in the EAR file to OSGi web application bundles.

Note: If you do not convert a WAR file manually, it is converted automatically when the containing EBA file is imported as an asset. However, by completing all of the manual steps described in this topic, you can ensure that your web application bundle is configured correctly for your deployment environment.

To convert a WAR file to an OSGi web application bundle, complete the following steps:

1. Change the file extension from `.war` to `.jar`.
2. Define general bundle metadata by adding the following headers to the bundle manifest file, `META-INF/MANIFEST.MF`:

   Bundle-ManifestVersion
   The version of the syntax in which the bundle manifest file is written. For OSGi Service Platform Release 4, set the value to 2.

   Bundle-Name
   A human-readable name for the bundle.

   Bundle-SymbolicName
   A non-localizable name that identifies the bundle uniquely.

   Bundle-Version
   The version of the bundle. For more information, see the description of the Bundle-Version header in the bundle manifest file.

   Import-Package
   The external packages on which the bundle depends. For more information, see the description of the Import-Package header in the bundle manifest file.

   Export-Package
   The packages that are visible outside the bundle. For more information, see the description of the Export-Package header in the bundle manifest file.
3. Define bundle-type-specific metadata by adding the following headers to the bundle manifest file:

   Export-EJB
   The presence of this header identifies the bundle as containing enterprise beans that are to be loaded and run by the EJB container. Optionally, you can specify, as the value of the this header, the list of enterprise beans that you want to export as OSGi services. For more information, see the description of the Export-EJB header in the bundle manifest file.

   Web-ContextPath
   The default context from which the web content is hosted.

   You must set the value of the Web-ContextPath header to the value of the <context-root> element for the corresponding web module in the application.xml file of the enterprise application EAR file.
4. Specify the bundle classpath by adding a **Bundle-Classpath** header to the bundle manifest file.

   You must set the value of the Bundle-Classpath header to a comma separated list of the names of all the JAR files and class subfolders that are contained in the `WEB-INF\lib` folder of the WAR file.

Converting an EJB JAR file to an OSGi EJB bundle

When converting an enterprise archive (EAR) file to an enterprise bundle archive (EBA) file, you complete manual tasks to convert any enterprise bean (EJB) Java archive (JAR) files in the EAR file to OSGi EJB bundles.

To convert an EJB JAR file to an OSGi application bundle, complete the following steps:

1. Define general bundle metadata by adding the following headers to the bundle manifest file, `META-INF/MANIFEST.MF`:

Bundle-ManifestVersion
The version of the syntax in which the bundle manifest file is written. For OSGi Service Platform Release 4, set the value to 2.

Bundle-Name
A human-readable name for the bundle.

Bundle-SymbolicName
A non-localizable name that identifies the bundle uniquely.

Bundle-Version
The version of the bundle. For more information, see the description of the Bundle-Version header in the bundle manifest file.

Import-Package
The external packages on which the bundle depends. For more information, see the description of the Import-Package header in the bundle manifest file.

Export-Package
The packages that are visible outside the bundle. For more information, see the description of the Export-Package header in the bundle manifest file.

2. Define bundle-type-specific metadata by adding the following headers to the bundle manifest file:

Export-EJB
The presence of this header identifies the bundle as containing enterprise beans that are to be loaded and run by the EJB container. Optionally, you can specify, as the value of the this header, the list of enterprise beans that you want to export as OSGi services. For more information, see the description of the Export-EJB header in the bundle manifest file.

Converting a utility JAR file to an OSGi bundle

When converting an enterprise archive (EAR) file to an enterprise bundle archive (EBA) file, you complete manual tasks to convert any utility JAR files in the EAR file to OSGi bundles.

To convert a utility JAR file to an OSGi application bundle, define general bundle metadata by adding the following headers to the bundle manifest file, META-INF/MANIFEST.MF:

Bundle-ManifestVersion
The version of the syntax in which the bundle manifest file is written. For OSGi Service Platform Release 4, set the value to 2.

Bundle-Name
A human-readable name for the bundle.

Bundle-SymbolicName
A non-localizable name that identifies the bundle uniquely.

Bundle-Version
The version of the bundle. For more information, see the description of the Bundle-Version header in the bundle manifest file.

Import-Package
The external packages on which the bundle depends. For more information, see the description of the Import-Package header in the bundle manifest file.

Export-Package
The packages that are visible outside the bundle. For more information, see the description of the Export-Package header in the bundle manifest file.

:

Converting a persistence archive file to an OSGi bundle

When converting an enterprise archive (EAR) file to an enterprise bundle archive (EBA) file, you complete manual tasks to convert any persistence archive files in the EAR file to OSGi bundles.

To convert a persistence archive file to an OSGi application bundle, complete the following steps:

1. Define general bundle metadata by adding the following headers to the bundle manifest file, `META-INF/MANIFEST.MF`:

   Bundle-ManifestVersion
   The version of the syntax in which the bundle manifest file is written. For OSGi Service Platform Release 4, set the value to 2.

   Bundle-Name
   A human-readable name for the bundle.

   Bundle-SymbolicName
   A non-localizable name that identifies the bundle uniquely.

   Bundle-Version
   The version of the bundle. For more information, see the description of the Bundle-Version header in the bundle manifest file.

   Import-Package
   The external packages on which the bundle depends. For more information, see the description of the Import-Package header in the bundle manifest file.

   Export-Package
   The packages that are visible outside the bundle. For more information, see the description of the Export-Package header in the bundle manifest file.

2. Define bundle-type-specific metadata by adding the following headers to the bundle manifest file:

   Meta-Persistence
   The file path to the persistence.xml file.

Converting Java 2 security settings in an enterprise application to OSGi

When converting an enterprise archive (EAR) file to an enterprise bundle archive (EBA) file, you can have any Java 2 security settings converted automatically to OSGi, and then manually refine them to obtain the required OSGi security configuration.

In an enterprise application, the `was.policy` file defines Java 2 security permissions. In the `was.policy` file, you declare fine-grained security settings by using `grant codeBase` statements to grant permissions to application components.

In an OSGi application, permissions that define application-level security are specified in a `permissions.perm` file in the `META-INF` directory of the OSGi application. However, you can, in addition to the application-level `permissions.perm` file, create a `permissions.perm` file in the `OSGI-INF` directory of each bundle, to define finer-grained bundle-level access control.

When your Java 2 security settings in the `was.policy` are converted automatically, a `permissions.perm` file is created for you in the `META-INF` directory of the OSGi application. However, the automatic conversion process ignores `grant codeBase` statements, so that all the permissions in the `was.policy` file are copied to the `permissions.perm` file as application-level permissions. Therefore, you should, after conversion, review the permission settings in the `permissions.perm` file and move permissions to bundle-specific `permissions.perm` files as necessary.

To convert your Java 2 security settings to OSGi, complete the following steps:

1. Ensure you have completed the following conversion tasks, depending on the components of your EAR file:

- Change the file extension from .EAR to .EBA.
- Convert any web application archive (WAR) files to OSGi web application bundles.
- Convert any enterprise bean (EJB) Java archive (JAR) files to OSGi EJB bundles.
- Convert any utility JAR files to OSGi bundles.
- Convert any persistence archive files to OSGi bundles.

2. Import the EBA file as an asset. The Java 2 security settings are converted automatically during the import operation.
3. Export the EBA file to a location of your choice.
4. Open the `permissions.perm` file in the `META-INF` directory of the EBA file.
5. Review the permission settings in the `permissions.perm` file.
6. For those bundles that require bundle-specific permissions, create a `permissions.perm` file in the `OSGI-INF` directory of the bundle, and move the appropriate permissions to the newly-created file.
7. Update the previously imported EBA file with the modified EBA file.

Converting a Spring application to an OSGi application

To convert an application that is created using the Spring Framework to an OSGi application and move from the Spring Framework to standards-based technologies, you must modify the application manually. If a Spring application contains only web application archive (WAR) files, you can convert it automatically to run in OSGi Applications, but it still uses the Spring Framework.

About this task

In a Spring application, the Spring Framework manages features such as transactions, persistence, and dependency injection, and handles the communication between the servlets in the web container and the classes that handle the business logic of the application.

After you convert the application to an OSGi application that uses OSGi Applications support, the Blueprint Container manages the transactions, persistence and dependency injection.

If the application is an enterprise archive (EAR) file that contains only web application archive (WAR) files, you can convert it automatically. You might convert a Spring application in this way if a WAR file uses other library JAR files that must remain unchanged for the application to work. See “Converting a web application archive file to an OSGi web application bundle” on page 672.

Otherwise, you need to identify the Spring components and replace them with the equivalent code to make them plain old Java objects (POJOs), then modify the relevant XML files so that the Blueprint container manages those objects.

To convert a Spring application, you change it as follows:

- Create a well-defined interface to delegate to. The interface represents the classes that handle the business logic of the application.
- Create a service for each class, so that the servlet in the web container can use them.
- Change code that is specific to the Spring Framework in the classes to use the equivalent in Java EE, for example Java EE persistence classes.
- Create a handler servlet and interface to replace those from the Spring Framework.
- Modify XML and manifest files to use syntax that is correct for the Blueprint Container.

At the end of each step, the application is still usable, so you can decide whether to make all, or just some, of these changes.

The following procedure describes these steps in more detail.

Procedure

1. Create a well defined interface to delegate to, for example to replace a dispatcher servlet in the Spring application. The following example replaces the Spring HttpRequestHandler interface in an example application with the MyApplicationHandler interface.
   a. Create an interface to replace the Spring HttpRequestHandler interface.

```
package com.ibm.ws.eba.example.springconversion;

import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

interface MyApplicationHandler {

 void setMyApplicationHandle(MyApplicationUserInterface b);

 void handleRequest(HttpServletRequest request, HttpServletResponse response)
throws Exception;

}
```

   b. In each class that imports and implements the Spring HttpRequestHandler interface, implement the new interface. For example, change the following code:

```
implements HttpRequestHandler
```

      to :

```
implements MyApplicationHandler
```

   c. If the method creates an exception that is not in a base Java package, for example a ServletException exception, you can change it to use more general exception handling and avoid additional OSGi package imports. For example, change the following code:

```
handleRequest(HttpServletRequest request, HttpServletResponse response)
throws ServletException, IOException
```

      to:

```
handleRequest(HttpServletRequest request, HttpServletResponse response)
throws Exception
```

   To replace the Spring interface with this new interface, you must also replace the servlet, as described in step 4 on page 679.
2. At this point, you could continue to use the Spring classes and use the Blueprint Container to manage those objects. To do this, change the `blueprint.xml` file, as described in step 7 on page 680.

   The configuration for dependency injection that the Blueprint Container uses is similar to the configuration for the Spring Framework. For example, if the Spring Framework calls the setMyApplicationHandle method to inject the *MyApplicationUserInterface* variable, this injection continues to work in the Blueprint Container, as long as the `blueprint.xml` file is configured correctly.
3. Change the managed bean that handles persistence to use standard Java EE persistence classes. In the following example, the Spring JpaTemplate interface handles persistence. It is equally valid if using JPA directly through an entity manager.
   a. Replace the JpaTemplate interface with Java EE persistence classes. For example, remove the following import statement:

```
import org.springframework.orm.jpa.JpaTemplate;
```

      Replace it with the following import statements:

```
import javax.persistence.EntityManager;
import javax.persistence.PersistenceContext;
import javax.persistence.Query;
```

   b. Use the relevant calls that are available in the API for those interfaces. For example, to replace the JpaTemplate code with EntityManager code, remove the following code:

```
@PersistenceUnit(unitName = "springExample")
  private JpaTemplate jpaTemplate;

  public void setJpaTemplate(JpaTemplate j)
  {
    jpaTemplate = j;
  }
```

Replace it with the following code:

```
@PersistenceContext(unitName = "myApplication")
  private EntityManager em;
  public void setEntityManager(EntityManager e) {
    em = e;
  }
```

c. If a persistence unit is inside a web application, separate the persistence unit from the WAR and create a persistence bundle. The persistence bundle must contain the entity classes and the `persistence.xml` file. The bundle manifest must have a Meta-Persistence header that points to the persistence unit, as shown in the following example:

```
Manifest-Version: 1.0
Bundle-ManifestVersion: 2
Bundle-Name: MyPersistenceBundle
Bundle-SymbolicName: com.ibm.ws.eba.example.persistence
Bundle-Version: 1.0.0
Meta-Persistence: WEB-INF/classes/META-INF/persistence.xml
Import-Package: javax.persistence
```

d. Replace each instance of a call from the bean that handles persistence with an equivalent call that uses the EntityManager interface, the Query interface, or both. For example, in the example Spring application, the following code snippet shows two methods that call the jpaTemplate.find method:

```
@SuppressWarnings("unchecked")
public boolean checkEMailAddressUniqueness(String emailAddress)
{
  boolean result = false;

  List<UserInfo> users = jpaTemplate.find(uniqueEmailAddressQuery, emailAddress);

  if (users.isEmpty()) {
    result = true;
  }

  return result;
}

public boolean checkUsernameUniqueness(String username)
{
  boolean result = false;

  UserInfo user = jpaTemplate.find(UserInfo.class, username);

  if (user == null) {
    result = true;
  }

  return result;
}
```

The following code snippet shows replacement code:

```
private static final String uniqueEmailAddressQuery = "select u from UserInfo u
where u.emailAddress = ?1";

@SuppressWarnings("unchecked")
public boolean checkEMailAddressUniqueness(String emailAddress)
{
  boolean result = false;
```

```
  Query q = em.createQuery(uniqueEmailAddressQuery);
  q.setParameter(1, emailAddress);

  List<UserInfo> users = q.getResultList();

  if (users.isEmpty()) {
    result = true;
  }

return result;
}

public boolean checkUsernameUniqueness(String username)
{
  boolean result = false;

  UserInfo user = em.find(UserInfo.class, username);

  if (user == null) {
    result = true;
  }

    return result;
  }
```

4. Create and register a handler servlet to replace the one from the Spring Framework.
   a. Create a servlet to forward requests to the appropriate handler in the Blueprint Container to process the business logic. This servlet is managed by the web container. The JNDI lookup is constructed as follows:

      `osgi:service/`*`class_name`*`/`*`ldap_filter`*

      The following code snippet creates the MyApplicationHandlerServlet servlet that passes an HTTP request to the MyApplicationHandler class in the Blueprint Container:

```
package com.ibm.ws.eba.example.springconversion;

import javax.naming.InitialContext;
import javax.naming.NamingException;
import javax.servlet.http.HttpServlet;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

public class MyApplicationHandlerServlet extends HttpServlet {

 private static final long serialVersionUID = -3705932907251688199L;

 @Override
 public void service(HttpServletRequest request, HttpServletResponse response)
 {
  // Get servlet name
  String servletName = this.getServletConfig().getServletName();

  // Get business logic class from service registry that is
  // associated with the servlet

  try {
       InitialContext ic = new InitialContext();
       MyApplicationHandler myApplicationLogicClass = (MyApplicationHandler)
       ic.lookup("osgi:service/com.ibm.ws.eba.example.springconversion.
       MyApplicationHandler/(servlet.name="+servletName+")");
       myApplicationLogicClass.handleRequest(request, response);
   } catch (NamingException e) {
       e.printStackTrace();
   } catch (Exception e) {
           // TODO Auto-generated catch block
           e.printStackTrace();
  }
```

```
 }

}
```

b. Register the new servlet by changing the servlet classes to define the servlet you just created, rather than the Spring servlet. To do this, modify the `web.xml` file in the `WEB-INF` folder of the WAR file.

For example, change the following servlet definition in the `web.xml` file:

```
<servlet>
    <servlet-name>RegistrationServlet</servlet-name>
 <servlet-class> org.springframework.web.context.support.HttpRequestHandlerServlet
 </servlet-class>
  </servlet>
```

to:

```
<servlet>
    <servlet-name>RegistrationServlet</servlet-name>
 <servlet-class>com.ibm.ws.eba.example.springconversion.MyApplicationHandlerServlet
</servlet-class>
  </servlet>
```

c. Delete the following elements from the `web.xml` file:

```
<context-param>
<listener>
```

5. Separate the persistence unit from the EAR file and create a persistence bundle. The persistence bundle must contain the entity classes and the `persistence.xml` file. The bundle manifest must have a Meta-Persistence header that points to the persistence unit, as shown in the following example:

```
Manifest-Version: 1.0
Bundle-ManifestVersion: 2
Bundle-Name: MyPersistenceBundle
Bundle-SymbolicName: com.ibm.ws.eba.example.persistence
Bundle-Version: 1.0.0
Meta-Persistence: WEB-INF/classes/META-INF/persistence.xml
Import-Package: javax.persistence
```

6. If you removed the persistence unit from a WAR file, delete the following element from the `web.xml` file in the `WEB-INF` folder of the WAR file:

```
<persistence-unit-ref>
```

7. Change the XML so that the Blueprint Container manages the objects, rather than the Spring Framework.

a. Delete the `springapp-service.xml` file in the `WEB-INF` folder of the WAR file.

b. Create the `OSGI-INF/blueprint/` directory.

c. Create a file named `blueprint.xml` in the `OSGI-INF/blueprint/` directory. The following code shows an example `blueprint.xml` file:

```
<blueprint xmlns:tx="http://aries.apache.org/xmlns/transactions/v1.0.0"
           xmlns:jpa="http://http://aries.apache.org/xmlns/jpa/v1.0.0">

  <bean id="myApplicationImpl"
    class="com.ibm.ws.eba.example.springconversion.impl.MyApplicationImpl">
    <jpa:context property="entityManager" unitname="myApplication" />
    <tx:transaction method="*" value="Required"/>
  </bean>

  <bean id="RegistrationServlet"
    class="com.ibm.ws.eba.example.springconversion.Registration">
    <tx:transaction method="*" value="Required"/>
    <property name="myApplicationHandle" ref="myApplicationService" />
  </bean>

  <service id="myApplicationService" ref="myApplicationImpl" interface=
```

```
        "com.ibm.ws.eba.example.springconversion.MyApplicationUserInterface" />

      <service id="registrationService" ref="RegistrationServlet" interface=
         "com.ibm.ws.eba.example.springconversion.MyApplicationHandler" >
        <service-properties>
          <entry key="servlet.name" value="RegistrationServlet"/>
        </service-properties>
      </service>

    </blueprint>
```

8. Update the `persistence.xml` file in the `war/WEB-INF/classes/META-INF/` directory. For example, you can change the JNDI lookups to use a service from a service registry. The following code is an example:

```
<persistence xmlns="http://java.sun.com/xml/ns/persistence"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://java.sun.com/xml/ns/persistence
   http://java.sun.com/xml/ns/persistence/persistence_1_0.xsd"
   version="1.0">

   <persistence-unit name="myApplication" transaction-type="JTA">
      <description>Persistence unit for the Spring conversion sample application
      </description>

      <provider>com.ibm.websphere.persistence.PersistenceProviderImpl
      </provider>

      <jta-data-source>osgi:service/javax.sql.DataSource/
        (osgi.jndi.service.name=jdbc/userdb)
      </jta-data-source>
      <non-jta-data-source>osgi:service/javax.sql.DataSource/
        (osgi.jndi.service.name=jdbc/userdbnonjta)
      </non-jta-data-source>
      <class>com.ibm.ws.eba.example.springconversion.Post</class>
      <class>com.ibm.ws.eba.example.springconversion.UserInfo</class>
      <exclude-unlisted-classes/>
   </persistence-unit>
</persistence>
```

9. Create the enterprise bundle archive (EBA) structure for the application.
   a. Create a `META-INF` directory in the root of the project and create an application manifest, `APPLICATION.MF`. The following code shows an example application manifest file:

```
Manifest-Version: 1.0
Application-ManifestVersion: 1.0
Application-Name: MyApplication
Application-SymbolicName: com.ibm.ws.eba.example.springconversion
Application-Version: 1.0
Application-Content: com.ibm.ws.eba.example.springconversion
```

   b. Delete the `context.xml` file from the `war/META-INF/` directory.
   c. In the `war/META-INF/` directory, create a bundle manifest file, `MANIFEST.MF`. The following code shows an example bundle manifest file:

```
Manifest-Version: 1.0
Bundle-ManifestVersion: 2
Bundle-Name: MyApplication
Bundle-SymbolicName: com.ibm.ws.eba.example.springconversion
Bundle-Version: 1.0.0
Bundle-Vendor: IBM
Bundle-ClassPath: WEB-INF/classes,
 WEB-INF/lib/aspectjrt.jar,WEB-INF/lib/aspectweaver.jar,
 WEB-INF/lib/commons-collections-3.2.jar,WEB-INF/lib/commons-lang-2.1.jar,
 WEB-INF/lib/JSON4J.jar,WEB-INF/lib/jstl.jar,WEB-INF/lib/jta.jar,
 WEB-INF/lib/openjpa-1.3.0-SNAPSHOT.jar,WEB-INF/lib/persistence.jar,
 WEB-INF/lib/serp-1.13.1.jar,WEB-INF/lib/standard.jar
Web-ContextPath: myApplication
```

```
Import-Package: javax.servlet;version="2.5",
 javax.servlet.http;version="2.5",
 javax.servlet.jsp;version="2.1",
 javax.servlet.jsp.tagext;version="2.1",
 org.osgi.framework;version="1.5.0",
 javax.persistence
```

Accessing Enterprise JavaBeans in OSGi applications

There are alternative mechanisms that you can use in a client bundle to access an enterprise bean in a service bundle. To maximize application availability during an update to a service bundle that contains one or more enterprise beans, use OSGi service references to access the enterprise beans.

From an OSGi client bundle, you can access an enterprise bean in a service bundle in any of the following ways:

- Define a <reference> element, in the Blueprint XML file of the client bundle, that refers to the enterprise bean.
- Use an @EJB annotation.
- Define an EJB reference that is mapped to the JNDI name of the bean.
- Use an "osgi:service/" JNDI lookup.

The alternative ways of accessing an enterprise bean, and the corresponding differences in application behaviour during an update to the service bundle, are discussed in more detail in the remaining sections of this topic.

Using a <reference> element to access an enterprise bean

You can access an enterprise bean by defining a reference element for the bean in the Blueprint XML file of the client bundle; for more information, see References and the Blueprint Container.

The enterprise bean must be in the list specified by the Export-EJB header in the bundle manifest file of the service bundle, or the value of the Export-EJB header must be set to a single space character so that all enterprise beans in the bundle are exported; for more information, see the description of the Export-EJB header in the bundle manifest file.

To access the enterprise bean from a blueprint-managed bean, you can inject the enterprise bean through a property on the blueprint-managed bean; for details, see References and the Blueprint Container.

To access the enterprise bean from a component that is not blueprint-managed, such as a servlet, use a "blueprint:comp/" JNDI lookup; for details, see JNDI lookup for blueprint components.

If you subsequently update the service bundle, the client bundle does not have to be restarted. During the update operation, an end user might experience a brief delay, because the service reference is damped, so the client bundle waits for the update operation to complete, rather than a runtime exception being thrown.

Using an @EJB annotation or an EJB reference to access an enterprise bean

You can create a reference to an enterprise bean by using an @EJB annotation in the source code of the client bundle, or by defining an EJB reference in an ejb-jar.xml or web.xml file and using a JNDI lookup in the source code. In either case, you map the reference to the enterprise bean JNDI name in an ibm-ejb-jar-bnd.xml or ibm-web-bnd.xml file in the bundle, or in the WebSphere Application Server administrative console when you deploy the bundle.

WebSphere Application Server automatically generates an enterprise bean JNDI name and maps the enterprise bean to it. In addition, you can explicitly map the enterprise bean to a JNDI name in the ibm-ejb-jar-bnd.xml file in the service bundle, or in the WebSphere Application Server administrative console when you deploy the bundle.

If you explicitly map the enterprise bean, and you subsequently update the service bundle, the client does not have to be restarted, but the service bundle is briefly unavailable, during which time a runtime exception is thrown if the client bundle attempts to invoke a method on the enterprise bean.

If you do not explicitly map the enterprise bean, and you subsequently update the service bundle, the JNDI name changes. The EJB reference to the JNDI name in the client bundle is updated automatically and the client bundle is restarted, during which time the client bundle is unavailable. In addition, the service bundle is briefly unavailable during the update operation, and if the client bundle becomes available before the service bundle and attempts to invoke a method on the enterprise bean, a runtime exception is thrown.

Using an "osgi:service/" lookup to access an enterprise bean

You can access an enterprise bean by using, in the source code of the client bundle, an "osgi:service/" lookup, in either of the following ways:

- Use a JNDI lookup with a URL of the following form:

  `osgi:service/`*`interface_name/optional_filter`*

  For example:

  ```
  try {
    InitialContext ic = new InitialContext();
    return (BloggingService)
      ic.lookup("osgi:service/com.ibm.samples.websphere.osgi.blog.api.BloggingService");
  } catch (NamingException e) {
      .
      .
      .
  ```

- Inject a reference to the enterprise bean by using an @Resource annotation of the following form:

  `@Resource(lookup="osgi:service/`*`interface_name/optional_filter`*`")`

  For example:

  ```
  @Resource(lookup="osgi:service/com.ibm.samples.websphere.osgi.blog.api.BloggingService")
  BloggingService bloggingService;
  ```

If you subsequently update the service bundle, the client bundle continues to run without interruption, but a ServiceUnavailableException is thrown if the code attempts to use the service object while the service bundle is being updated, so the source code must be written to handle this situation.

For details of the OSGi URL scheme, see section 126.6 of the OSGi Service Platform Release 4 Version 4.2 Enterprise Specification.

Summary

The following table summarizes the degree of availability during an update to an OSGi application that contains enterprise beans, depending on the enterprise bean access mechanism used:

Access mechanism	Summary of application availability
OSGi service reference	The client bundle remains available. The service reference is damped, so client threads block until the EJB service becomes available again.

Access mechanism	Summary of application availability
@EJB annotation or EJB reference, with explicit JNDI name mapping	The client bundle remains available. If the client bundle attempts to use the injected EJB, a runtime exception is thrown during the service bundle update.
"osgi:service/" JNDI lookup or injected reference	The client bundle remains available. If the client bundle attempts use the injected EJB, a runtime exception is thrown during the service bundle update. This behavior is similar to using an @EJB annotation or EJB reference with explicit JNDI name mapping, but more client code is required to achieve the same result.
@EJB annotation or EJB reference, without explicit JNDI name mapping	The client bundle is restarted. If the client bundle becomes available before the service bundle, attempts use the injected EJB will result in runtime exceptions being thrown until the service bundle update is complete.

Sample OSGi applications

OSGi Applications support includes sample applications that demonstrate how to write and package bundles into an enterprise bundle archive (EBA) file.

Two sample OSGi applications are provided: “Blog” and “Blabber”. Both applications demonstrate all of the following OSGi Applications features:

- Using Blueprint management.
- Using bean injection.
- Using services from the OSGi service registry.
- Publishing services to the OSGi service registry.
- Using the Java Persistence API (JPA).

The samples are provided in the `OSGi_blogSample.zip` and `OSGi_blabberSample.zip` compressed archive files, which can be downloaded from the Samples download page. The EBA file for each sample application is in the `installableApps` directory of the sample compressed file, and the source code is provided in other subdirectories of the sample compressed file.

For information about how to install and run each sample application, see the `sample_osgi_blog_readme` and `sample_osgi_blabber_readme` respectively. These files are available in the root directory of the associated sample compressed file. They are also available in the information center as topics “OSGi blog sample application” on page 685 and “OSGi blabber sample application” on page 690.

Blog sample application

The blog sample application is a traditional blogging application, used for publishing essay-length articles and allowing readers to comment on them. The application contains the following bundles:

- com.ibm.ws.eba.example.blog.persistence.

  This bundle contains JPA-related code, and the interfaces that enable the main application code to update and query blog entries.
- com.ibm.ws.eba.example.blog_1.0.0.

  This bundle contains the main application logic code and interacts between the web front end and the back end persistence code layer.
- com.ibm.ws.eba.example.blog.web.

  This bundle contains the static web content and backing Java code for the web front end of the application.
- com.ibm.ws.eba.example.blog.api.

This bundle contains the API for the sample.

- com.ibm.ws.eba.example.blog.persistence_1.1.0.

  This bundle contains an optional upgraded persistence bundle that also supplies a comment service.

To run the blog sample application, you can use all the bundles that are listed, or all the bundles except the upgraded persistence bundle (the last in the list).

For more information, see “OSGi blog sample application.”

Blabber sample application

The blabber sample application is a microblogging application, used to enable many different people to share brief comments. The application contains the following bundles:

- com.ibm.ws.eba.example.blabber.persistence.

  This bundle contains code that relates to the Java Persistence API (JPA) layer and the interface for the main application code.

- com.ibm.ws.eba.example.blabber.

  This bundle contains the main application code and the code for the web front end of the application.

For more information, see “OSGi blabber sample application” on page 690.

OSGi blog sample application

The blog sample application is a traditional blogging application, used for publishing essay-length articles and allowing readers to comment on them. This sample application shows how to write and package bundles into an enterprise bundle archive (EBA) file. The sample includes example code for Blueprint management, bean injection, using and publishing services from and to the OSGi service registry, and the use of Java persistence.

Before you begin

The blog sample application consists of five bundles, but can be run with four bundles because the fifth bundle is an upgrade to the persistence bundle.

The sample application requires that the supplied `com.ibm.samples.websphere.osgi.logging.api.jar` and `com.ibm.samples.websphere.osgi.logging.impl.jar` bundles are installed into the internal bundle repository. The following procedure describes how to do this. These two JAR files, and the blog sample EBA file, are provided in the `installableApps` directory of the `OSGi_blogSample.zip` compressed archive file.

About this task

The bundles are divided into the following functional areas:

- `com.ibm.samples.websphere.osgi.blog.persistence`, which contains code relating to the Java Persistence API (JPA) layer, and also contains interfaces that are used by the main application code to update and query blog entries.
- `com.ibm.samples.websphere.osgi.blog_1.0.0`, which contains the main application logic code, and interacts between the web front end and the back end persistence code layer.
- `com.ibm.samples.websphere.osgi.blog.web`, which contains the static web content and backing Java code for the web front end for the application.
- `com.ibm.samples.websphere.osgi.blog.api`, which contains the API for the whole sample.
- `com.ibm.samples.websphere.osgi.blog.persistence_1.1.0`, which contains an upgraded persistence bundle that also supplies a comment service.

You can use scripts to completely install the sample application, or you can use scripts to complete the initial configuration of the application then use the administrative console to install the application into the application server. You can also use, modify and remove the sample, and upgrade the persistence service that is provided by the sample.

Procedure

Configure and install the blog sample.
You can either configure and install the sample using scripts (the first optional step in the instructions that follow), or you can configure the sample using scripts then install the sample using the administrative console (the second optional step in the instructions that follow).
The scripts that you use to do this are provided in the `scripts` directory of the `OSGi_blogSample.zip` compressed archive file. The `createBlogDb.sql` script contains the necessary configuration commands to create the required Derby database and associated tables. The `blogSampleInstall.py` script contains the required jython to create data sources, and to install the blog sample with default configuration. You should fully qualify the path to the script if you do not run it from the directory that contains the script.

Note: If you have data sources already defined in your environment, and these data sources have the same name as the data sources that are specified in the `blogSampleInstall.py` script, then the sample might not install and run successfully.

In the following steps you must substitute your own values for the variables *app_server_root*, *profileName*, *serverName*, *nodeName*, *blogSample.eba_Location*, *com.ibm.samples.websphere.osgi.logging.api.jar_Location*, *com.ibm.samples.websphere.osgi.logging.impl.jar_Location*, *uncompressed_sample_directory*, and *path_to_ant*.

- Optional: Configure and install the sample using scripts.
  1. Create and configure the “BLOGDB” Derby database and associated tables by running the following command.

     On UNIX platforms:

     ```
     app_server_root/derby/bin/embedded/ij.sh scripts/createBlogDb.sql
     ```

     On Windows platforms:

     ```
     app_server_root\derby\bin\embedded\ij.bat scripts\createBlogDb.sql
     ```

  2. Create the data sources, create the business-level application and import the .eba file as an asset by running the following command.

     Note: The target application server must be running before you use this script.

     On UNIX platforms:

     ```
     app_server_root/profiles/profileName/bin/wsadmin.sh
          -f scripts/blogSampleInstall.py fullInstall serverName nodeName
          blogSample.eba_Location
          com.ibm.samples.websphere.osgi.logging.api.jar_Location
          com.ibm.samples.websphere.osgi.logging.impl.jar_Location
     ```

     On Windows platforms:

     ```
     app_server_root\profiles\profileName\bin\wsadmin.bat
          -f scripts\blogSampleInstall.py fullInstall serverName nodeName
          blogSample.eba_Location
          com.ibm.samples.websphere.osgi.logging.api.jar_Location
          com.ibm.samples.websphere.osgi.logging.impl.jar_Location
     ```

- Optional: Configure the sample using scripts, then install the sample using the administrative console.
  1. Create and configure the “"BLOGDB" ” Derby database and associated tables by running the following command.

     On UNIX platforms:

     ```
     app_server_root/derby/bin/embedded/ij.sh scripts/createBlogDb.sql
     ```

     On Windows platforms:

app_server_root\derby\bin\embedded\ij.bat scripts\createBlogDb.sql

2. Create the data sources by running the following command.

   On UNIX platforms:

   app_server_root/profiles/*profileName*/bin/wsadmin.sh
   -f scripts/blogSampleInstall.py setupOnly *serverName nodeName*

   On Windows platforms:

   app_server_root\profiles*profileName*\bin\wsadmin.bat
   -f scripts\blogSampleInstall.py setupOnly *serverName nodeName*

3. Use the administrative console to add the com.ibm.samples.websphere.osgi.logging.api.jar file to the internal bundle repository.
   a. Navigate to **Environment** > **OSGi bundle repositories** > **Internal bundle repository**
   b. Click **New**.
   c. Select the file system that hosts the com.ibm.samples.websphere.osgi.logging.api.jar file, then click **Browse**.
   d. Browse to the *uncompressed_sample_dir*/installableApps directory.
   e. Select the com.ibm.samples.websphere.osgi.logging.api.jar file, then click **OK**.
   f. Click **OK**.
   g. Click **Save**.
4. Repeat the previous step to add the com.ibm.samples.websphere.osgi.logging.impl.jar file to the internal bundle repository.
5. Use the administrative console to import the application (EBA file) as an asset, and to configure the business-level application.
   a. Import the asset.
      1) Navigate to **Applications** > **New application** > **New Asset**.
      2) On the Upload asset panel, browse to the *uncompressed_sample_dir*/installableApps directory.
      3) Select the com.ibm.samples.websphere.osgi.blog.eba file, then click **Next**.
      4) On the Select options for importing an asset panel, click **Next**.
      5) On the Summary panel, click **Finish**.
      6) Click **Save**.
   b. Create the business-level application and add the asset.
      1) Navigate to **Applications** > **New application** > **New Business Level Application**.
      2) On the New Application panel, enter a name for the business-level application. For example, “blog”.
      3) Click **Apply**.
      4) In the Deployed assets pane, click **Add** > **Add Asset**.
      5) Select the com.ibm.samples.websphere.osgi.blog.eba asset, then click **Continue**.
      6) On the Set options panel, click **Next**.
      7) Select a target for the composition unit, then click **Next**.
      8) Modify the context root if required, then click **Next**.
      9) Modify the virtual host if required, then click **Next**.
      10) On the Summary panel, click **Finish**.
      11) Click **Save**.
6. Start the application.
   a. Select the newly-created business-level application.
   b. Click **Start**.

Use the blog sample.

- Use your browser to navigate to `http://server:port/context_root/` (by default `http://localhost:9080/blog/`). The View blog screen is displayed.
- Register yourself as an Author. You need to do this before you can create blog entries.
  1. Click **Create Author**.
  2. Complete the form.
  3. Click **Submit**.
- Create a blog entry.
  1. Navigate back to `http://localhost:9080/blog/` (or click **Blog Home**).
  2. Click **Create New Post**.
  3. Complete the form. Use the email address that you specified when you created the Author.
  4. Click **Submit**.

  The View blog screen is redisplayed, and should contain your post.

Upgrade the persistence service.

To add the new persistence bundle to the blog application, use the administrative console to load the `com.ibm.samples.websphere.osgi.blog.persistence_1.1.0.jar` file into the internal bundle repository, then modify the asset to expect a new bundle version. Complete the following steps:

- Load the persistence bundle into the internal bundle repository.
  1. Navigate to **Environment** > **OSGi bundle repositories** > **Internal bundle repository**.
  2. Click **New**.
  3. Browse to the *uncompressed_sample_dir*`/installableApps` directory.
  4. Select the `com.ibm.samples.websphere.osgi.blog.persistence_1.1.0.jar` file, then click **OK**.
  5. Save your changes to the master configuration.
- Add the persistence bundle to the blog application.
  1. Navigate to **Applications** > **Application types** > **Assets**.
  2. Click **com.ibm.samples.websphere.osgi.blog.eba** to view the asset information.
  3. Scroll to the end of the asset information, then click **Update bundle versions in this application**.
  4. Find the `com.ibm.samples.websphere.osgi.blog.persistence` bundle in the list.
  5. Click the down arrow beside the text “no preference”. You are offered a choice between version 1.0.0 or 1.1.0 of the persistence bundle.
  6. Select version 1.1.0, then work through the preview, create and save screens.
- Update the application to use the new bundle version.
  1. Navigate to **Applications** > **Application types** > **Business-level applications**.
  2. Click the blog sample application to display its details.
  3. Click **com.ibm.samples.websphere.osgi.blog.eba** to view the asset information.
  4. Click **Update to latest deployment**, then click **OK**.
  5. Save your changes to the master configuration.
- Stop and restart the blog application.
  1. Navigate to **Applications** > **Application types** > **Business-level applications**.
  2. Select the check box alongside the blog sample application, then click **Stop**.
  3. Wait until the status column shows that the application has stopped, then click **Start**.
  4. Use your browser to navigate to `http://server:port/context_root/` (by default `http://localhost:9080/blog/`) then refresh the screen. The View blog screen is displayed. There is a new option to add comments to blog posts.

Modify the blog sample

All the source code for this application is provided in sub-directories below the *uncompressed_sample_dir* directory. Each part of the project has its own ant `build.xml` script. To build the whole application into a newly-available EBA file, you use the ant `build.xml` file located in the *uncompressed_sample_dir* directory. WebSphere Application Server ships a version of ant in its `bin` directory called `ws_ant`. To build the sample, you also need a JAR file on the ant classpath. To simplify matters, you can edit the **was.root** property in the supplied `build.properties` file to point to this JAR file.

- Put the JAR file `j2ee.jar` on the ant classpath:

  This JAR file is available in the `dev/JavaEE` directory of Websphere Application Server. Edit the **was.root** property in the supplied *uncompressed_sample_dir*`/scripts/build.properties` file, and point it to your *app_server_root* directory. If you have copied the JAR file to another location, modify the **was.root** property to point to this location.
- Run the following ant command from the *uncompressed_sample_dir* directory:

  path_to_ant `-propertyfile scripts/build.properties -buildfile build.xml`

  The newly-built binary file (EBA file) is in the *uncompressed_sample_dir*`/output` directory.

  Note: This is the only location to which this EBA file is written. The script does not overwrite the original binary file located in the *uncompressed_sample_dir*`/installableApps` directory.

Remove the blog sample.

To remove the blog sample, you complete the following 3 steps:

1. Remove the application configuration and the data sources, either by using a script (the first optional step in the instructions that follow), or by using the administrative console (the second optional step in the instructions that follow).
2. Remove the shared logging bundles from the internal bundle repository.
3. Remove the database.

Note: Only remove the bundles if you have no other applications installed that use them. Both the blog and blabber sample applications use the shared logging bundles, so if both applications are installed these bundles should not be removed.

The uninstall script is provided in the `scripts` directory of the `OSGi_blogSample.zip` compressed archive file. The `blogSampleUninstall.py` script contains the required jython to remove data sources and to remove the installation of the blog sample with default configuration. You should fully qualify the path to the script if you do not run it from the directory that contains the script.

In the following steps you must substitute your own values for the variables *app_server_root*, and *profileName*.

- Optional: Remove the application configuration and the data sources by running the following command.

  Note: The target application server must be running before you use this script.

  On UNIX platforms:

  ```
  app_server_root/profiles/profileName/bin/wsadmin.sh
            -f scripts/blogSampleUninstall.py
  ```

  On Windows platforms:

  ```
  app_server_root\profiles\profileName\bin\wsadmin.bat
            -f scripts\blogSampleUninstall.py
  ```

- Optional: Remove the application configuration and the data sources by using the administrative console.
  1. Remove the application configuration.
     a. Navigate to **Applications** > **Application types** > **Business-level applications**.
     b. Select the business-level application representing the blog sample application, then click **Stop**.

c. Click the business-level application representing the blog sample application to view the configuration details.
d. Select all the deployed assets, then click **Delete**.
e. Click **OK** to confirm removal.
f. Click **Save**.
g. Select the business-level application representing the blog sample application, then click **Delete**.
h. Navigate to **Applications** > **Application types** > **Assets**.
i. Select the `com.ibm.samples.websphere.osgi.blog.eba` asset, then click **Delete**.
j. Click **OK** to confirm removal.
k. Click **Save**.

2. Remove the data sources.
   a. Navigate to **Resources** > **JDBC** > **Data sources**.
   b. Select the two data sources configured for the blog application.
   c. Click **Delete**.
   d. Click **Save**.

- Remove the shared logging bundles from the internal bundle repository by using the administrative console.
  1. Navigate to **Environment** > **OSGi bundle repositories** > **Internal bundle repository**.
  2. Select the following bundles:
     - `com.ibm.samples.websphere.osgi.logging.api.jar`
     - `com.ibm.samples.websphere.osgi.logging.impl.jar`
     - `com.ibm.samples.websphere.osgi.blog.persistence_1.1.0`
  3. Click **Delete**.
  4. Click **Save**.
- Remove the database.

  On UNIX platforms, open a command prompt, then enter the following command:

  ```
  cd app_server_root/derby
  rm -fr BLOGDB
  ```

  On Windows platforms, delete the *app_server_root*`\derby\BLOGDB` directory.

OSGi blabber sample application

The blabber sample application is a microblogging application, used to enable many different people to share brief comments. This sample application shows how to write and package bundles into an enterprise bundle archive (EBA) file. The sample includes example code for Blueprint management, bean injection, using and publishing services from and to the OSGi service registry, and the use of Java persistence.

Before you begin

The sample application requires that the supplied `com.ibm.samples.websphere.osgi.logging.api.jar` and `com.ibm.samples.websphere.osgi.logging.impl.jar` bundles are installed into the internal bundle repository. The following procedure describes how to do this. These two JAR files, and the blabber sample EBA file, are provided in the `installableApps` directory of the `OSGi_blabberSample.zip` compressed archive file.

About this task

The blabber sample application consists of two bundles, divided into the following functional areas:

- `com.ibm.samples.websphere.osgi.blabber.persistence`, which contains code relating to the Java Persistence API (JPA) layer, and also contains the interface that is used by the main application code.

- `com.ibm.samples.websphere.osgi.blabber`, which contains the main application logic code, and interacts between the web front end and the back end persistence code layer.

You can use scripts to completely install the sample application, or you can use scripts to complete the initial configuration of the application then use the administrative console to install the application into the application server. You can also use, modify and remove the sample.

Procedure

Configure and install the blabber sample.
You can either configure and install the sample using scripts (the first optional step in the instructions that follow), or you can configure the sample using scripts then install the sample using the administrative console (the second optional step in the instructions that follow).
The scripts that you use to do this are provided in the `scripts` directory of the `OSGi_blabberSample.zip` compressed archive file. The `createblabberDb.sql` script contains the necessary configuration commands to create the required Derby database and associated tables. The `blabberSampleInstall.py` script contains the required jython to create data sources, and to install the blabber sample with default configuration. You should fully qualify the path to the script if you do not run it from the directory that contains the script.

Note: If you have data sources already defined in your environment, and these data sources have the same name as the data sources that are specified in the `blabberSampleInstall.py` script, then the sample might not install and run successfully.

In the following steps you must substitute your own values for the variables *app_server_root*, *profileName*, *serverName*, *nodeName*, *blabberSample.eba_Location*, *com.ibm.samples.websphere.osgi.logging.api.jar_Location*, *com.ibm.samples.websphere.osgi.logging.impl.jar_Location*, *uncompressed_sample_directory*, and *path_to_ant*.

- Optional: Configure and install the sample using scripts.
  1. Create and configure the “BLABBERDB” Derby database and associated tables by running the following command.

     On UNIX platforms:

     ```
     app_server_root/derby/bin/embedded/ij.sh scripts/createBlabberDb.sql
     ```

     On Windows platforms:

     ```
     app_server_root\derby\bin\embedded\ij.bat scripts\createBlabberDb.sql
     ```

  2. Create the data sources, create the business-level application and import the .eba file as an asset by running the following command.

     Note: The target application server must be running before you use this script.

     On UNIX platforms:

     ```
     app_server_root/profiles/profileName/bin/wsadmin.sh
          -f scripts/blabberSampleInstall.py fullInstall serverName nodeName
          blabberSample.eba_Location
          com.ibm.samples.websphere.osgi.logging.api.jar_Location
          com.ibm.samples.websphere.osgi.logging.impl.jar_Location
     ```

     On Windows platforms:

     ```
     app_server_root\profiles\profileName\bin\wsadmin.bat
          -f scripts\blabberSampleInstall.py fullInstall serverName nodeName
          blabberSample.eba_Location
          com.ibm.samples.websphere.osgi.logging.api.jar_Location
          com.ibm.samples.websphere.osgi.logging.impl.jar_Location
     ```

- Optional: Configure the sample using scripts, then install the sample using the administrative console.
  1. Create and configure the “"BLABBERDB" ” Derby database and associated tables by running the following command.

On UNIX platforms:

```
app_server_root/derby/bin/embedded/ij.sh scripts/createBlabberDb.sql
```

On Windows platforms:

```
app_server_root\derby\bin\embedded\ij.bat scripts\createBlabberDb.sql
```

2. Create the data sources by running the following command.

   On UNIX platforms:

   ```
   app_server_root/profiles/profileName/bin/wsadmin.sh
        -f scripts/blabberSampleInstall.py setupOnly serverName nodeName
   ```

   On Windows platforms:

   ```
   app_server_root\profiles\profileName\bin\wsadmin.bat
        -f scripts\blabberSampleInstall.py setupOnly serverName nodeName
   ```

3. Use the administrative console to add the `com.ibm.samples.websphere.osgi.logging.api.jar` file to the internal bundle repository.
   a. Navigate to **Environment** > **OSGi bundle repositories** > **Internal bundle repository**
   b. Click **New**.
   c. Select the file system that hosts the `com.ibm.samples.websphere.osgi.logging.api.jar` file, then click **Browse**.
   d. Browse to the *uncompressed_sample_dir*`/installableApps` directory.
   e. Select the `com.ibm.samples.websphere.osgi.logging.api.jar` file, then click **OK**.
   f. Click **OK**.
   g. Click **Save**.
4. Repeat the previous step to add the `com.ibm.samples.websphere.osgi.logging.impl.jar` file to the internal bundle repository.
5. Use the administrative console to import the application (EBA file) as an asset, and to configure the business-level application.
   a. Import the asset.
      1) Navigate to **Applications** > **New application** > **New Asset**.
      2) On the Upload asset panel, browse to the *uncompressed_sample_dir*`/installableApps` directory.
      3) Select the `com.ibm.samples.websphere.osgi.blabber.app.eba` file, then click **Next**.
      4) On the Select options for importing an asset panel, click **Next**.
      5) On the Summary panel, click **Finish**.
      6) Click **Save**.
   b. Create the business-level application and add the asset.
      1) Navigate to **Applications** > **New application** > **New Business Level Application**.
      2) On the New Application panel, enter a name for the business-level application. For example, “blabber”.
      3) Click **Apply**.
      4) In the Deployed assets pane, click **Add** > **Add Asset**.
      5) Select the `com.ibm.samples.websphere.osgi.blabber.app.eba` asset, then click **Continue**.
      6) On the Set options panel, click **Next**.
      7) Select a target for the composition unit, then click **Next**.
      8) Modify the context root if required, then click **Next**.
      9) Modify the virtual host if required, then click **Next**.
      10) On the Summary panel, click **Finish**.
      11) Click **Save**.
6. Start the application.

a. Select the newly-created business-level application.
b. Click **Start**.

Use the blabber sample.

- Use your browser to navigate to `http://server:port/context_root/` (by default `http://localhost:9080/blabber/`). The main blabber screen is displayed.
- Register yourself as a user. You need to do this before you can create blabber entries.
  1. Click **Click here to sign-up!**.
  2. Complete the form.
  3. Click **Create my account!**.

  The status update home page is displayed.
- Explore the blabber application.

  From the status update home page, you can select any of the following options:
  – Set a status message.
  – Search for and track other users.
  – View your profile.
  – Sign out.

  Within each of the previous options, there is an option to return to the status update home page.

  Note:
  – When you enter some status then click **Update**, your status message is displayed on the current page.
  – You can only view or use the tracking option if the application has more than one user.

Modify the blabber sample.

All the source code for this application is provided in sub-directories the *uncompressed_sample_dir* directory. Each part of the project has its own ant `build.xml` script. To build the whole application into a newly-available EBA file, you use the ant `build.xml` file located in the *uncompressed_sample_dir* directory. WebSphere Application Server ships a version of ant in its `bin` directory called `ws_ant`. To build the sample, you also need several JAR files on the ant classpath. To simplify matters, you can edit the **was.root** property in the supplied `build.properties` file to point to these JAR files.

- Put the following jar files on the ant classpath:
  – `javax.j2ee.persistence.jar`
  – `javax.j2ee.jsp.jar`
  – `javax.j2ee.servlet.jar`
  – `com.ibm.ws.prereq.jaxrs.jar`

  These JAR files are available in the `plugins` directory of Websphere Application Server. Edit the **was.root** property in the supplied *uncompressed_sample_dir*`/scripts/build.properties` file, and point it to your *app_server_root* directory. If you have copied the jars to another location, modify the **was.root** property to point to this location.
- Run the following ant command from the *uncompressed_sample_dir* directory:

  path_to_ant `-propertyfile scripts/build.properties -buildfile build.xml`

  The newly-built binary file (EBA file) is in the *uncompressed_sample_dir*`/output` directory.

  Note: This is the only location to which this EBA file is written. The script does not overwrite the original binary file located in the *uncompressed_sample_dir*`/installableApps` directory.

Remove the blabber sample.

To remove the blabber sample, you complete the following 3 steps:

1. Remove the application configuration and the data sources, either by using a script (the first optional step in the instructions that follow), or by using the administrative console (the second optional step in the instructions that follow).
2. Remove the shared logging bundles from the internal bundle repository.
3. Remove the database.

Note: Only remove the bundles if you have no other applications installed that use them. Both the blabber and blog sample applications use the shared logging bundles, so if both applications are installed these bundles should not be removed.

The uninstall script is provided in the `scripts` directory of the `OSGi_blabberSample.zip` compressed archive file. The `blabberSampleUninstall.py` script contains the required jython to remove data sources and to remove the installation of the blabber sample with default configuration. You should fully qualify the path to the script if you do not run it from the directory that contains the script.

In the following steps you must substitute your own values for the variables *app_server_root*, and *profileName*.

- Optional: Remove the application configuration and the data sources by running the following command.

  Note: The target application server must be running before you use this script.

  On UNIX platforms:

  ```
  app_server_root/profiles/profileName/bin/wsadmin.sh
           -f scripts/blabberSampleUninstall.py
  ```

  On Windows platforms:

  ```
  app_server_root\profiles\profileName\bin\wsadmin.bat
           -f scripts\blabberSampleUninstall.py
  ```

- Optional: Remove the application configuration and the data sources by using the administrative console.
  1. Remove the application configuration.
     a. Navigate to **Applications** > **Application types** > **Business-level applications**.
     b. Select the business-level application representing the blabber sample application, then click **Stop**.
     c. Click the business-level application representing the blabber sample application to view the configuration details.
     d. Select all the deployed assets, then click **Delete**.
     e. Click **OK** to confirm removal.
     f. Click **Save**.
     g. Select the business-level application representing the blabber sample application, then click **Delete**.
     h. Navigate to **Applications** > **Application types** > **Assets**.
     i. Select the `com.ibm.samples.websphere.osgi.blabber.app.eba` asset, then click **Delete**.
     j. Click **OK** to confirm removal.
     k. Click **Save**.
  2. Remove the data sources.
     a. Navigate to **Resources** > **JDBC** > **Data sources**.
     b. Select the two data sources configured for the blabber application.
     c. Click **Delete**.
     d. Click **Save**.

- Remove the shared logging bundles from the internal bundle repository by using the administrative console.
  1. Navigate to **Environment** > **OSGi bundle repositories** > **Internal bundle repository**.
  2. Select the following bundles:
     - `com.ibm.samples.websphere.osgi.logging.api.jar`
     - `com.ibm.samples.websphere.osgi.logging.impl.jar`
  3. Click **Delete**.
  4. Click **Save**.
- Remove the database.

  On UNIX platforms, open a command prompt, then enter the following command:

  ```
  cd app_server_root/derby
  rm -fr BLABBERDB
  ```

  On Windows platforms, delete the *app_server_root*\derby\BLABBERDB directory.

Chapter 18. Developing Portlet applications

This page provides a starting point for finding information about portlet applications, which are special reusable Java servlets that appear as defined regions on portal pages. Portlets provide access to many different applications, services, and web content.

Portlet aggregation and preferences

Supported optional features of the JSR-286 Portlet Specification

The simple portal framework, which builds on top of the portlet container, is JSR-286-compliant. However, the WebSphere Application Server implementation supports a subset of the optional features in the JSR-286 Portlet Specification.

The following table lists the optional features that are available in the JSR-286 Portlet Specification and indicates to what extent these optional features are available in WebSphere Application Server.

Table 83. Optional features in the JSR-286 Portlet Specification. The Availability column describes whether the product supports a specification feature.

Feature	Availability
Container runtime options	The following container runtime options are supported: • javax.portlet.escapeXml • javax.portlet.servletDefaultSessionScope • javax.portlet.actionScopedRequestAttributes
Setting the HTML head section elements using the MimeResponse.MARKUP_HEAD_ELEMENT property	This property is not supported as its setting does not have an effect.
Custom portlet modes and custom window states	The feature is supported, but without special treatment.
Portlet-managed modes	This feature is fully supported.
Dynamically setting the portlet title using the RenderResponse.setTitle(String) method	This feature is partially supported. You need to make use of this feature in a portlet document filter or an aggregation JavaServer Pages (JSP) file.
Dynamically setting the next possible portlet modes using the RenderResponse.setNextPossiblePortletModes(Collection<PortletMode>) method	This feature is not supported.
Expiration and validation-based caching	This feature is fully supported. You need to activate the portlet fragment caching and a cachespec.xml defined as a prerequisite.
Aliases in public render parameters	The aliases in public render parameters are supported in the PortletServingServlet servlet and the aggregation tag library.
Aliases and wild cards in eventing	These aliases and wild cards are not supported as setting these functions does not have an effect.

Aggregation tag library attributes

The aggregation tag library is used to aggregate multiple portlets on one page. This topic describes the attributes within the aggregation tag library.

Supported arguments include:

`init`

This tag initializes the portlet framework and has to be used in the beginning of the JSP. All other tags described in this section are only valid in the body of this tag, therefore the init tag usually encloses the whole body of a JSP. In case the current URL contains an action flag the action method of the corresponding portlet is called. The state and insert tags are sub-tags of the init tag.

The init tag has the following attributes:

- portletURLPrefix = ”<any string>”

This URL defines the prefix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is a required attribute.

- portletURLSuffix = ”<any string>”

  This URL defines the suffix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is attribute optional.

- portletURLQueryParams = ”<any string>”

  This URL defines the query parameters used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is attribute optional.

scope, portlet

The scope tag and portlet tag are used to provide information that is necessary when a portlet application is installed under a multiple part context root, for example, /context1/context2. These tags also define which portlet windows should participate in portlet coordination via public render parameters, and add a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- context = "/<context1>/<context2>"

  Specifies the context root of the portlet application in which the portlet is deployed. This attribute is required.

- portletname = "<portlet-name>"

  Specifies the portlet-name. This attribute is required.

- windowId = ”<any string>”

  Defines the window ID for the concrete portlet instance. This attribute is required.

The following is an example of how to use the scope and portlet tags:

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>

<portlet:scope>
    <portlet:portlet context="/myportletcontext1/myportletcontext2" portletname="MyPortlet" windowId="sample"/>
</portlet:scope>

<portlet:init portletURLPrefix="/myportalcontext/ ">
....
</portlet:init>
```

state

The state tag creates a URL pointing to the given portlet using the given state. You can place this URL either into a variable specified by the var attribute or you can write it directly to the output stream. This tag is useful to create URLs for HTML buttons, images, and other items such that when the URL is invoked, the state changes defined in the URL are applied to the given portlet.

The state tag has the following attributes:

- url = ”<context>/<portlet-name>”

  Identifies the portlet for this tag by using the context and portlet-name to address the portlet. This attribute is required.

- windowId = ”<any string>”

  Defines the window ID for the portlet URL created by this tag. This is attribute optional.

- var = ”<any string>”

  If defined the URL is written into a variable with the given scope and name, not to the output stream. This is attribute optional.

- scope = ”page|request|session|application”

  This attribute is only valid if the var attribute is specified. If defined, the URL is not written to the output stream but a variable is created in the given scope with the given name. The default is page. This is attribute optional.

- portletMode = ”view|help|edit|<custom>”

  This attribute sets the portlet mode.
- portletWindowState = ”maximized|minimized|normal|<custom>”

  This attribute sets the window state.
- action = ”true/false”

  This attribute defines whether this is an action URL. This is attribute optional. The default is false.

urlParam

Adds a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- name = ”<any string>”

  Indicates the name of the parameter. This is attribute required.
- value = ”<any string>”

  Indicates the value of the parameter. This is attribute required.

insert

This tag calls the render method of the portlet and retrieves the content as well as the title. You can optionally place the content and title of the specified portlet into variables using the contentVar and titleVar attributes.

The insert tag has the following attributes:

- url = ”<context>/<portlet-name>” (mandatory) Identifies the portlet for this tag by using the context and portlet-name to address the portlet

  This is attribute required.
- windowId = ”<any string>”

  Defines the window ID of the portlet. This is attribute optional.
- contentVar = ”<any string>”

  If defined, the portlet's content is not written to the output stream but written into a variable with the given scope and name. This is attribute optional.
- contentScope = ”page|request|session|application”

  This attribute is only valid if the contentVar tag is used. If defined, the portlet's content is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.
- titleVar = ”<any string>”

  If defined the portlet's title is written into a variable with the given scope and name. If it is not defined, the title is ignored and not written to the output stream. This is attribute optional.
- titleScope = ”page|request|session|application”

  This attribute is only valid if titleVar tag is used. If defined, the portlet's title is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.

Example: Using the portlet aggregation tag library

You can use the aggregation tag library to aggregate multiple portlets to have multiple and different content on one page. The library can be used by every JavaServer Pages (JSP) file that has been included by a servlet.

To use the portlet aggregation tag library, you must declare the tag-lib at the top of the JSP file using, `<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>`, as in the following example. The following JSP file example shows how to aggregate portlets on one page.

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>
<%@ page isELIgnored="false" import="java.util.Enumeration"%>

<portlet:init portletURLPrefix="/dummy/portletTagTest/" portletURLSuffix="/more" portletURLQueryParams="p1=v1&p2=v2">
```

```
   <portlet:insert url="worldclock/StdWorldClock" contentVar="worldclockcontent" titleVar="worldclocktitle"/>
    <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockview"
       portletWindowState="maximized">
        <portlet:urlParam name="namea" value="valuea"/>
        <portlet:urlParam name="nameb" value="valueb"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" portletMode="edit" var="worldclockedit" portletWindowState="normal">
        <portlet:urlParam name="name1" value="value1"/>
        <portlet:urlParam name="name2" value="value2"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockmin"
       portletWindowState="minimized">
        <portlet:urlParam name="namemin" value="valuemin"/>
        <portlet:urlParam name="namemin" value="valuemin"/>
    </portlet:state>

    <portlet:insert url="worldclock/StdWorldClock" windowId="min" contentVar="simplecontent" titleVar="simpletitle"/>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simpleview"
  portletWindowState="maximized">
        <portlet:urlParam name="name3" value="value3"/>
        <portlet:urlParam name="name4" value="value4"/>
        <portlet:urlParam name="name5" value="value5"/>
        <portlet:urlParam name="name5" value="value5a"/>
        <portlet:urlParam name="name5" value="value5b"/>
        <portlet:urlParam name="name5" value="value5c"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="edit" var="simpleedit"
  action="true" portletWindowState="normal">
        <portlet:urlParam name="name6" value="value6"/>
        <portlet:urlParam name="name6" value="value6z"/>
            </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simplemin"
  portletWindowState="minimized">
        <portlet:urlParam name="name1" value="value1"/>
        <portlet:urlParam name="name2" value="value2"/>
    </portlet:state>

    <portlet:insert url="test/TestPortlet1" contentVar="testcontent" titleVar="testtitle"/>
    <portlet:state url="test/TestPortlet1" portletMode="view" var="testview" portletWindowState="maximized"/>
    <portlet:state url="test/TestPortlet1" portletMode="edit" var="testedit" portletWindowState="maximized"/>

<!--  This table is the outtermost table for creating two-column portal layout  -->

Portlet aggregation using JavaServer Pages

The aggregation tag library generates a portlet aggregation framework to address one or more portlets on one page If you write JavaServer Pages, you can aggregate multiple portlets on one page using the aggregation tag library. This tag library does not provide full featured portal aggregation implementation, but provides a good migration scenario if you already have aggregating servlets and JavaServer Pages and want to switch to portlets.

To allow the customer to create a simple portal aggregation, the aggregation tag library also provides the following features.

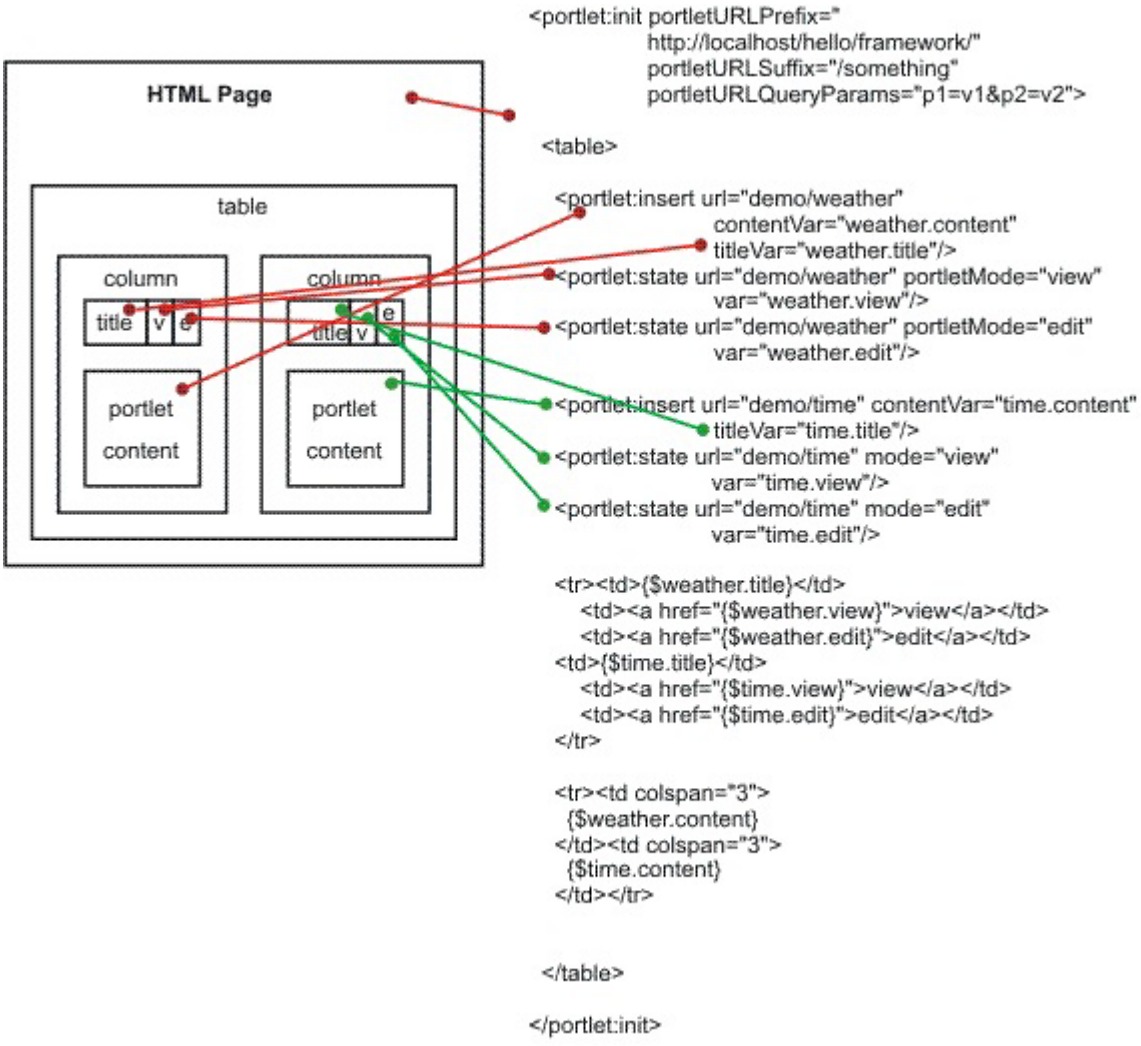
- Invoke a portlet's action method
- Render multiple portlets on one page
- Provide links to change the portlet's mode or window state

- Display the portlet's title
- Retain the portlet cookie state

The aggregation tag library and JavaServer Pages that use the aggregation tag library will only work with the WebSphere Application Server portlet container implementation because the protocol between the tags and the container is not standardized.

Refer to the Aggregation tag library attributes article for information on the aggregation tag library attributes.

The following diagram depicts how an HTML page would look like and what tags are used in order to create the page. Refer to the Aggregation tag library attributes article for information on the aggregation tag library attributes.



When you use the aggregation tag library, you must set the portletUrlPrefix attribute of the init tag to the aggregating application. You need to:

- Ensure that the portletUrlPrefix attribute is set to the following in the aggregator page.

  `"http://" + <server_address> + ":" + <server_port> + "/" + <aggregator context> + "/" <aggregator mapping>`
- Reference the aggregation JSP page within the `web.xml` file through a servlet mapping ending with `/*`. For example, `/aggregation/*`

When aggregating multiple portlets on a single page, special care must be used with the naming conventions of form attribute names in your portlets. Because your portlets are all on the same page, they all share the same HttpServletRequest. When one portlet is viewed the entire page is refreshed and form data is re-posted. Therefore, if there are multiple portlets that are aggregated on a single page with the same form attribute names, there could be logic corruption when form data is re-posted.

Aggregation tag library attributes

The aggregation tag library is used to aggregate multiple portlets on one page. This topic describes the attributes within the aggregation tag library.

Supported arguments include:

init

This tag initializes the portlet framework and has to be used in the beginning of the JSP. All other tags described in this section are only valid in the body of this tag, therefore the init tag usually encloses the whole body of a JSP. In case the current URL contains an action flag the action method of the corresponding portlet is called. The state and insert tags are sub-tags of the init tag.

The init tag has the following attributes:

- portletURLPrefix = ”<any string>”

  This URL defines the prefix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is a required attribute.
- portletURLSuffix = ”<any string>”

  This URL defines the suffix used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is attribute optional.
- portletURLQueryParams = ”<any string>”

  This URL defines the query parameters used for PortletURLs. Portlet URLs are created either by the state tag or within a portlet's render method, which is called by using the insert tag. This is attribute optional.

scope, portlet

The scope tag and portlet tag are used to provide information that is necessary when a portlet application is installed under a multiple part context root, for example, /context1/context2. These tags also define which portlet windows should participate in portlet coordination via public render parameters, and add a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- context = "/<context1>/<context2>"

  Specifies the context root of the portlet application in which the portlet is deployed. This attribute is required.
- portletname = "<portlet-name>"

  Specifies the portlet-name. This attribute is required.
- windowId = ”<any string>”

  Defines the window ID for the concrete portlet instance. This attribute is required.

The following is an example of how to use the scope and portlet tags:

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>

<portlet:scope>
    <portlet:portlet context="/myportletcontext1/myportletcontext2" portletname="MyPortlet" windowId="sample"/>
</portlet:scope>

<portlet:init portletURLPrefix="/myportalcontext/ ">
....
</portlet:init>
```

state

The state tag creates a URL pointing to the given portlet using the given state. You can place this URL either into a variable specified by the var attribute or you can write it directly to the output stream. This tag is useful to create URLs for HTML buttons, images, and other items such that when the URL is invoked, the state changes defined in the URL are applied to the given portlet.

The state tag has the following attributes:

- url = ”<context>/<portlet-name>”

  Identifies the portlet for this tag by using the context and portlet-name to address the portlet. This attribute is required.
- windowId = ”<any string>”

  Defines the window ID for the portlet URL created by this tag. This is attribute optional.
- var = ”<any string>”

  If defined the URL is written into a variable with the given scope and name, not to the output stream. This is attribute optional.
- scope = ”page|request|session|application”

  This attribute is only valid if the var attribute is specified. If defined, the URL is not written to the output stream but a variable is created in the given scope with the given name. The default is page. This is attribute optional.
- portletMode = ”view|help|edit|<custom>”

  This attribute sets the portlet mode.
- portletWindowState = ”maximized|minimized|normal|<custom>”

  This attribute sets the window state.
- action = ”true/false”

  This attribute defines whether this is an action URL. This is attribute optional. The default is false.

urlParam

Adds a render parameter to the newly created URL.

The urlParam tag has the following attributes:

- name = ”<any string>”

  Indicates the name of the parameter. This is attribute required.
- value = ”<any string>”

  Indicates the value of the parameter. This is attribute required.

insert

This tag calls the render method of the portlet and retrieves the content as well as the title. You can optionally place the content and title of the specified portlet into variables using the contentVar and titleVar attributes.

The insert tag has the following attributes:

- url = ”<context>/<portlet-name>” (mandatory) Identifies the portlet for this tag by using the context and portlet-name to address the portlet

  This is attribute required.
- windowId = ”<any string>”

  Defines the window ID of the portlet. This is attribute optional.
- contentVar = ”<any string>”

  If defined, the portlet's content is not written to the output stream but written into a variable with the given scope and name. This is attribute optional.
- contentScope = ”page|request|session|application”

This attribute is only valid if the contentVar tag is used. If defined, the portlet's content is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.

- titleVar = ”<any string>”

  If defined the portlet's title is written into a variable with the given scope and name. If it is not defined, the title is ignored and not written to the output stream. This is attribute optional.

- titleScope = ”page|request|session|application”

  This attribute is only valid if titleVar tag is used. If defined, the portlet's title is written into a variable with the given scope and name, not to the output stream. The default is page. This is attribute optional.

Example: Using the portlet aggregation tag library

You can use the aggregation tag library to aggregate multiple portlets to have multiple and different content on one page. The library can be used by every JavaServer Pages (JSP) file that has been included by a servlet.

To use the portlet aggregation tag library, you must declare the tag-lib at the top of the JSP file using, `<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>`, as in the following example. The following JSP file example shows how to aggregate portlets on one page.

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>
<%@ page isELIgnored="false" import="java.util.Enumeration"%>

<portlet:init portletURLPrefix="/dummy/portletTagTest/" portletURLSuffix="/more" portletURLQueryParams="p1=v1&p2=v2">

   <portlet:insert url="worldclock/StdWorldClock" contentVar="worldclockcontent" titleVar="worldclocktitle"/>
    <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockview"
       portletWindowState="maximized">
        <portlet:urlParam name="namea" value="valuea"/>
        <portlet:urlParam name="nameb" value="valueb"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" portletMode="edit" var="worldclockedit" portletWindowState="normal">
        <portlet:urlParam name="name1" value="value1"/>
        <portlet:urlParam name="name2" value="value2"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" portletMode="view" var="worldclockmin"
       portletWindowState="minimized">
        <portlet:urlParam name="namemin" value="valuemin"/>
        <portlet:urlParam name="namemin" value="valuemin"/>
    </portlet:state>

    <portlet:insert url="worldclock/StdWorldClock" windowId="min" contentVar="simplecontent" titleVar="simpletitle"/>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simpleview"
  portletWindowState="maximized">
        <portlet:urlParam name="name3" value="value3"/>
        <portlet:urlParam name="name4" value="value4"/>
        <portlet:urlParam name="name5" value="value5"/>
        <portlet:urlParam name="name5" value="value5a"/>
        <portlet:urlParam name="name5" value="value5b"/>
        <portlet:urlParam name="name5" value="value5c"/>
    </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="edit" var="simpleedit"
  action="true" portletWindowState="normal">
        <portlet:urlParam name="name6" value="value6"/>
        <portlet:urlParam name="name6" value="value6z"/>
            </portlet:state>
    <portlet:state url="worldclock/StdWorldClock" windowId="min" portletMode="view" var="simplemin"
  portletWindowState="minimized">
        <portlet:urlParam name="name1" value="value1"/>
        <portlet:urlParam name="name2" value="value2"/>
    </portlet:state>

    <portlet:insert url="test/TestPortlet1" contentVar="testcontent" titleVar="testtitle"/>
    <portlet:state url="test/TestPortlet1" portletMode="view" var="testview" portletWindowState="maximized"/>
    <portlet:state url="test/TestPortlet1" portletMode="edit" var="testedit" portletWindowState="maximized"/>

}

</STYLE>
```

Portlet preferences

Preferences are set by portlets to store customized information. By default, the PortletServingServlet servlet stores the portlet preferences for each portlet window in a cookie. However, you can change the location to store them in either a session, an `.xml` file, or a database.

Storing portlet preferences in cookies

The attributes of the cookie are defined as follows:

Path
context/portlet-name/portletwindow

Name:
The name of the cookie has the fixed value of **PortletPreferenceCookie**.

Value
The value of the cookie contains a list of preferences by mapping to the following structure:

*['/' pref-name *['=' pref-value]]

All preferences start with '/' followed by the name of the preference. If the preference has one or more values, the values follow the name separated by the '=' character. A null value is represented by the string '#*!0_NULL_0!*#'. As an example, the cookie value may look like, `/locations=raleigh=boeblingen/regions=nc=bw`

Customizing the portlet preferences storage

You can override how the cookie is handled to store preferences in a session, an `.xml` file or database. To customize the storage, you must create a filter, servlet or JavaServer Pages file as new entry point that wraps the request and response before calling the portlet. Examine the following example wrappers to understand how to change the behavior of the PortletServingServlet to store the preferences in a session instead of cookies.

The following is an example of how the main servlet manages the portlet invocation.

```
public class DispatchServlet extends HttpServlet
{
    ...
  public void service(HttpServletRequest request, HttpServletResponse response)
  throws ServletException, IOException
  {
 response.setContentType("text/html");

 // create wrappers to change preference storage
 RequestProxy req = new RequestProxy(request);
 ResponseProxy resp = new ResponseProxy(request, response);

 // create url prefix to always return to this servlet
                ...
                req.setAttribute("com.ibm.wsspi.portlet.url.prefix", urlPrefix);

 // prepare portlet url
 String portletPath = request.getPathInfo();
```

```
                ...

 // include portlet using wrappers
 RequestDispatcher rd = getServletContext().getRequestDispatcher(modifiedPortletPath);
                rd.include(req, resp);
  }
}
```

In the following example, the request wrapper changes the cookie handling to retrieve the preferences out of the session.

```
public class RequestWrapper extends HttpServletRequestWrapper
{
    ...
    public Cookie[] getCookies() {
        Cookie[] cookies = (Cookie[]) session.getAttribute("SessionPreferences");
        return cookies;
    }
}
```

In the following example, the response wrapper changes the cookie handling to store the preferences in the session:

```
public class ResponseProxy extends HttpServletResponseWrapper
{
   ...
    public void addCookie(Cookie cookie) {
        Cookie[] oldCookies = (Cookie[]) session.getAttribute("SessionPreferences");
        int newPos = (oldCookies == null) ? 0 : oldCookies.length;
        Cookie[] newCookies = new Cookie[newPos+1];
        session.setAttribute("SessionPreferences", newCookies);

        if (oldCookies != null) {
        System.arraycopy(oldCookies, 0, newCookies, 0, oldCookies.length);
        }
        newCookies[newPos] = cookie;
    }
}
```

Portlet coordination

You can use either the events mechanism or the public render parameters mechanism to coordinate portlets within a portal.

JSR 286 defines these two mechanisms as follows:

- Events: Loose-coupling of portlets during action phase.
- Public render parameters: Sharing of view state between portlets.

The WebSphere Application Server portlet container supports both concepts with one exception. The wiring of events on a portal level is not supported.

To make use of the public render parameters on a portal page defined with the aggregation tag library, you must explicitly declare the portal scope:

```
<%@ taglib uri="http://ibm.com/portlet/aggregation" prefix="portlet" %>
<%@ page isELIgnored ="false"%>

<!-- define portal scope for public render parameters -->
<portlet:scope>
  <portlet:portlet context="/simpleportlet" portletname="SimplePortlet1" windowId="id1"/
  <portlet:portlet context="/simpleportlet2" portletname="SimplePortlet2" windowId="id2"/>
</portlet:scope>

<portlet:init portletURLPrefix="/my-webapp-context/my-portal-jsp-url-pattern/">
<!-- insert your portlets here, wrapped with your html markup -->
...
   <portlet:insert url="simpleportlet/SimplePortlet1" windowId="id1" titleVar="portlettitle_1"/>
```

```
...
   <portlet:insert url="simpleportlet2/SimplePortlet2" windowId="id2" titleVar="portlettitle_1"/>
...
</portlet:init>
```

The public render parameters are only visible to the portlet windows mentioned within this defined scope. This condition assumes, as a prerequisite, that the corresponding portlets have also declared support for a given public render parameter in their portlet.xml file, according to the JSR 286 specification:

```
...
   <portlet>
      <portlet-name>portlet_name1</portlet-name>
       ...
       <supported-public-render-parameter>foo</supported-public-render-parameter>
   </portlet>
   <portlet>
      <portlet-name>portlet_name2</portlet-name>
       ...
       <supported-public-render-parameter>foo</supported-public-render-parameter>
   </portlet>
   <public-render-parameter>
       <identifier>foo</identifier>
       <qname xmlns:x="http://example.com/params">x:foo2</qname>
   </public-render-parameter>
...
```

Converting portlet fragments to an HTML document

A portlet only delivers fragment output whereas a servlet typically delivers document output. However, you can use the PortletServingServlet servlet, which is similar to the FileServingServlet servlet, to address portlets like servlets.

About this task

A default document servlet filter, the DefaultFilter filter, is applied to the PortletServingServlet servlet to return the portlet‘s content inside of a document. This filter only applies to requests, not to includes or forwards using the RequestDispatcher method. A servlet filter that is used to embed the portlet‘s content into a document is called the document servlet filter. You can define additional document servlet filters in a `.xml` file. The FilterRequestHelper attribute within com.ibm.wsspi.portletcontainer.util is provided to assist the document servlet filters in analyzing a request regarding filter chain and portlet information. It is used in supporting dynamic portlet titles, as a marker for redirection for document servlet filters and to ensure that document conversion is completed once.

Procedure

1. Add a new document servlet filter. The filter capability is a server feature, therefore all filters must be installed into the server to use the filter capability of the server. The filters need to be available in any classes or library directory on a server level. You must also register the filter in a `plugin.xml` file within the root of a Java archive (JAR) file. The following is an example of how to register the filter in a `plugin.xml` file.

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <?eclipse version="3.0"?>
   <plugin id="sample.plugin" name="Customer_Plugin" provider-name="Customer" version="1.0.0">
     <extension point="com.ibm.ws.portletcontainer.portlet-document-filter-config">
       <portlet-document-filter class-name="sample.filter.CustomFilter" order="200" />
     </extension>
   </plugin>
   ```

2. Optional: Set dynamic portlet titles by providing the dynamic title as a request attribute. The PortletServingServlet servlet supports dynamic portlet titles by providing the dynamic title as a request attribute, FilterRequestHelper.DYNAMIC_TITLE. This attribute returns the dynamic portlet title if it has been set by the portlet, otherwise it returns the static portlet title of the `portlet.xml` file if defined.

DYNAMIC_TITLE = 'javax.portlet.title' The DefaultFilter uses this request attribute to set the document title while converting the fragment into a document. If you want the filter to support browser caching or dynamic portlet titles, you must cache the complete portlet content.

3. Specify cache handling for the portlet rendering call to support dynamic title. Redirection for document servlet filters

   A document servlet filter can set a marker as request attribute, FilterRequestHelper.REDIRECT. This marker ensures that the portlet container returns to the document servlet filter after the portlet action has been called prior to any render calls. You must define the following constants, REDIRECT = 'com.ibm.websphere.portlet.action' and REDIRECT_VALUE = 'redirect'. The DefaultFilter uses this request attribute to provide special cache handling for the portlet rendering call to support dynamic title.

4. Convert the portlet's fragment into a valid document. Document conversion must be completed only once. Therefore each document servlet filter must ensure that the fragment has not yet been converted to a document previously. If the document servlet filter converts the fragment to a document, the request attribute FilterRequestHelper.DOCUMENT must be set to FilterRequestHelper.DOCUMENT_VALUE. This request attribute marks whether the conversion still needs to be completed. The following constants are defined, DOCUMENT = 'com.ibm.websphere.portlet.filter' and DOCUMENT_VALUE = 'document'. The DefaultFilter uses this request attribute to check whether it should convert the fragment to an Hypertext Markup Language (HTML) document. For example, this allows another document servlet filter in front to convert the fragment into a valid Wireless Markup Language (WML) document instead.

Assembling portlets

Portlet Uniform Resource Locator (URL) addressability

You can request a portlet directly through a Uniform Resource Locator (URL) to display its content without portal aggregation. The PortletServingServlet servlet registers each web application that contains portlets. It is similar to the FileServingServlet servlet of the web container that serves resources. The PortletServingServlet servlet supports direct rendering of portlets into a full browser page by a URL request.

You can invoke each portlet by its context root and name with the URL mapping /<portlet-name> that is created for each portlet. For example:

```
http://<host>:<port>/<context-root>/<portlet-name> For example,
 http://localhost:9080/portlets/TestPortlet1
```

The context root identifies the web application archive (WAR) file that contains the portlet. The portlet name uniquely identifies the portlet with a portlet application of a WAR file. The DefaultDocumentFilter servlet only supports HTML, UTF8 encoding and an extended URL form based on the basic URL form as shown above.

You can only display one portlet at a time using the PortletServingServlet servlet. If you want to aggregate multiple portlets on the page, you need to use the aggregation tag library. Refer to the Portlet aggregation using JavaServer Pages article for additional information.

Because a portlet only delivers fragment output whereas a servlet usually delivers document output, a mechanism is introduced to convert the fragment into a document, called the PortletDocumentFilter filter. By default, the PortletDocumentFilter filter only supports converting HTML. The conversion is implemented using a servlet filter before the PortletServingServlet servlet is initiated to return the portlet‘s content inside of a document. This default document servlet filter only applies to URL requests, not for includes or forwards using the RequestDispatcher method. You can create servlet filters to support other markups additional document servlet filters. Refer to the Converting portlet fragments to an HTML document article, for additional information.

The PortletServingServlet servlet does not persist portlet preferences in a XML file or database. It places the portlet preferences directly into a cookie to store the preferences persistently. Refer to the Portlet preferences article, for additional information on how to change this behavior.

Portlet URL syntax

You can add additional portal context such as portlet mode or window state. You can access the PortletServingServlet servlet by using a URL mapping that has the following structure:

```
http://host:port/context/portlet-name [/portletwindow[/ver [/action |
 /resource[/id=custom-id][/cacheability]] [/mode] [/state] [rparam][/?name]]]
```

Any differing URL structure results in a com.ibm.wsspi.portletcontainer.InvalidURLException exception. Empty strings are not permitted as parameter values and creates an InvalidURLException exception. The following is a list of valid parameters:

http:// host:port/context/*portlet-name*
: This is the minimum URL required to access a portlet. A default portlet window called “default” is created. The *portlet-name* variable is case-sensitive.

/*portletwindow*
: This parameter identifies the portlet window. You must set this parameter if you choose to add more portal context information to the URL.

/ver=*major.minor*
: This optional parameter is used to define the version of the portlet API that is used. You must set this parameter if you choose to add more portal context information to the URL. Only versions “1.0” and “2.0” are supported. Any other version creates an InvalidURLException exception.

/action
: This is a required parameter if you call the action method of the portlet. The action parameter causes the action process of the portlet to be called. After the action has been completed, a redirect is automatically issued to call the render process. To control the subsequent render process, a document servlet filter can set a request attribute with name “com.ibm.websphere.portlet.action” and value “redirect” to specify that the portlet serving servlet directly returns after action without calling the render process.

/mode=view | edit | help | *custom-mode*
: This optional parameter defines the portlet mode that is used to render the portlet. The default mode is “view”. The value is not case-sensitive. For example, “Vew”, “view” or “VIEW” results in the same mode.

/state=normal | maximized | minimized | *custom-state*
: This optional parameter defines the window state that is used to render the portlet. The default state is “normal”. The value is not case-sensitive, for example, “Normal”, “normal”, or “NORMAL” results in the same state.

*** [/rparam=***name* ***[=***value***]]**
: This optional parameter specifies render parameters for the portlet. Repeat this parameter chain to provide more than one render parameter. For example, /rparam=invitation/ rparam=days=Monday=Tuesday.

?name=value&name2=value2 ...
: Query parameters may follow optionally. They are not explicitly supported by the portlet container, but they do not invalidate the URL format.

/action | /resource
: This parameter defines the methods of the portlet that is called. Valid values are no, action or resource parameter. No specific method defined calls the render method. The resource parameter is only supported for JSR 286 portlets.

/resource [/id=custom-id] [/cacheability=cacheLevelFull | cacheLevelPortlet | cacheLevelPage]
Set this parameter to define the method of the portlet to be called. No redirection occurs. No other method of the portlet is called. To control the resource parameter, you can add an additional ID parameter to provide a resource serving identifier that is passed through to the portlet. The cacheability parameter defines the cache level of this resource URL. This parameter is only supported with JSR 286 portlets .

The following list includes examples of valid JSR 168 and JSR 286 URLs:

- http:// localhost:9080/sample/WorldClock
- http:// localhost:9080/sample/WorldClock/myPortlet/ver=1.0/mode=edit/rparam=timezone=UTC
- http:// localhost:9080/sample/WorldClock/myPortlet/ver=1.0/action/state=maximized?timezone=UTC
- http://localhost:9080/sample/WorldClock/myPortlet/ver=2.0/resource/id=somePicture.jpg

Example: Configuring the extended portlet deployment descriptor to disable PortletServingServlet

Portlet URL serving supports direct access to all functions and states of a portlet by creating the appropriate URLs. In a production setup where the portlet is served through an enterprise portal application that applies its own access control, is considered a security risk. By setting the portletServingEnabled property to false, an administrator can ensure that a sensitive portlet is never accessed by direct URL serving.

Extensions for the portlet deployment descriptor are defined within a file called `ibm-portlet-ext.xmi`. This deployment descriptor is an optional descriptor that you can use to configure WebSphere extensions for the portlet application and its portlets. For example, you can disable the PortletServingServlet servlet for the portlet application in the extended portlet deployment descriptor.

The `ibm-portlet-ext.xmi` extension file is loaded during application startup. If there are no extension files specified with this setting, the default values of the portlet container are used.

The default for the portletServingEnabled attribute is true. The following is an example of how to configure the application so that a PortletServingServlet servlet is not created for any portlet on the portlet application.

```
<?xml version="1.0" encoding="UTF-8"?>
<portletappext:PortletApplicationExtension xmi:version="1.0"
    xmlns:xmi="http://www.omg.org/XMI"
    xmlns:portletappext="portletapplicationext.xmi"
    xmlns:portletapplication="portletapplication.xmi"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmi:id="PortletApp_ID_Ext"
    portletServingEnabled="false">
  <portletappext:portletApplication href="WEB-INF/portlet.xml#myPortletApp"/>
</portletappext:PortletApplicationExtension>
```

Chapter 19. Developing SCA composites

This page provides a starting point for finding information about Service Component Architecture (SCA) composites, which consist of components that implement business functions in the form of services.

You typically do not deploy SCA composites directly onto a product server. To deploy SCA composites, you import SCA composites as assets to the product repository and add the assets to business-level applications.

Selecting the implementation type for an SCA composite

A benefit of Service Component Architecture (SCA) is that you can use existing assets in an application, without having to change the asset implementation. Many enterprises have application assets developed using a variety of technologies and frameworks, including assets previously deployed in a WebSphere Application Server environment, which is predominantly Java Platform, Enterprise Edition (Java EE) or Java-centric. SCA supports several service implementation technologies.

Before you begin

Determine which application files or artifacts (assets) you want to deploy in an SCA application. If necessary, develop the files or artifacts.

About this task

You can use SCA composites to:

- Reuse existing service implementations in the definition of an SCA component for use in an SCA composite application.
- Enable the services within those technologies to be exposed or use a service over the supported access bindings without changing the business logic of the service.

Each component within an SCA assembly specifies the implementation technologies which provide the specific business logic which implements the services described in the component definition. A composite is composed of 1-to-many components, each of which can be made up of differing implementation technologies.

SCA supports the following implementation programming model technologies. The product supports all of these implementation types on OSOA but does not support the implementation types OSGi, Java EE (JEE), Spring, or Widget on OASIS.

implementation.java
The implementation conforms to the SCA Java Component Implementation specification.

implementation.composite
The implementation conforms to an SCA composite as defined in the SCA Assembly Model specification.

implementation.web
The implementation conforms to Java EE 1.5 for Web modules and Web archive (WAR) files.

implementation.ejb
The implementation conforms to Java EE 1.5 for Enterprise JavaBeans (EJB) 2.1 and 3.0 Stateless Session Beans.

implementation.jee
The implementation conforms to Java EE 1.5 for enterprise archive (EAR) files.

implementation.osgiapp
The implementation conforms to the OSGi application programming model as supplied in the product.

implementation.spring
The implementation conforms to the SCA Spring Component Implementation specification.

WebSphere Application Server does not include the Spring 2.5.5 package. You must obtain the Spring 2.5.5 package from the supplying vendor.

implementation.widget
The implementation is SCA-enhanced JavaScript contained within an HTML page. Unlike the other implementation types, this component runs on the server but it is returned to browsers from the server. You wire services that JavaScript code references through SCA bindings.

Procedure

1. Select the implementation type to use for the SCA component.

Table 84. Supported SCA implementation types. Based on the implementation technology of an asset, select the SCA implementation type to use in the SCA component.

Asset implementation technology	SCA implementation type
SCA Java	`implementation.java`
SCA assembly	`implementation.composite`
Java EE application (EAR)	`implementation.jee`
Java EE EJB module, session bean, or message-driven bean	`implementation.ejb`
Java EE Web module in a Java EE application	`implementation.web`
Enterprise bundle archive (EBA) artifact that uses OSGi bundles and Blueprint components	`implementation.osgiapp`
Bean that follows the Java 2 Platform, Standard Edition (J2SE) programming model in a Spring 2.5.5 container.	`implementation.spring`
HTML page enriched with JavaScript code that contains SCA for return to a browser. An SCA service returns data in JavaScript. The data can be in Atom collections or in JavaScript Object Notation (JSON) format.	`implementation.widget`

2. Configure the binding for the selected implementation type and use the binding in an SCA component or application.

   See topics in the related links for information on specifying implementations and bindings.

Results

The SCA composite makes the appropriate environmental transitions to connect the implementation technology to any exposed bindings that are also in the composite definition.

What to do next

Deploy the SCA composite or application in a business-level application.

Developing Service Component Architecture (SCA) services

To develop SCA service implementations, you can use either a top-down development approach starting with an existing Web Services Description Language (WSDL) file or you can use a bottom-up development approach starting from an existing Java interface or implementation. When using either the top-down or bottom-up development methodologies, you can develop service clients or use tools to map business exceptions on remotable interfaces.

Developing SCA services from existing WSDL files

You can develop a Service Component Architecture (SCA) service implementation when starting with an existing Web Services Description Language (WSDL) file.

Before you begin

Locate the WSDL file that defines the SCA service that you want to implement. You can develop a WSDL file or obtain one from an existing SCA service. The WSDL file describes your service interface as a WSDL portType and includes XSD schema definitions of your business data.

The product supports Web Services Description Language (WSDL) Version 1.1 definitions that also conform to the WS-I Basic Profile Version 1.1 and Simple SOAP Binding Profile 1.0 standards, and use the document literal style. All these conditions are required for support.

About this task

There are two ways to develop an SCA service implementation:

- Top-down development starting with an existing Web Services Description Language (WSDL)
- Bottom-up development starting from existing Java code that uses Java Architecture for XML Binding (JAXB) data types

The top-down development approach takes advantage of the interoperable XML-based WSDL, and XSD interface and data definitions.

This task describes the steps when using the top-down development approach to develop an SCA service implementation in Java when starting from a WSDL interface and XSD data definitions.

Note: It is a best practice to use the top-down methodology to develop SCA service implementations because this approach uses the capabilities of the XML interface description and provides greater ease in interoperability across platforms, bindings, and programming languages.

Use the **wsimport** command-line tool to generate the Java representations of your business service interfaces and your business data when an existing WSDL file describes the wanted SCA service interface as a WSDL portType, along with XSD schema definitions of your business data. The **wsimport** tool generates Java classes that you can use to write a Java implementation that reflects your business logic. The result is a Plain Old Java Object (POJO) implementation of the generated interface using the generated JAXB data types. By adding the @Service annotation to the Java implementation, the annotation defines the Java implementation as an SCA service implementation.

The generated annotated Java classes that correspond to your business data contain all the necessary information that the JAXB runtime environment requires to build and parse the XML for marshaling and unmarshaling. In other words, the data programming model is limited to object instantiation and the use of getter and setter methods, and you do not need to write code to convert the data between the XML wire format and the Java application.

Note: The product uses XML marshaling as defined by JAXB to marshal and unmarshal data across a remotable interface. If you start with a remotable Java interface for your implementation rather than starting with a WSDL portType interface, be careful when selecting the input and output Java data types and ensure that you understand which data is preserved across JAXB marshaling and unmarshalling. However, when authoring an implementation on a local interface, you can use any Java type because local interfaces use pass-by-reference semantics, which implies no data is copied.

Note: The product does not support using a WSDL file when the Java mapping requires holder classes. The product uses the JAX-WS specification to define the mapping between WSDL files and Java,

including the mapping between a WSDL portType object and a Java interface. When you have WSDL portType objects with operations that use in-out parameters or operations that use multiple output parameters, the JAX-WS specification uses instances of the javax.xml.ws.Holder class in the mapping of the WSDL portType object to a Java interface. When using the product, do not use a WSDL file when the Java mapping requires holder classes. Instead, use a WSDL file that does not map to holder classes.

When you develop an SCA service when starting from an existing WSDL file, the interface is considered a remotable interface. The remotable interface uses pass-by-value semantics, which implies your data is copied.

You can use and deploy the resulting Java implementation as an SCA component that is defined in a composite definition. The composite definition defines SCA artifacts, such as service references, imports, and exports. The component is defined in terms of development artifacts such as the WSDL, the Java implementation, and bindings that are defined during deployment.

The JAXB APIs require that you register Java class types that you want to marshal or unmarshall with a JAXBContext class. The product runtime environment registers these Java class types for you by introspecting your Java interface. When this introspection occurs, be careful of possible problems when polymorphism (inheritance) is used. When an interface is defined in terms of a base superclass type, and you want to pass argument instances of a derived subclass type at run time, the subclasses are not known to the JAXBContext class by simply introspecting the interface parameter types.

In JAXB, you can use the javax.xml.bind.annotation.XmlSeeAlso annotation to solve this problem with polymorphism. Place the @XmlSeeAlso annotation on the generated Java interface that is generated with the @WebService annotation, to refer to additional JAXB derived subclass classes that are added to the JAXBContext class along with those classes introspected from the interface parameters.

Procedure

1. Use the **wsimport** command-line tool to develop SCA Java representations of your business service interfaces and your business data.

   The **wsimport** tool processes a WSDL file and generates Java classes and the JAXB data types that are used to create the SCA service.

   It is important to include all generated classes within your application archive, including the classes that you might not directly reference in your Java implementation. Even if you have simple interfaces that pass simple parameter types like String and Integer, or where no JAXB data types are necessary, be sure to include all classes, including indirect references, in this code generation step.

   - Run the wsimport command to generate the artifacts.

   The **wsimport** tool is located in the *app_server_root*/bin/ directory.

   The **-keep** option specifies to keep the generated Java source files and the compiled class files.
2. Locate the Java interface that directly corresponds to your WSDL portType from the generated artifacts. The interface is generated with an @WebService annotation, and it is an interface and not a class file.
3. Complete the implementation of your SCA service. Write a Java implementation of the generated Java interface that reflects your business logic. The Java implementation is a Plain Old Java Object (POJO) implementation of the generated interface using the generated JAXB data types. This implementation is annotated based on the SCA Java component implementation programming model.
4. Annotate the Java implementation. Add the @Service annotation to the Java implementation to specify this implementation is an SCA service. When you complete this step, you have created an SCA component implementation.
5. Define a component within a composite definition using this component implementation. In the definition of your composite, define a component that refers to the original WSDL portType interface and the SCA implementation.

a. Under the <component> element, create a <implementation.java> child element that refers to the class name of your POJO component implementation.
b. Under the <component> element, create a <service> child element.
c. Under the <service> element, create a <interface.wsdl ..> element that refers to the WSDL portType. The @name attribute of the <service> element must match the unqualified class name of your Java interface.

You now have a component with a well-defined component name and service name with a well-defined interface.

In addition to these aspects of your component definition described by these development procedures, there are other aspects of defining a component. These aspects include adding bindings, configuring property values, defining intents, attaching policy sets, and resolving references. You can create multiple components using this same implementation, but all component definitions are the same with respect to the <implementation.java>, <interface.wsdl> and <service> elements described in this step.

6. Deploy the SCA service by creating the SCA business level application from a deployable composite.

   In the previous step, you defined a component providing your SCA service within a composite definition. This composite is either a deployable composite, or one that is used recursively as a composite implementation of a component in a higher-level composite. To learn how to deploy the SCA service, read about deploying and administering business-level applications.

Results

You have created an SCA implementation by starting with an existing WSDL file.

Example

The following example illustrates using an existing WSDL interface to generate a Java interface that is used to create a Java implementation that is an SCA service.

1. Copy the following sample account.wsdl WSDL file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>

<wsdl:definitions xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
     xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
     xmlns:account="http://www.myaccount.com/account"
     targetNamespace="http://www.myaccount.com/account"
     name="AccountService">

      <wsdl:types>
         <schema targetNamespace="http://www.myaccount.com/account"
             xmlns="http://www.w3.org/2001/XMLSchema"
             xmlns:xsd="http://www.w3.org/2001/XMLSchema"
             xmlns:account="http://www.myaccount.com/account">

               <element name="computeAccountAverage">
                 <complexType>
                     <sequence>
                         <element name="account" type="account:Account" />
                         <element name="days" type="xsd:int" />
                     </sequence>
                 </complexType>
             </element>
             <element name="computeAccountAverageResponse">
                 <complexType>
                     <sequence>
                         <element name="return" type="xsd:float" />
                     </sequence>
                 </complexType>
             </element>

             <complexType name="Account">
                 <attribute name="accountNumber" type="xsd:int" />
                 <attribute name="accountID" type="xsd:string" />
```

```
                <attribute name="accountType" type="xsd:string" />
                <attribute name="balance" type="xsd:float" />
            </complexType>

        </schema>
    </wsdl:types>

    <wsdl:message name="computeAccountAverageRequest">
        <wsdl:part element="account:computeAccountAverage"
            name="parameters" />
    </wsdl:message>

    <wsdl:message name="computeAccountAverageResponse">
        <wsdl:part element="account:computeAccountAverageResponse"
            name="parameters" />
    </wsdl:message>

    <wsdl:portType name="AccountService">
        <wsdl:operation name="computeAccountAverage">
            <wsdl:input message="account:computeAccountAverageRequest" name="accountReq"/>
            <wsdl:output message="account:computeAccountAverageResponse" name="accountResp"/>
        </wsdl:operation>
    </wsdl:portType>

    <wsdl:binding name="AccountServiceSOAP" type="account:AccountService">
        <soap:binding style="document"
            transport="http://schemas.xmlsoap.org/soap/http" />
        <wsdl:operation name="computeAccountAverage">
           <soap:operation
                soapAction="computeAccountAverage" />
            <wsdl:input name="accountReq">
               <soap:body use="literal" />
            </wsdl:input>
            <wsdl:output name="accountResp">
                <soap:body use="literal" />
            </wsdl:output>
        </wsdl:operation>

     </wsdl:binding>

    <wsdl:service name="AccountWSDLService">
        <wsdl:port binding="account:AccountServiceSOAP"
            name="AccountServicePort">
            <soap:address location=""/>
        </wsdl:port>
    </wsdl:service>
</wsdl:definitions>
```

2. Run the **wsimport** command from the *app_server_root*/bin/ directory.After generating the template files using the **wsimport** command, the following Java files are generated:

```
com/myaccount/account/Account.java
com/myaccount/account/AccountService.java
com/myaccount/account/AccountWSDLService.java
com/myaccount/account/ComputeAccountAverage.java
com/myaccount/account/ComputeAccountAverageResponse.java
com/myaccount/account/ObjectFactory.java
com/myaccount/account/package-info.java
```

3. Identify the generated Java interface from the generated classes.

```
//
// Generated By:JAX-WS RI IBM 2.1.1 in JDK 6 (JAXB RI IBM JAXB 2.1.3 in JDK 1.6)
//
package com.myaccount.account;
...
@WebService(name = "AccountService", targetNamespace = "http://www.myaccount.com/account")
...
public interface AccountService {
    /**
     *
     * @param days
     * @param account
     * @return
     *     returns float
     */
```

```
    @WebMethod(action = "computeAccountAverage")
    @WebResult(targetNamespace = "")
    @RequestWrapper(localName = "computeAccountAverage", targetNamespace = "http://www.myaccount.com/account",
            className = "com.myaccount.account.ComputeAccountAverage")

    @ResponseWrapper(localName = "computeAccountAverageResponse", targetNamespace = "http://www.myaccount.com/account",
            className = "com.myaccount.account.ComputeAccountAverageResponse")
    public float computeAccountAverage(
        @WebParam(name = "account", targetNamespace = "")
        Account account,
        @WebParam(name = "days", targetNamespace = "")
        int days);

}
```

This code example is a Java interface, not merely a Java class. The @WebService annotation is present in this Java interface. It is important to know that this example is not the same as the generated @WebServiceClient class, com.myaccount.account.AccountWSDLService, which is not an interface and is not needed in your SCA application.

4. Complete the implementation of your SCA service by writing a Java implementation of this generated Java interface. Be sure to add the SCA @Service annotation to the implementation.

```
package com.myaccount.account;
import org.osoa.sca.annotations.Service;
@Service(AccountService.class)
public class AccountServiceImpl implements AccountService
    public float computeAccountAverage( Account account, int days) {

        // Write your business logic here.  Account is a
        // generated JAXB type and so use the JAXB programming model.
        // For example, object instantation is performed using
        // the ObjectFactory.createAccount()) method.
    }
}
```

By completing this step, you have completed a component implementation. Not only is this component implementation a Java implementation of a Java interface, but the @Service annotation signifies that this is a Java component implementation of an SCA service interface. The implementation class itself does not need all the JAX-WS or JAXB annotations. The runtime environment loads the appropriate annotations from the generated classes that the implementation refers to.

5. Create a component using the component implementation. You create a component definition in a composite that references the original WSDL portType interface and the SCA implementation. In SCA, a component is a configured instance of a component implementation. There are other aspects of defining a component that are not shown here such as configuring bindings, configuring property values, defining intents, attaching policy sets, and resolving references. Shown here are the aspects of component creation that are common for all component definitions using the implementation developed in this example. This example also includes bindings that you can modify or omit for other components using this component implementation.

```
<?xml version="1.0" encoding="UTF-8"?>

<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
     targetNamespace="http://account.customer"
         name="accountComposite">
     <component name="BankingComponent">
         <implementation.java class="com.myaccount.account.AccountServiceImpl"/>

         <!-- The @name value matches the contents of the @Service which in turn
              comes from the WSDL portType. -->

         <service name="AccountService">

              <!-- This statement specifies the QName of the WSDL portType,
                   "http://www.myaccount.com/account#AccountService" in the syntax as
                   illustrated in the interface.wsdl statement. -->

             <interface.wsdl interface="http://www.myaccount.com/account#wsdl.interface(AccountService)" />
             <binding.ws/>

  <!-- This example uses the SCA web services binding.  However, it does not matter which SCA binding
       you choose.  -->
```

```
        </service>
    </component>
</composite>
```

6. After your component is defined as part of a deployable composite, either directly or recursively through use of one or more layers of components with composite implementation, you are ready to deploy the SCA service by creating an SCA business level application.

Developing SCA services with existing Java code

You can develop an Service Component Architecture (SCA) service implementation when starting with an existing Java application.

About this task

There are two ways to develop an SCA service implementation:

- Top-down development starting with an existing Web Services Description Language (WSDL)
- Bottom-up development starting from existing Java code that uses Java Architecture for XML Binding (JAXB) data types

The bottom-up development approach provides a simplified way to begin developing SCA services for the Java developer that does not desire to work with WSDL or XML schema (XSD) authoring or when building new SCA services that expose existing legacy implementations with Java interfaces.

The top-down development approach takes advantage of the interoperable XML-based WSDL, and XSD interface and data definitions.

This task describes the steps when using the bottom-up development approach to develop an SCA service implementation when starting with Java.

When using the bottom-up development methodology, begin by writing a Java interface and implementation that describes the desired business logic. This implementation is then packaged into an application archive file such as a web application archive (WAR) file or a Java archive (JAR) file that is subsequently is used by an SCA component that is configured with deployment information containing the bindings when the SCA application is deployed.

Note: It is a best practice to use the top-down methodology to develop SCA service implementations because this approach leverages the capabilities of the XML interface description and provides a greater ease in interoperability across platforms, bindings, and programming languages. To learn more about using the top-down methodology, read about developing SCA services from existing WSDL files.

Note: The product uses XML marshalling as defined by JAXB to marshal and unmarshal data across a remotable interface. If you start with a remotable Java interface for your implementation rather than starting with a WSDL portType interface, be careful when selecting the input and output Java data types and ensure you understand which data is preserved across JAXB marshalling and unmarshalling. However, when authoring an implementation on a local interface, you can use any Java type because local interfaces use pass-by-reference semantics, which implies no data is copied.

Note: The data marshalling and unmarshalling that is used to instantiate the copying of data over remotable interfaces is defined by the JAXB specification rather than by Java serialization or the java.io.Serializable or java.io.Externalizable interfaces. Because of this behavior, certain existing Java types are not suitable for use on remotable interfaces, as these types are not serialized using Java serialization. For data types that are not annotated, the class is introspected and its Java properties determine the data that is preserved in the copy. For data types that take advantage of JAXB annotations, you can customize the mapping of Java classes to XSD types and of Java

instances to XML documents. Custom Java serialization routines such as the readObject() or writeObject() are not applicable in this scenario. The SCA runtime environment takes an XML centric view of the business data and leverages the JAXB standards to define the mappings between the Java programming model and the XML data format on the wire.

Procedure

1. Access the existing Java interface that you want to expose as an SCA service.
2. Determine if you are using a local or a remotable interface.
   - If you are using a remotable interface, add the @Remotable annotation to the Java interface. The input and output Java data types on the remotable interface use pass-by-value semantics which implies your data is copied using XML serialization as defined by JAXB.
3. Complete the implementation of your SCA service. Write a Java implementation of the generated Java interface that reflects your business logic. The Java implementation is a Plain Old Java Object (POJO) implementation of the original interface.
4. Annotate the Java implementation. Add the @Service annotation to the Java implementation to specify this is an SCA service. When you complete this step, you have created an SCA component implementation.
5. Define a component within a composite definition using this component implementation. In the deinition of your composite, define a component that refers back to the original Java interface and the SCA implementation.
   a. Under the `<component>` element, create a `<implementation.java>` child element that refers to the class name of your POJO component implementation.
   b. Under the `<component>` element, create a `<service>` child element.
   c. Under the `<service>` element, create a `<interface.java ..>` element that refers back to the original Java interface. The @name attribute of the `<service>` element must match the unqualified class name of your Java interface.

   You now have a component with a well-defined component name and service name with a well-defined interface.

   In addition to these aspects of your component definition described by these development procedures, there are other aspects of defining a component. These aspects include adding bindings, configuring property values, defining intents, attaching policy sets, and resolving references. You can create multiple components using this same implementation, but all component definitions are the same with respect to the `<implementation.java>`, `<imterface.java>` and `<service>` elements described in this step.
6. Deploy the SCA service by creating the SCA business level application from a deployable composite.

   In the previous step, you defined a component providing your SCA service within a composite definition. This composite is either a deployable composite, or one that is used recursively as a composite implementation of a component in a higher-level composite. To learn how to deploy the SCA service, read about deploying and administering business-level applications.

Results

You have developed an SCA service using the bottom-up methodology by starting with an existing Java interface or implementation.

Example

The following example illustrates how to create a component implementation of a remotable SCA service interface starting from existing Java code:

1. Start with Java interface `myintf.NameGetter` using type `mypkg.Person`.

```
//NameGetter.java
package myintf;
import mypkg.Person;
```

```
public interface NameGetter {
    public String getName(Person p);
}

//Person.java

package mypkg;

public class Person {

    protected String firstName;
    protected String lastName;

    public String getFirstName() {
        return firstName;
    }

    public void setFirstName(String value) {
        this.firstName = value;
    }

    public String getLastName() {
        return lastName;
    }

    public void setLastName(String value) {
        this.lastName = value;
    }
}
```

In this example, the mypkg.Person class is well-suited for use over a remotable interface, because it follows the JavaBeans pattern and contains a public getter and setter pair for its important data fields. The XML wire format used by the runtime environment will serialize and deserialize this class. However, other existing Java types that do not adhere to the JavaBeans pattern can cause problems as they dol not serialize correctly and data loss occurs. For this reason, it is a best practice to use a top-down development approach, starting from schema definitions and generating JAXB classes for use in the application programming model. See the developing SCA services from existing WSDL files to learn more about the top-down development approach.

2. Because we are creating a service with a remotable interface, add the @Remotable annotation.

```
//NameGetter.java
package myintf;

import mypkg.Person;
import org.osoa.sca.annotations.Remotable;

@Remotable
public interface NameGetter {
    public String getName(Person p);
}
```

3. Unless you have an existing Java implementation, write a Java implementation of the generated Java interface that reflects your business logic.

```
package myintf;
import mypkg.Person;

public class NameGetterImpl implements NameGetter {

    public String getName(Person p) {
        // Example "business logic"
        return p.getFirstName() + " " + p.getLastName();
    }

}
```

4. Add the @Service annotation to the Java implementation.

```
package myintf;
import mypkg.Person;
import org.osoa.sca.annotations.Service;

@Service(NameGetter.class)
public class NameGetterImpl implements NameGetter {

    public String getName(Person p) {
        // Example "business logic"
        return p.getFirstName() + " " + p.getLastName();
    }

}
```

5. Create a component using the component implementation. You will create a component definition in a composite that references the original Java implementation class, as well as its Java interface. In SCA, a component is a configured instance of a component implementation. There are other aspects of defining a component that are not shown here such as configuring bindings, configuring property values, defining intents, attaching policy sets, and resolving references. Shown here are the aspects of component creation that are common for all component definitions using the implementation developed in this example. This example also includes bindings that you can modify or omit for other components using this component implementation.

```
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
    targetNamespace="http://org.services.naming"
        name="NameServices">

      <component name="NamingServicesComponent">
         <implementation.java class="myintf.NameGetterImpl"/>
         <service name="NameGetter">

             <!-- The interface.java is not required because the run time can introspect it. -->

             <interface.java interface="myintf.NameGetter"/>

             <!-- The choice of bindings is not important for the example.  Here, both the SCA default and
                  web services bindings are configured. -->
             <binding.ws/>
             <binding.sca/>
         </service>
     </component>

</composite>
```

6. After your component is defined as part of a deployable composite, either directly or recursively through use of one or more layers of components with composite implementation, you are ready to deploy the SCA service by creating an SCA business level application.

Developing SCA service clients

You can develop a Service Component Architecture (SCA) service client starting with either a Java interface or a WSDL file for the SCA service that you want to invoke.

About this task

You can develop SCA service clients that can both access and invoke an SCA service that are based on the Service Component Architecture specification. An SCA client can consume a diverse set of services such as enterprise beans, web services, and other SCA services, through the capabilities of the respective SCA bindings and by using the Plain Old Java Object (POJO) client programming model.

To develop SCA service clients, you can start with either an existing Web Services Description Language (WSDL) file and use the **wsimport** tool to generate the Java interface or you can start with an existing Java interface.

Developing SCA client components starting with an existing WSDL file

When you have an existing WSDL file that describes your SCA service interface as a WSDL portType, along with XSD schema definitions of your business data, you can use the **wsimport** tool to generate the SCA Java representations of your business service interfaces and your business data. The **wsimport** tool generates Java classes that you can use to write a Java implementation that reflects your business logic. You can use the generated output of the proxy class and the JAXB data binding types in your Java client to invoke the SCA service using the simple POJO programming model.

The generated annotated Java classes that correspond to your business data contain all the necessary information that the Java Architecture for XML Binding (JAXB) runtime environment requires to build and parse the XML for marshaling and unmarshaling. In other words, the data programming model is limited to object instantiation and the use of getter and setter methods, and you do not need to write code to convert the data between the XML wire format and the Java application.

Now that you have the generated annotated Java classes, you must use the Java interface and data type classes to create the reference proxy as described in the developing SCA clients starting with a Java interface section.

Developing SCA client components starting with a Java interface

When you have a Java interface to your SCA service, obtained either by starting from a WSDL and generating the Java classes or by starting with Java code, use the Java interface and data type classes to create the reference proxy. If your client is designed so that its reference proxy is injected from the SCA container, the Java interface is the same type as your proxy field and this file contains the corresponding @Reference annotation. You can only create the static reference from another SCA component implementation that acts as a client of the original service. If your reference proxy is created programmatically, you must create a proxy variable that has the same type as your Java interface, and use an API such as `CompositeContext.getService(Class <B>interfaze, ...)` to create the reference proxy. The generated Java interface type is the interface parameter that is passed to this API. Read about locating and invoking SCA services to learn more about creating the reference proxy dynamically.

Regardless of whether the proxy is created by injection methods or programmatically, the Java interface is the class of the proxy and the generated JAXB types are the parameter types which includes inputs, outputs, and exceptions.

Considerations for local and remotable interfaces

It is important to understand that a remotable interface uses an XML wire format for data. Therefore, clients must use a JAXB-based programming model for the data types. In contrast, a local interface uses pass-by-reference semantics, so there is no data copy. Using the local interface, data is read and written without any special programming model such as JAXB.

Though WSDL-based interfaces are always remotable, you can also mark a Java interface that is not generated from a WSDL file as remotable by annotating it with the @Remotable annotation. The @Remotable annotation results in a data copy with XML serialization as defined by JAXB.

Defining the remotable interface is straightforward when you start with a WSDL interface, because you use the **wsimport** tool to generate the JAXB data types that you use when you write your SCA client. The remotable interface is less apparent when starting from a remotable Java interface, unless the Java types are decorated with JAXB annotations. XML serialization behaves differently than Java serialization. For an POJO that is not annotated, Java serialization preserves instance data including private fields, whereas JAXB serialization preserves JavaBeans properties.

The focus of this topic is the use of remotable interfaces.

You can develop a component that consumes or acts as a client of the target service using a component reference. In addition to consuming a service from another component's reference, the product also provides a mechanism for consuming an SCA service over the default binding from a non-SCA component.

Procedure

1. Determine if you are developing the SCA service client starting with an existing WSDL file or with an existing Java interface.
2. Develop the client Java interfaces and data types from a WSDL file if you are not starting with an existing Java interface. Use the **wsimport** command to generate the SCA service client Java interfaces.
3. Create the reference proxy based on the Java interface.
   a. Create a reference proxy field or setter method that has the same type as the generated Java interface
   b. Annotate this field or setter with the @Reference annotation.

   Now you have completed the steps required to add the reference to your Java component implementation
4. Create a component definition using the Java implementation.

   In the composite definition, add a <reference> element that refers back to the original interface and the field or setter of your SCA implementation. The reference is added as a child element of your component. The component is part of a composite definition.

   The <reference> name attribute must correspond to the field or setter that contains the @Reference annotation. For a field that contains the @Reference annotation, the name attribute must match exactly. For a setter that contains the @Reference annotation, use the usual Java conventions for translating an annotated setter into a corresponding field, which in turn must match the name attribute.

   For the interface:

   - If your SCA client development started with an existing WSDL file, create an <interface.wsdl> element as a child element of the <reference> element that points to the WSDL portType.
   - If your SCA client development started from existing Java interface, create an <interface.java> element as a child element of the <reference> element that points to the original Java interface. This is optional, since the runtime environment can introspect the Java interface.

   In addition to these aspects of your component definition described by these development procedures, there are other aspects of defining a component. These aspects include adding bindings, configuring property values, defining intents, attaching policy sets, and resolving references. You can create multiple components using this same implementation, but all component definitions are the same with respect to the <implementation.wsdl> element and <reference> element described in this step.
5. Deploy the SCA component by creating the SCA business level application from a deployable composite.

   In the previous step, you defined a component providing your SCA service within a composite definition. This composite is either a deployable composite, or one that is used recursively as a composite implementation of a component in a higher-level composite. To learn how to deploy the SCA service, read about deploying and administering business-level applications.

Results

You have created an SCA component that can consume an existing SCA service using a WSDL or Java interface.

Example

The following example illustrates using an existing WSDL interface to generate a Java interface that is used to create a Java implementation that is an SCA client. If you are starting with an existing Java interface, begin with step 4 to follow this example.

1. Copy the following sample account.wsdl WSDL file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>

<wsdl:definitions xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
     xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
     xmlns:account="http://www.myaccount.com/account"
```

```
targetNamespace="http://www.myaccount.com/account"
name="AccountService">

 <wsdl:types>
    <schema targetNamespace="http://www.myaccount.com/account"
        xmlns="http://www.w3.org/2001/XMLSchema"
        xmlns:xsd="http://www.w3.org/2001/XMLSchema"
        xmlns:account="http://www.myaccount.com/account">

          <element name="computeAccountAverage">
            <complexType>
                <sequence>
                    <element name="account" type="account:Account" />
                    <element name="days" type="xsd:int" />
                </sequence>
            </complexType>
        </element>
        <element name="computeAccountAverageResponse">
            <complexType>
                <sequence>
                    <element name="return" type="xsd:float" />
                </sequence>
            </complexType>
        </element>

        <complexType name="Account">
            <attribute name="accountNumber" type="xsd:int" />
            <attribute name="accountID" type="xsd:string" />
            <attribute name="accountType" type="xsd:string" />
            <attribute name="balance" type="xsd:float" />
        </complexType>

     </schema>
</wsdl:types>

<wsdl:message name="computeAccountAverageRequest">
    <wsdl:part element="account:computeAccountAverage"
        name="parameters" />
</wsdl:message>

<wsdl:message name="computeAccountAverageResponse">
    <wsdl:part element="account:computeAccountAverageResponse"
        name="parameters" />
</wsdl:message>

<wsdl:portType name="AccountService">
    <wsdl:operation name="computeAccountAverage">
        <wsdl:input message="account:computeAccountAverageRequest" name="accountReq"/>
        <wsdl:output message="account:computeAccountAverageResponse" name="accountResp"/>
    </wsdl:operation>
</wsdl:portType>

<wsdl:binding name="AccountServiceSOAP" type="account:AccountService">
    <soap:binding style="document"
        transport="http://schemas.xmlsoap.org/soap/http" />
    <wsdl:operation name="computeAccountAverage">
       <soap:operation
            soapAction="computeAccountAverage" />
        <wsdl:input name="accountReq">
           <soap:body use="literal" />
        </wsdl:input>
        <wsdl:output name="accountResp">
            <soap:body use="literal" />
        </wsdl:output>
    </wsdl:operation>

 </wsdl:binding>

<wsdl:service name="AccountWSDLService">
    <wsdl:port binding="account:AccountServiceSOAP"
        name="AccountServicePort">
```

```
            <soap:address location=""/>
          </wsdl:port>
        </wsdl:service>
    </wsdl:definitions>
```

2. Run the **wsimport** command from the *app_server_root*/bin/ directory.After generating the template files using the **wsimport** command, the following Java files are generated:

```
com/myaccount/account/Account.java
com/myaccount/account/AccountService.java
com/myaccount/account/AccountWSDLService.java
com/myaccount/account/ComputeAccountAverage.java
com/myaccount/account/ComputeAccountAverageResponse.java
com/myaccount/account/ObjectFactory.java
com/myaccount/account/package-info.java
```

3. Identify the generated Java interface from the generated classes.

```
//
// Generated By:JAX-WS RI IBM 2.1.1 in JDK 6 (JAXB RI IBM JAXB 2.1.3 in JDK 1.6)
//
package com.myaccount.account;
...
@WebService(name = "AccountService", targetNamespace = "http://www.myaccount.com/account")
...
public interface AccountService {
    /**
     *
     * @param days
     * @param account
     * @return
     *     returns float
     */
    @WebMethod(action = "computeAccountAverage")
    @WebResult(targetNamespace = "")
    @RequestWrapper(localName = "computeAccountAverage", targetNamespace = "http://www.myaccount.com/account",
         className = "com.myaccount.account.ComputeAccountAverage")
    @ResponseWrapper(localName = "computeAccountAverageResponse", targetNamespace = "http://www.myaccount.com/account",
         className = "com.myaccount.account.ComputeAccountAverageResponse")
    public float computeAccountAverage(
        @WebParam(name = "account", targetNamespace = "")
        Account account,
        @WebParam(name = "days", targetNamespace = "")
        int days);

}
```

This code example is a Java interface, not merely a Java class. The @WebService annotation is present in this Java interface. It is important to know that this example is not the same as the generated @WebServiceClient class, com.myaccount.account.AccountWSDLService. This class is not an interface and is actually not needed in your SCA application.

4. Now that you have Java interface either by generating the Java interface from a WSDL file or you have an existing Java interface, you are ready to develop your SCA client from the Java interface.
5. Place the @Reference annotation on a public or protected field or setter, with the same type as your Java interface.

```
package com.myaccount.client;

import bank.process.BankProcess;
import org.osoa.sca.annotations.Reference;
import org.osoa.sca.annotations.Service;

import com.myaccount.account.*;

@Service(BankProcess.class)
public class AccountClientComponent implements BankProcess {

   // Note the type, 'AccountService', is the Java interface generated from
   // from the WSDL portType
    private AccountService accountServiceRef;

    //
    // Injected by the SCA container
    //
```

```
        @Reference
        public void setAccountServiceRef(AccountService accountServiceRef) {
            this.accountServiceRef = accountServiceRef;
        }

        public String someMethod(String input) {

            //... some business logic ...

            //  We'll show a simple example of JAXB API usage
            ObjectFactory factory = new ObjectFactory();
            Account account = factory.createAccount();
            account.setAccountNumber(4);
            account.setAccountID("CHECKING");

            int days = 5;

            float avg = accountServiceRef.computeAccountAverage(account, days);

            //... the rest of the business logic ...
        }
    }
```

6. Create a component using the component implementation. When using a WSDL portType interface, you must create component definitions in the composite definition that references the original portType along with the SCA Java implementation. In SCA, a component is a configured instance of a component implementation. There are other aspects of defining a component that are not shown here such as configuring bindings, configuring property values, defining intents, attaching policy sets, and resolving references. Shown here are the aspects of component creation that are common for all component definitions using the implementation developed in this example. This example also includes bindings that you can modify or omit for other components using this component implementation.

```
<?xml version="1.0" encoding="UTF-8"?>

<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
     targetNamespace="http://bank.process/customer"
         name="bpComposite">

      <component name="BankProcessComponent">

          <implementation.java class="com.myaccount.client.AccountClientComponent"/>
         <!-- The @name attribute corresponds to the setter that is annotated with the @Reference annotation. -->

         <reference name="accountServiceRef">
              <!-- This statement specifies the QName of the WSDL portType,
                    "http://www.myaccount.com/account#AccountService" in the syntax as
                   illustrated in the interface.wsdl statement.  -->

             <interface.wsdl interface="http://www.myaccount.com/account#wsdl.interface(AccountService)" />
             <binding.ws uri="http://localhost:9080/BankingComponent/AccountService"/>

  <!-- This example uses the SCA web services binding.  However, it does not matter which specific binding
 you choose.  You can also choose to use the SCA default binding or the SCA EJB binding.  -->

          </reference>
     </component>
</composite>
```

7. Configure the composite definition when starting with a Java interface.

   The following snippet is another example of the syntax if you develop an SCA client starting with a Java interface rather than with a WSDL portType. To simplify this example, use the same AccountService Java interface from the previous step but in this case, assume that it was not generated from a WSDL file.

```
<?xml version="1.0" encoding="UTF-8"?>

<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
     targetNamespace="http://bank.process/customer"
         name="bpComposite">

      <component name="BankProcessComponent">

         <implementation.java class="com.myaccount.client.AccountClientComponent"/>
```

```
        <!-- The @name value corresponds to the setter that is annotated with the @Reference annotation. -->
               <reference name="accountServiceRef">

             <!-- Because the runtime can introspect the interface, it is unnecessary to specify
                  the interface.java in the composite definition. This is what the interface looks like if you include it.

                        <interface.java interface="com.myaccount.account.AccountService"/>  -->

              <!-- The SCA binding type is omitted. It does not matter which specific SCA binding you choose. -->
        </reference>
    </component>
</composite>
```

8. After a component is defined as part of a deployable composite, either directly or recursively through use of one or more layers of components with composite implementation, you are now ready to deploy the SCA component by creating a SCA business level application.

Developing asynchronous SCA services and clients

You can create applications that use Service Component Architecture (SCA) OASIS specifications to asynchronously run request-response services.

Before you begin

Note: SCA OASIS specifications support the asynchronous running of request-response services. This enables a client thread to continue doing other work while the service runs. You can use SCA OASIS annotations and APIs in Java interfaces to enable asynchronization in services.

To learn about asynchronous invocations of SCA services, see the SCA OASIS Java Common Annotations and APIs specification. For a list of common annotations in SCA OASIS specifications, see `http://docs.oasis-open.org/opencsa/sca-j/javadoc/index.html`.

About this task

An SCA client and an SCA service have independent capabilities for asynchronous invocation which can be intermixed. This means that a client can synchronously run an asynchronous service or asynchronously run a synchronous service. Typically, a client asynchronously runs an asynchronous service.

When developing an asynchronous service and client, consider the following:

- Use the SCA OASIS annotation `@AsyncInvocation` in the Java service interface to enable asynchronization.
- Use the SCA OASIS annotation `@AsyncFault` in the Java service interface for exception errors.
- In the composite definition, use the `implementation.java` type for the SCA component.
- Asynchronous interfaces are supported by `binding.sca` only.

Topics in the procedure cover developing SCA services and clients that run asynchronously.

Procedure

1. Develop an asynchronous SCA service.
2. Develop an asynchronous SCA client.

What to do next

Deploy the SCA composites in a business-level application.

For SCA OASIS applications, an `sca-contribution.xml` file is required for deployable composites in the `META-INF/` directory, and not in a subdirectory.

Developing asynchronous SCA services

You can create services that use Service Component Architecture (SCA) OASIS specifications to asynchronously run request-response services.

Before you begin

To learn about asynchronous invocations of SCA services, see the SCA OASIS Java Common Annotations and APIs specification. For a list of common annotations in SCA OASIS specifications, see `http://docs.oasis-open.org/opencsa/sca-j/javadoc/index.html`.

About this task

To develop an asynchronous SCA service, you can create three files:

- A Java service interface that uses the SCA OASIS `@AsyncInvocation` annotation and, for exception errors, the `@AsyncFault` annotation
- A Java service implementation that has an `@Service` annotation which refers to the service interface
- An SCA OASIS composite

Procedure

1. Create an asynchronous service interface.

   You can derive an interface from the business interface between the client and the service. For example, suppose that the service has the following business interface:

   ```
   package broker;
   public interface StockQuote {
   float getPrice(String symbol) throws UnknownSymbolException;
   }
   ```

   Copy the business interface and modify it to create an equivalent asynchronous service interface:

   ```
   package broker.impl;
   import broker.UnknownSymbolException;
   import org.oasisopen.sca.ResponseDispatch;
   import org.oasisopen.sca.annotation.AsyncFault;
   import org.oasisopen.sca.annotation.AsyncInvocation;

   @AsyncInvocation
   public interface StockQuote {
       @AsyncFault(UnknownSymbolException.class)
       void getPriceAsync(String symbol, ResponseDispatch<Float> dispatch); }
   ```

   An asynchronous service interface is a contract between the SCA container and the service implementation. It is not used by the client.

   Use the `@AsyncInvocation` annotation on the interface to indicate it is asynchronous. Derive each method from its equivalent method in the business interface as follows:

   - Append the characters `Async` to the method name.
   - Change the return type to `void`.
   - Add a `ResponseDispatch` argument which is typed by the method's original return type.
   - Move exceptions from the `throws` clause to `@AsyncFault` annotations.

   For simplicity, use the same simple name for the asynchronous service interface as for the business interface, but specify a different package name. By default, an SCA service name is the simple name of its interface, so using the same interface names helps to ensure that a consistent SCA service name is used.

2. Create the asynchronous service implementation.

   For example, create an implementation that references the `StockQuote` SCA service interface:

   ```
   package broker.impl;
   import broker.UnknownSymbolException;
   import org.oasisopen.sca.ResponseDispatch;
   import org.oasisopen.sca.annotation.Service;
   @Service(StockQuote.class)
   ```

```
public class StockQuoteImpl {
    public void getPriceAsync(String symbol, ResponseDispatch<Float> dispatch) {
         if (!isValidSymbol(symbol))
             dispatch.sendFault(new UnknownSymbolException());
         else
             dispatch.sendResponse(getPrice(symbol));
     }
     private boolean isValidSymbol(String symbol) {
         // fill in
     }
     private Float getPrice(String symbol) {
         // fill in
     }
}
```

The `@Service` annotation must refer to the asynchronous service interface.

Each method is passed a `ResponseDispatch` object which must be used to return a response to the client. The example shows the response being sent inside the method body but this is not required. The method can save the input arguments, including the `ResponseDispatch` object, for another thread to handle.

Do not perform a long-running computation directly in the method body because this might cause the client to receive a timeout exception. Instead, queue the work to another thread. One approach for queueing work to another thread is to use an asynchronous bean.

3. Create a composite file.

   For example, create an SCA OASIS composite that defines an `implementation.java` component which uses the implementation `StockQuoteImpl` class:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912"
           targetNamespace="http://www.example.com" name="StockQuoteComposite">
    <component name="StockQuoteComponent">
        <implementation.java class="broker.impl.StockQuoteImpl"/>
    </component>
</composite>
```

   Asynchronous services must use the `binding.sca` binding type because it is the only binding that supports asynchronous invocation. However, `binding.sca` is the default binding so you do not need to include it in the composite file.

What to do next

Develop an asynchronous SCA client to run an SCA service.

Developing asynchronous SCA clients

You can create clients that use Service Component Architecture (SCA) OASIS specifications to run asynchronously.

Before you begin

To learn about asynchronous invocations of SCA services, see the SCA OASIS Java Common Annotations and APIs specification. For a list of common annotations in SCA OASIS specifications, see `http://docs.oasis-open.org/opencsa/sca-j/javadoc/index.html`.

About this task

An SCA client can synchronously run an asynchronous service or asynchronously run a synchronous service. Typically, a client asynchronously runs an asynchronous service.

To develop an asynchronous SCA client, you can create three files:

- A Java client interface
- A Java client implementation that has an `@Reference` annotation
- An SCA OASIS composite

To dispatch client-side asynchronous requests, you can use a default SCA work manager.

A few limitations apply when using asynchronous interfaces from an SCA client:

- If the client application or its host server is stopped, responses to active asynchronous requests are lost, and are not delivered when the application is restarted.
- Because the SCA container invokes an asynchronous request from a separate thread, the client must not modify any arguments passed to the request until after it receives the response.
- Asynchronous invocation is not supported with services obtained using the `org.oasisopen.sca.client.SCAClientFactory` interface.
- A client can synchronously invoke an asynchronous service. The SCA container waits for up to 120 seconds for a response from the asynchronous service.

Procedure

1. Create an asynchronous client interface.

   You can derive an interface from the business interface between the client and the service. For example, suppose that the service has the following business interface:

   ```
   package broker;
   public interface StockQuote {
   float getPrice(String symbol) throws UnknownSymbolException;
   }
   ```

   Copy the business interface and modify it to create an equivalent asynchronous client interface:

   ```
   package broker.client;
   import broker.UnknownSymbolException;
   import java.util.concurrent.Future;
   import javax.xml.ws.AsyncHandler;
   import javax.xml.ws.Response;
   public interface StockQuote {
       float getPrice(String symbol) throws UnknownSymbolException;
       Response<Float> getPriceAsync(String symbol);
       Future<?>getPriceAsync(String symbol, AsyncHandler<Float> callback);
   }
   ```

   An asynchronous client interface is a contract between the client and the SCA container. It is not used by the service.

   An asynchronous client interface has additional methods to support polling or callback delivery. Derive the polling method from its equivalent method in the business interface as follows:

   - Append the characters `Async` to the method name.
   - Change the return type to `javax.xml.ws.Response`.

   Derive the callback method from its equivalent method in the business interface as follows:

   - Append the characters `Async` to the method name.
   - Change the return type to `java.util.concurrent.Future`.
   - Add a `javax.xml.ws.AsyncHandler` argument which is typed by the return type of the original method.

2. Create the asynchronous client implementation.

   For example, create an implementation that uses the callback interface:

   ```
   package broker.client;
   import broker.UnknownSymbolException;
   import java.util.concurrent.ExecutionException;
   import javax.xml.ws.AsyncHandler;
   import javax.xml.ws.Response;
   import org.oasisopen.sca.annotation.Reference;
   public class StockQuoteClientImpl {
       @Reference
       public StockQuote quoteService;

       public void getStockPrice(String symbol)  {
           CallbackHandler callback = new CallbackHandler(symbol);
           quoteService.getPriceAsync(symbol, callback);
   ```

```
    }

    private class CallbackHandler implements AsyncHandler<Float>{
        private String symbol;
        public CallbackHandler(String symbol) {
            this.symbol = symbol;
        }
       public void handleResponse(Response<Float>arg0) {
           try {
               Float price = arg0.get();
               // Process the response
           } catch (ExecutionException e) {
              if (e.getCause() instanceof UnknownSymbolException) {
                  // Process the exception
              }
           } catch (Throwable t) {
               // Process the exception
           }
    }
}
```

3. Create a composite file.

   For example, create an SCA OASIS composite that defines an `implementation.java` component which uses the implementation `StockQuoteClientImpl` class:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912"
           targetNamespace="http://www.example.com" name="StockQuoteClientComposite">
    <component name="StockQuoteClientComponent">
        <implementation.java class="broker.client.StockQuoteClientImpl"/>
    </component>
</composite>
```

   Asynchronous clients must use the `binding.sca` binding type because it is the only binding that supports asynchronous invocation. However, `binding.sca` is the default binding so you do not need to include it in the composite file.

4. Configure the default SCA work manager.

   The SCA container uses the default SCA work manager to dispatch client-side asynchronous requests. See Configuring the default SCA Work manager for the SCA layer.

What to do next

Deploy the SCA client and service in a business-level application.

Using business exceptions with SCA interfaces

You can implement exceptions for remotable interfaces in the Service Component Architecture (SCA) environment to provide additional flow of control for error conditions to meet the needs of your business application.

About this task

To develop SCA service implementations, you can use either a top-down development approach starting with an existing Web Services Description Language (WSDL) file or you can use a bottom-up development approach starting from an existing Java interface or implementation. When using either the top-down or bottom-up development methodologies, you can use tools to map business exceptions on remotable interfaces.

In order to achieve the SOA goal of providing an interoperable platform that is both language and technology neutral, the SCA runtime environment takes an XML-centric view of interfaces and data. When working with Java code, the Java API for XML-Based Web Services (JAX-WS) standard is used to define the mapping between Java code and the XML-based Web Services Description Language (WSDL) file. This mapping also includes the Java programming model with respect to exceptions. Exceptions for

remotable interfaces in the SCA environment is defined by the JAX-WS specification. This topic describes the best practices for using business exceptions with SCA interfaces.

Differences between business exceptions and fault beans

To better understand the implications of implementing business exceptions in an SCA environment, it is helpful to understand differences between an exception and a fault bean.

The JAX-WS specification distinguishes between a checked exception and the fault bean that it wrappers. However, this distinction might not be clear because a single class can serve the checked exception and the fault bean functions, especially when you use the bottom-up approach of developing an SCA service starting with a Java interface. When you use the top-down development approach of developing an SCA service starting with a WSDL file, section 2.5 of the JAX-WS specification describes the wrapper pattern for how the fault message maps to a Java checked exception that wraps a fault bean. The fault bean maps to the fault element and in SCA environments, the mapping is defined by Java Architecture for XML Binding (JAXB) data binding. The fault bean represents the cross-platform view of the fault message data and includes a schema description. You can use the Java exception within the Java runtime environment and as part of the Java programming model. However, the exception is not part of the interoperable data representation.

When developing SCA services using the bottom-up approach, the distinction between an exception, the fault bean, and the mapping from Java to WSDL or XSD schema is clear if you follow the wrapper pattern described in section 2.5 of the JAX-WS specification. If you have existing Java exceptions, use the standard mapping defined in section 3.7 of the JAX-WS specification for service specific exceptions. In SCA environments, these service specific exceptions are referred to as business exceptions. The mapping for the business exceptions is different than the mapping described in section 2.5 of the JAX-WS specification. Because this wrapper pattern only applies for certain exceptions, this approach has limitations when using the bottom-up development approach. The possible limitations of using the wrapper pattern to implement error handling when using bottom-up development of SCA applications provides additional reasons to consider the advantages of the best practice of top-down development of SCA applications.

Top-down development, starting from a WSDL operation with fault messages

It is a best practice to use the top-down methodology to develop SCA service implementations because this approach leverages the capabilities of the XML interface description and provides a greater ease in interoperability across platforms, bindings, and programming languages. A WSDL operation can be defined, along with one or more fault messages, provided each fault message is defined in terms of a fault element. When the **wsimport** command-line tool is used to generate Java code the tool generates Java exception code that wraps a fault element in the format specified by the Java API for XML-Based Web Services (JAX-WS) specification, section 2.5.

Bottom-up development, starting from a Java operation with throws clause

Bottom-up development of SCA services occurs when you start with existing Java code. Using this development approach, do not design a remotable interface that might cause a technology exception such as java.sql.SQLException. This exception is more appropriate for a local interface rather than a coarse-grained remotable interface.

Procedure

1. For top-down development of SCA applications, implement a wrapper pattern for business exceptions. The wrapper pattern is based on section 2.5 of the JAX-WS specification.
   a. Obtain your WSDL file; for example:

```
<wsdl:types>
    ...
    <element name="errorCode" type="xsd:int"/>
    ...
</wsdl:types>
```

```
<wsdl:message name="BadInputMsg">
    <wsdl:part element="tns:errorCode" name="parameters"/>
</wsdl:message>

<wsdl:portType name="GuessAndGreet">
    <wsdl:operation name="sendGuessAndName">
            <wsdl:input.../>
            <wsdl:fault message="tns:BadInputMsg" name="BadInputMsg"/>
```

b. Generate the Java artifacts using the **wsimport** tool. You can define the fault according to section 2.5 of the JAX-WS specification; for example:

```
Interface
   public Person sendGuessAndName(...) throws BadInputMsg;
```

c. Wrap an exception in a fault; for example:

```
import javax.xml.ws.WebFault;

@WebFault(name = "errorCode", targetNamespace = "....")
public class BadInputMsg extends Exception
{
    private int faultInfo;

    public BadInputMsg(String message, int faultInfo) {
        super(message);
        this.faultInfo = faultInfo;
    }

    public BadInputMsg(String message, int faultInfo, Throwable cause) {
        super(message, cause);
        this.faultInfo = faultInfo;
    }

    public int getFaultInfo() {
        return faultInfo;
    }
}
```

2. For bottom-up development of SCA applications, implement or convert the exception to follow the wrapper pattern or use the default mapping for of a JAX-WS service specific exception.

   If you have a Java business exception, the complexity of this scenario increases, especially if your exception wraps fault data. For example, the exception wraps data such as an error code or an object that it needs to provide to the client that receives the exception. In this scenario, there are two options:

   - Convert the Java business exception to follow the wrapper pattern as described in section 2.5 of the JAX-WS specification.

     Using the wrapper pattern for the exception enables the exception to map easily from the WSDL to Java code format and then from the Java code to WSDL format. If you modify the exception to follow the wrapper pattern, you can use the **wsgen** tool to convert from Java code to WSDL and later use the **wsimport** tool to convert from WSDL to Java code, the exception is similar to the one that you modified. To achieve this end goal, you must perform the following steps:

     a. Add constructors that take the fault bean as input parameters.
     b. Implement a public getFaultInfo() method that returns the fault bean.
     c. Add the @javax.xml.ws.WebFault annotation. See the example that wraps an exception in a fault.

   - Use the default mapping of a JAX-WS service specific exception or business exception as described in section 3.7 of the JAX-WS specification.

     If you use the **wsgen** command-line tool to generate the WSDL, the tool uses this pattern for business exceptions. If you do not generate the WSDL file before deployment, the application server runtime environment implicitly generates the business exception using this pattern.

     Use this option when you:

     – cannot change the exception class to follow the JAX-WS wrapper pattern.
     – rely on the runtime environment to map the Java code into WSDL such as declaring a `<binding.ws>` binding on a service that is deployed without a WSDL file.

Either of these options work without any additional complexity as long as the exception does not contain fault data.

For exceptions with fault data, the data is handled correctly for each field that contains a public getter or setter method. However, data is lost without a getter or setter pair. In other words, serialize or deserialize the exception by viewing it as a Java code.

When using this second option, the following items are important:

- The supported fault pattern is not easily determined. One exception with fault data and also with the getter and setter methods is that some are handled correctly while others are not. Running the **wsgen** tool at development time generates the schema based on the exception getter methods without assuring that the corresponding setter methods exist in order to populate the exception during unmarshalling.
- If you run **wsimport** tool against the generated WSDL, you get a different exception class. Your client and service programming model are different which might confuse the Java programmer. However, this generated Java exception follows the pattern described in the JAX-WS specification in section 2.5. You might need to add customization for JAXB data binding in order to generate the client. The results can produce exception names similar to `MyException_Exception`.
- Although the service-specific exception pattern is described in section 3.7 of the JAX-WS specification, not all details for the pattern are specified. Other software implementing JAX-WS might implement the pattern differently. This is not critical, since the WSDL file is interoperable across platforms.

Example 1: No fault

The following examples illustrates using the bottom-up development of SCA applications and using the business exception mapping as described in section 3.7 of the JAX-WS specification.

The string message is the fault in this example, and it is serialized and deserialized successfully.

```
public class RealSimpleException extends Exception {
    public RealSimpleException(String message) {
        super(message);
    }
    public RealSimpleException(String message, Throwable cause) {
        super(message, cause);
    }
}
```

This example works correctly because the string `userdata` fault has associated public getter and setter methods. The string message is also handled correctly.

```
public class TestException extends Exception {

    private String userdata;

    public TestException(String message) {
        super(message);
    }

    public TestException(String message, String userdata) {
        super(message);
        this.userdata = userdata;
    }

    public String getUserdata() {
        return userdata;
    }

    public void setUserdata(String userdata) {
        this.userdata = userdata;
    }

}
```

This example does not work correctly because the errorCode fault data does not have a setter method. The SCA runtime is not able to correctly determine how to populate the exception with this fault data. The exception occurs, but it is displayed with data loss.

```
package java.sql;

public class SQLException extends Exception ... {
 ...
 public SQLException(String theReason, String theSQLState, int theErrorCode) ...

 public int getErrorCode()
}
```

What to do next

Increase portability of your exception classes in top-down development

One issue that you might encounter with Java exceptions generated from WSDL in the top-down manner is that the fault bean might not be Java-serializable. In other words, the fault bean might not implement java.io.Serializable. This does not present a problem if the bindings that your application uses are in XML wireformat because, in that scenario, XML serialization is used instead of Java serialization. However, XML serialization limits the usefulness of your exception class. Therefore, it might not be suitable to use with SCA binding configurations using a wireformat with Java serialization, or in other contexts in which Java serialization is used to serialize and deserialize an exception.

To avoid this limitation, annotate your schema definition for the fault element type with a JAXB customization designed for this purpose. When this customization is present, the JAXB type that is generated, that corresponds to the fault bean, is marked as implementing the java.io.Serializable interface, and is therefore Java serializable, in addition to being serializable to XML, because the class is also still a conforming JAXB type.

Example:

```
<schema targetNamespace="http://com.mycompany/banking/" jaxb:version="2.0"
  xmlns:jaxb="http://java.sun.com/xml/ns/jaxb"
  xmlns="http://www.w3.org/2001/XMLSchema">
   <annotation>
     <appinfo>
       <jaxb:globalBindings>
         <jaxb:serializable uid="1"/>
      </jaxb:globalBindings>
     </appinfo>
   </annotation>

    <!-- Continue with the rest of the schema definition-->

 </schema>
```

SCA programming tip for binding neutrality

The JAX-WS defined mapping between exceptions in Java and an XML wireformat relies on the use of the fault bean to pass back data from the service provider throwing the exception to the client that is catching it. Normal Java-centric mechanisms, such as exception chaining, are not preserved in mapping between the Java application and the wire. Therefore, the best way to write application code that can be used across binding configurations using either of a Java serialization wireformat or an XML wireformat is to rely exclusively on the fault bean for communicating useful application level data relating to the exception.

Even though using a chained exception across a binding that uses a Java-serialization based wireformat works fine, using a chained exception across a binding using XML wireformat might not work. Therefore relying on a chained exception would not be a recommended practice in an SCA environment, because SCA strives to provide a binding-neutral programming model.

Considerations for developing SCA applications using EJB bindings

When developing Service Component Architecture (SCA) applications that you intend to use with Enterprise JavaBeans (EJB) bindings, keep in mind that the SCA EJB binding is architected in a Java-centric manner, in contrast to the XML-centric implementations of the SCA default binding and the SCA web services binding.

The EJB transports marshal and unmarshal application data into the wire format by using Java serialization, whereas the web services and default bindings use XML serialization. This difference also affects the programming model in that the SCA clients and implementations using the EJB binding must use java.io.Serializable types, in contrast to the Java Architecture for XML Binding (JAXB) data types-based programming model that is used for the SCA default and web services bindings.

SCA reference

In this case, you have an existing EJB that you want to invoke with an SCA client using a reference that is configured with an EJB binding.

When you develop an SCA client that will invoke an existing EJB using the SCA EJB binding, you must use a Java interface when developing the SCA client rather than using a WSDL interface. The EJB binding marshalling of application data into the wire data format is performed using Java serialization, not XML serialization as defined by JAXB.

To learn more about SCA references, read about developing SCA service clients. However, when you are using the SCA EJB binding, the information in this topic takes precedence.

Because you obtain the Java interface and parameter types from the EJB provider for use in your client, you do not have to worry about the effects of marshalling and unmarshalling when writing your client. However, when you provide these data types across new services, problems can occur if you pass these data types across new services, because they might not serialize correctly over other bindings, such as the default binding, because of the difference in Java serialization and the JAXB XML marshalling and unmarshalling.

The following example illustrates the problematic scenario of starting with an existing EJB interface and using a Java serializable data type that does not serialize well using JAXB marshalling and unmarshalling.

```
public interface NameService extends javax.ejb.EJBObject {

    public String computeName(Person p) throws RemoteException;
}
// This snippet is intended as an example of a type that is problematic.
public class Person implements java.io.Serializable {

    private int code;
    private String name;

    // The code field must be passed into constructor.  However, this causes problems for
    // for SCA default and web services bindings that use JAXB marshalling/unmarshalling.

    public Person(int code) {
        this.code = code;
    }

    public Person() {
    }

    public String getName() {
        return name;
    }

    public void setName(String value) {
        this.name = value;
    }

}
```

The following SCA client A example works correctly. The `Person` object that is instantiated directly in the `ClientAImpl` implementation is correctly marshalled to invoke the EJB with a remote interface of `NameService`.

```
// Client A  ClientAImpl.java
 .....
@Reference
public NameService nameService

public someClientMethod() {
    // No problem when Person object is instantiated by client
    Person person = new Person(5);
    String name = nameService.computeName(person);
}
```

In contrast, the following example demonstrates the problem with the `Person` type. The client code has been refactored so that it contains a reference to `NameService`, and it obtains the `Person` object that is passed into the `computeName` method over a new remotable interface, rather than constructing it directly.

```
// Problem client interface

import org.osoa.sca.annotations.Remotable;
@Remotable
public interface PersonFilter {
     boolean filterPerson(Person p);
}

// Problem client implementation

@Service(PersonFilter.class)
public class PersonFilterImpl implements PersonFilter {
     @Reference
     public NameService nameService

     boolean filterPerson(Person p) {
     // ...  business logic
    String name = nameService.computeName(person);
     // ...  business logic
     }
}
```

If the `PersonFilterImpl` class receives a `Person` object from the client over the `PersonFilter` interface and the implementation is invoked using the SCA default binding, the data is not handled correctly. The default binding does not preserve the `code` field of the `Person` object that is passed to the `PersonFilterImpl` class.

For a class without JAXB annotations, JAXB marshalling and unmarshalling preserves JavaBeans properties, but not private data such as the `code` field, which does not have a setter and is only established in the constructor. When the `Person` object is passed to the `NameService` EJB, the `code` value is set to the default value of `0` regardless of what the `PersonFilter` client passed to the `PersonFilterImpl` class.

If the `Person` type was written in the JavaBeans style with getters and setters for all important data, then this type works correctly in the example for the `PersonFilterImpl` client. However, if you are consuming an existing EJB, you do not have control over the types it already uses on its interface. Not all existing Java types are optimal for SCA Java programming. To address the problems in this example, you must create a new type for use on the `PersonFilter` interface and translate the data for this type into a `Person` object within the `PersonFilterImpl` class which directly invokes the EJB with the remote interface `NameService`.

In this example, if the `PersonFilter` interface was defined as a local interface, then the concerns with preserving data integrity do not apply. The runtime environment performs pass-by-reference semantics across local interfaces that are appropriate for tightly-coupled clients and services such that no data is copied.

SCA service

If you write a new SCA service and intend to expose it over the SCA EJB binding so that an EJB client can invoke the service, it is a best practice to develop the SCA service using the top-down methodology starting with an existing WSDL file or XSD schema and generating the JAXB classes that are used to write the service implementation. Using this approach, you can easily address the differences between Java serialization and JAXB marshalling and unmarshalling by specifying that the generated JAXB classes are Java serializable.

To enable the generated JAXB classes to work correctly over the SCA EJB binding, add the `serializable` customization to the schema definition so that the generated JAXB classes are Java serializable and implement the `java.io.Serializable` interface. For example:

```
<schema targetNamespace="http://com.mycompany/banking/" jaxb:version="2.0"
 xmlns:jaxb="http://java.sun.com/xml/ns/jaxb"
 xmlns="http://www.w3.org/2001/XMLSchema">
  <annotation>
    <appinfo>
      <jaxb:globalBindings>
        <jaxb:serializable uid="....."/>
     </jaxb:globalBindings>
    </appinfo>
  </annotation>

   <!-- Continue with the rest of the schema definition-->

</schema>
```

As a result, you can use your Java implementation with the generated JAXB data types over the EJB binding, which uses Java serialization. At this point, because you have the generated JAXB artifacts, you can also use your Java implementation with the generated JAXB data types over the SCA default and SCA web services bindings, which use XML serialization as defined by JAXB.

If you develop your SCA service using the bottom-up approach starting with Java code, you must use types that implement the `java.io.Serializable` interface as required when writing an EJB. See the developing SCA services with existing Java code documentation for more information regarding requirements for your user-defined types. Also, see the SCA reference section to learn how to avoid problems with your user-defined types when using EJB bindings because of the differences between Java serialization and JAXB marshalling and unmarshalling.

Specifying bindings in an SCA environment

After you develop an Service Component Architecture (SCA) component, you can use bindings to specify how SCA services and references enable the component to communicate with other applications.

About this task

Services and references enable a component to communicate with other applications. By design, however, the SCA services and references say nothing about how this communication occurs. Bindings are used to determine how a component communicates with the world outside its domain. SCA services use bindings to describe the access mechanism that clients must use to call the service. SCA references use bindings to describe the access mechanism that is used to call a service. Depending on what the SCA component is communicating with, a component might or might not have explicitly specified bindings.

The product supports the following binding types:

- SCA binding

The SCA binding is also referred to as the default binding. It is the binding that is used when no other binding is specified for configuration of a component reference or service. It is the natural binding to use when your SCA client invokes an SCA service in the same domain.

SCA default bindings are not compatible across implementations by architecture; however, some interoperability scenarios are enabled between Open SCA and Classic SCA as implemented in the BPM Suite of products like WebSphere Process Server.

Components communicating within the same domain only need to explicitly configure a default binding on a service or reference when there is at least one non-default binding, such as the SCA web services binding or the SCA EJB binding, that is also configured.

- Web service binding

  The SCA web services binding applies to the services and references of components. The web service binding is designed for SOAP-based Web Services-Interoperability (WS-I) compliant web services. This binding defines the manner in which a service is made available as a web service, and in which a reference can invoke or access a web service. The web service binding enables SCA applications to expose SCA services as web services to external clients that might or might not be implemented as an SCA component. This binding is a Web Services Description Language (WSDL)-based binding which means that the web service binding either references an existing WSDL binding or enables you to specify enough information to generate a WSDL file. When an existing WSDL binding is not referenced, you can generate a WSDL binding. You can further customize an SCA web services binding using SCA policy sets.

  Web services technology plays an important role in most SOA solutions relevant today, including SCA. The SCA web service binding type enables SCA applications to expose services as web services to external clients as well as enabling SCA components access to external web services. External clients that access SCA services exposed as web services may or may not be implemented as an SCA component. You can use the web service binding element `<binding.ws>` within either a component service or a component reference definition. When the web service binding is used with a component service, this binding type enables clients to access a service offered by a particular component as a web service. When the web service binding is used with a component reference, components in an SCA component can consume an external web service and access as if it was any other SCA component. Only WSDL Version 1.1 is supported.

- EJB binding

  EJB session beans are a common technology used to implement business services. The ability to integrate SCA with services based on session beans is useful because it preserves the investment incurred during the creation of those business services, while enabling the enterprise to embrace the newer SCA technology in incremental steps. The simplest form of integration is to simply enable SCA components to invoke session beans as SCA services. There is also a need to expose services such that they are consumable by programmers skilled in the EJB programming model. This enables existing session bean assets to be enhanced to exploit newly deployed SCA services without the EJB programmers having to learn a new programming model.

  The SCA EJB binding enables SCA to integrate with existing Java EE applications. It exposes SCA services as stateless session beans to external clients. The binding element `<binding.ejb>` is used within a component service or component reference definition. Support is provided for the EJB binding when using both 2.x and 3.0 EJB styles for both the SCA service and reference.

- JMS binding

  Use the SCA Java Message Service (JMS) binding to compose and assemble SCA services from new and existing services that are available using the JMS programming interface. By taking advantage of the ability to integrate SCA with existing services based on JMS, you can preserve your investment in enterprise messaging technology, while enabling the enterprise to embrace the new SCA technology in incremental steps.

  The SCA JMS binding enables an open, implementation neutral, service-oriented description of the SCA service assembly and composition. Use the binding element `<binding.jms>` within a component service or component reference definition. SCA services using the JMS binding are exposed using the Java EE Connector Architecture (JCA)-based messaging provider in WebSphere Application Server.

The product supports the default messaging provider or WebSphere MQ as the messaging engine.

- Atom binding

  Use the Atom binding to work with services that provide or consume entries described in the Atom Syndication Format and Atom Publishing Protocol. An SCA component can reference existing external web feeds defined using the Atom protocol and work with them inside a Java implementation. Also, you can use the Atom binding to compose new services and expose them as an Atom feed.

  The product supports the Atom binding for OSOA, but not for OASIS.

- HTTP binding

  Use the HTTP binding to expose SCA services for consumption by remote JavaScript-enabled web browser clients. Using this binding, clients can invoke Remote Procedure Calls (RPC) to server-side SCA components.

  The product supports the HTTP binding for OSOA, but not for OASIS.

Procedure

1. Select a binding type to use for an SCA component.
   - Use the SCA default binding when you want to invoke an SCA service from an SCA client.
   - Use the SCA web services binding to specify that an SCA service is made available as a web service or an SCA reference can invoke a web service.
   - Use the SCA EJB binding to integrate SCA with services based on session beans.
   - Use the SCA JMS binding to compose and assemble SCA services from new and existing services.
   - Use the Atom binding to expose collections of data as an Atom feed or to reference existing external Atom feeds.
   - Use the HTTP binding with a wire format of JSON-RPC to expose services to remote web browser clients.
2. Configure the selected binding and use it in an SCA component or application.

Results

SCA components can use the configured bindings to communicate with other SCA services and references.

What to do next

Deploy the SCA component or application.

Configuring the SCA default binding

You can configure the Service Component Architecture (SCA) default binding for services and references.

About this task

Bindings determine how a component communicates with the world outside its domain. Services use bindings to describe the access mechanism that clients must use to call the service. References use bindings to describe the access mechanism used to call a service. The SCA binding is also referred to as the default binding. The default binding is the binding that is used when no other binding is specified for a configuration of a component reference or service. Use this binding when an SCA client invokes an SCA service in the same domain. It is not intended to be interoperable in any way with other implementations of SCA runtime environments.

Procedure

- Configure an SCA service with the SCA default binding.

If the service is only exposed over the default binding, then you do not need to explicitly add the <binding.sca> element because this binding is default binding for SCA. If your SCA service has more than one binding and the SCA default binding must be one of them, you must specify the <binding.sca> element in the composite definition.

- Configure an SCA reference with the SCA default binding.

  For the reference, you also do not need to specify the <binding.sca> element. For an reference with a default binding, the reference specifies a target attribute indicating the target service. To indicate the target at the reference, specify target=componentName/serviceName. If only one service exists for the service component, then you only need to specify the componentName; for example: target=ComponentName.

Results

You have implicitly or explicitly configured the SCA default binding for your SCA service or reference.

Example

The following examples illustrate multiple scenarios for configuring the SCA default bindings.

Top level composite with SCA service binding

```
<?xml version="1.0" encoding="UTF-8"?>

   <composite xmlns="http://www.osoa.org/xmlns/sca/1.0" targetNamespace="http://mysca/samples" name="MyComposite">

      <component name="HelloWorldServiceComponent">
         <implementation.java class="test.HelloWorldImpl"/>
      </component>

   </composite>
```

Top level composite with SCA reference binding

```
<?xml version="1.0" encoding="UTF-8"?>

   <composite xmlns="http://www.osoa.org/xmlns/sca/1.0"  targetNamespace="http://mysca/samples"
       name="ClientComposite">

      <component name="ClientComponent">
        <implementation.java class="test.GreetingsServiceImpl"/>
        <reference name="helloWorldService" target="TargetComponent"/>
      </component>

   </composite>
```

OR:

```
<?xml version="1.0" encoding="UTF-8"?>

   <composite xmlns="http://www.osoa.org/xmlns/sca/1.0"  targetNamespace="http://mysca/samples"
        name="ClientComposite">

      <component name="ClientComponent">
        <implementation.java class="test.GreetingsServiceImpl"/>
        <reference name="helloWorldService" target="TargetComponent/HelloWorld"/>
        <!-- compName/serviceName -->
        </component>

   </composite>
```

Top level composite with SCA service binding with transaction policy attribute defined

```
<?xml version="1.0" encoding="UTF-8"?>

   <composite xmlns="http://www.osoa.org/xmlns/sca/1.0"  targetNamespace="http://neworder/sca/jdbc"
       name="NewOrderComposite">
```

```
      <component name="NewOrderServiceComponent">
         <service name="NewOrderService" requires="propagatesTransaction.false"/>
         <implementation.java class="neworder.sca.jdbc.NewOrderServiceImpl" requires="managedTransaction.local"/>
      </component>

   </composite>
```

Top level composite with SCA service binding supporting WSDL interface

```
<?xml version="1.0" encoding="UTF-8"?>

   <composite xmlns="http://www.osoa.org/xmlns/sca/1.0"  targetNamespace="http://mysca/samples"
         name="ClientComposite">

        <component name="ClientComponent">
           <service name="HelloWorldService">
             <interface.wsdl interface="http://helloworld#wsdl.interface(HelloWorld)"/>
           </service>
          <implementation.java class="test.HelloWorldImpl"/>
         </component>

   </composite>
```

Top level composite with SCA reference binding supporting WSDL interface

```
<?xml version="1.0" encoding="UTF-8"?>

    <composite xmlns="http://www.osoa.org/xmlns/sca/1.0" targetNamespace="http://mysca/samples" name="ClientComposite">

       <component name="ClientComponent">
         <implementation.java class="test.GreetingsServiceImpl"/>
         <reference name="helloWorldService" target="MyServiceComponent">
            <interface.wsdl interface="http://helloworld#wsdl.interface(HelloWorld)"/>
         </reference>
       </component>

</composite>
```

Intra composite over SCA default binding

```
<?xml version="1.0" encoding="UTF-8"?>

   <composite xmlns="http://www.osoa.org/xmlns/sca/1.0" targetNamespace="http://mysca/samples"
         name="Service1Composite">

       <component name="HWServiceComponent">
         <implementation.java class="test.HelloWorldImpl"/>
         <reference name="component2Ref" target="Component2"/>
      </component>

        <component name="Component2">
        <implementation.java class="test.Component2Impl"/>
        </component>

   </composite>
```

SCA Service with workManager specified for the service

```
<?xml version="1.0" encoding="UTF-8"?>

   <composite xmlns="http://www.osoa.org/xmlns/sca/1.0"  xmlns:wm="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
         targetNamespace="http://mysca/samples" name="Composite2">

      <component name="Component2">
        <service name="OneWayService">
          <!-- This service uses the @oneway annotation to specify this operation only has an input message
                and no output message.   -->
           <wm:workManager value="wm/scatest"/>
           <!-- This service specifies a workManager where the jndiName is wm/scatest. -->
        </service>
        <implementation.java class="test.Component2Impl"/>
        <reference name="component3" target="Component3"/>
      </component>
```

```
    <!-- component service with @oneway (non blocking operation -->
    <component name="Component3">
      <!-- By not defining the workManager, the SCADefaultWorkmanager that is created by the SCA
           runtime environment is used here. -->
      <implementation.java class="test.Component3Impl"/>
    </component>

</composite>
```

What to do next

Deploy the SCA component or application.

Configuring Java serialization for the SCA default binding

You can convert objects to a wire format, or *serialize* the objects, before transmitting them. You can serialize objects for applications that use the Service Component Architecture (SCA) default binding.

About this task

When using the default binding, objects are serialized to one of several wire formats before being sent. By default, objects are serialized to XML and sent as text over the wire. However, XML serialization occurs only with classes that are JAXB serializable. These classes require a default, no-argument constructor as well as getter and setter methods for each field.

To use non-JAXB serializable objects, you must specify a different wire format in the composite definition file. Specify the default binding element `wireFormat.javaObject` as a child element.

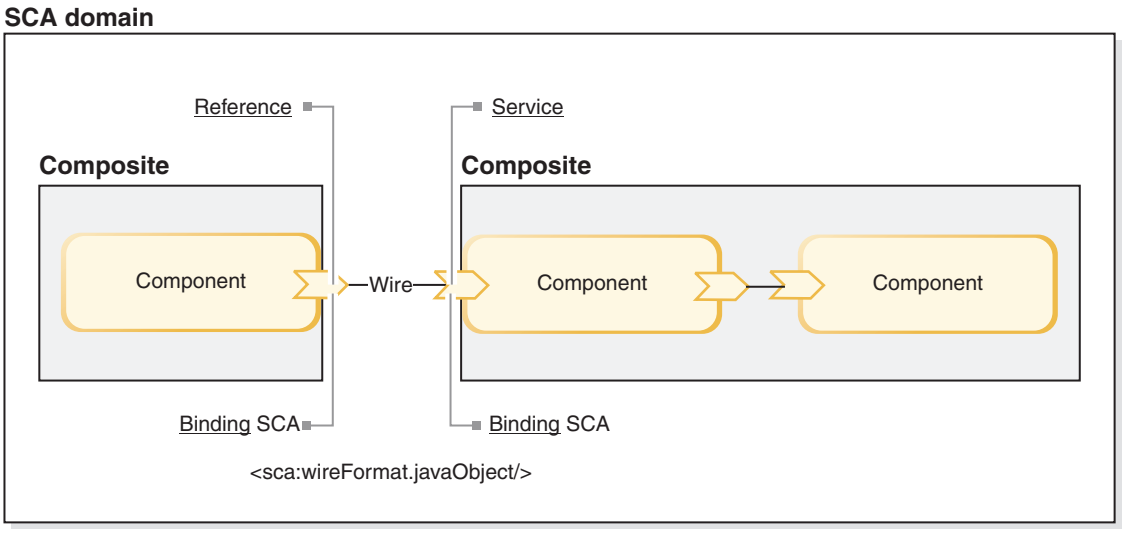

Figure 3. For non-JAXB serializable objects, use the wire format javaObject for the SCA default binding

When `wireFormat.javaObject` is used, objects use Java serialization instead of XML and travel as a stream of bytes over the wire. This enables you to use, for example, non-JAXB serializable Enterprise JavaBeans with the default binding.

Procedure

1. Open an editor on the composite definition file for your SCA application.
2. Add Java serialization in the default binding of the composite definition file.
   a. Add the product SCA namespace to the composite:

```
<composite xmlns:sca="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06">
```

b. For each service or reference `<binding.sca>` element, add a `wireFormat.javaObject` child element using that namespace:

```
<sca:wireFormat.javaObject/>
```

3. Save the changes to the composite definition file.

Results

You have configured Java serialization over the default bindings for your SCA service or reference.

Using the incorrect wire format might cause a runtime exception in your application.

Example

The following composite definition file configures Java serialization in the SCA default binding:

```
<?xml version="1.0" encoding="UTF-8"?>

<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
      targetNamespace="http://scajavaserialize"
      xmlns:sca="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
      name="sca-java-serialize-backend">

  <component name="SCAJavaSerializationBackendComponent">
    <implementation.java class="test.bindings.sca.SerializeBackendImpl"/>

    <service name="SerializeBackendService">
      <interface.java
         interface="test.bindings.sca.SerializeBackendService"
         callbackInterface="test.bindings.sca.SerializeCallback">
      <binding.sca>
         <sca:wireFormat.javaObject/>
      </binding.sca>

      <callback>
         <binding.sca>
            <sca:wireFormat.javaObject/>
         </binding.sca>
      </callback>
    </service>

  </component>

</composite>
```

What to do next

Deploy your SCA component in an application.

Using the SCA default binding to find and locate SCA services

The product supports APIs that Service Component Architecture (SCA) and non-SCA clients can use to find and invoke SCA services over the SCA default binding.

About this task

A non-SCA client can use the OASIS SCAClientFactory API to obtain a service proxy for an OASIS SCA service in the same domain (product cell). An OASIS SCA client also can use this API as an alternative to wiring a reference in the composite file.

A non-SCA client can use the product CompositeContext API to obtain a service proxy for an OSOA SCA service in the same domain. An OSOA SCA client also can use this API as an alternative to wiring a reference in the composite file.

The SCA service must be deployed, running, and accessible over the default binding, `<binding.sca>`.

Procedure

- Obtain a service proxy for an OASIS SCA service in the same domain.

  The following example shows how to use the OASIS SCAClientFactory API:

  ```
  import org.oasisopen.sca.client.SCAClientFactory
  SCAClientFactory scaClientFactory = SCAClientFactory.newInstance(URI.create("default"));
  EchoService echoService = scaClientFactory.getService(EchoService.class, "SCASimpleEchoService");
  ```

- Obtain a service proxy for an OSOA SCA service in the same domain.

  The following example shows how to use the product CompositeContext API:

  ```
  import com.ibm.websphere.sca.context.CurrentCompositeContext;
  import com.ibm.websphere.sca.context.CompositeContext;
  CompositeContext compositeContext = CurrentCompositeContext.getContext();
  EchoService echoService =
    (EchoService) compositeContext.getService(EchoService.class, "SCASimpleEchoService");
  ```

What to do next

To improve performance, the caller can cache the service proxy that is returned by `SCAClientFactory.getService()` or `CompositeContext.getContext()`. Caching `echoService` in the example can avoid calls to the service registry for subsequent requests, resulting in better performance.

Configuring the SCA web service binding

You can expose a Service Component Architecture (SCA) application as a web service by configuring an SCA web service binding.

About this task

The web service binding enables SCA applications to expose services as web services to external clients and gives SCA components access to external web services. External clients that access SCA services exposed as web services might or might not be implemented as an SCA component. You can use the web service binding element `<binding.ws>` within either a component service or a component reference definition. When this binding is used with a component service, the web service binding enables clients to access a service that is offered by a particular component as a web service. If the web service binding is used with a component reference, components in an SCA composite can consume an external web service and access it like any other SCA component.

The product supports Web Services Description Language (WSDL) Version 1.1 definitions that also conform to the WS-I Basic Profile Version 1.1 and Simple SOAP Binding Profile 1.0 standards, and use the document literal style. For OASIS-level applications only, the rpc-literal style is also supported as long as it conforms to the above WS-I profiles. All these conditions are required for support.

An SCA web service binding is a WSDL-based binding; meaning that the binding either references an existing WSDL document or enables you to specify enough information to generate a WSDL document.

You can typically use the same policy set functionality, that you use for defining qualities of service on Java EE-based web services that are running in the application server, to define quality of service definitions on SCA clients and services that use the SCA web service binding. When the instructions for administratively configuring these policy set definitions are different for SCA-based web services than they are for Java EE-based web services, then special topics and instructions are provided in this information

center. If there are no special instructions for SCA, configure the corresponding quality of service on the SCA-based web service the same way that you would configure that quality of service for a Java EE-based web service.

Note: An SCA web service binding provides support for providing and consuming services using the SOAP Version 1.1 over HTTP and SOAP V1.2 over HTTP protocols.

Note: The product does not support the following functions:

- Java API for XML-Based Web Services (JAX-WS) handlers when using a SCA web service binding
- Message Transmission Optimization Mechanism (MTOM) or SOAP with Attachments (SwA) binary message optimizations

Use an SCA web service binding without implementing JAX-WS handlers. Do not use SwA binary message optimizations or MTOM optimizations for transferring binary data between SCA clients and services that use the SCA web services binding. Instead of implementing MTOM or SwA binary message optimizations to send binary data, use the base64Binary XML Schema Definition (XSD) encoding to embed the data within the SOAP message.

Procedure

1. Configure an SCA service with an SCA web service binding.

   Depending on whether you develop your SCA service using the top-down approach starting with an existing WSDL file or you develop your SCA service using the bottom-up approach starting with existing Java code, you might or might not have a WSDL file available. Also, the WSDL file might define only a portType or it might include a port definition as well.

   - For SCA applications that are developed top-down starting from a WSDL port, you must refer to the port definition in the existing WSDL file by adding a `<binding.ws>` element as a child of your `<service>` element. An example of the syntax for this step follows:

     ```
     <binding.ws wsdlElement="<port target Namespace>#wsdl.port(<service name attr>/<port name attr>)"/>
     ```

     The location attribute of the `<address>` element for the port is ignored by the runtime environment when determining the URL at which your service is invoked.

     The following WSDL file and composite definition illustrate this scenario:

     WSDL file

     ```
     <wsdl:definitions targetNamespace="http://www.ibm.com/" xmlns:tns="http://www.ibm.com/" ...>
          ....
         <wsdl:portType name="MyPortType ">
          ....
         <wsdl:binding name="MyBinding" type="tns:MyPortType">
          ....
         <wsdl:service name="MyService">
             <wsdl:port binding="tns:MyBinding" name="MyPort">
                 <wsdlsoap:address location=""/>
             </wsdl:port>
         </wsdl:service>
     ```

     Composite definition

     ```
     <composite...>
         <component name="MyComponent">
           <implementation.java class="test.MyCompImpl"/>
             <service name="GuessAndGreetWrapped">
                 <interface.wsdl interface="http://www.ibm.com/#wsdl.interface(MyPortType)" />
                 <binding.ws wsdlElement="http:// www.ibm.com/#wsdl.port(MyService/MyPort)" />
             </service>
         </component>
          ...
     </composite>
     ```

   - For SCA applications that are developed top-down starting from a WSDL portType, you must create an empty `<binding.ws>` element as the child of your `<service>` element. The empty `<binding.ws>` element directs the runtime environment to generate a port that corresponds to your WSDL portType definition. The generated port uses a SOAP 1.1 over HTTP WSDL binding.

The following WSDL file and composite definition illustrate this scenario:

WSDL file

```
<wsdl:definitions targetNamespace="http://www.ibm.com/" xmlns:tns="http://www.ibm.com/" ...>
      ....
     <wsdl:portType name="MyPortType ">
```

Composite definition

```
<composite...>
     <component name="MyComponent">
       <implementation.java class="test.MyCompImpl"/>
         <service name="GuessAndGreetWrapped">
             <interface.wsdl interface="http://www.ibm.com/#wsdl.interface(MyPortType)" />
             <binding.ws/>
         </service>
     </component>
      ...
</composite>
```

- For SCA applications that are developed bottom-up starting from existing Java code, you must create an empty `<binding.ws>` element as the child of your `<service>` element. The empty `<binding.ws>` element directs the runtime environment to generate a WSDL portType that corresponds to your Java interface, and a port with a SOAP 1.1 over HTTP WSDL binding.

  The following example demonstrates the `<binding.ws>` element for this scenario:

```
<composite...>
     <component name="MyComponent">
       <implementation.java class="test.MyCompImpl"/>
         <service name="GuessAndGreetWrapped">
             <binding.ws/>
         </service>
     </component>
      ...
</composite>
```

2. Determine the endpoint URL and test the endpoint of your deployed SCA service.

   After you configure the SCA service with a web service binding, you can test the endpoint for your deployed SCA service. Accessing the endpoint with a web browser displays the Axis2 cover page.

   The endpoint URL is determined based on one of the following scenarios:

   - If there is no `uri` attribute on the binding, the component resembles:

     ```
     <component name="C1">
       <service name="S1">
       <binding.ws/>
     ```

     Then the endpoint is:

     `http://<host>:<port>/C1_name/S1_name`

   - If the `uri` attribute on the binding is relative, the component resembles:

     ```
     <component name="C1">
       <service name="S1">
       <inding.ws name="B1" uri="U1"/>
     ```

     Then the endpoint is:

     `http://<host>:<port>/C1/U1`

   - If the `uri` attribute on the binding is absolute, which applies to OASIS only and not to OSOA, the component resembles:

     ```
     <component name="C1">
       <service name="S1">
       <inding.ws name="B1" uri="/U1"/>
     ```

     Then the endpoint is:

     `http://<host>:<port>/U1`

   For SCA services that are configured using `wsdlElement#wsdl.service`, the ports are appended; for example:

   `http://<host>:<port>/Component_name/Service_name/Port_name`

   For OASIS, `wsdl.service` is not supported.

3. View WSDL or XSD documents for the SCA service with the web service binding.

Append the query string ?wsdl to the endpoint URL. Accessing the URL with a web browser returns the outermost WSDL. You can then view included and imported documents using relative URLs.

4. Configure an SCA reference (client) with an SCA web service binding.
   a. Configure the reference with an <interface.wsdl> element that refers to the portType of the target service. Read about developing SCA service clients to learn how to configure the reference with an <interface.wsdl>.
   b. Resolve the SCA reference to an actual endpoint of a deployed web service using one of the mechanisms provided by the SCA web service binding support.
      - When the target web service is deployed as an SCA component service in the same domain as the client component, you can resolve the reference to the target component using the @target attribute of the <reference> element for OSOA composites or the <binding.ws> element for OASIS composites. Using the @target attribute eliminates the need to know the specific URL of the deployed target service.

        For example, assume the target service is defined as follows:

        ```
        <component name="TargetComponent">
          <implementation.java .../>
          <service name="MyService">
              <interface.wsdl ... />
              <binding.ws ... />
          </service>
        </component>
        ```

        A reference in an OSOA composite can be wired to this service as follows:

        ```
        <component name="ClientComponent">
          <implementation.java .../>

            <!-- Resolution uses @target attribute on reference element. -->
            <reference name="myRef" target="TargetComponent/MyService">
               <interface.wsdl ... />

               <!-- The binding does not need endpoint-related info added. -->

               <binding.ws/>
            </reference>
        </component>
        ```

        A reference in an OASIS composite can be wired to this service as follows:

        ```
        <component name="ClientComponent">
          <implementation.java .../>

            <reference name="myRef">
               <interface.wsdl ... />

               <!-- Resolution done using the @target attribute on binding element. -->
               <binding.ws target="TargetComponent/MyService"/>
            </reference>
        </component>
        ```

        In these examples, the binding.ws element does not specify a wsdlElement attribute. The SCA run time creates a SOAP binding, WSDL service, and WSDL port on each side. If your service binding specifies a SOAP binding, either directly or indirectly using the WSDL port, your reference binding must specify a compatible SOAP binding.
      - If the target web service is not an SCA service in the same domain as the client, you must use a binding-specific endpoint resolution mechanism. You can also resolve a reference to an SCA service in the same domain by using the binding-specific mechanisms, instead of using the @target annotation.
        1) You can define the endpoint for a deployed web service in an existing WSDL file using <wsdlsoap:address>. For example:

           ```
           <wsdl:definitions targetNamespace="http://my.work/test/"
                   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
               xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/" ... >
               ...
               <wsdl:portType name="MyPortType">
               ...
               <wsdl:binding name="MyBinding" type="tns:MyPortType">
           ```

```
    ...
    <wsdl:service name="MyService">
      <wsdl:port name="MyPort" binding="tns:MyBinding">
        <wsdlsoap:address
           location="http://www.mywork.com:9080/TargetComponent/MyService "/>
     </wsdl:port>
   </wsdl:service>
</wsdl:definitions>
```

The client points to the WSDL port using a @wsdlElement attribute on the <binding.ws> element using the following syntax:

```
<port target Namespace>#wsdl.port(service_name_attribute/port_name_attribute)"/>
```

For example:

```
<component name="ClientComponent">
  <implementation.java .../>
    <reference name="myRef">
       <interface.wsdl ... />
       <binding.ws wsdlElement="http://my.work/test/#wsdl.port(MyService/MyPort)"/>
    </reference>
</component>
```

2) If the endpoint is not present in the WSDL for the service, there are several ways to specify the endpoint using the reference. In the following WSDL file, the endpoint (wsdlsoap:*address*) is not specified.

```
<wsdl:definitions targetNamespace="http://my.work/test/"
        xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
    xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"   ... >
  ...
  <wsdl:portType name="MyPortType">
  ...
  <wsdl:binding name="MyBinding" type="tns:MyPortType">
  ...
    <wsdl:service name="MyService">
      <wsdl:port name="MyPort" binding="tns:MyBinding">
      ...
        <!-- In this case, the endpoint is not specified. -->
        <wsdlsoap:address location=""/>
     </wsdl:port>
   </wsdl:service>
</wsdl:definitions>
```

For OSOA, you can add the endpoint to the composite definition. Add the @uri attribute to the <binding.ws> element to specify the endpoint. For example:

```
<!-- An OSOA example composite definition. -->
<component name="ClientComponent">
  <implementation.java .../>
    <reference name="myRef">
         <interface.wsdl ... />
         <binding.ws wsdlElement="http://my.work/test/#wsdl.port(MyService/MyPort)"
            uri="http://www.mywork.com:9080/TargetComponent/MyService" />
    </reference>
</component>
```

For OASIS based references, one approach is to add a WSDL binding to the reference. Then add @uri to the component <binding.ws> element.

```
<!-- An OASIS example composite definition. -->
<component name="ClientComponent">
  <implementation.java .../>
    <reference name="myRef">
         <interface.wsdl interface="http://my.work/test/#wsdl.interface(MyPortType)"/>
         <binding.ws uri="http://www.mywork.com:9080/TargetComponent/MyService"
                     wsdlElement="http://my.work/test/#wsdl.binding(MyBinding)" />
    </reference>
</component>
```

5. Optional: If your service or reference interface is bidirectional such that a callback is defined, you must also configure the web service binding on the callback.
   - Configure callback for your SCA web services binding using the WSDL port.

     Configuring callback for your SCA web services binding is similar to configuring an SCA service with the SCA web services binding; however, you add a second service, the callback. When you configure an SCA service with the SCA web services binding, you define a WSDL port, either explicitly by pointing directly to a WSDL port definition, or implicitly by giving the runtime enough information to calculate a WSDL port. Similarly, you must also define a WSDL port for the callback.

A difference for the callback is that the runtime environment defines the WSDL port that is used for the callback because the runtime environment must keep this port tightly coupled to the forward call. Therefore, the most you can do when developing your SCA application using the top-down approach and defining a callback for this service, is to point to a WSDL binding. For example:

```
<!-- Configuring a service with callback with web service binding -->
 <component name="HelloWorldServiceComponent">
   <implementation.java class="..." />
   <service name="HelloWorldService">
     <interface.wsdl interface="http://www.ibm.com/sca/#wsdl.interface(HelloWorld)"
                     callbackInterface=" http://www.ibm.com/sca/#wsdl.interface(HelloWorldCallback)"/>
     <binding.ws wsdlElement="http://www.ibm.com/sca/#wsdl.port(HelloWorldService/HelloWorldSoapPort)"/>
       <callback>
         <binding.ws wsdlElement="http://www.ibm.com/sca/#wsdl.binding(HelloWorldCallbackSoapBinding)"/>
       </callback>
    </service>
 </component>
```

The following example shows a configuration of a client component with reference to this service with callback defined. The reference and service configuration each share the same view of which direction is the forward direction and which is the callback direction.

```
<!-- Configuring a reference with callback with web service binding. -->
 <component name="HelloWorldClientComponent">
   <implementation.java class="..." />
   <reference name="helloWorldRef">
     <interface.wsdl interface="http://www.ibm.com/sca/#wsdl.interface(HelloWorld)"
                     callbackInterface=" http://www.ibm.com/sca/#wsdl.interface(HelloWorldCallback)"/>
     <binding.ws wsdlElement="http://www.ibm.com/sca/#wsdl.port(HelloWorldService/HelloWorldSoapPort)"/>
       <callback>
         <binding.ws wsdlElement="http://www.ibm.com/sca/#wsdl.binding(HelloWorldCallbackSoapBinding)" />
       </callback>
   </reference>
 </component>
```

- Configure callback for your SCA web service binding using the WSDL portType.

  Similar to the scenario of configuring a service with a web service binding when starting with a WSDL port, you also configure an empty <binding.ws> element to configure callback using the WSDL portType. The following composite definition example illustrates the scenario when starting with two WSDL portType definitions that has such that one interface uses a forward direction and the other interface uses callback:

```
<!-- Configuring a service with callback with web service binding -->
 <component name="HelloWorldServiceComponent">
   <implementation.java class="..." />
   <service name="HelloWorldService">
     <interface.wsdl interface="http://www.ibm.com/sca/#wsdl.interface(HelloWorld)"
                     callbackInterface=" http://www.ibm.com/sca/#wsdl.interface(HelloWorldCallback)"/>
     <binding.ws/>
        <callback>
           <binding.ws/>
        </callback>
   </service>
 </component>
```

```
<!-- Configuring a reference with callback with web service binding -->
 <component name="HelloWorldClientComponent">
   <implementation.java class="..." />
   <reference name="helloWorldRef">
     <interface.wsdl interface="http://www.ibm.com/sca/#wsdl.interface(HelloWorld)"
                     callbackInterface=" http://www.ibm.com/sca/#wsdl.interface(HelloWorldCallback)"/>
     <binding.ws/>
       <callback>
         <binding.ws/>
       </callback>
    </reference>
 </component>
```

- Configure callback for your SCA web service binding using the Java interface.

  For the bottom-up case starting with a Java interface, the composite definition is identical to the WSDL port and portType scenarios, except that you must replace the <interface.wsdl> elements with the <interface.java> element. For example:

```
<interface.java interface="helloworld.HelloWorldService"
        callbackInterface="helloworld.HelloWorldCallback"/>
```

- (Optional: OASIS only) Configure your service to use SOAP 1.1 or 1.2.

  You can configure your SCA web service to require a particular SOAP version by providing an intent. For example:

  ```
  <binding.ws requires="sca:SOAP.v1_2"/>
  ```

  Supported intents are `sca:SOAP.v1_1` and `sca:SOAP.v1_2`.

Results

You have a configured SCA web service binding service or reference.

There are additional ways for the web service binding to generate a WSDL port that are not described in this topic. These additional methods rely on WSDL generation at run time. This can cause problems if the generated WSDL does not match the original WSDL obtained from a service provider.

You can avoid problems by ensuring that client package references the original WSDL obtained from a web service provider. If you use the shortcut of omitting a client-side reference to the WSDL, be sure to do so only in the case when you are sure the WSDL port that is generated for the client is identical to the WSDL port of the deployed service because the service port is generated using the same algorithm.

For an example that is not problematic, suppose you write a service using the bottom-up style, starting from a Java interface, and deploy the service with a `<binding.ws>` element with no attributes. This directs the runtime environment to generate the WSDL port for this service. Also suppose an SCA client is developed with access to the original Java classes used to write the service implementation. This SCA client is used to test the SCA service using a client-side reference with web service binding. You can configure this reference without any knowledge of the service WSDL. In this case, the reference interface is the original Java interface of the service, and you can resolve the reference using the `<reference>` @target mechanism. See the resolving SCA references documentation for more information about using the @target attribute to resolve an SCA reference. Using this approach, there is no WSDL to obtain or refer to in constructing the client. This works because the product runtime environment maps the service-side Java to WSDL in an identical manner as it maps the client-side Java to WSDL.

In contrast, the following scenario is problematic. Suppose that you write an SCA client with a web service binding reference to a web service that is hosted on a platform other than the product. It might seem reasonable to generate your Java client from the service provider, and then ignore the WSDL from that point on, avoiding the additional syntax in your client-side composite definition. To do this, you use the `<binding.ws>` element @uri attribute to specify the endpoint URL where the service is hosted. This scenario is problematic because it forces the runtime environment to generate a WSDL port for the client which might result in subtle mismatches between the WSDL generated for the client side and the actual WSDL port description of the deployed web service.

What to do next

Deploy your composite that has the SCA web services binding service or reference.

Note: If the composite uses a bidirectional interface as an SCA service interface and a NullPointerException results when you add your SCA module or application to a business-level application (for example, using the wsadmin AdminTask.addCompUnit command), you might need to add the SCA @Callback annotation to the forward Java interface.

A NullPointerException can occur whether you are using a top-down development style (starting from WSDL or XSD) or a bottom-up style (starting from Java). With the top-down style, a composite definition typically includes a bidirectional interface definition such as the following:

```
<interface.wsdl interface="http://forward.my/intf#wsdl.interface(ForwardIntf)"
    callbackInterface="http://callback.my/intf#wsdl.interface(CallbackIntf)"/>
```

With the bottom-up style, a composite definition typically includes a bidirectional interface definition such as the following:

```
<interface.java interface="my.forward.intf.ForwardIntf"
    callbackInterface="my.callback.intf.CallbackIntf"/>
```

The NullPointerException can occur if the forward Java interface is not annotated with @Callback, or more specifically @org.osoa.sca.annotations.Callback. In the top-down example, the forward Java interface is the class generated from portType, `http://forward.my/intf/ForwardIntf` using the wsimport tool or `my.forward.intf.ForwardIntf` if the default options are used. In the bottom-up example, the forward Java interface is the class `my.forward.intf.ForwardIntf`.

To fix the NullPointerException problem, add the @Callback annotation to the forward Java interface and recompile. The @Callback annotation is a class-level annotation with a single argument, the callback interface Class object; for example:

```
...
import org.osoa.sca.annotations.Callback
@Callback(my.callback.intf.CallbackIntf.class)
public interface ForwardIntf  {
...
```

If you are using the recommended top-down development style, the forward Java interface is a generated class. It is generated from the WSDL portType using the wsimport tool. Use the `-s` or `-keep` option so that wsimport generates the Java source files, and then add the @Callback annotation manually to the generated class and recompile.

Configuring web service binding custom endpoints to support a proxy server

You can configure custom service endpoints for Service Component Architecture (SCA) web service bindings that are accessed by Hypertext Transfer Protocol (HTTP).

Before you begin

Before you begin this task, install your SCA application.

About this task

When a service is exposed over the SCA web service binding, the service endpoint is specific to the server in which the service is hosted. Clients use this endpoint URI to access the service. In some cases, you may want clients to indirectly reference the service by using a proxy server as the service endpoint. For example, a proxy server is required to implement clustered web service binding endpoints. To enable clients to use a proxied endpoints, there are two ways to do this:

- If your endpoints are specified in the SCA contributions composite definition or WSDL document location attribute, you must specify the proxy server endpoint instead of the WebSphere server specific endpoint.
- If your client resolves the endpoint by using the `target` attribute in your client composite definition, use the administrative console to configure the custom endpoints for SCA composites that are accessed by the Hypertext Transfer Protocol (HTTP) protocol. This approach is the most flexible for SCA clients within the same domain as their service providers. When using the `target` attribute, SCA references can resolve the service endpoints without the client specifying endpoints in the composite definition or WSDL document.

Procedure

1. In the administrative console, click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name*** > **Provide HTTP endpoint URL information**.
2. Select the HTTP endpoint URL prefix.

   When entering custom endpoints, specify one and only one endpoint URL prefix each for the HTTP and HTTPS protocols.

Results

You have configured web service bindings custom endpoints.

What to do next

You can configure the bindings to do transport layer authentication.

Configuring the SCA web service binding to transport SOAP messages over JMS

You can configure a Service Component Architecture (SCA) web service binding to transport SOAP messages over Java Message Service (JMS) protocol.

Before you begin

For information about web service bindings, read “Configuring the SCA web service binding” on page 747.

About this task

Web services technology plays an important role in most service-oriented architecture (SOA) solutions relevant today, including SCA. The web service binding type enables SCA applications to expose services as web services to external clients and gives SCA components access to external web services. Using JMS as a transport for web services provides a reliable asynchronous messaging transport for request and response.

This topic describes how to configure a web service binding to flow SOAP messages over JMS.

Note: The web service binding supports Web Services Description Language (WSDL) Version 1.1. Further, the web service binding supports industry standard SOAP/JMS protocol and IBM proprietary SOAP over JMS protocol.

Procedure

1. Identify and configure JMS resources using the administrative console or the wsadmin scripting tool.

   Refer to topics on creating JMS resources based on different JMS providers.

   For example, to identify and configure JMS resources based on the default JMS provider, do the following:

   a. Create a service integration bus and associate a bus member.
   b. Create destinations for the request and response for the service integration bus.
   c. Create destinations for the request and response under JMS resources.
   d. Create an activation specification that is associated with a request destination.
   e. Create connection factories to process the request and to send the response.
2. Configure an SCA service with an SCA web service binding to transport SOAP messages over JMS.

   Configure a web service binding as described in “Configuring the SCA web service binding” on page 747 with three additional attributes under the `<binding.ws>` element to use a JMS transport:

   - Web service binding endpoint `uri` attribute
   - `@activationSpec` attribute
   - Response `@responseConnectionFactory` attribute

   a. Open an editor on the SCA composite definition file that specifies an SCA service with a web service binding.
   b. In the composite definition file, configure the web service binding endpoint `uri` attribute.

Specify the uniform resource identifier (URI) in SOAP over JMS endpoint uniform resource locator (URL) syntax. A JMS endpoint URL accesses web services with a JMS transport. The URL specifies the JMS destinations, connection factory, and port component name for the web service request.

Specify the URI in syntax that supports either of the following protocols:

- Industry standard SOAP/JMS protocol (recommended)
- IBM proprietary SOAP over JMS protocol (deprecated)

URI based on industry standard SOAP over JMS protocol

The syntax for a URI based on industry standard SOAP over JMS protocol is as follows:

```
uri=jms:jndi:<destination_JNDI_name>?<property>=<value>&<property>=<value>& ...
```

The URL consists of the `jms:` transport type, followed by the `jndi:` variant type, followed by the Java Naming and Directory Interface (JNDI) name of the destination queue or topic, followed by the query string containing a list of property and value pairs that specify JMS endpoint information. The `jndi:` variant means that JNDI is used to locate object names in the endpoint URL string.

For *property*, you can specify URL properties such as the following:

Table 85. JMS endpoint URL properties typically used for a URI based on industry standard SOAP over JMS protocol. The properties are jndiConnectionFactoryName, targetService, and replyToName.

Property name	Description
jndiConnectionFactoryName	Specifies the JNDI name of the connection factory that is used by the client run time to establish a connection to the JMS messaging engine. jndiConnectionFactoryName is optional for the service `uri` attribute.
targetService	Specifies the target service to which to deliver the message. For a forward call from a service to a reference, targetService has the format `serviceComponentName/serviceName`. In a callback `uri`, targetService has the format `referenceComponentName/referenceName`.
replyToName	Specifies the JNDI name of the JMS destination to which the response message is sent. replyToName is a JMS-related property that enables the client to use a previously defined, permanent queue rather than a temporary queue, for receiving replies.

For a complete list of properties supported, refer to the topic on JMS endpoint URL syntax.

A URI based on industry standard SOAP over JMS protocol resembles the following:

```
uri="jms:jndi:jms/MyBankAccountService_Request?jndiConnectionFactoryName
 =jms/MyBankAccountService_CF&amp;replyToName=jms/MyBankAccountService_Response
 &amp;targetService=AccountServiceComponent/AccountService"
```

URI based on IBM proprietary SOAP over JMS protocol

Attention: IBM proprietary SOAP over JMS protocol is deprecated.

The syntax for a URI based on IBM proprietary SOAP over JMS protocol is as follows:

```
uri=jms:/[queue|topic]?<property>=<value>&<property>=<value>& ...
```

The URL consists of the `jms:` transport type, followed by either `/queue` or `/topic` to specify the JMS destination type, followed by the query string containing a list of property and value pairs that specify the JMS endpoint information.

For *property*, you can specify URL properties such as the following:

Table 86. JMS endpoint URL properties typically used for a URI based on IBM proprietary SOAP over JMS protocol. The properties are destination, connectionFactory, replyToDestination, and targetService.

Property name	Description
destination	Specifies the JNDI name of the destination queue or topic.
connectionFactory	Specifies the JNDI name of the connection factory. connectionFactory is optional for the service `uri` attribute.
replyToDestination	Specifies the JNDI name to which a response is sent. replyToDestination is optional for the service `uri` attribute.
targetService	Specifies the target service to which to deliver the message. For a forward call from a service to a reference, targetService has the format `serviceComponentName/serviceName`. In a callback `uri`, targetService has the format `referenceComponentName/referenceName`.

For a complete list of properties supported, refer to the IBM proprietary SOAP over JMS protocol topic.

A URI based on IBM proprietary SOAP over JMS protocol resembles the following:

```
uri="jms:/queue?destination=jms/MyBankAccountService_Request&amp;connectionFactory
 =jms/MyBankAccountService_CF&amp;replyToDestination=jms/MyBankAccountService_Response
 &amp;targetService=AccountServiceComponent/AccountService"
```

c. In the composite definition file, configure an `@activationSpec` attribute under the `<binding.ws>` element.

   The attribute identifies the activation specification that the service uses to connect to the JMS destination and to process incoming request messages.

   For the destination associated with this activation specification, specify the request destination defined in the web service binding endpoint `uri`; for example:

   ```
   soapjms:activationSpec="jms/AccountActivationSpec"
   ```

   Qualify the OSOA SCA composite by setting `xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"`.

   Qualify the OASIS SCA composite by setting `xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.1"`.

d. In the composite definition file, configure a response `@responseConnectionFactory` attribute under the `<binding.ws>` element to send a response back to the client when request-response messaging pattern is used.

   For example:

   ```
   soapjms:responseConnectionFactory="jms/Account_Response_CF"
   ```

   Qualify the OSOA SCA composite by setting `xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"`.

   Qualify the OASIS SCA composite by setting `xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.1"`.

After these updates are made to the `<binding.ws>` element, the OSOA SCA composite definition file resembles:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
 xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
 targetNamespace="http://www.ibm.com/samples/sca/mybank"
 name="MyBank">
  <component name="AccountServiceComponent">
    <implementation.java
      class="samples.mybank.AccountServiceImpl"/>
    <service name="AccountService">
      <interface.wsdl
      interface=
          "http://www.mybank.com/account#wsdl.interface(AccountService)" />
      <binding.ws
          wsdlElement=
            "http://www.mybank.com/account#wsdl.port(AccountService/AccountServicePort)"

          uri="jms:jndi:jms/MyBankAccountService_Request?jndiConnectionFactoryName
              =jms/MyBankAccountService_CF&amp;replyToName=jms/MyBankAccountService_Response
              &amp;targetService=AccountServiceComponent/AccountService"

          soapjms:activationSpec="jms/MyBankAccountService_AS"

          soapjms:responseConnectionFactory="jms/MyBankAccountService_CF"/>
    </service>
  </component>
</composite>
```

The OASIS SCA composite definition file is similar except for the namespace prefixes, which are:

```
xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912"
xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.1"
```

3. Configure an SCA reference (client) with an SCA web service binding to transport SOAP message over JMS.

   Configure a web service binding with a web service binding endpoint `uri` attribute specific to JMS transport under the `<binding.ws>` element.

a. Open an editor on the SCA composite definition file that specifies an SCA reference with a web service binding.
b. In the composite definition file, configure the web service binding endpoint `uri`.

   Specify the URI in SOAP over JMS endpoint URL syntax. The URL specifies the JMS destinations, connection factory, and port component name for the web service request. A JMS endpoint URL can be based on industry standard SOAP/JMS protocol (recommended) or on IBM proprietary SOAP over JMS protocol. For a description of the URI syntax, see step 2(b). In SOAP over JMS support for web service bindings, you must use the `<binding.ws>` `uri` attribute for endpoint resolution to the target component; you cannot use the SCA reference `@target` attribute.

   The URI resembles the following:

```
uri="jms:jndi:jms/MyBankAccountService_Request?jndiConnectionFactoryName
 =jms/MyBankAccountService_CF&amp;replyToName=jms/MyBankAccountService_Response
 &amp;targetService=AccountServiceComponent/AccountService"
```

After you define the URI in the `<binding.ws>` element, the OSOA SCA composite definition file resembles:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
targetNamespace="http://www.ibm.com/samples/sca/mybank"
name="MyBankClient">
  <component name="AccountSummaryService">
    <implementation.java
      class="samples.mybank.AccountSummaryServiceImpl"/>
    <reference name="accountService">
    <interface.wsdl
      interface=
        "http://www.mybank.com/account#wsdl.interface(AccountService)" />
    <binding.ws
      wsdlElement=
        "http://www.mybank.com/account#wsdl.port(AccountService/AccountServicePort)"

       uri="jms:jndi:jms/MyBankAccountService_Request?jndiConnectionFactoryName
            =jms/MyBankAccountService_CF&amp;replyToName=jms/MyBankAccountService_Response
            &amp;targetService=AccountServiceComponent/AccountService"/>
    </reference>
  </component>
</composite>
```

In an OASIS SCA composite definition file, the binding element cannot include both the `uri` and `wsdlElement` attributes. You must use one or the other. If you use `wsdlElement`, the WSDL port definition in the WSDL file specifies the URI as shown in the following example:

```
<wsdl:service name="AccountService">
  <wsdl:port binding="account:AccountServiceSOAP" name="AccountServicePort">
    <soap:address
      location="jms:jndi:jms/MyBankAccountService_Request?jndiConnectionFactoryName
        =jms/MyBankAccountService_CF&amp;replyToName=jms/MyBankAccountService_Response
        &amp;targetService=AccountServiceComponent/AccountService"/>
  </wsdl:port>
</wsdl:service>
```

Results

You have a configured an SCA web service binding service or reference.

Example

Configuring a request-response Message Exchange Pattern for SOAP over JMS

This example describes a `<binding.ws>` element in the composite definition file for a request-response message exchange pattern from an SCA component reference to an SCA component service.

The following example shows an OSOA SCA component with a reference binding:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
           xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
           targetNamespace="http://www.ibm.com/samples/sca/mybank" name="MyBankClient">
  <component name="AccountSummaryService">
    <implementation.java class="samples.mybank.AccountSummaryServiceImpl"/>
    <reference name="accountService">
      <interface.wsdl interface="http://www.mybank.com/account#wsdl.interface(AccountService)"/>
      <binding.ws
        wsdlElement="http://www.mybank.com/account#wsdl.port(AccountService/AccountServicePort)"
        uri="jms:jndi:jms/MyBankAccountService_Request?jndiConnectionFactoryName
          =jms/MyBankAccountService_CF&amp;replyToName=jms/MyBankAccountService_Response
          &amp;targetService=AccountServiceComponent/AccountService"/>
    </reference>
  </component>
</composite>
```

The following example shows an OSOA SCA component with a service binding:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
           xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
           targetNamespace="http://www.ibm.com/samples/sca/mybank" name="MyBank">
  <component name="AccountServiceComponent">
    <implementation.java class="samples.mybank.AccountServiceImpl"/>
    <service name="AccountService">
      <interface.wsdl interface="http://www.mybank.com/account#wsdl.interface(AccountService)"/>
        <binding.ws
          wsdlElement="http://www.mybank.com/account#wsdl.port(AccountService/AccountServicePort)"
          uri="jms:jndi:jms/MyBankAccountService_Request?jndiConnectionFactoryName
            =jms/MyBankAccountService_CF&amp;replyToName=jms/MyBankAccountService_Response
            &amp;targetService=AccountServiceComponent/AccountService"
          soapjms:activationSpec="jms/MyBankAccountService_AS"
          soapjms:responseConnectionFactory="jms/MyBankAccountService_CF"/>
    </service>
  </component>
</composite>
```

You can use these composite definition examples for @OneWay Message Exchange Pattern. When using @OneWay, the reference binding URI does not need to specify `replyToName` because there is no reply for the @OneWay call.

Configuring an SCA callback for SOAP over JMS

This example describes a `<binding.ws>` element in the composite definition file for a callback message exchange pattern between an SCA component reference and an SCA component service.

The following example shows an OSOA SCA component with a reference binding:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
           xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
           targetNamespace="http://www.ibm.com/samples/sca/mybank" name="MyBankClient">
  <component name="AccountSummaryService">
    <implementation.java class="samples.mybank.AccountSummaryServiceImpl"/>
    <reference name="accountService">
      <interface.wsdl
         interface="http://www.mybank.com/account#wsdl.interface(AccountService)"
         callbackInterface="http://www.mybank.com/account#wsdl.interface(AccountServiceCallback)"/>
      <binding.ws
         wsdlElement="http://www.mybank.com/account#wsdl.port(AccountService/AccountServicePort)"
         uri="jms:jndi:jms/MyBankAccountService_Request?jndiConnectionFactoryName
            =jms/MyBankAccountService_CF&amp;replyToName=jms/MyBankAccountService_Response&amp;
            targetService=AccountServiceComponent/AccountService"/>
        <callback>
          <binding.ws
             wsdlElement="http://www.mybank.com/account#wsdl.binding(AccountServiceCallback)"
             uri="jms:jndi:jms/MyBankAccountService_Callback?jndiConnectionFactoryName
              =jms/MyBankAccountService_CF&amp;replyToName=jms/MyBankAccountService_Response&amp;
```

```
            targetService=AccountServiceComponent/AccountService"
           soapjms:activationSpec="jms/$MyBankAccountService_Callback_AS"
           soapjms:responseConnectionFactory="jms/MyBankAccountService_CF"/>
        </callback>
    </reference>
  </component>
</composite>
```

For the OASIS SCA composite, the `soapjms` namespace is:

```
xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.1"
```

`targetService` is the target service to which a message is delivered. In a forward call from a service to a reference, specify the targetService in the format *serviceComponentName/serviceName*. In the callback URI, specify the targetService in the format *referenceComponentName/referenceName*.

The callback binding on the reference becomes an SCA service binding for the callback call. Hence activationSpec and responseConnectionFactory must be defined.

The following example shows an OSOA SCA component with a service binding:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
           xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
           targetNamespace="http://www.ibm.com/samples/sca/mybank" name="MyBank">
  <component name="AccountServiceComponent">
    <implementation.java class="samples.mybank.AccountServiceImpl"/>
    <service name="AccountService">
      <interface.wsdl interface="http://www.mybank.com/account#wsdl.interface(AccountService)"
           callbackInterface="http://www.mybank.com/account#wsdl.interface(AccountServiceCallback)"/>
        <binding.ws
           wsdlElement="http://www.mybank.com/account#wsdl.port(AccountService/AccountServicePort)"
           uri="jms:jndi:jms/MyBankAccountService_Request?jndiConnectionFactoryName
            =jms/MyBankAccountService_CF&amp;replyToName=jms/MyBankAccountService_Response&amp;
            targetService=AccountServiceComponent/AccountService"
           soapjms:activationSpec="jms/MyBankAccountService_AS"
           soapjms:responseConnectionFactory="jms/MyBankAccountService_CF" />
          <callback>
            <binding.ws
               wsdlElement="http://www.mybank.com/account#wsdl.binding(AccountServiceCallback)"
               uri="jms:jndi:jms/MyBankAccountService_Callback?jndiConnectionFactoryName
                =jms/MyBankAccountService_CF&amp;replyToName=jms/MyBankAccountService_Response&amp;
                targetService=AccountServiceComponent/AccountService" />
          </callback>
    </service>
  </component>
</composite>
```

For the OASIS SCA composite, the `soapjms` namespace is:

```
xmlns:soapjms="http://www.ibm.com/xmlns/prod/websphere/sca/1.1"
```

The service binding callback element does not need to specify a JMS endpoint URI because the callback URI is derived from the reference binding.

The callback binding on the service becomes a SCA reference binding for the callback call from the service back to the reference. Hence activationSpec and responseConnectionFactory need not be defined.

In some examples, the `uri` value is shown on multiple lines for publication. In your composite definition, place the `uri` value on one line.

What to do next

Deploy the SCA composite in an application and test the flow of messages over the web service binding.

Configuring EJB bindings in SCA applications

Use this task to learn how to use Enterprise JavaBeans (EJB) bindings in SCA applications.

Support is provided for EJB bindings in 2.x and 3.x-style beans, for service and reference.

The EJB bindings do not support `interface.wsdl` files.

The following is an example of an composite definition that has a service exposed over an EJB 3.x binding:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0" targetNamespace="http://neworder/sca/jdbc"
name="NewOrderComposite">

<component name="NewOrderEJB3ServiceComponent">
<implementation.java class="neworder.sca.jdbc.NewOrderServiceImpl" requires="managedTransaction.local"/>
<service name="NewOrderService" requires="suspendsTransaction">
<interface.java interface="neworder.sca.jdbc.NewOrderService"/>
<binding.ejb ejb-version="EJB3"/>
</service>
</component>
</composite>
```

A client that wants to invoke the resultant enterprise bean would treat it like any other enterprise bean and not like a regular SCA service. CompositeContext.getService is not supported for a non-SCA binding, therefore, a getService() on the CompositeContext would not work here. The following is the client code for the previous example:

```
InitialContext ctxt = new InitialContext();
  Object remoteObj = ctxt.lookup("ejb/sca/ejbbinding/NewOrderEJB3ServiceComponent/NewOrderService#neworder.sca.jdbc.NewOrderServiceRemote");
  NewOrderServiceRemote newOrderRemote = (NewOrderServiceRemote) PortableRemoteObject.narrow(remoteObj, NewOrderServiceRemote.class);
```

The following is an example of an composite definition that contains references to both EJB 2.x and EJB 3.x bindings:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
targetNamespace="http://erww.workload" name="ConvertComposite">

<component name="ConvertInputOutputServiceComponent">
<implementation.java class="convert.inputoutput.sca.ConvertInputOutputServiceImpl"

<reference name="priceQuoteSessionReference">
<interface.java interface="priceQuoteSession.PriceQuoteSession"/>
<binding.ejb uri="corbaname:iiop:localhost:2809/NameServiceServerRoot#ejb/session/PriceQuoteSessionFacadeBean"/>
</reference>
</component>
</composite>
```

Different binding.ejb attributes can be used for service side EJB bindings or reference side EJB bindings. The following information explains how the default value is calculated for each side:

Service side

The service side EJB binding applies only to Java archive (JAR)-packaged SCA applications.

EJB 2.0-level beans

URI is the JNDI name for the home; it can be calculated with the default short name in the following form:

`/sca/ejbbinding/`*`component_name`*`/`*`service_name`*

Therefore, the URI can be calculated as:

`corbaname:iiop:localhost:2812/NameServiceServerRoot#ejb/sca/ejbbinding/`*`component_name`*`/`*`service_name`*

You can use it to look up home.

EJB 3.x-level beans

The URI contains the component-id, therefore, it is calculated the same as the EJB 2.0 beans as follows:

```
sca/ejbbinding/component_name/service_name
```

The URI can be calculated as:

```
corbaname:iiop:localhost:2812/NameServiceServerRoot#ejb/sca/ejbbinding/component_name/service_name#package.qualified.interface of
SCA Java interface with prefix of Remote or Local to the class name
```

You can use it directly to get the business interface.

The following code example displays as if it were a session bean:

```
<session name="ServiceNameBean" component-id="sca/ejbbinding/component_name/service_name"/>
```

When an SCA service is exposed through an EJB service binding, the service is exposed through an enterprise bean. During deployment, the SCA runtime generates a session bean for the service exposed through the EJB binding. The caller of the composite service can invoke this service by accessing the generated enterprise bean as if they are invoking any enterprise bean.

The generated enterprise bean for the composite service is in the *profile_root*/installedApps/*cell_name*/*sca.composite.nameApp.ear*/ directory. Callers need to include the client required classes, such as remote or home, of the generated bean in the classpath or bundle the classes in the JAR file. In addition, if the caller application is running on a non-WebSphere application server, a "Bare" Java Standard Edition (SE), or a version of WebSphere Application Server previous to version 7.0 without the Feature Pack for EJB 3.0, then you must run the **createEJBStubs** command for the generated EJB module to generate client-side stubs and include the generated subs at the client application. The **createEJBStubs** command is under the *profile_root*/installedApps/*cell_name*/*sca.composite.nameApp.ear*/ directory. See the topic on the create stubs command.

Reference side

The reference side EJB binding applies to both JAR-packaged applications and web application archive (WAR)-packaged applications, if not otherwise stated.

- The URI is used to lookup either the EJB 2.x home or EJB 3.x business interface. Follow the naming convention of the Java Enterprise Edition (JEE) specification if you are using an existing JEE EJB module. If you use an SCA service with the binding.ejb attribute, use the value mentioned above. For more information about the EJB 3.x JNDI name, see the topic EJB 3.x bindings overview.
- homeInterface: Not used
- ejb-link-name: Only applies to WAR-packaged SCA applications. When URI is not defined, use it to look up an EJB module that is defined in the same enterprise archive (EAR) as the WAR.
- session-type: default value "stateless"
- ejb-version: default value "EJB2"

Attention: A lookup issue for EJB 3.x reference bindings might occur when the URI follows the corbaname:iiop:host:port/NameServiceServerRoot##*ejb3_binding_longform* pattern This problem exists only for EJB 3.x reference bindings. When the EJB 3.x reference binding URI follows the corbaname:iiop:host:port/NameServiceServerRoot##*ejb3_binding_longform* pattern, where *ejb_binding_longform* is ejb/<component-id#<package.qualified.interface>, and if more than one enterprise bean that is implementing the same interface is deployed on that server, lookup may not be directed to the correct EJB with corresponding component ID.

An example of a URI where this problem can occur is as follows:

```
uri="corbaname:iiop:host:port/NameServiceServerRoot#ejb/EJB3CounterSample/EJB3Beans.jar
/StatelessCounterBean#com.ibm.websphere.ejb3sample.counter.RemoteCounter
```

There are two enterprise beans implementing the com.ibm.websphere.ejb3sample.counter.RemoteCounter interface. To avoid this issue:

- Use a URI that does not start with "corbaname:"
- Use a binding name in the URI that is an EJB binding short form, for example, corbaname:iiop:host:port/NameServiceServerRoot#<package.qualified.interface>.
- Use a binding name in the URI that is a unique user-defined binding name.
- Ensure that the two enterprise beans that are deployed on the server do not implement the same interface.
- Ensure that the EJB binding URI is pointing to an EJB 2.0 bean.

To resolve this problem, follow these guidelines:

- If the EJB reference binding is accessing an enterprise bean that is located in the same cell, the URI should not start with "corbaname:."
- For same cell lookup, the URI pattern should be one of the following.

  ```
  uri="ejb/EJB3CounterSample/EJB3Beans.jar/StatelessCounterBean#com.ibm.websphere.ejb3sample.counter.RemoteCounter"
  ```

  or

  ```
  uri="cell/clusters/cluster_name/ejb/EJB3CounterSample/EJB3Beans.jar
  /StatelessCounterBean#com.ibm.websphere.ejb3sample.counter.RemoteCounter"
  ```

  or

  ```
  uri="cell/nodes/node_name/servers/server_name//ejb/EJB3CounterSample/EJB3Beans.jar
  /StatelessCounterBean#com.ibm.websphere.ejb3sample.counter.RemoteCounter"
  ```
- Even in cross cell access, the recommended method is to create a namespace binding for the enterprise bean that is accessed by the EJB reference binding. After the namespace binding is created, use the namespace binding in the URI of the EJB reference binding as uri="cell/persistent/*name_in_namespace_binding*".

| Different patterns of the SCA EJB reference binding URI are based on the user setup and configurations.
| If the SCA EJB reference binding is accessing a stateless session bean on the same server, the EJB
| reference binding URI can be designated as the JNDI name, uri="ejb/com/app/resumebank/
| ResumeBankHome". If the SCA EJB reference binding is referencing another SCA service with an EJB
| binding in the same server, the URI can be designated as the JNDI name, uri="ejb/com/app/resumebank/
| ResumeBankHome".

If the EJB reference binding is accessing a stateless session bean that is deployed in the same cell, the URI can be based on cluster/node/server setup, for example:

```
uri="cell/clusters/cluster2/ejb/com/app/resumebank/ResumeBankHome"
uri="cell/nodes/node_name/servers/server_name/ejb/com/app/resumebank/ResumeBankHome"
```

If the EJB reference binding is accessing a stateless session bean on a different cell (cross cell) or a mixed cell, you need to create a namespace binding, either an enterprise bean or Corba type, in the administrative console and use the name in namespace binding in EJB reference binding URI such as, uri="cell/persistent/*name_in_namespace_binding*". For example, uri="cell/persistent/*neworder*" where *neworder* is name in the namespace binding.

Using EJB bindings in SCA applications in a cluster environment

Use this task to learn how to use Enterprise JavaBeans (EJB) bindings that are deployed in Service Component Architecture (SCA) applications in a cluster environment.

Service side

When an SCA service is exposed with a binding.ejb element, the service is exposed through an enterprise bean. During deployment, the SCA runtime generates a session bean for the service that is exposed through EJB binding. The caller of the composite service can invoke this service by accessing the generated EJB.

If the service is exposed through an EJB 2 bean, the EJB is bound at:

`ejb/sca/ejbbinding/`*`component_name`*`/`*`service_name`*

For example:

`ejb/sca/ejbbinding/CompanyComponent/Company`

If the service is exposed through an EJB 3.x bean, the EJB is bound at:

`ejb/sca/ejbbinding/`*`component_name`*`/`*`service_name#fullyQualifiedServiceInterfaceName`*`Remote`

For example:

`ejb/sca/ejbbinding/CompanyComponent/Company#com.app.jobbank.CompanyRemote`

The generated EJB for the composite service will be under *profile_root*`/installedApps/`*`cell_name`*`/`*`composite_name`*`.ear/`.

Callers need to include client required classes (such as remote or home) of this generated bean in their classpath (or bundle the classes in their JAR file).

Lookup and invoke of this generated service EJB from a clustered environment is the same as lookup and invoke of any EJB in a product clustered setup. Refer to "Naming considerations in clustered and cross-server environments" in the *EJB 3.x application bindings overview* topic.

Reference side

When used on the reference side, the binding.ejb element should specify a URI attribute with values that match the value that is typically used when an EJB client calls the initialContext.lookup() method. The general convention is:

`"corbaname:iiop:`*`host`*`:`*`port`*`/NameServiceServerRoot#`*`JNDI_name`*`"`

where *JNDI_name* is the JNDI name of the target EJB.

For example:

`uri="corbaname:iiop:localhost:2809/NameServiceServerRoot#ejb/session/PriceQuoteSessionFacadeBean"`

JNDI name syntax differs if the target EJB is an EJB 2 or EJB 3.x bean.

When the referred EJB service is in a different cell, the URI might resemble one of the following:

`uri="corbaname:iiop:localhost:2809/NameServiceServerRoot#cell/clusters/cluster1/ejb/session/PriceQuoteSessionFacadeBean"`

or

`uri="corbaname::/NameServiceServerRoot#cell/clusters/cluster1/ejb/session/PriceQuoteSessionFacadeBean"`

or

`uri="cell/clusters/cluster1/ejb/session/PriceQuoteSessionFacadeBean"`

if the target EJB is on the same machine but on different cluster.

In advanced scenarios on multiple-server environments, a simpler and more portable way to access the target EJB application from an SCA composite is to set up a namespace binding and use the namespace binding name in the URI attribute of the binding.ejb along with `cell/persistent/`. For example:

```
uri="cell/persistent/PriceQuote"
```

where PriceQuote is the `name` field in the namespace.

The namespace binding can be of type EJB or CORBA based on the advanced scenario.

If the target EJB application which the composite is trying to access is on same cell, but on a different server, node or cluster, configure an EJB namespace binding. You can do this from the administrative console:

1. Click **Environment** > **Naming** > **Name space bindings**.
2. Select the cell scope.
3. Click **New**.
4. On the Specify binding type page, select the **EJB** binding type.
5. On the Specify basic properties page, specify the binding identifier, name in namespace, enterprise bean location such as server cluster or single server (with node), and JNDI name as needed. Use the **Name in name space** field to construct the URI as `cell/persistent/`*`name_in_namespace`*.

If the composite is running on a Version 7.0 cell and the target EJB application is running on a Version 6.1 product, configure a CORBA namespace binding with the correct Corbaname URL of the target EJB. Example Corbaname URL syntax is:

```
"corbaname:iiop:host:port/NameServiceServerRoot#jndi_name"
```

After you configure the namespace binding, use the **Name in name space** field to construct the URI; for example, `uri="cell/persistent/PriceQuote"` where PriceQuote is the value in the **Name in name space** field of the binding.

An advantage of using a namespace binding is, even when the target EJB changes, the composite definition does not need to change. Only the namespace binding needs to change accordingly.

SCA EJB reference binding URI patterns

Use an EJB reference binding URI pattern that is appropriate for the user setup and configuration:

- If an EJB reference binding accesses a stateless session bean on the same server, the EJB reference binding URI can be a Java Naming and Directory Interface (JNDI) name of the stateless session bean. For example:

  ```
  uri="ejb/com/app/resumebank/ResumeBankHome"
  ```

- If the EJB reference binding references another SCA service with the EJB binding on the same server, then the EJB reference binding URI can be either of the following:
  - The JNDI name of the stateless session bean. For example,

    ```
    uri="ejb/com/app/resumebank/ResumeBankHome"
    ```

  - A binding that uses the SCA reference target mechanism instead of the binding URI:

    ```
    <reference name="service1" target="component_name/service_name">
    ....
    <binding.ejb/>
    </reference>
    ```

- If the EJB reference binding is accessing a stateless session bean that is deployed in the same cell, the EJB reference binding URI can be based on the cluster/node/server setup. See the following examples:
  - Accessing a stateless session bean deployed in the same cell and on cluster2

    ```
    uri="cell/clusters/cluster2/ejb/com/app/resumebank/ResumeBankHome"
    ```

  - Accessing a stateless session bean deployed in the same cell but on a different node.

```
uri="cell/nodes/node_name/servers/server_name/ejb/com/app/resumebank/ResumeBankHome"
```

- If an EJB reference binding accesses a stateless session bean on a cell other than the current cell or on a mixed cell, then you can configure a reference binding URI in either of the following ways:
  - Create a namespace binding of either a Corba or EJB type using the administrative console. After configuring the namespace binding, use the **Name in name space** value to construct the URI as:

    ```
    uri="cell/persistent/name_in_namespace_binding"
    ```

    For example, if `neworder` is the name in the namespace binding, then the URI is `uri="cell/persistent/neworder"`.
  - Use corbaname for the EJB reference binding URI. For example:

    ```
    corbaname:iiop:<hostName><port>/NameServiceServerRoot#jndi_name
    ```

    where *hostName* and *port* are the respective host and port, and where the target stateless session bean is running. *jndi_name* is the JNDI name of the EJB which differs between EJB2 and EJB3.

Configuring EJB bindings in SCA OASIS applications

You can configure Enterprise JavaBeans (EJB) service and reference bindings for use in SCA OASIS applications.

About this task

Note: The SCA stateless session bean binding is a protocol binding that you can use to integrate SCA with EJB-based services. The product provides OASIS support for both EJB 3.x and 2.x bindings for services and references.

- Configure an EJB service binding to expose an SCA service as a stateless session bean for consumption by Java Platform, Enterprise Edition (Java EE) applications.
- Configure an EJB reference binding to enable SCA components to invoke stateless session beans.

Procedure

- Configure EJB service bindings and invoke them in caller applications.

  Steps follow for configuring EJB 3.x and 2.x bindings:

  EJB 3.x binding

  1. Configure an EJB 3.x binding in a composite definition.

     The following example shows an OASIS composite definition that has a service exposed over an EJB 3.x binding:

     ```
     <composite xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912"
                targetNamespace="http://www.ibm.com/samples/sca/ejb/jobbank"
                name="JobBank">
        <component name="CompanyComponent">
           <implementation.java class="com.app.jobbank.CompanyImpl"/>
           <!-- Expose service over the EJB 3.x binding -->
              <service name="Company">
                 <interface.java interface="com.app.jobbank.Company"/>
                 <binding.ejb/>
              </service>
        </component>
     </composite>
     ```

     The default ejb-version is `EJB3` in an SCA OASIS implementation. You do not need to specify ejb-version. However, you can explicitly define ejb-version; for example:

     ```
     <binding.ejb ejb-version="EJB3"/>
     ```

     Do not specify the uniform resource identifier (URI) for the EJB service binding in the composite definition. The run time will generate a unique URI, which is used as the JNDI name for the session bean endpoint that is generated for the SCA service, and ignore any URI for the EJB service binding in the composite definition.

2. Package the SCA composite with the service interface and implementation in a Java archive (JAR) and deploy the JAR in a business-level application.

   During SCA service startup, the run time generates a stateless session bean endpoint in memory that a Java EE client can invoke using the Java EE client programming model.

   The JNDI name for a generated session bean has the following format:

   ejb/sca/ejbbinding/*component_name*/*service_name*#*package.qualified.sca.interface*

   The JNDI name for the generated session bean for the jobbank composite service in step 1 is:

   ejb/sca/ejbbinding/CompanyComponent/Company#com.app.jobbank.Company

3. Invoke the SCA service from a Java EE client application.

   The following code shows how to lookup and invoke an SCA service exposed as an EJB 3.x binding from a Java EE caller application:

```
// Look up EJB for the SCA service
Object remoteObj =
   initialContext.lookup("ejb/sca/ejbbinding/CompanyComponent/Company#com.app.jobbank.Company");
Company company = (Company) PortableRemoteObject.narrow(remoteObj, Company.class);
// Invoke component service by invoking EJB method
String result = company.getCompanyInfo("ACME");
```

   The Java EE caller application should use an SCA service interface as an EJB remote interface for the lookup and invocation. In the sample code, `Company` is an SCA service or business interface that is declared under the `<interface.java>` element. Thus, the only class required by the Java EE caller application is an SCA service or business interface.

   The SCA service can be looked up based on the WebSphere topology like a typical EJB; for example:

"cell/nodes/*node_name*/servers/*server_name*/ejb/sca/ejbbinding/CompanyComponent/Company#com.app.jobbank.Company"

"cell/clusters/*cluster_name*/ejb/sca/ejbbinding/CompanyComponent/Company#com.app.jobbank.Company"

"corbaname:iiop:host:port/NameServiceServerRoot#ejb/sca/ejbbinding/CompanyComponent/Company#com.app.jobbank.Company"

EJB 2.x binding

1. Configure an EJB 2.x binding in a composite definition.

   The following example shows an OASIS composite definition that has a service exposed over an EJB 2.x binding:

```
<composite xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912"
           targetNamespace="http://www.ibm.com/samples/sca/ejb/jobbank"
           name="JobBank">
   <component name="CompanyComponent">
      <implementation.java class="com.app.jobbank.CompanyImpl"/>
      <!-- Expose service over the EJB 3.x binding -->
      <service name="Company">
         <interface.java interface="com.app.jobbank.Company"/>
         <binding.ejb ejb-version="EJB2"/>
      </service>
   </component>
</composite>
```

   You must explicitly define ejb-version as `EJB2`.

   Do not specify the URI for the EJB service binding in the composite definition. The run time will generate a unique URI, which is used as the JNDI name for the session bean endpoint that is generated for the SCA service, and ignore any URI for the EJB service binding in the composite definition.

2. Package the SCA composite with the stateless session bean service binding in a JAR and deploy the JAR in a business-level application.

   During deployment, the SCA run time generates a 2.x stateless session bean. The JNDI name pattern for a generated session bean is:

   ejb/sca/ejbbinding/*component_name*/*service_name*

   The JNDI name for the generated session bean for the jobbank composite service in step 1 is:

   ejb/sca/ejbbinding/CompanyComponent/Company

The generated session bean for the composite service is under the directory, *profile_root*/installedApps/*cell_name*/*sca.composite.name*App.ear; for example: *profile_root*/installedApps/*cell_name*/JobBankApp.ear.

3. Invoke the SCA service from a Java EE client application.

   The Java EE caller application invoking this SCA service should do either of the following:

   – Bundle generated classes from the directory in step 2 with the client application.

   – Add the generated EJB module JAR file from the directory in step 2 to the client class path.

   If the caller application is running on a non-WebSphere application server, a "Bare" Java Standard Edition (SE), or a version of WebSphere Application Server previous to version 7.0 without the Feature Pack for EJB 3.0, then you must run the **createEJBStubs** command for the generated EJB module to generate client-side stubs and include the generated subs at the client application. The **createEJBStubs** command is under the *profile_root*/installedApps/*cell_name*/*sca.composite.nameApp.ear*/ directory. See the topic on the create stubs command.

   If the caller of the SCA service is another SCA reference with an EJB binding, the caller SCA composite does not need to include the generated home, remote interface because the SCA reference binding implementation can invoke the SCA service binding implementation using only the SCA interface.

- Configure EJB reference bindings.

  An EJB reference binding enables SCA components to invoke stateless session beans.

  The following example shows an SCA composite definition that contains an SCA reference with an EJB binding:

```
<composite xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912"
           targetNamespace="http://www.ibm.com/samples/sca/ejb/jobbank"
           name="JobBank">

  <component name="CompanyComponent">

     <reference name="extEJBService">
        <interface.java interface="com.app.resumebank.ResumeBank"/>
        <binding.ejb uri="ejb/com/app/resumebank/ResumeBankHome"/>
     </reference>

  </component>
</composite>
```

  An EJB reference binding supports invocation of both local and remote stateless session beans.

  The binding URI should be the JNDI name of the stateless session bean which the SCA reference is trying to invoke. The JNDI name of the session bean can be in the EJB 2.x or EJB 3.x format based on whether the target EJB version is 2.x or 3.x. The JNDI name can be local if the target is a local session bean or remote if the target is remote.

  You do not need to specify an ejb-version attribute under the <binding.ejb> element for an EJB reference binding.

  Also, you do not need to package the target session bean home interface or client stubs with an SCA component with an EJB reference binding. The EJB session bean binding implementation can dynamically look up, create, and invoke the bean without the usual EJB client classes.

  For the SCA reference interface, use either the target EJB interface or its compatible interface. Interface compatibility rules are defined under Section 3.1, *Compatibility of Interfaces used for SCA Services & References with EJB Session Bean Interfaces*, of the EJB Session Bean Binding Specification 1.1.

  Some of the supported binding `uri` formats are in the following list. For binding `uri`, follow EJB 2.x or EJB 3.x JNDI lookup name formats based on the target EJB type.

  Corba url format

```
<binding.ejb uri="corbaname:iiop:host:port/NameServiceServerRoot#jndi_name"/>
```

  Local session bean

```
<binding.ejb uri="ejblocal:jndi_name"/>
```

  uri based on the topology

Cluster

```
<binding.ejb uri="cell/clusters/cluster_name/jndi_name" />
```

Server

```
<binding.ejb uri="cell/nodes/node_name/servers/server_name/jndi_name" />
```

Persistent namespace

```
<binding.ejb uri="cell/persistent/name_in_persistent_namespace_binding"/>
```

Results

You have configured an EJB service or reference binding for an SCA OASIS application.

Use of the bindings has the following limitations:

- A local EJB invocation from a Java EE application to an SCA service with an EJB 2.x or EJB 3.x binding is not supported.
- A Java EE application running on a non-WebSphere application server, on “bare” Java Standard Edition (SE), or on a WebSphere application server previous to Version 7.0 without the Feature Pack for EJB 3.0 cannot invoke the SCA EJB 3.x service binding.
- The product does not support an SCA composite that has both EJB 2.x and EJB 3.x services in different components but implements the same interface.

What to do next

Ensure that your components do not use an SCA OASIS implementation that the product does not support.

Table 87. Unsupported sections of SCA OASIS specifications. The product does not support these sections of the SCA EJB Session Bean Binding specification.

Section	Not supported in SCA OASIS implementation

2 Session Bean Binding Schema	`binding.ejb/@uri` for SCA service binding
	• The SCA stateless EJB implementation automatically generates a unique URI based on the component name, service name, and service interface. The URI is used as the EJB service endpoint.
	See step 1 in the "Configure EJB service bindings and invoke them in caller applications" procedure.
	`corbaname:rir:#ejb/MyHome`
	• The product supports the `cobra url` format:
	`corbaname:iiop:host:port/NameServiceServerRoot#jndi_name`
	`ejb-link-name`
	• The product does not support `ejb-link-name` in the SCA OASIS implementation.

Configuring the SCA JMS binding

You can configure the Service Component Architecture (SCA) Java Message Service (JMS) binding for services and references to support messaging between SCA applications and JMS providers.

Before you begin

Use the administrative console to enable the SIB service and **Configuration reload enabled** option on the application server where the application runs. Restart the server to enable the dynamic reloading of the SIB configuration files for this server. See the SIB service settings information to learn more about enabling the SIB service.

When you use the JMS binding, it is important that you follow best practice guidelines on design, configuration, and tuning of the messaging topology. Following these guidelines is especially important when you design systems for high throughput or high availability. Read the documentation on using JMS bindings in this information center, specifically “Multiple-server bus with clustering.” The developerWorks articles “Configuring and tuning WebSphere MQ for performance on Windows and UNIX” and “Performance tuning for Java Messaging Service on WebSphere Application Server on z/OS” also provide useful information.

About this task

Bindings determine how a component communicates with the world outside its domain. SCA services use bindings to describe the access mechanism that clients must use to call the service. SCA references use bindings to describe the access mechanism used to call a service.

Using the SCA JMS binding, you can make SCA components available over JMS or you can use existing JMS applications within an SCA environment. You can use the SCA JMS binding element, `<binding.jms>`, within either a component service or a component reference definition. When a JMS binding is applied within a component service interface definition, the JMS binding enables clients to access an SCA service that is offered by a JMS provider. When the JMS binding is applied on a component reference, the SCA component can consume an external JMS application or another SCA component using JMS.

WebSphere Application Server supports asynchronous messaging using JMS. The default messaging provider enables enterprise applications deployed on WebSphere Application Server to perform asynchronous messaging without the need for you to install a JMS provider. The default messaging provider is installed and runs as part of WebSphere Application Server. The product supports the default messaging provider or WebSphere MQ as the messaging engine.

The SCA JMS Binding specification describes the `<binding.jms>` binding element and available attributes and options. To learn more about the `<binding.jms>` binding element, see the SCA JMS Binding specification documentation.

The product supports both the OASIS and the OSOA SCA JMS binding specification. Unless otherwise specified, the information in this topic pertains to applications for both the OSOA and OASIS specification.

SCA with JMS supports the following messaging exchange patterns:

- request-response messaging
- one-way messaging
- one-way messaging with callback

A *request* is a message that is sent to an SCA service or sent by an SCA reference. A *response* is a message that is received back at a reference or a message that is sent by a service in response to a previous request message. In SCA, a response is always a reply to a previous request. In a one-way message, a request message is sent and a response is not expected.

This task describes the steps necessary to enable SCA applications for JMS using request-response or one-way messaging.

Procedure

1. Identify the SCA business-level application that you want to enable for JMS messaging.
2. Identify and configure the JMS resources for your SCA application.

   You can configure JMS resources for the default messaging provider before deployment of the SCA application. During deployment of the SCA application, the product can dynamically create any JMS resources that the JMS binding needs that do not exist if the composite definition file is configured for dynamic resource creation.

SCA applications are bound to JMS resources through their binding definitions in a corresponding composite definition file. The composite definition file for JMS uses Java Naming and Directory Interface (JNDI) names to identify JMS administered objects that are used by the SCA runtime environment on behalf of the SCA application to provide access over the specified binding.

You can configure the following JMS resource references in the JNDI directory or choose for the product to dynamically create the resources for you:

- a service integration bus
- a request queue and a response queue. A response queue is only required for request-response messaging. The physical queues and the logical queues must be defined.
- an activation specification to handle the request to the service
- a connection factory to process the response

To learn more about manually creating JMS resources, see the documentation on JMS resources for the default messaging provider. To learn more about dynamically creating JMS resources, see the dynamic JMS resource creation during deployment information.

3. Configure an SCA service with the SCA JMS binding.

   To expose an SCA service over the JMS binding, add the `<binding.jms>` element within the service definition.

   Within the `<binding.jms>` element, define the following:

   - an `<activationSpec>` element to identify the activation specification that the binding uses to connect to a JMS destination to process request messages
   - a response `<connectionFactory>` element for request-response messaging patterns
   - a response `<destination>` element that describes the JMS destination for responses from the JMS binding. Specifying the response destination is optional because the runtime environment obtains the JMSReplyTo destination that is set on the incoming request message to determine the response destination. If the JMSReplyTo attribute is not set on the request message, the response `<destination>` element is used to identify the response destination. This element is not applicable for one-way messaging patterns.

4. Configure an SCA reference with the SCA JMS binding.

   To consume or expose a JMS application or SCA reference with the JMS binding, add the `<binding.jms>` element within the SCA reference definition.

   Within the `<binding.jms>` element, define the following:

   - a `<connectionFactory>` element to identify the JNDI name of the connection factory used to process messages sent from the reference to the referenced service
   - a `<destination>` element to identify the JMS queue or topic that is used to send messages to the referenced service
   - a response `<destination>` element that describes the JMS destination queue used to process responses from the JMS binding. This element is optional for request-response messaging and not applicable for one-way messaging

   Note: Differences between the OSOA and OASIS JMS binding specifications might affect migration of applications from OSOA to OASIS. Some commonly encountered differences include:

   - The validation schemas used for the OASIS applications are defined by the OASIS SCA specification. The OASIS binding schema definition mandates that binding elements appear in the exact order as defined in the schema. For OSOA applications, element order does not affect validation so, when migrating applications from OSOA, ensure the binding elements are in the order specified by the OASIS binding schema.
   - For the `<destination>`, `<connectionFactory>`, and `<activationSpec>` elements, the name attribute is `jndiName` in OASIS.
   - In OASIS composites, callback references must specify a destination element. The specified destination is used only if the destination cannot be determined from the

scaCallbackDestination or JMSReplyTo properties of the service request message. In OSOA composites, callback references can omit the destination element if it is known that one of the properties is always set.

For information on other differences, consult the OASIS specification for additional information about specific elements.

5. Optional: Configure JMS message correlation.

   You can optionally configure a JMS correlation identification for a request message and its response. Because of the asynchronous nature of JMS, it is important to determine if message correlation is required. A request-response messaging pattern is not equivalent to synchronous messaging.

   You can use the @correlationScheme element to identify the correlation scheme used when sending a reply or callback messages.

   For OSOA, the valid values for this element are: `RequestMsgIDToCorrelID`, `RequestCorrelIDToCorrelID`, and `none`. The default value is `RequestMsgIDToCorrelID`.

   For OASIS, the valid values for this element are: `sca:messageID`, `sca:correlationID`, and `sca:none`.

   To configure JMS message correlation, you can specify a `correlationID` element within the composite definition file that is used within the JMS header to link two messages.

6. Optional: Invoke an operation using JMS operation selection
   - Use the default JMS binding operation selection.
   - Use JMS user property operation selection.
   - Use a JMS custom operation selector.

   Using the @nativeOperation attribute in a composite definition, your application can override operation selection; for example, in OSOA:

```
<service>
  <binding.jms>
  ...
    <operationProperties
      name="operationToInvoke"
      nativeOperation="selectedOperation"/>
  ...
  </binding.jms>
</service>
```

   Or, in OASIS:

```
<service>
  <binding.jms>
  ...
    <operationProperties
      name="operationToInvoke"
      selectedOperation="selectedOperation"/>
  ...
  </binding.jms>
</service>
```

   In this example, when the configured operation selector selects the operation named *selectedOperation*, the run time invokes operation *operationToInvoke* on the target service implementation. The overriding occurs whether the service binding is configured using default JMS operation selection, JMS user property operation selection, or a JMS custom selector.

Results

You have defined the JMS resources you need for your SCA application, configured the SCA JMS binding for your SCA services and references, and deployed your application. Your application is now ready for use.

Example

The following example illustrates two SCA component implementations and the use of request-response and one-way messaging.

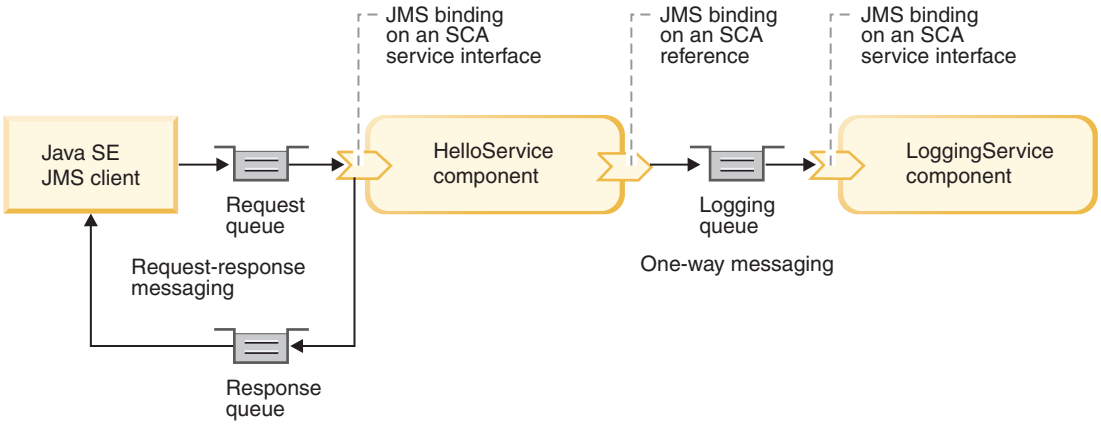

Figure 4. SCA JMS binding example

The HelloService component implementation illustrates the request-response message pattern. This HelloService component exposes the service interface with the name, `getGreeting`, that is used to illustrate a return response of `hello` plus the value of `getGreeting`.

The LoggingService component implementation is a logging service. This component exposes a one-way service interface with the name, `log`, that receives a message and logs the message in a repository.

The HelloService has an SCA reference to the LoggingService. Each time the HelloService service receives a message, it calls the LoggingService service to log the message.

In this example, a Thin Client for JMS application sends a message, formatted as a JMS `ObjectMessage` message type to the SCA HelloService using the `jms/SCA_sample_Request` queue. The ObjectMessage sets the `scaOperationName` property to the value, `getGreetings`. The HelloServiceComponent receives the message over the JMS HelloService binding. The HelloServiceComponent then sends a request to the referenced service, LoggingService, and the one-way operation is complete. HelloServiceComponent sends a response of `hello` plus the value of `getGreetings` to the client application using the `jms/SCA_sample_Response` queue to complete the request-response operation.

Configuring an SCA JMS binding for a request-response service from a JMS client to SCA service

The following example describes a `<binding.jms>` element within the component definition file for a request-response message exchange pattern from a JMS client to an SCA service:

OSOA composite

```
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
  targetNamespace="http://www.ibm.com/soa/sca/samples"
   xmlns:hw="http://www.ibm.com/soa/sca/samples"
  xmlns:ts="http://tuscany.apache.org/xmlns/sca/1.0"
   name="HelloServiceComposite">

  <component name="HelloServiceComponent">
    <implementation.java class="soa.sca.samples.jms.HelloServiceImpl"/>
    <service name="HelloService">
       <interface.java interface="soa.sca.samples.jms.HelloService"/>
         <binding.jms>
           <ts:wireFormat.jmsObject/>
           <destination name="jms/SCA_sample_Request" type="queue"/>
           <activationSpec name="jms/SCA_sample_AS"/>
           <response>
```

```
            <destination name="jms/SCA_sample_Response" type="queue"/>
            <connectionFactory name="jms/SCA_sample_CF"/>
          </response>
        </binding.jms>
    </service>
  </component>

</composite>
```

OASIS composite

```
<composite xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912"
  targetNamespace="http://www.ibm.com/soa/sca/samples"
   xmlns:hw="http://www.ibm.com/soa/sca/samples"
  xmlns:ts="http://tuscany.apache.org/xmlns/sca/1.1"
   name="HelloServiceComposite">

  <component name="HelloServiceComponent">
    <implementation.java class="soa.sca.samples.jms.HelloServiceImpl"/>
    <service name="HelloService">
       <interface.java interface="soa.sca.samples.jms.HelloService"/>
         <binding.jms>
           <ts:wireFormat.jmsObject/>
           <destination jndiName="jms/SCA_sample_Request" type="queue"/>
           <activationSpec jndiName="jms/SCA_sample_AS"/>
           <response>
              <destination jndiName="jms/SCA_sample_Response" type="queue"/>
              <connectionFactory jndiName="jms/SCA_sample_CF"/>
           </response>
        </binding.jms>
    </service>
  </component>

</composite>
```

- The <destination> describes the JMS destination. The destination type is either a queue or topic. This example illustrates the JMS destination queue type. The destination is used to process requests by the JMS binding to the component implementation that contains the service interface
- The <activationSpec> element identifies the activation specification that the binding uses to connect to a JMS destination to process request messages. The activation specification name must be a JNDI name. The <activationSpec> element is only supported within the SCA <service> tag.
- The <response> element defines the resources used for processing response messages. In this example, the response element specifies the resources for sending messages from the <service> back to the client.
- The response <destination> element describes the JMS destination queue that is used to process responses from the service interface.
- The response <connectionFactory> element identifies the JNDI name of the connection factory that the binding uses to process response messages.
- The <ts:wireFormat.jmsObject/> specifies to the JMS binding that the payload of the message is of the type, javax.jms.Message (ObjectMessage).

The following example describes a <binding.jms> element within the component definition file for a one-way interaction from one SCA service to another SCA service. The <binding.jms> binding definition is similar to the HelloService; however, because the message operation is one-way, there is not a response definition.

OSOA composite

```
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
  targetNamespace="http://www.ibm.com/soa/sca/samples"
  xmlns:hw="http://www.ibm.com/soa/sca/samples"
  xmlns:ts="http://tuscany.apache.org/xmlns/sca/1.0"
  name="HelloServiceComposite">

 <component name="LoggingService">
```

```
  <implementation.java class="soa.sca.samples.jms.LoggingServiceImpl"/>

  <service name="LoggingService">
   <interface.java interface="soa.sca.samples.jms.LoggingService"/>
         <binding.jms>
           <ts:wireFormat.jmsObject/>
           <destination name="jms/SCA_Logging_Request" type="queue"/>
           <activationSpec name="jms/SCA_sample_AS"/>
         </binding.jms>
  </service>

 </component>
</composite>
```

OASIS composite

```
<composite xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912"
  targetNamespace="http://www.ibm.com/soa/sca/samples"
  xmlns:hw="http://www.ibm.com/soa/sca/samples"
  xmlns:ts="http://tuscany.apache.org/xmlns/sca/1.1"
  name="HelloServiceComposite">

 <component name="LoggingService">
  <implementation.java class="soa.sca.samples.jms.LoggingServiceImpl"/>

  <service jndiName="LoggingService">
   <interface.java interface="soa.sca.samples.jms.LoggingService"/>
         <binding.jms>
           <ts:wireFormat.jmsObject/>
           <destination jndiName="jms/SCA_Logging_Request" type="queue"/>
           <activationSpec jndiName="jms/SCA_sample_AS"/>
         </binding.jms>
  </service>

 </component>
</composite>
```

Configuring an SCA JMS binding for two-way service from a JMS client to SCA reference

The following example describes a <binding.jms> element within the component definition file for a request-response message exchange pattern from a JMS client to an SCA reference:

OSOA SCA reference

```
<reference name="helloWorldService">
    <interface.java interface="my.HelloWorldService"/>
    <binding.jms>
       <connectionFactory name="jms/helloWorldServiceCF"/>
       <destination name="jms/HelloWorldService"/>
       <response>
           <destination name="jms/SCA_sample_Response"/>
       </response>
    </binding.jms>
</reference>
```

OASIS SCA reference

```
<reference name="helloWorldService">
    <interface.java interface="my.HelloWorldService"/>
    <binding.jms>
        <connectionFactory jndiName="jms/helloWorldServiceCF"/>
        <destination jndiName="jms/HelloWorldService"/>
        <response>
            <destination jndiName="jms/SCA_sample_Response"/>
        </response>
    </binding.jms>
</reference>
```

- The <connectionFactory> element is used in the SCA reference to identify the JNDI name of the connection factory used to process messages sent from the reference to the referenced service. The <activationSpec> element is not supported in a reference.
- The <destination> element is the JMS queue or topic that is used to send messages to the referenced component implementation.
- The response <destination> element is the JMS resource that is used to receive response messages to the SCA reference.

Authenticating with a secure bus

You can specify an authentication alias on the reference binding or service binding in the composite file to authenticate with a secure bus. Use the authentication-alias attribute to specify the predefined authentication alias instead of specifying it in the activation specification or connection factory settings.

A <binding.jms> element does not propagate the identity of the client. For details on creating a J2C authentication alias, see Managing Java 2 Connector Architecture authentication data entries for JAAS.

OSOA SCA composite

```
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
    targetNamespace="http://www.ibm.com/soa/sca/samples"
    xmlns:hw="http://www.ibm.com/soa/sca/samples"
    xmlns:ts="http://tuscany.apache.org/xmlns/sca/1.0"
    xmlns:websphere="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
    name="HelloServiceComposite">
  <component name="HelloServiceComponent">
    <implementation.java class="soa.sca.samples.jms.HelloServiceImpl"/>
    <service name="HelloService">
      <interface.java interface="soa.sca.samples.jms.HelloService"/>
      <binding.jms websphere:authentication-alias="SCA_Auth_Alias">
        <destination name="jms/SCA_sample_Request" type="queue"/>
        <activationSpec name="jms/SCA_sample_AS"/>
        <response>
          <destination name="jms/SCA_sample_Response" type="queue"/>
          <connectionFactory name="jms/SCA_sample_CF"/>
        </response>
        <ts:wireFormat.jmsObject/>
      </binding.jms>
    </service>
  </component>
</composite>
```

OASIS SCA composite

```
<composite xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912"
    targetNamespace="http://www.ibm.com/soa/sca/samples"
    xmlns:hw="http://www.ibm.com/soa/sca/samples"
    xmlns:ts="http://tuscany.apache.org/xmlns/sca/1.1"
    xmlns:websphere="http://www.ibm.com/xmlns/prod/websphere/sca/1.1"
    name="HelloServiceComposite">
  <component name="HelloServiceComponent">
    <implementation.java class="soa.sca.samples.jms.HelloServiceImpl"/>
    <service name="HelloService">
      <interface.java interface="soa.sca.samples.jms.HelloService"/>
      <binding.jms websphere:authentication-alias="SCA_Auth_Alias">
        <destination jndiName="jms/SCA_sample_Request" type="queue"/>
        <activationSpec jndiName="jms/SCA_sample_AS"/>
        <response>
          <destination jndiName="jms/SCA_sample_Response" type="queue"/>
          <connectionFactory jndiName="jms/SCA_sample_CF"/>
        </response>
        <ts:wireFormat.jmsObject/>
      </binding.jms>
    </service>
  </component>
</composite>
```

What to do next

Based on your business needs, you can configure an SCA JMS binding wire format or configure transactions for the SCA JMS binding.

Explore the JMS binding samples to better understand how to invoke an SCA component service using a JMS client. For information on JMS samples, see “SCA samples.” To download JMS binding samples from a product website:

1. Go to the **Samples, Version 8.5** information center.
2. On the **Downloads** tab, click **FTP** or **HTTP** in the **Service Component Architecture** section.
3. In the authentication window, click **OK**.
4. From the **SCA.zip** compressed file, download the `SCA/JMS` directory and follow instructions in `SCA/JMS/documentation/readme.html` to build the files.

   Instead of building deployable files, you can use the prebuilt `jms-callback-service.jar`, `jms-twoway-oneway-service.jar`, and `jms-twoway-service.jar` files in the `SCA/installableApps` directory of the compressed file.

After you obtain your SCA components, deploy the components in an application and test the JMS binding.

Configuring SCA JMS binding wire formats

You can configure the messaging data formats between an SCA application and a JMS producer or consumer, by configuring your SCA application to take advantage of a supported message type and data format.

Before you begin

Configure the JMS binding for your SCA application.

About this task

JMS producers and consumers use a variety of message types to hold application data payloads. You can use the JMS BytesMessage, ObjectMessage, or TextMessage message types. In some cases, the TextMessage message type might be expected to contain additional structure such as application data in serialized XML format.

Wire format describes the format of the data that is on the wire. For the SCA JMS binding, the wire format is the format of the data in the JMS message that flows through the JMS provider. Because of the variety of message types and formats, SCA services and references that are configured with a JMS binding might require additional configuration so that the runtime environment can perform the marshalling and unmarshalling required to translate between application data formats and the format of the JMS message on the wire. The additional configuration of message types is the specification of the wire format for message handling.

Whether you are configuring an SCA service or reference, it is important to recognize if the wire format is previously established by your existing messaging application infrastructure, or if you are selecting the wire format along with your SCA application. If you are starting with an application with a preexisting messaging infrastructure and you are adding your SCA application to this environment, the wire format is likely already determined by the messaging infrastructure. If you are starting with an SCA application and you intend for this application to interact with future JMS message producers or consumers, you can specify the wire format within your SCA application.

For the cases when the wire format is predetermined, it is expected behavior that the wire format enables a natural mapping to the format expected by your preexisting message producers and consumer when dealing with input and non-exception output. However, exception conditions might not be handled

according to the convention for the wire format type in your existing messaging application infrastructure. If you want exceptions to flow over the JMS binding, you might need to adjust the producers or consumers interacting with your SCA application over the JMS binding according to the exception handling behavior.

JMS binding wire format is supported for applications coded to both the OSOA and OASIS specifications. Unless otherwise specified, the information in this topic pertains to both OSOA and OASIS applications.

Procedure

1. Determine if you are using a wire format that is predetermined by your existing messaging infrastructure or if you are starting with an SCA application and defining the message wire format.
2. Determine the message type to use for your wire format.

   See Supported message types for SCA JMS binding wire formats.
3. If you are using a wire format predetermined by your existing messaging infrastructure, add the corresponding wire format element into the composition definition file.
4. Ensure that your SCA service and service client implementation and interfaces map appropriately for the specific wire format that you selected.
5. (optional) If you want exception checking to occur over the JMS binding, ensure that the JMS producer and consumer that is interoperating with your SCA application follows the SCA JMS binding exception handling procedures described previously.
6. If you are starting with an SCA application and defining the message infrastructure, add the appropriate wire format element into the composition definition file, and ensure that your future JMS producer or consumer applications understand how to interoperate with this message data format.

Results

You have configured the messaging data format between an SCA application and a JMS producer or consumer.

Examples of configuring SCA JMS binding wire formats

The following examples illustrate the configuration of composite definition files using the various wire format schemes. Component references are configured in an analogous manner

TextMessage with serialized XML wire format that maps data using JAXB

This example illustrates the TextMessage with serialized XML wire format that maps data using JAXB, which is the default wire format:

OSOA

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
    targetNamespace="http://test/soa/sca/"
    xmlns:ts="http://tuscany.apache.org/xmlns/sca/1.0"
    name="JBC">

      <component name="JAXBComponent">
        <implementation.java class="test.backend.HelloWorldJAXBBackendImpl" />
        <service name="HelloWorldJAXBService">
          <interface.wsdl interface="http://test.hello#wsdl.interface(HelloWorld)"/>
          <binding.jms>
            <destination name="jms/Request1" type="queue" create="never"/>
            <activationSpec name="jms/AS1"/>
            <response>
              <destination name="jms/Response1" type="queue" create="never"/>
              <connectionFactory name="jms/CF" create="never"/>
            </response>
           <!-- No wire format element is necessary, the default is used. -->
```

```
        </binding.jms>
      </service>
    </component>
</composite>
```

OASIS

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912"
    targetNamespace="http://test/soa/sca/"
    xmlns:ts="http://tuscany.apache.org/xmlns/sca/1.1"
    name="JBC">

      <component name="JAXBComponent">
        <implementation.java class="test.backend.HelloWorldJAXBBackendImpl" />
        <service name="HelloWorldJAXBService">
          <interface.wsdl interface="http://test.hello#wsdl.interface(HelloWorld)"/>
          <binding.jms>
            <!-- No wire format element is necessary, the default is used. -->
            <destination jndiName="jms/Request1" type="queue" create="never"/>
            <activationSpec jndiName="jms/AS1"/>
            <response>
              <destination jndiName="jms/Response1" type="queue" create="never"/>
              <connectionFactory jndiName="jms/CF" create="never"/>
            </response>
         </binding.jms>
      </service>
    </component>
</composite>
```

ObjectMessage wire format that maps to the `java.lang.Object` class

This example illustrates the ObjectMessage wire format that maps to the `java.lang.Object` class:

OSOA

```
<component name="SerializableComponent">
    <implementation.java class="test.backend.HelloWorldSerializableBackendImpl"/>
    <service name="HelloWorldSerializableService">
        <interface.java interface="test.HelloWorldSerializableService"/>
        <binding.jms>
          <destination name="jms/Request2" type="queue" create="never"/>
          <activationSpec name="jms/AS2"/>
          <response>
            <destination name="jms/Response2"/>
            <connectionFactory name="jms/CF" create="never"/>
          </response>
          <!-- The wire format element must appear last in the binding definition
               to conform to the OSOA schema. -->
          <ts:wireFormat.jmsObject/>
        </binding.jms>
    </service>
</component>
```

OASIS

```
<component name="SerializableComponent">
    <implementation.java class="test.backend.HelloWorldSerializableBackendImpl"/>
    <service name="HelloWorldSerializableService">
        <interface.java interface="test.HelloWorldSerializableService"/>
        <binding.jms>
          <!-- The wire format element must appear first in the binding definition
               to conform to the OASIS schema. -->
          <ts:wireFormat.jmsObject/>
          <destination jndiName="jms/Request2" type="queue" create="never"/>
          <activationSpec jndiName="jms/AS2"/>
          <response>
            <destination jndiName="jms/Response2"/>
            <connectionFactory jndiName="jms/CF" create="never"/>
```

```
          </response>
        </binding.jms>
    </service>
</component>
```

TextMessage wire format that maps to single string messages

This example illustrates the TextMessage wire format that maps to single string messages:

OSOA

```
<component name="JMSTextBackendComponent">
    <implementation.java class="test.backend.HelloWorldTextBackendImpl" />
    <service name="HelloWorldTextService">
       <interface.java interface="test.HelloWorldTextService"/>
       <binding.jms>
          <destination name="jms/Request3"/>
          <activationSpec name="jms/AS3"/>
          <response>
             <destination name="jms/Response3"/>
             <connectionFactory name="jms/CF" create="never"/>
          </response>
          <!-- The wire format element must appear last in the binding definition
               to conform to the OSOA schema. -->
          <ts:wireFormat.jmsText/>
      </binding.jms>
    </service>
</component>
```

OASIS

```
<component name="JMSTextBackendComponent">
    <implementation.java class="test.backend.HelloWorldTextBackendImpl" />
    <service name="HelloWorldTextService">
       <interface.java interface="test.HelloWorldTextService"/>
       <binding.jms>
          <!-- The wire format element must appear first in the binding definition
               to conform to the OASIS schema. -->
          <ts:wireFormat.jmsText/>
          <destination jndiName="jms/Request3"/>
          <activationSpec jndiName="jms/AS3"/>
          <response>
             <destination jndiName="jms/Response3"/>
             <connectionFactory jndiName="jms/CF" create="never"/>
          </response>
      </binding.jms>
    </service>
</component>
```

BytesMessage wire format that maps to single byte array messages

This example illustrates the BytesMessage wire format that maps to single byte array messages:

OSOA

```
<component name="JMSBytesBackendComponent">
    <implementation.java class="test.backend.HelloWorldBytesBackendImpl" />
    <service name="HelloWorldBytesService">
      <interface.java interface="test.HelloWorldBytesService"/>
      <binding.jms>
        <destination name="jms/Request4"/>
        <activationSpec name="jms/AS4"/>
        <response>
          <destination name="jms/Response4"/>
          <connectionFactory name="jms/CF" create="never"/>
        </response>
        <!-- The wire format element must appear last in the binding definition
             to conform to the OSOA schema. -->
```

```
        <ts:wireFormat.jmsBytes/>
      </binding.jms>
    </service>
</component>
```

OASIS

```
<component name="JMSBytesBackendComponent">
    <implementation.java class="test.backend.HelloWorldBytesBackendImpl" />
    <service name="HelloWorldBytesService">
      <interface.java interface="test.HelloWorldBytesService"/>
      <binding.jms>
        <!-- The wire format element must appear first in the binding definition
             to conform to the OASIS schema. -->
        <ts:wireFormat.jmsBytes/>
        <destination jndiName="jms/Request4"/>
        <activationSpec jndiName="jms/AS4"/>
        <response>
          <destination jndiName="jms/Response4"/>
          <connectionFactory jndiName="jms/CF" create="never"/>
        </response>
      </binding.jms>
    </service>
</component>
```

JMS message wire format that does not extract the message payload and maps to the `javax.jms.Message` class

This example illustrates the JMS Message wire format that does not extract the message payload and maps to the `javax.jms.Message` class:

OSOA

```
<component name="JMSTextBackendComponent">
    <implementation.java class="test.backend.HelloWorldTextBackendImpl" />
    <service name="HelloWorldTextService">
      <interface.java interface="test.HelloWorldTextService"/>
      <binding.jms>
        <destination name="jms/Request4"/>
        <activationSpec name="jms/AS4"/>
        <response>
          <destination name="jms/Response4"/>
          <connectionFactory name="jms/CF" create="never"/>
        </response>
        <!-- The wire format element must appear last in the binding definition
             to conform to the OSOA schema. -->
        <ts:wireFormat.jmsText/>
      </binding.jms>
    </service>
</component>
```

OASIS

```
<component name="JMSTextBackendComponent">
    <implementation.java class="test.backend.HelloWorldTextBackendImpl" />
    <service name="HelloWorldTextService">
      <interface.java interface="test.HelloWorldTextService"/>
      <binding.jms>
        <!-- The wire format element must appear first in the binding definition
             to conform to the OASIS schema. -->
        <ts:wireFormat.jmsText/>
        <destination jndiName="jms/Request4"/>
        <activationSpec jndiName="jms/AS4"/>
        <response>
          <destination jndiName="jms/Response4"/>
          <connectionFactory jndiName="jms/CF" create="never"/>
        </response>
      </binding.jms>
    </service>
</component>
```

Examples of TextMessage messages using JAXB

The following examples illustrate the contents of TextMessage messages produced by using JAXB marshalling in the default wire format. These examples are based on using the bottom-up approach of developing SCA applications starting with a Java interface, rather than the best practice of starting with a WSDL interface, such that the runtime environment generates the WSDL file.

- For a client invoking an SCA reference with the following interface method:

```
package com.ibm.test.soa.sca;
public String getGreetings(String name);
```

  The binding produces a TextMessage request message with XML payload similar to the following:

```
<ns2:getGreetings xmlns:ns2="http://sca.soa.test.ibm.com/">
   <arg0>Mike</arg0>
</ns2:getGreetings>
```

  The response message must be a TextMessage with XML payload similar to the following:

```
<ns2:getGreetingsResponse xmlns:ns2="http://sca.soa.test.ibm.com/">
   <return>Hello Mike</return>
</ns2:getGreetingsResponse>
```

  Similarly, an SCA service bound to a destination, from which TextMessage messages of this format were delivered, requires the same service interface method; for example:

```
package com.ibm.test.soa.sca;
public String getGreetings(String name);
```

- For a client invoking an SCA reference with the following interface method:

```
package com.ibm.test.soa.sca;
public void getGreeting(FullName name, String string);
```

  In this example, the `FullName` type is mapped to Java using JAXB using the following schema definition:

```
<schema targetNamespace="http://www.ibm.com/test/soa/sca/"
    elementFormDefault="qualified"
    xmlns=http://www.w3.org/2001/XMLSchema>

    <complexType name="FullName">
      <sequence>
        <element name="firstName" type="string"/>
        <element name="lastName" type="string"/>
      </sequence>
    </complexType>
</schema>
```

  The binding produces a TextMessage request message with XML payload similar to the following:

```
<ns2:getGreetings xmlns:ns2="http://sca.soa.test.ibm.com/">
   <arg0>Mike</arg0>
</ns2:getGreetings>
```

  The response message must be a TextMessage request message with XML payload similar to the following:

```
<ns3:getGreeting xmlns:ns3="http://sca.soa.test.ibm.com/"
   xmlns:ns2="http://www.ibm.com/test/soa/sca/">
   <arg0>
        <ns2:firstName>Bob</ns2:firstName>
        <ns2:lastName>Jones</ns2:lastName>
   </arg0>
   <arg1>home</arg1>
</ns3:getGreeting>
```

  Similarly, an SCA service bound to a destination, from which TextMessage messages of this format were delivered, requires the same service interface method; for example:

```
package com.ibm.test.soa.sca;
public String getGreeting(FullName name, String string);
```

Supported message types for SCA JMS binding wire formats:

For a Service Component Architecture (SCA) application that has a Java Message Service (JMS) binding to send and receive messages, the application must use a message type and data format that the JMS binding supports. Supported message types include JMS BytesMessage, ObjectMessage, and TextMessage. The message type to use depends on whether you are configuring an SCA service or reference and whether the JMS wire format of the service or reference is already determined.

The supported message types apply to applications coded to both the OSOA and OASIS specifications. Unless otherwise specified, the information in this topic pertains to both OSOA and OASIS applications.

The following sections describe supported message types:

- Message types for SCA services when the JMS binding wire format is predetermined
- Message types for SCA references when the JMS binding wire format is predetermined
- Message types for SCA services and references when the JMS binding wire format is not predetermined

Message types for SCA services when the JMS binding wire format is predetermined

For an SCA service to consume messages that are produced in a predetermined JMS binding wire format, use the following message types:

- **TextMessage or BytesMessage with serialized XML wire format that maps data using JAXB**

  The TextMessage or BytesMessage wire format uses Java Architecture for XML Binding (JAXB) technology to marshal and unmarshal data into XML. This wire format is the default wire format. Thus, this wire format applies if no wire format element is specified in the composite definition file. To specify this wire format, add the following wire format element to the composite definition file:

  OSOA

  ```
  {http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsdefault
  ```

  OASIS

  ```
  {http://docs.oasis-open.org/ns/opencsa/sca/200912}wireFormat.jmsDefault
  ```

  – **Mapping a request message payload to input arguments**

    The TextMessage or BytesMessage payload contains XML data that represents serialized input arguments. The format of the service is described by a WSDL interface that is specified by either a `interface.wsdl` element from the component service definition, or by a WSDL that is generated by the Java interface of the SCA service if the `interface.wsdl` element is not explicitly defined.

    This runtime environment Java-to-WSDL mapping is based on the JAXB and JAX-WS specifications. The default behavior results in a document-literal wrapped WSDL interface, except when there is a single parameter method. A single argument input parameter is **not** wrapped by a "wrapper" element corresponding to the operation name.

    JAXB unmarshalling is used to deserialize incoming XML payloads into the service arguments that are passed to the component implementation.

  – **Mapping an output return value to a response message payload**

    The return value of the service method is marshalled in a similar manner to the unmarshalling of the request message input. The marshalling uses JAXB and JAX-WS technology to map to XML in a WSDL defined format such that the WSDL is specified explicitly or the runtime environment generates the WSDL from the Java interface. The resulting serialized XML is never wrapped by the operation name, even if the WSDL defines a wrapper element.

    If the request payload is a BytesMessage, the non-wrapped XML is set as the payload of a response BytesMessage. If the request payload received is a TextMessage, the non-wrapped XML is set as a TextMessage. The response format is always the same as the request message format.

  – **Mapping exceptions to a response message payload**

    If you have a checked exception, the runtime environment will not marshall the exception. Instead, the runtime environment serializes the fault, as defined by JAX-WS, into an XML payload of a response TextMessage. If you have an unchecked exception, an instance of `RuntimeException` is set

as the payload of a response ObjectMessage. In both cases, a Boolean message property with the name, `org_apache_tuscany_sca_fault`, is set to`true` on the response message. To learn more about exceptions and faults, see the documentation on using business exceptions with SCA interfaces.

- **TextMessage with serialized XML wire format that maps data using JAXB**

  The TextMessage wire format uses JAXB technology to marshal and unmarshal data into XML. To specify this wire format, add the following wire format element to the composite definition file:

  OSOA

  ```
  {http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsTextXML
  ```

  OASIS

  ```
  {http://tuscany.apache.org/xmlns/sca/1.1}wireFormat.jmsTextXML
  ```

  – **Mapping a request message payload to input arguments**

    The TextMessage payload contains XML data that represents serialized input arguments. The format of the service is described by a Web Services Description Language (WSDL) interface that is specified by either a `interface.wsdl` element from the component service definition, or by a WSDL that is generated by the Java interface of the SCA service if the `interface.wsdl` element is not explicitly defined. This runtime environment Java-to-WSDL mapping is based on the JAXB and Java API for XML-Based Web Services (JAX-WS) specifications. This mapping results in a document-literal wrapped WSDL interface; however, the presence of the operation-level wrapper does not impact operation selection for the messages. JAXB unmarshalling is used to deserialize incoming XML payloads into the service arguments that are passed to the component implementation.

  – **Mapping an output return value to a response message payload**

    The return value of the service method is marshalled in a similar manner to the unmarshalling of the request message input. The marshalling uses JAXB and JAX-WS technology to map to XML in a WSDL defined format such that the WSDL is specified explicitly or the runtime environment generates the WSDL from the Java interface. The resulting serialized XML is the payload of a TextMessage response message.

  – **Mapping exceptions to a response message payload**

    If you have a checked exception, the runtime environment will not marshall the exception. Instead, the runtime environment serializes the fault, as defined by JAX-WS, into an XML payload of a response TextMessage. If you have an unchecked exception, an instance of `RuntimeException` is set as the payload of a response ObjectMessage. In both cases, a Boolean message property with the name, `org_apache_tuscany_sca_fault`, is set to`true` on the response message. To learn more about exceptions and faults, see the documentation on using business exceptions with SCA interfaces.

- **ObjectMessage wire format that maps to the `java.lang.Object` class**

  The ObjectMessage wire format uses serialized Java objects. To specify this wire format, add the following wire format element to the composition definition file:

  OSOA

  ```
  {http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsObject
  ```

  OASIS

  ```
  {http://tuscany.apache.org/xmlns/sca/1.1}wireFormat.jmsObject
  ```

  – **Mapping a request message payload to input arguments**

    The ObjectMessage payload returned by a `getObject()` method is typically an array that maps to the input parameters of your service method. In the case of a single non-array object, the object is mapped to the single argument of a method with only one parameter. The parameter type must be serializable by Java and implement the Java serialization interface, `java.io.Serializable`.

    For a method with exactly one parameter, the payload returned from `getObject()` can either be unwrapped, as described in the previous special case, or wrapped in an array of size one that maps to the single input parameter. When the runtime cannot determine if the payload array is a wrapper array that maps to the input parameters of your service method or if the payload array is the actual argument itself, the default behavior is to map the payload directly to the single argument of the

method. You can override this behavior by setting the `wrapSingle` attribute on the `wireFormat.jmsObject` element to `true`. When `wrapSingle` is set to `true`, the content of the payload array, which is a single element because the size of the array is one, is mapped to the single argument of the method. The payload array itself is not mapped to the method argument.

– **Mapping an output return value to a response message payload**

The return value of the service method is set as the ObjectMessage payload. The return type must also be Java-serializable and implement the Java serialization interface, `java.io.Serializable`. In the case of a void return type, the response payload is set to the value, `null`.

– **Mapping exceptions to a response message payload**

If you have a checked exception, the runtime environment sets the exception as the ObjectMessage payload. For an unchecked exception, an instance of `RuntimeException` is set as the payload of a response ObjectMessage. In both cases, a Boolean message property with name `org_apache_tuscany_sca_fault` is set to `true` on the response message.

- **TextMessage wire format that maps to single `String` messages**

Use the `wireFormat.jmsText` format to map between the payload of a TextMessage and a single `String` argument or return value. To specify this wire format, add the following wire format element to the composition definition file:

OSOA

```
{http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsText
```

OASIS

```
{http://tuscany.apache.org/xmlns/sca/1.1}wireFormat.jmsText
```

– **Mapping a request message payload to input arguments**

When using this wire format, the service interface method must contain a single parameter of type `String`; for example: `void myMethod(String str)`. The TextMessage payload that is returned by the `getText()` method is mapped to this single parameter.

– **Mapping an output return value to a response message payload**

The return type of the service method is typically either `String` or `void`. If the return type is `String`, the return value is set as the response TextMessage payload. If the return type is `void`, a `null` value is set as the payload. For a return value of type other than `String`, the payload is defined by setting a `String.valueOf()` on the return value.

– **Mapping exceptions to a response message payload**

Rather than defining a convention for mapping exceptions to a TextMessage, ObjectMessage messages are used to map exceptions. If you have a checked exception, the runtime environment sets the exception as the ObjectMessage payload. For an unchecked exception, an instance of `RuntimeException` is set as the payload of a response ObjectMessage message. In both cases, a Boolean message property with name `org_apache_tuscany_sca_fault` is set to `true` on the response message.

- **BytesMessage with XML wire format that maps data using JAXB**

The BytesMessage wire format uses JAXB technology to marshal and unmarshal data into XML. To specify this wire format, add the following wire format element to the composite definition file:

OSOA

```
{http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsBytesXML
```

OASIS

```
{http://tuscany.apache.org/xmlns/sca/1.1}wireFormat.jmsBytesXML
```

– **Mapping a request message payload to input arguments**

The input arguments are marshalled into an XML payload, and added to a request BytesMessage. The format of the service is described by a WSDL interface that is specified by either a `interface.wsdl` element from the component service definition, or by a WSDL that is generated by the Java interface of the SCA service if the `interface.wsdl` element is not explicitly defined. This runtime environment Java-to-WSDL mapping is based on the JAXB and JAX-WS specifications. This mapping results in a document-literal wrapped WSDL interface; however, the presence of the

operation-level wrapper does not impact operation selection for the messages. The product uses JAXB marshalling to serialize the Java client input argument into the XML payload.

– **Mapping exceptions to a response message payload**

The runtime environment first determines whether the response message represents an unchecked exception condition by looking for the `org_apache_tuscany_sca_fault` Boolean message property. If this property is set to `true` on the response message, the runtime environment expects an ObjectMessage as the response. When this condition occurs, a ServiceRuntimeException error is returned to the client. If this property is not set, or set to `false`, the message is a BytesMessage that can represent either a checked exception or normal output data. If a checked exception, the BytesMessage payload contains a fault in XML serialized form. The runtime environment deserializes the fault using JAXB unmarshalling, and returns the corresponding checked exception back to the client, wrappering the fault data. For more information about exceptions and faults, see the topic on using business exceptions with SCA interfaces.

– **Mapping an output return value to a response message payload**

The return value of the service method is marshalled in a similar manner to the unmarshalling of the request message input. The marshalling uses JAXB and JAX-WS technology to map to XML in a WSDL defined format such that the WSDL is specified explicitly or the runtime environment generates the WSDL from the Java interface. The resulting XML of the response BytesMessage is deserialized using JAXB unmarshalling and returned to the client.

- **BytesMessage wire format that maps to single byte array messages**

Use the `wireFormat.jmsBytes` format to map between the payload of a BytesMessage and a `byte[]` argument or return value. To specify this wire format, add the following wire format element to the composition definition file:

OSOA

```
{http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsBytes
```

OASIS

```
{http://tuscany.apache.org/xmlns/sca/1.1}wireFormat.jmsBytes
```

– **Mapping a request message payload to input arguments**

When using this wire format, the service interface method must contain a single parameter of type `byte[]`; for example: `void myMethod(byte[] bytes);`. The BytesMessage payload that is obtained using the `readBytes()` method is mapped to this single parameter.

– **Mapping an output return value to a response message payload**

The return type of the service method must be `byte[]` or `void`. If the return type is `byte[]`, the return value is set as the response BytesMessage payload.

– **Mapping exceptions to a response message payload**

When using this wire format, ObjectMessage messages are used to map exceptions, as in the ObjectMessage wire format case. If you have a checked exception, the runtime environment sets the exception as the ObjectMessage payload. For an unchecked exception, an instance of `RuntimeException` is set as the payload of a response ObjectMessage message. In both cases, a Boolean message property with name `org_apache_tuscany_sca_fault` is set to `true` on the response message.

- **JMS message wire format that does not extract the message payload and maps to the `javax.jms.Message` class**

You can use a wire format mechanism that instructs the JMS binding to provide the raw JMS message to the service implementation without extracting the payload out of the message. To use this wire format, the service interface must consist of a single method with one input parameter of `javax.jms.Message`, such as:

```
void methodA(javax.jms.Message msg);
```

The method name is not important; only the input parameter type is relevant. This method is similar to the `javax.jms.MessageListener` interface. The support for this method enables existing message-driven beans logic to be reused in SCA component implementations.

Use the default wire format to enable this mechanism to obtain the raw JMS message. To specify the default wire format, add the following wire format element to the composition definition file:

OSOA

```
{http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsdefault
```

OASIS

```
{http://docs.oasis-open.org/ns/opencsa/sca/200912}wireFormat.jmsDefault
```

Because this wire format is the default, the same result is achieved by not specifying a wire format element.

This wire format is not the same as the TextMessage JAXB XML format. In this scenario, the wire format selection does not describe a specific format of data on the wire. Instead, the specification of this wire format indicates to the runtime environment to identify this specialty case to obtain the raw JMS message and handle the incoming data by passing the raw JMS message to the application.

The response message is a TextMessage with a `null` payload. The response message is sent unless the `onMessage` method is annotated as a one-way operation.

Message types for SCA references when the JMS binding wire format is predetermined

For an SCA reference to produce messages that are consumed in a predetermined JMS binding wire format, use the following message types:

- **TextMessage with serialized XML wire format that maps data using JAXB**

  The TextMessage wire format uses JAXB technology to marshal and unmarshal data into XML. To specify this wire format, add the following wire format element to the composite definition file:

  OSOA

  ```
  {http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsTextXML
  ```

  OASIS

  ```
  {http://tuscany.apache.org/xmlns/sca/1.1}wireFormat.jmsTextXML
  ```

  – **Mapping input arguments to a request message payload**

    Using this wire format, the input arguments are marshalled into an XML payload, and added to a request TextMessage. The format of the service is described by a WSDL file interface that is specified by either a `interface.wsdl` element from the component service definition, or by a WSDL that is generated from the Java interface of the SCA service if the `interface.wsdl` element is not explicitly defined. The Java-to-WSDL mapping is based on the JAXB and Java API for XML-Based Web Services (JAX-WS) specifications. This mapping results in a document-literal wrapped WSDL file, and the wrapper element corresponds to the operation name. JAXB marshalling is used to serialize the Java client input arguments into the XML payload.

  – **Mapping a response message payload to output return value and exceptions**

    The runtime environment first determines whether the response message represents an unchecked exception condition by checking for the `org_apache_tuscany_sca_fault` Boolean message property. If this property is set to `true` on the response message, the runtime environment expects an ObjectMessage as the response. When this condition occurs, a ServiceRuntimeException error is returned to the client. If this property is not set, or set to `false`, the message is a TextMessage that can represent either a checked exception or output data.

    The return value of the service method is unmarshalled in a similar manner to the marshalling of the request message input. The marshalling uses JAXB and JAX-WS technology to map to XML in a WSDL defined format such that the WSDL is specified explicitly or the runtime environment generates the WSDL from the Java interface. The XML payload of the response TextMessage message is deserialized using JAXB unmarshalling and returned to the client.

    If you have a checked exception, the TextMessage payload contains a fault in XML serialized form. The runtime environment deserializes the fault using JAXB unmarshalling and the corresponding checked exception is sent back to the client, wrappering the fault data. To learn more about exceptions and faults, see the documentation on using business exceptions with SCA interfaces.

- **The BytesMessage or TextMessage with serialized XML wire format that maps data using JAXB**

The BytesMessage or TextMessage wire format uses JAXB technology to marshal and unmarshal data into XML. This wire format is the default wire format. Thus, this wire format applies if no wire format element is specified in the composite definition file. To specify this wire format, add the following wire format element to the composite definition file:

OSOA

```
{http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsdefault
```

OASIS

```
{http://docs.oasis-open.org/ns/opencsa/sca/200912}wireFormat.jmsDefault
```

– **Mapping input arguments to a request message payload**

  Using this wire format, the input arguments are marshalled into an XML payload, and added to a request BytesMessage. The format of the service is described by a WSDL file interface that is specified by either a `interface.wsdl` element from the component reference definition, or by a WSDL that is generated from the Java interface of the SCA service if an `interface.wsdl` element is not defined.

  The runtime Java-to-WSDL mapping is based on the JAXB and JAX-WS specifications. This mapping results in a document-literal wrapped WSDL file, and the wrapper element corresponds to the operation name, except when there is a single parameter method. A single argument input parameter is never wrapped by a wrapper element corresponding to the operation name. JAXB marshalling is used to serialize the Java client input arguments into the XML payload.

– **Mapping a response message payload to output return value and exceptions**

  The runtime environment first determines whether the response message represents an unchecked exception condition by checking for the `org_apache_tuscany_sca_fault` Boolean message property. If this property is set to `true` on the response message, the runtime environment expects an ObjectMessage as the response. When this condition occurs, a ServiceRuntimeException error is returned to the client. If this property is not set, or set to `false`, the message is a BytesMessage or TextMessage that can represent either a checked exception or output data.

  If you have a checked exception, the BytesMessage or TextMessage payload contains a fault in XML serialized form. The runtime environment deserializes the fault using JAXB unmarshalling and the corresponding checked exception is sent back to the client, wrappering the fault data. To learn more about exceptions and faults, see the topic on using business exceptions with SCA interfaces.

  For non-exception output data, the return value of the service method is unmarshalled in a similar manner to the marshalling of the request message input. The unmarshalling uses JAXB and JAX-WS technology to map to XML in a WSDL defined format such that the WSDL is specified explicitly or the runtime environment generates the WSDL from the Java interface. The XML payload is always expected to be in unwrapped format even if the WSDL defines a wrapper with an operation name. The XML payload of the response BytesMessage or TextMessage is deserialized using JAXB unmarshalling and returned to the client.

• **ObjectMessage wire format that maps to the `java.lang.Object` class**

  The ObjectMessage wire format uses serialized Java objects. To specify this wire format, add the following wire format element to the composition definition file:

  OSOA

  ```
  {http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsObject
  ```

  OASIS

  ```
  {http://tuscany.apache.org/xmlns/sca/1.1}wireFormat.jmsObject
  ```

  – **Mapping input arguments to a request message payload**

    The arguments that are passed to the SCA reference are wrapped in an array and are set into the request ObjectMessage payload using the `setObject()` method, except for methods with exactly one parameter. By default, arguments are not wrapped in an array for methods with a single argument unless the `wrapSingle` attribute is set to `true` on the `wireFormat.jmsObject` element.

  – **Mapping a response message payload to output return value and exceptions**

The runtime environment obtains the response ObjectMessage payload using the `getObject()` method. If the payload object is an unchecked exception, a ServiceRuntimeException error is returned to the client. If the payload object is an instance of a checked exception, the checked exception is returned to the client If the payload object represents non-exception output data, that payload object is returned back to the client application.

- **TextMessage wire format that maps to single string messages**

  Use the `wireFormat.jmsText` format to map between the payload of a TextMessage and a single `String` argument or return value. To specify this wire format, add the following wire format element to the composition definition file:

  OSOA

  ```
  {http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsText
  ```

  OASIS

  ```
  {http://tuscany.apache.org/xmlns/sca/1.1}wireFormat.jmsText
  ```

  – **Mapping input arguments to a request message payload**

    When using this wire format, the service interface method typically has a single parameter of type `String` ; for example: `void myMethod(String str)`. The single `String` passed to the SCA reference is set into the request TextMessage payload by the `setText()` method.

    For method signatures with different input parameters, the result of performing a `String.valueOf()` method on the first argument is set as the payload, regardless of how many arguments are present.

  – **Mapping a response message payload to output return value and exceptions**

    The return type of the service method is must be either `String` or `void`; for example: `String myMethod(String str)`.

    The runtime environment first determines whether the response message represents an exception condition by checking for the `org_apache_tuscany_sca_fault` Boolean message property. If this property is set to `true` on the response message, the runtime environment expects an ObjectMessage message as the response, and the message payload is obtained by the `getObject()` method. If the payload object is an unchecked exception, a ServiceRuntimeException is returned back to the client. If the payload object is an instance of a checked exception, that checked exception is returned to the client.

    If this property is not set, or set to `false`, the runtime environment expects non-exception output data and a TextMessage response. In this case, if the return type is `String`, a `getText()` method used to obtain the payload object that will be returned to the client application as a `String` value.

- **The BytesMessage with XML wire format that maps data using JAXB**

  The BytesMessage wire format uses JAXB technology to marshal and unmarshal data into XML. To specify this wire format, add the following wire format element to the composite definition file:

  OSOA

  ```
  {http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsBytesXML
  ```

  OASIS

  ```
  {http://tuscany.apache.org/xmlns/sca/1.1}wireFormat.jmsBytesXML
  ```

  – **Mapping input arguments to a request message payload**

    Using this wire format, the input arguments are marshalled into an XML payload, and added to a request BytesMessage. The format of the service is described by a WSDL file interface that is specified by either a `interface.wsdl` element from the component reference definition, or by a WSDL that is generated from the Java interface of the SCA service if an `interface.wsdl` element is not defined.

    The runtime Java-to-WSDL mapping is based on the JAXB and JAX-WS specifications. By default, this mapping results in a document-literal wrapped WSDL file, and the wrapper element corresponds to the operation name. JAXB marshalling is used to serialize the Java client input arguments into the XML payload.

  – **Mapping a response message payload to output return value and exceptions**

The runtime environment first determines whether the response message represents an unchecked exception condition by checking for the `org_apache_tuscany_sca_fault` Boolean message property. If this property is set to `true` on the response message, the runtime environment expects an ObjectMessage as the response. When this condition occurs, a ServiceRuntimeException error is returned to the client. If this property is not set, or set to `false`, the message is a BytesMessage that can represent either a checked exception or normal output data.

If you have a checked exception, the BytesMessage payload contains a fault in XML serialized form. The runtime environment deserializes the fault using JAXB unmarshalling and the corresponding checked exception is sent back to the client, wrappering the fault data. To learn more about exceptions and faults, see the topic on using business exceptions with SCA interfaces.

For non-exception output data, the return value of the service method is unmarshalled in a similar manner to the marshalling of the request message input. The unmarshalling uses JAXB and JAX-WS technology to map to XML in a WSDL defined format such that the WSDL is specified explicitly or the runtime environment generates the WSDL from the Java interface. The XML payload of the response BytesMessage is deserialized using JAXB unmarshalling and returned to the client.

- **BytesMessage wire format that maps to single byte array messages**

  Use the `wireFormat.jmsBytes` format to map between the payload of a BytesMessage and a single `byte[]` argument or return value. To specify this wire format, add the following wire format element to the composition definition file:

  OSOA

  ```
  {http://tuscany.apache.org/xmlns/sca/1.0}wireFormat.jmsBytes
  ```

  OASIS

  ```
  {http://tuscany.apache.org/xmlns/sca/1.1}wireFormat.jmsBytes
  ```

  – **Mapping input arguments to a request message payload**

    When using this wire format, the service interface method must contain a single parameter of type `byte[]`; for example: `void myMethod(byte[] bytes);`. The single argument is mapped to a BytesMessage payload using the `writeBytes()` method.

  – **Mapping a response message payload to output return value and exceptions**

    The return type of the service method must be `byte[]` or `void`.

    The runtime environment first determines whether the response message represents an exception condition by checking for the `org_apache_tuscany_sca_fault` Boolean message property. If this property is set to `true` on the response message, the runtime environment expects an ObjectMessage message as the response, and the message payload is obtained by the `getObject()` method. If the payload object is an unchecked exception, a ServiceRuntimeException error is returned to the client. If the payload object is an instance of a checked exception, that checked exception is returned to the client

    If this property is not set, or set to `false`, the runtime environment expects non-exception output data and a BytesMessage response message. In this case, a `readBytes()` method is used to obtain the payload object that will be returned to the client application as a `byte[]` value.

Message types for SCA services and references when the JMS binding wire format is not predetermined

Suppose you are adding a JMS binding to an SCA service or reference to produce messages that will be consumed at a future time by a JMS producer or consumer, and there is not a predetermined wire format.

It is a best practice to use the default wire format when starting with the SCA application. Use the JAXB programming model with the top-down approach to developing SCA applications as these service implementations and clients are easily used with the SCA default binding, the SCA web service binding, and the SCA JMS binding. Adopting an XML-centric view of your business data provides maximum portability across diverse platforms and technologies, and takes advantage of the design goals of a typical SOA environment. To learn more about top-down development of SCA applications, see the developing SCA applications from existing WSDL files documentation.

If you have business data that is described within Java classes that implement the Java serialization interface, `java.io.Serializable`, but the JAXB marshalling and unmarshalling does not satisfactorily preserve the data over the wire, you can use the ObjectMessage wire format.

Configuring JMS binding request and response wire formats:

You can configure the messaging data formats between an SCA application and a JMS producer or consumer, by configuring your SCA application to take advantage of a supported message type and data format. In general, each wire format can map to the service or reference side, and even into serialization and deserialization. As a result, you can configure each service or reference request and response to use different wire formats.

Before you begin

Configure the JMS binding for your SCA application. Then, configure the JMS binding wire format.

The product supports both the OASIS and the OSOA SCA JMS binding specification. Unless otherwise specified, the information in this topic pertains to applications for both the OSOA and OASIS specification.

About this task

In most cases, the response wire format can be the same as the request wire format for a messaging application. However, in certain scenarios this might not be reasonable, such as when the inputs and outputs of an operation cannot use the same wire format. In this situation, you can override the request wire format by explicitly configuring the response wire format with a `wireformat` element as a child on the `binding.jms response` element.

When choosing a request and response wire format, consider any restrictions imposed by the application itself and also the limitations of any particular wire format. For example, consider the following interface method:

```
public MyJavaObject method(MyJAXBObject mjo)
```

`MyJavaObject` is not an XML-serializable object and `MyJAXBObject` is not Java-serializable so you cannot use only one wire format. However, you can use `wireFormat.jmsTextXML` for the request wire format and `wireFormat.jmsObject` for the response.

Procedure

1. Open an editor on a composite definition file and configure a reference-side wire format.

   A reference-side wire format resembles the following:

   OSOA

```
<component name="JAXBJMSFrontendReqRespWFComponent">
  <implementation.java class="com.ibm.test.soa.sca.frontend.HelloWorldJAXBFrontendImpl"/>
    <reference name="hwJAXBService">
      <interface.java interface="com.ibm.test.soa.sca.HelloWorldJAXBService"/>
        <binding.jms>
          <destination name="jms/SCA_JMS_Request1"/>
          <connectionFactory name="jms/SCA_JMS_CF"/>
          <response>
            <destination name="jms/SCA_JMS_Response1"/>
            <connectionFactory name="jms/SCA_JMS_CF"/>
            <ts:wireFormat.jmsObject/>
          </response>
        </binding.jms>
    </reference>
</component>
```

   OASIS

```
<component name="JAXBJMSFrontendReqRespWFComponent">
  <implementation.java class="com.ibm.test.soa.sca.frontend.HelloWorldJAXBFrontendImpl"/>
    <reference name="hwJAXBService">
```

```
      <interface.java interface="com.ibm.test.soa.sca.HelloWorldJAXBService"/>
        <binding.jms>
          <destination jndiName="jms/SCA_JMS_Request1"/>
          <connectionFactory jndiName="jms/SCA_JMS_CF"/>
          <response>
            <ts:wireFormat.jmsObject/>
            <destination jndiName="jms/SCA_JMS_Response1"/>
            <connectionFactory jndiName="jms/SCA_JMS_CF"/>
          </response>
        </binding.jms>
    </reference>
</component>
```

In the example component configuration, the binding level wire format is the default because no wire format is specified. However, the response wire format is overridden by the `jmsObject` wire format.

2. Open an editor on a composite definition file and configure a service-side wire format.

   A service-side wire format resembles the following:

   OSOA

```
<component name="JAXBJMSBackendReqRespWFComponent">
  <implementation.java class="com.ibm.test.soa.sca.backend.HelloWorldJAXBBackendImpl"/>
    <service name="HelloWorldJAXBService">
      <interface.java interface="com.ibm.test.soa.sca.HelloWorldJAXBService"/>
        <binding.jms>
          <destination name="jms/SCA_JMS_Response1"/>
          <activationSpec name="jms/SCA_JMS_AS1"/>
          <response>
            <destination name="jms/SCA_JMS_Response1"/>
            <connectionFactory name="jms/SCA_JMS_CF"/>
            <ts:wireFormat.jmsObject/>
          </response>
        </binding.jms>
    </service>
</component>
```

   OASIS

```
<component name="JAXBJMSBackendReqRespWFComponent">
  <implementation.java class="com.ibm.test.soa.sca.backend.HelloWorldJAXBBackendImpl"/>
    <service name="HelloWorldJAXBService">
      <interface.java interface="com.ibm.test.soa.sca.HelloWorldJAXBService"/>
        <binding.jms>
          <destination jndiName="jms/SCA_JMS_Response1"/>
          <activationSpec jndiName="jms/SCA_JMS_AS1"/>
          <response>
            <ts:wireFormat.jmsObject/>
            <destination jndiName="jms/SCA_JMS_Response1"/>
            <connectionFactory jndiName="jms/SCA_JMS_CF"/>
          </response>
        </binding.jms>
    </service>
</component>
```

   The response wire format is always the same as the request wire format unless the response level wire format is explicitly configured.

Results

You have configured the request and response wire format for a messaging application.

Examples

More example component configurations that show request and response wire formats follow.

Component configuration for a multiple-parameter reference

OSOA

```
<component name="MultipleParameterFrontendReqRespWFComponent">
  <implementation.java class="com.ibm.test.soa.sca.frontend.MultipleParameterFrontendImpl"/>
    <reference name="mpService">

</component>
```

What to do next

Deploy and test the wire format configuration in your SCA application.

Configuring transactions for the SCA JMS binding

You can configure the Service Component Architecture (SCA) Java Message Service (JMS) binding for services and references to take advantage of transaction quality of service behaviors.

Before you begin

The information in this topic applies for both OSOA and OASIS SCA applications.

About this task

SCA provides declarative mechanisms in the form of intents for describing the transactional environment required by components.

The SCA JMS binding supports transacting message delivery with the global transaction of a component. The SCA transaction policies are specified as intents that represent quality of service behavior offered by the JMS binding on an SCA service or reference. However, the SCA JMS binding does not propagate transaction context; therefore, the client and service cannot participate in the same global transaction.

To learn more about SCA global transactions, see the SCA transaction intents documentation.

SCA references can use the `transactedOneWay` intent to transact one-way requests. When the `transactedOneWay` intent is used on an SCA reference, a one-way request on the reference is not sent until the global transaction of the client is committed. If the global transaction of the client is rolled back, the request is not sent.

SCA services can use the `transactedOneWay` intent to transact one-way requests only or the `exactlyOnce` intent to transact both one-way and request-response message patterns. When the `transactedOneWay` intent is used on an SCA service, a one-way request is received from the JMS binding as part of the component's global transaction. When the `exactlyOnce` intent is used on a service, both one-way and request-response message patterns are received from the JMS binding as part of the component's global transaction. The receipt of the message, and the sending of the response for request-response messaging, is not committed until the service transaction commits. If the service transaction is rolled back, the message is again made available for delivery or the message is sent to an exception destination that is based upon the configuration of the bus destination.

The SCA runtime environment typically performs a rollback of a global transaction only if the component produces an unchecked exception error. An unchecked exception error is a subclass of java.lang.RuntimeException or java.lang.Error class. A checked exception does not force a rollback. The component can force a rollback by using the UOWSynchronizationRegistry interface. For example:

```
com.ibm.websphere.uow.UOWSynchronizationRegistry uowSyncRegistry =
    com.ibm.wsspi.uow.UOWManagerFactory.getUOWManager();
uowSyncRegistry.setRollbackOnly();
```

If a reference does not require a `transactedOneWay` intent, then one-way requests are sent immediately. If a service does not require the `transactedOneWay` or `exactlyOnce` intent, requests are removed from the queue prior to the delivery of the request to the component. If the component processing fails, these requests cannot be delivered again.

Procedure

1. Specify the `transactedOneWay` or `exactlyOnce` intents on your SCA service or reference enable transacting message delivery with the global transaction of your component.

   The following example illustrates the use of the `transactedOneWay` and `exactlyOnce` intents. In this example, the component, `TransactionalComponent`, receives one-way and request-response messages from the DataUpdate service and subsequently sends one-way requests to the loggingService reference transactionally. If the component transaction rolls back, the active request is queued again and any requests to the reference are not sent.

   ```
   <component name="TransactionalComponent">
        <implementation.java class="example.TransactedImpl"
                requires="managedTransaction.global"/>
        <service name="DataUpdate" requires="exactlyOnce">
            <binding.jms>
               <destination name="jms/DataUpdate_Request" type="queue"/>
               <activationSpec name="jms/SCA_JMS_AS"/>
            </binding.jms>
        </service>

        <reference name="loggingService" requires="transactedOneWay">
            <binding.jms>
               <connectionFactory name="jms/SCA_JMS_CF"/>
            </binding.jms>
        </reference>
    </component>
   ```

2. Using the administrative console, configure the bus destination to handle failed messages.
   a. Start the administrative console.
   b. In the navigation pane, click **Service integration** > **Buses** > ***bus_name*** > **Destinations** > ***destination_queue_name*** or ***destination_topic_space_name*** .
   c. Under Exception destination, enter a value for the **Maximum failed deliveries per message** . This value specifies the maximum number of failed attempts to process a message, after which the message is forwarded from its intended destination to the exception destination. This property applies to individual messages.

Results

You have updated your SCA composite to use transacted message delivery.

Dynamic JMS resource creation during deployment

The product dynamically creates Java Message Service (JMS) resources necessary for a Service Component Architecture (SCA) composite, if those resources do not exist and relate to the WebSphere default messaging provider. The product creates the resources when adding the SCA composite to a business-level application. The dynamically created resources are created in a WebSphere default messaging provider service integration bus. The product does not create resources that relate to WebSphere MQ; those resources must exist. A dynamically created service integration bus resource is given a name that is specified in the JMS binding or, if the binding does not specify a resource name, is given a default name. When an SCA composite uses a mixture of existing and non-existent resources, the product dynamically creates the resources that do not exist.

Dynamic resource creation is supported for applications coded to both the OSOA and OASIS specifications. Unless otherwise specified, the information in this topic pertains to both OSOA and OASIS applications.

Restriction: Dynamic resource creation is not supported for multiple-server configurations. For stand-alone application servers, dynamic resource creation is enabled by default. To disable dynamic resource creation, set the `admin.jms.DRC.disable` system property to `true`.

- Default naming of resources
- Deployment validation error or warning messages
- Dynamic resource creation for JMS bindings

Default naming of resources

When a JMS binding does not specify a Java Naming and Directory Interface (JNDI) name for a resource, the product dynamically creates a service integration bus resource and assigns the resource a default name, `DefaultSCABus`.

Restriction: You must have SIBus service enabled for your application server. Before deploying your SCA composite, enable the SIBus service of the server, and then stop and restart the server.

For an SCA service that uses a JMS binding, the product uses the following default names if JNDI name values are not supplied in the composite definition.

Table 88. Default names for service resources. The product uses the default names when the composite definition omits JNDI name values.

Resource	Default name
Activation specification	`jms/DefaultSCAActivationSpec`
Activation specification create	OSOA: `ifnotexist` OASIS: `ifNotExist`
Destination	`jms/<componentName>_<serviceName>_ServiceRequestDestination`
Response connection factory name	`jms/DefaultSCAConnectionFactory`
Response connection factory create	OSOA: `ifnotexist` OASIS: `ifNotExist`

The product assigns computed destination names for values that are not provided in the JMS binding element based on the component name and service name, separated with underscores. For example, the computed destination name for a JMS binding in the HelloService service of the HelloServiceComponent component is `jms/HelloServiceComponent_HelloService_ServiceRequestDestination`.

The product assigns the destination a default value only when no JNDI name is supplied in the composite definition and the default activation specification is being used. If the composite definition defines an activation specification that exists already, the destination from the activation specification is used instead of the default value.

For an SCA reference that uses a JMS Binding, the product uses the following default names if JNDI name values are not supplied in the composite definition.

Table 89. Default names for reference resources. The product uses the default names when the composite definition omits JNDI name values.

Resource	Default name
Connection factory	`jms/DefaultSCAConnectionFactory`
Connection factory create	OSOA: `ifnotexist` OASIS: `ifNotExist`

Table 89. Default names for reference resources (continued). The product uses the default names when the composite definition omits JNDI name values.

Resource	Default name
Response connection factory	`jms/DefaultSCAConnectionFactory`
Response connection factory create	OSOA: `ifnotexist` OASIS: `ifNotExist`

The product assigns the response connection factory a default value only when no JNDI name is supplied in the composite definition and the response destination has been defined.

Deployment validation error or warning messages

The product validates a composite definition when adding an SCA asset to a business-level application. If the validation results in an error, the product does not add the asset to the application. If a warning results, the product issues a warning but adds the asset to the application.

Errors or warnings from validation of service JMS bindings

When a composite definition sets a `create` attribute to `always` for any of the following service JMS bindings, deployment stops with an error if the resource exists:
- Destination
- Activation specification
- Response destination
- Response connection factory

When a composite definition sets a `create` attribute to `never` for any resource, and that resource does not exist, the product issues a warning but the deployment continues and can complete successfully.

Errors or warnings from validation of reference JMS bindings

When a composite definition does not define a callback service or `destination` attribute, deployment stops with an error.

When a composite definition sets a `create` attribute to `always` for any of the following reference JMS bindings, deployment stops with an error if the resource exists:
- Destination
- Connection factory
- Response destination
- Response connection factory

When a composite definition sets a `create` attribute to `never` for any resource, and that resource does not exist, the product issues a warning but the deployment continues and can complete successfully.

An error occurs when an activation specification or connection factory has a default value assigned, and a non-default bus is used. This error can happen if the composite definition has an existing resource defined, such as a destination, and it uses a non-default bus. If the activation specification or connection factory has not been defined, the product supplies the default name.

Dynamic resource creation for JMS bindings

The product follows patterns for dynamic resource creation that are similar, although different, for services and references.
- Service resource creation
- Reference resource creation

Service resource creation:

When a service JMS binding is deployed, the product attempts to create resources for the binding. The composite definition might not specify JNDI names for the resources. The resources might not exist. There are four typical patterns for dynamic service resource creation:

Composite definition does not define resources

A composite definition that does not define resources resembles:

```
<binding.jms>
</binding.jms>
```

If a composite definition does not define resources, the product does the following:

- Assigns default names to all resources using the default service integration bus.
- Creates the default service integration bus `DefaultSCABus` if it does not exist.
- Creates the default destination `jms/<componentName>_<serviceName>_ServiceRequestDestination` on the default bus.
- Creates the default activation specification `jms/DefaultSCAActivationSpec` if it does not exist and uses the default bus and default destination.
- Creates the default response connection factory `jms/DefaultSCAConnectionFactory` if it does not exist and uses the default bus.

When the product creates a destination, a bus destination and a destination resource are created. The bus destination name and the destination resource name are derived from the JNDI name, with / replaced by _.

Composite definition defines destination and activation specification

A composite definition that defines both a destination and an activation specification resembles:

OSOA

```
<binding.jms>
  <destination name="jms/myDestination_Request" type="queue"/>
  <activationSpec name="jms/myActivationSpec"/>
</binding.jms>
```

OASIS

```
<binding.jms>
  <destination jndiName="jms/myDestination_Request" type="queue"/>
  <activationSpec jndiName="jms/myActivationSpec"/>
</binding.jms>
```

If a composite definition defines a destination and activation specification, the product performs actions that depend on whether resources exist for the destination and activation specification.

Resources for both the destination and activation specification do not exist:

- Creates the default service integration bus `DefaultSCABus` if it does not exist.
- Creates the destination `jms/myDestinationRequest` on the default bus.
- Creates the activation specification `jms/myActivationSpec` if it does not exist and uses the default bus and default destination.

The destination resource does not exist, but the activation specification resource exists:

- Creates the destination `jms/myDestinationRequest` on the bus that the activation specification uses.

The destination resource exists, but the activation specification resource does not exist:

- Creates the activation specification `jms/myActivationSpec` with the bus that the destination uses.

Composite definition defines the destination only

A composite definition that defines a destination resembles:

OSOA

```
<binding.jms>
  <destination name="jms/myDestination_Request" type="queue"/>
</binding.jms>
```

OASIS

```
<binding.jms>
  <destination jndiName="jms/myDestination_Request" type="queue"/>
</binding.jms>
```

If a composite definition defines a destination, the product performs actions that depend on whether the resource exists for the destination.

Destination resource does not exist:

- Creates the default service integration bus `DefaultSCABus` if it does not exist.
- Creates the destination `jms/`*`myDestinationRequest`* on the default bus.
- Creates the default activation specification `jms/DefaultSCAActivationSpec` if it does not exist and uses the default bus and the destination `jms/`*`myDestinationRequest`*.

Destination resource exists:

- The destination must use the default bus. Otherwise, the product returns an error and does not add the asset to the business-level application.
- Creates the default activation specification `jms/DefaultSCAActivationSpec` if it does not exist and uses the default bus and the destination `jms/`*`myDestinationRequest`*.

Composite definition defines the activation specification only

A composite definition that defines an activation specification resembles:

OSOA

```
<binding.jms>
  <activationSpec name="jms/myActivationSpec"/>
</binding.jms>
```

OASIS

```
<binding.jms>
  <activationSpec jndiName="jms/myActivationSpec"/>
</binding.jms>
```

If a composite definition defines an activation specification, the product performs actions that depend on whether a resource exists for the activation specification.

Activation specification resource does not exist:

- Creates the default service integration bus `DefaultSCABus` if it does not exist.
- Creates the default destination `jms/`*`<componentName>`*`_`*`<serviceName>`*`_ServiceRequestDestination` on the default bus.
- Creates the activation specification `jms/`*`myActivationSpec`* and uses the default bus and default destination.

Activation specification resource exists:

- Does not create a destination. The run time uses the destination from the existing activation specification.

Response connection factory for JMS bindings that provide a two-way service

JMS bindings that provide a two-way service require a response connection factory. When an asset with a two-way service is added to a business-level application, the product behaves in the following manner:

Composite definition defines the response connection factory

- Creates the response connection factory if it does not exist.

- If any resources for the binding already exist, creates the response connection factory using the bus that the existing resource uses. Otherwise, the product uses the default bus.
- If other resources for the binding do not exist, creates the other resources using the bus that an existing response connection factory uses.

Composite definition does not define the response connection factory

- Assigns the default name `jms/DefaultSCAConnectionFactory` and creates the response connection factory if it does not exist.
- If the product creates a response connection factory using the default name, the response connection factory can only be created on the default bus. Otherwise, the product returns an error and does not add the asset to the business-level application.

  If this error occurs, specify a JNDI name for the response connection factory in the composite definition to correct the error.

Reference resource creation:

When a reference JMS binding is deployed, the product attempts to create resources for the binding. The composite definition must define a destination. The connection factory, response destination, and response connection factory might not be defined. The resources that are defined might not exist. There are four typical patterns for dynamic reference resource creation:

Composite definition defines the destination only

A composite definition that defines a destination resembles:

OSOA

```
<binding.jms>
  <destination name="jms/myDestination_Request" type="queue"/>
</binding.jms>
```

OASIS

```
<binding.jms>
  <destination jndiName="jms/myDestination_Request" type="queue"/>
</binding.jms>
```

The destination resource might not exist.

Destination resource does not exist:

- Creates the default SIBus `DefaultSCABus` if it does not exist.
- Creates the destination `jms/`*`myDestination_Request`* on the default bus.
- Creates the default connection factory `jms/DefaultSCAConnectionFactory` if it does not exist and uses the default bus.

Destination resource exists:

- Creates the default service integration bus `DefaultSCABus` if it does not exist.
- Creates the default connection factory `jms/DefaultSCAConnectionFactory` if it does not exist and uses the default bus.

Composite definition defines destination and connection factory

A composite definition that defines both a destination and a connection factory resembles:

OSOA

```
<binding.jms>
  <destination name="jms/myDestination_Request" type="queue"/>
  <connectionFactory name="jms/myConnectionFactory"/>
</binding.jms>
```

OASIS

```
<binding.jms>
  <destination jndiName="jms/myDestination_Request" type="queue"/>
  <connectionFactory jndiName="jms/myConnectionFactory"/>
</binding.jms>
```

Each of these resources might not exist.

Resources for both the destination and connection factory do not exist:

- Creates the default service integration bus `DefaultSCABus` if it does not exist.
- Creates the destination `jms/`*`myDestination_Request`* on the default bus.
- Creates the connection factory `jms/myConnectionFactory` if it does not exist and uses the default bus and default destination.

The destination resource exists, but the connection factory resource does not exist:

- Creates the connection factory `jms/myConnectionFactory` with the bus that the destination uses.

The destination resource does not exist, but the connection factory resource exists:

- Creates the destination `jms/`*`myDestination_Request`* on the bus that the connection factory uses.

Invoking operations using JMS binding operation selection

You can invoke an operation using JMS binding operation selection. By default, a JMS binding uses the JMS binding operation selection.

Before you begin

Configure the JMS binding for your SCA application.

About this task

The JMS binding operation selection is the default binding selection. Thus, this operation selection applies if no operation selection element is specified in the composite definition file. To specify the JMS binding operation selection, add the following operation selection element to the composite definition file:

OSOA

```
{http://tuscany.apache.org/xmlns/sca/1.0}operationSelector.jmsdefault
```

OASIS

```
{http://docs.oasis-open.org/ns/opencsa/sca/200912}operationSelector.jmsDefault
```

Specify a JMS binding operation selection on an SCA service interface and on an SCA reference.

Procedure

1. In a composite definition file, specify a JMS binding operation selection on an SCA service interface.

   Because a given service can define multiple operations, the runtime environment must define mechanisms and algorithms to take a message from a destination bound from an SCA service using the SCA JMS binding, and invoke the correct operation on the SCA service implementation.

   The JMS binding defines a `String` message property called `scaOperationName`. When receiving a request at a service, or a callback at a reference, the JMS binding uses the following algorithm to determine the operation name:

   a. If there is only one operation on the service interface, it is assumed that this operation is the operation name for the request.
   b. Otherwise, if the JMS property `scaOperationName` is set, the value of this property is used as the operation name.

c. Otherwise, if the message is a JMS text or bytes message containing XML, then the selected operation name is taken from the local name of the root element of the XML payload. This operation selection behavior is only supported over the jmsdefault and the jmsTextXML and jmsBytesXML wire formats.

d. Otherwise, it is assumed that the operation name is `onMessage`.

2. In a composite definition file, specify a JMS user property operation selection on an SCA reference.

   When using the JMS user operation selector on the service side, the reference side or service side callback must set the matching JMS user property. In the service-side example, the operation selector uses the value of the `jmsTestUserProp` to determine the target operation. You can set this property for the reference or callback side by specifying one or more header properties in the `operationProperties` element; for example:

```
<operationProperties name="proxyMethodName">
<headers>
<property name="jmsTestUserProp">remoteMethodName</property>
</headers>
</operationProperties>
```

   In the example, a call to the `proxyMethodName` on the reference side sets the `jmsTestUserProp` user property to `remoteMethodName`. The `proxyMethodName` target operation is set to `remoteMethodName` when the service-side operation selector is configured as in the previous step.

Results

You have configured a JMS binding operation selection.

What to do next

Deploy and test the operation selection in your SCA application.

Invoking operations using JMS user property operation selection

You can invoke an operation using JMS user property operation selection.

Before you begin

Configure the JMS binding for your SCA application.

About this task

The JMS user property operation selection is a predefined operation selector that determines the target operation from the value of a given JMS user property. You can define the name of the JMS user property using the `propertyName` attribute of the `operationSelector.jmsUserProp` element. To specify the JMS user property operation selection, add the following operation selection element to the composite definition file:

OSOA

```
{http://tuscany.apache.org/xmlns/sca/1.0}operationSelector.jmsUserProp
```

OASIS

```
{http://tuscany.apache.org/xmlns/sca/1.1}operationSelector.jmsUserProp
```

Specify a JMS user property operation selection on an SCA service interface and on an SCA reference.

Procedure

1. In a composite definition file, specify a JMS user property operation selection on an SCA service interface.

   On the service side, the `jmsUserProp` operation selection uses the value of the given JMS user property to determine the target operation. For example:

```
<binding.jms>

...
    <ts:operationSelector.jmsUserProp propertyName="jmsTestUserProp"/>
...
</binding.jms>
```

The operation selector requires that you set a JMS user property to the target operation name. If the property is not set or there is no matching operation, the operation selector does not default to any other value, unlike the default JMS binding operation selector.

2. In a composite definition file, specify a JMS user property operation selection on an SCA reference.

   When using the JMS user operation selector on the service side, the reference side or service side callback must set the matching JMS user property. In the service-side example, the operation selector uses the value of the `jmsTestUserProp` to determine the target operation. You can set this property for the reference or callback side by specifying one or more header properties in the `operationProperties` element; for example:

```
<operationProperties name="proxyMethodName">
  <headers>
    <property name="jmsTestUserProp">remoteMethodName</property>
  </headers>
</operationProperties>
```

   In the example, a call to the `proxyMethodName` on the reference side sets the `jmsTestUserProp` user property to `remoteMethodName`. The `proxyMethodName` target operation is set to `remoteMethodName` when the service-side operation selector is configured as in the previous section.

Results

You have configured a JMS user property operation selection.

What to do next

Deploy and test the operation selection in your SCA application.

Invoking operations using custom operation selectors

If your application cannot use a default JMS binding operation selection or JMS user property operation selection to determine the target operation, you can use a JMS custom operation selector to invoke operations.

Before you begin

Configure the JMS binding for your SCA application.

It is recommended that your SCA component implementations contain only business logic to improve their portability, such as over other bindings. To improve portability, use the custom operation selector to hold the JMS-specific logic that handles an incoming JMS Message, enabling the component implementation to focus on binding-neutral business logic.

About this task

You can configure a JMS custom operation selector in an SCA composite definition without any changes to the application. To specify the JMS custom operation selection, add the following operation selection element to the composite definition file:

OSOA

```
{http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06}operationSelector.jmsCustom
```

OASIS

```
{http://www.ibm.com/xmlns/prod/websphere/sca/1.1}operationSelector.jmsCustom
```

The custom operation selector must implement the following interface:

```
package com.ibm.websphere.soa.sca.operationselector.jms.OperationSelector;
import javax.jms.Message;

public interface OperationSelector {
  public String getOperationName(Message msg);
  public WireFormatContext getWireFormatContext();
  public void setWireFormatContext(WireFormatContext ctx);
```

The interface exposes an instance of javax.jms.Message and enables interaction with the JMS user properties and message body. After doing operation selection, you do not need to use the `reset()` method to reposition the byte stream cursor for a BytesMessage. The run time automatically resets the cursor in all cases so that the wire format handler is not impacted by the operation selector reading the message first.

If the message body of a BytesMessage is read using any of the `read` methods available on a BytesMessage, reposition the byte stream to the beginning using the `reset()` method so that message processors can read the data in the entire message body intended for the targeted operation.

The wire format context is held by an instance of the com.ibm.websphere.soa.sca.wireformat.WireFormatContext class, which is passed with each invocation. The WireFormatContext class provides a java.util.Map interface where you can set property key and value pairs in the context. The WireFormatContext interface also provides several methods to extract useful information about the current context such as component and service names, invocation types, and the ability to mark exceptions. Refer to the Java documentation for the com.ibm.websphere.soa.sca.wireformat.WireFormatContext interface for a complete list of methods.

Procedure

1. In a composite definition file, configure a custom operation selector.

   Use the `operationSelector.jmsCustom` element and the `class` attribute to identify the customer operation selection implementation class. The custom operation selector applies when receiving a request at a service, or a callback at a reference.

   OSOA

   ```
   <component name="AccountComponent">
     <implementation.java ...>
     <service name="AccountService">
       <binding.jms>
         <destination ...>
         <response>
         ...
         </response>
         <xmlns:fep="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
                   fep:operationSelector.jmsCustom
                   class="com.ibm.test.soa.sca.opsel.SimpleCustomOpSel"/>
       </binding.jms>
     </service>
   </component>
   ```

   OASIS

   ```
   <component name="AccountComponent">
     <implementation.java ...>
     <service name="AccountService">
       <binding.jms>
         <xmlns:fep="http://www.ibm.com/xmlns/prod/websphere/sca/1.1"
                   fep:operationSelector.jmsCustom
                   class="com.ibm.test.soa.sca.opsel.SimpleCustomOpSel"/>
         <destination ...>
         <response>
         ...
         </response>
       </binding.jms>
     </service>
   </component>
   ```

2. Write code that implements the JMS custom operation selector class.
   For the SimpleCustomOpSel example class, you can use code such as the following:

```
package com.ibm.test.soa.sca.opsel;

import com.ibm.websphere.soa.sca.operationselector.jms.OperationSelector.*;
import javax.jms.*;

public class SimpleCustomOpSel implements OperationSelector {

    private WireFormatContext opSelContext;

    @Override
    public String getOperationName(Message msg) {
        String retVal = computeOperationName(msg);
        return retVal;
    }

    @Override
    public WireFormatContext getWireFormatContext() {
        return opSelContext;
    }

    @Override
    public void setWireFormatContext(WireFormatContext ctx) {
        this.opSelContext = ctx;
    }

    /*
     * There is a pre-packaged operationSelector that can do this,
     * <ts:operationSelector.jmsUser>.
     */
     private String computeOperationName(Message msg) {
         String opName = null;
         Integer val = null;
         try {
             val = msg.getIntProperty("MyPropertyName");
             if (val.equals(Integer.valueOf("1"))) {
                 opName = "addOperation";
             } else if (val.equals(Integer.valueOf("2"))) {
...
```

Results

You have configured a custom operation selector.

What to do next

Package the operation selection implementation class with your application. The class must be loadable by an application-level class loader.

Deploy and test the operation selector in your SCA application.

Using Atom bindings in SCA applications

You can use an Atom binding in a Service Component Architecture (SCA) application to expose collections of data as an Atom feed or to reference existing external Atom feeds.

Before you begin

If you are unfamiliar with the Atom protocol, refer to documentation on the Atom Syndication Format, an XML-based document format that describes web feeds, and the Atom Publishing Protocol, a protocol for publishing and updating web resources.

About this task

Use the Atom binding to work with services that provide or consume entries described in the Atom Syndication Format and Atom Publishing Protocol. An SCA component can reference existing external web feeds defined using the Atom protocol and work with them inside a Java implementation. Also, you can use the Atom binding to compose new services and expose them as an Atom feed.

This topic describes the following procedures:

- Expose an Atom feed service using an Atom binding.
- Use an Atom binding reference to access services exposed by SCA applications using the Atom binding or to access external Atom feeds.

Procedure

- Expose an Atom feed service using an Atom binding.
  1. Configure the Atom feed service in an SCA composite definition.

     Specify the uniform resource identifier (URI) of the Atom feed in a service in the composite definition of an SCA composite. The following example of a composite definition has a service exposed over the Atom binding:

```
<component name="NewsServiceComponent">
  <implementation.java class="com.ibm.test.atom.NewsServiceImpl"/>
  <service name="NewsService">
    <t:binding.atom uri="http://localhost:9080/newsService"/>
  </service>
</component>
```

     The example Atom binding URI, `http://localhost:9080/newsService`, is an absolute URI. To run applications that use an Atom binding in product clusters, specify a relative URI; for example:

```
<t:binding.atom uri="/newsService"/>
```

  2. Access the service.

     For example, to access the `NewsService` service, either use an SCA reference in another component or directly access the URI `http://localhost:9080/newsService` from a web browser. If accessed from a web browser, the browser handles the output as an Atom feed.

     The following example shows XML tagging for an Atom feed returned from the `NewsService` service:

```
<?xml version="1.0" encoding="UTF-8"?>
<feed xmlns="http://www.w3.org/2005/Atom">
  <title type="text">Feed</title>
  <id>Feed1329090360</id>
  <entry>
    <id>Item1</id>
    <title type="text">item</title>
    <content type="application/xml">
      <ns2:root xmlns:ns2="http://tuscany.apache.org/xmlns/sca/databinding/jaxb/1.0"
          xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="item">
      <name xmlns="">First Item Name</name>
      <title xmlns="">First Item Title</title>
    </ns2:root>
  </content>
  <link href="Item1"></link>
 </entry>
</feed>
```

  3. Manipulate the Atom feed using HTTP actions.

     You can manipulate the collections of items exposed by an Atom service by using the four basic actions of the HTTP protocol:
     - POST (create or add)
     - GET (retrieve or query)
     - PUT (update)
     - DELETE (remove)

     The Java implementation class for the component should implement the org.apache.tuscany.sca.data.collection.Collection interface or an interface that extends the Collection interface. The following methods are defined in the org.apache.tuscany.sca.data.collection.Collection interface:

public abstract Entry[] getAll()
Returns every entry in the feed
public abstract Entry[] query(String s)
Queries the feed for entries based on some matching criteria
public abstract Object post(Object obj, Object obj1)
Adds a new entry to the feed
public abstract Object get(Object obj) throws NotFoundException
Returns a single entry identified by the provided key value.
public abstract void put(Object obj, Object obj1) throws NotFoundException
Updates an existing entry identified by the provided key value
public abstract void delete(Object obj) throws NotFoundException
Deletes an existing entry identified by the provided key value

- Use an Atom binding reference to access services exposed by SCA applications using the Atom binding or to access external Atom feeds.
  1. Configure an Atom binding reference to access an exposed service.

     Specify a reference in the composite definition of an SCA composite that accesses an exposed service. The following example is a reference definition that accesses the `NewsService` service:

```
<reference name="newsServiceRef" target="NewsServiceComponent/NewsService">
    <t:binding.atom/>
</reference>
```

  2. Configure an Atom binding reference to access an external Atom feed.

     Specify a reference in the composite definition of an SCA composite that accesses an external Atom feed, for example:

```
<reference name="atomFeed">
    <tuscany:binding.atom uri="http://feeds.feedburner.com/blogspot/Dcni?format=xml"/>
</reference>
```

  3. Work with the Atom binding reference inside a Java implementation.

     A Java implementation class for an SCA component that contains the two example references might define them as follows:

```
@Reference(required = false)
public Collection newsServiceRef;

@Reference(required = false)
public Collection atomFeed;
```

  4. Use the Collection API in the implementation to manipulate the feed.

     For example, to add a new entry to the `NewsService` feed, the implementation might call:

```
MyEntry entry = new MyEntry("Title", "Content");
newsServiceRef.post("mykey-10-15", entry);
```

     To retrieve an entry from the external feed, the implementation code might use the following example code:

```
atomFeed.get("idtag-20090321");
```

What to do next

Deploy your SCA component in an application.

If the Atom feed service is deployed to a cluster and the target attribute, @target, is used to point to the service, the target URI resolves to an HTTP port for an individual cluster member. To maintain failover and load balancing in this situation, you can use an absolute URI on the `binding.atom` element that points to a proxy server endpoint rather than the target attribute on the reference element. For more information, see the topics on resolving SCA references and on routing HTTP requests to an SCA service when using an external web server.

Securing data exposed by Atom bindings

You can secure collections of data that are exposed by an Atom binding in a Service Component Architecture (SCA) application. An Atom binding can expose data as an Atom feed or reference existing external Atom feeds.

Before you begin

If you are unfamiliar with the Atom protocol, refer to documentation on the Atom Syndication Format, an XML-based document format that describes web feeds, and the Atom Publishing Protocol, a protocol for publishing and updating web resources.

For information about using Atom bindings in this product, refer to “Using Atom bindings in SCA applications” on page 806.

transition: In Version 8.5, the default value for the web authentication property `webAuthReq` is `persisting`, which enables credential persistence that allows login information to be available to unprotected web clients and enables additional access to user information. You must set the `webAuthReq` property to `lazy` to prevent unprotected web clients additional access to user information through persisting credentials. For more information, see Security hardening features enablement and migration. You can set `webAuthReq` to lazy on the administrative console Web security - General settings page:

1. Click **Security** > **Global security** > **Authentication** > **web and SIP security** > **General settings**.
2. Select **Authenticate only when the URI is protected**, which enables lazy authentication.
3. Click **Apply**.

For more information, see Web authentication settings.

About this task

Use the Atom binding to work securely with services that provide or consume entries described in the Atom Syndication Format and Atom Publishing Protocol.

Procedure

1. Configure the Atom feed service security in an SCA composite definition.

   You can secure services that are exposed over an Atom binding using intents. Administrative and application security must be enabled for the intents to be enforced. The following three intents are valid options for the `requires` attribute on the `binding.atom` element:

   authentication.transport
   Requires any client invoking the service to provide valid authentication information

   confidentiality.transport
   Requires any client invoking the service to do so over a secure transport that provides confidentiality of the transport

   integrity.transport
   Requires any client invoking the service to do so over a secure transport that provides integrity of the transport

   Edit a composite definition that exposes a Java service over the Atom binding so that the exposed service requires a client to authenticate and communicate over a secure transport; for example:

```
<component name="NewsServiceComponent">
  <implementation.java class="test.abdera.NewsServiceImpl"/>
  <service name="NewsService">
    <t:binding.atom uri="/NewsServiceComponent/newsService"
        requires="authentication.transport confidentiality.transport"/>
  </service>
</component>
```

   For information about authorization policy, refer to documentation on SCA authorization and security identity policies.

2. Invoke a secure service that is exposed over an Atom binding.

   You can access the service directly from a browser or a client that supports Atom feeds. To access the feed directly, you can use the uniform resource indicator (URI) that the service specifies.

If the service requires confidentiality or integrity, use the https protocol. If the service requires authentication, the user is prompted by the browser to enter valid credentials. If a Java client is used to access the service, include the authentication information in the HTTP header.

The following example invokes a service using a reference URI. If the service being referenced requires confidentiality or integrity, use the https protocol.

```
<reference name="atomFeed">
    <tuscany:binding.atom uri="https://localhost:9443/newsService"/>
</reference>
```

You can also invoke the service using a reference target:

```
<reference name="atomFeed" target="NewsServiceComponent/NewsService">
    <tuscany:binding.atom/>
</reference>
```

For this example, the invocation is secure only if the service specifies the `confidentiality.transport` or `integrity.transport` intent.

To authenticate when invoking a service over an Atom binding, you have two options:

- Use single sign-on (SSO) to authenticate.

  If SSO is enabled and there has been a successful authentication before, the credentials are propagated with the request. For information about enabling SSO, see the topic on implementing single sign-on to minimize web user authentications.
- Configure an authentication-alias, and send a specific user name and password with the request.

  You can use this option for references in `implementation.java` components. This option is not supported for references in `implementation.widget` components.

  a. Create an authentication-alias using the administrative console Java 2 Connector (J2C) authentication data entry page or wsadmin commands. See topics on J2C authentication data entries.

  b. In the composite definition, define the product SCA namespace and specify the alias name on the `binding.atom` element using the `authentication-alias` attribute.

```
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
...
xmlns:qos="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
...
<reference name="atomFeed" target="NewsServiceComponent/NewsService">
    <tuscany:binding.atom qos:authentication-alias="AtomAlias"/>
</reference>
```

What to do next

Test the service security.

Using Widget implementation in JavaScript with Atom bindings

The JavaScript code in an HTML file can use Service Component Architecture (SCA) references that are defined in a Tuscany Widget implementation. Use Widget implementation to work with data in Atom collections that an SCA service returns in JavaScript.

Before you begin

You can use an Atom binding in an SCA application to expose collections of data as an Atom feed or to reference existing external Atom feeds. If you are unfamiliar with the Atom protocol, refer to documentation on the Atom Syndication Format, an XML-based document format that describes web feeds, and the Atom Publishing Protocol, a protocol for publishing and updating web resources.

About this task

An SCA component can define SCA references for use in JavaScript code. Use Tuscany Widget implementation to define the references. The implementation supports references that use an Atom binding, and does not support the definition of SCA services.

The SCA composite that uses the Widget implementation must be deployed inside a Web application archive (WAR) file.

Procedure

1. Configure a Widget implementation in an SCA composite definition.

   Create an SCA composite definition file for a component that uses Tuscany `implementation.widget`. For example:

   ```
   <composite>
     <component name="Store">
       <tuscany:implementation.widget location="ui/store.html"/>
          <reference name="shoppingCart">
           <tuscany:binding.atom uri="/ShoppingCart/Cart"/>
          </reference>
     </component>
   </composite>
   ```

   This example defines a Store component that uses Tuscany `implementation.widget` in an HTML file at `ui/store.html`.

2. Enable the SCA reference in an HTML file.

   In the HTML file, `ui/store.html`, define two required script elements that enable SCA references. Specify the following for the first element:

   ```
   <script type="text/javascript>>
        dojo.registerModulePath("tuscany", "/Store/tuscany");
        dojo.require("tuscany.AtomService");
   </script>
   ```

   This definition is required when using Atom binding references. The `dojo.registerModulePath` method tells the `dojo` object where to find requirements in the Tuscany namespace. The first argument is always `"tuscany"`. The second argument is specified in the format */SCA_component_name*`/tuscany`. The `dojo.require` statement for `"tuscany.AtomService"` causes the browser to load the JavaScript file from the `/Store/tuscany/AtomService.js` file. The product dynamically generates this file to connect the Atom binding references to Atom services.

   Specify the following for the second element:

   ```
   <script type="text/javascript" src="/Store/store.js"></script>
   ```

   This definition is required in any HTML file that is used as an implementation for a Widget implementation component. For the script `src` attribute, specify the uniform resource identifier (URI) in the format */SCA_component_name/modified_implementation.widget_location_attribute*; for example, `/Store/store.js`. The modified location attribute is the Widget implementation location attribute without a leading path and with a file extension of `.js`.

3. Define the SCA reference in JavaScript in the HTML file.

   An HTML file that contains the above example reference might resemble:

   ```
   //@Reference
   var catalog = new tuscany.sca.Reference("shoppingCart");
   ```

   The `//@Reference` comment is required. The SCA run time interprets the comment in the same manner that a Java class interprets an `@Reference` tag.

4. Use JavaScript to manipulate the feed reference.

   For example, to retrieve an entire feed, the HTML file might use the following example code:

   ```
   var items = shoppingCart.get("");
   ```

   To retrieve a single entry, the implementation might call:

   ```
   var item = shoppingCart.get("Item1");
   ```

   To add a new entry to the feed, the HTML file might use the following example code:

```
var entry =
  '<entry xmlns="http://www.w3.org/2005/Atom"><title>item</title><content type="text/xml">'
   + '<Item xmlns="http://services/">' + <name xmlns="">' + itemName + '</name>'
   + '<price xmlns="">' + itemPrice + '</price>' + '</Item>' + '</content></entry>';

shoppingCart.post(entry);
```

What to do next

Deploy your SCA component in an application.

For additional examples, see the topic on using Widget implementation in JavaScript with Atom or HTTP bindings.

Using HTTP bindings in SCA applications

You can use an HTTP binding with a wire format of JSON-RPC in a Service Component Architecture (SCA) application to expose services to remote web browser clients. JSON-RPC is a remote procedure call (RPC) protocol encoded in the JavaScript Object Notation (JSON) format.

About this task

Use the HTTP binding to expose SCA services for consumption by remote web clients. This topic describes how to expose a Java implementation as a service to be consumed by a browser client using native Dojo interfaces and RPC libraries.

To use native SCA references in JavaScript code, see the topic on using Widget implementation in JavaScript with HTTP bindings.

Procedure

1. Configure the Java service in an SCA composite definition.

   Expose a Java service over the HTTP binding in the composite definition; for example:

```
<composite>
  <service name="EchoService" promote="EchoComponent">
    <interface.java interface="echo.Echo"/>
    <tuscany:binding.http uri="/EchoService"/>
      <tuscany:wireFormat.jsonrpc/>
    </tuscany:binding.http>
  </service>

  <component name="EchoComponent">
    <implementation.java class="echo.EchoComponentImpl"/>
  </component>
</composite>
```

   This example exposes the methods defined in the `echo.Echo` interface to web browser clients. The `echo.EchoComponentImpl` class implements the Echo interface and provides the implementation for the component. The service is exposed on the `"/EchoService"` relative uniform resource identifier (URI).

   The example HTTP binding URI, `/EchoService`, is a relative URI. To run applications that use an HTTP binding in product clusters, specify a relative URI. You cannot run applications in product clusters if the binding specifies an absolute URI, such as `http://localhost:9080/newsService`.

2. Access the service from a web browser.

   For example, to access the `EchoService` service, use the Dojo toolkit application programming interfaces in an HTML file or JavaServer Pages (JSP) file to access the service available at `/EchoService`:

```
<html>
<head>
<meta http-equiv="Content-Type" content="text/html; charset=ISO-8859-1">
<title>Echo...</title>
<script type="text/javascript" src="./dojo/dojo.js"></script>
<script>
  dojo.require("dojo.io.script")
  dojo.require("dojo.rpc.RpcService")
  dojo.require("dojo.rpc.JsonService")
```

```
  dojo.require("dojo.rpc.JsonpService")

  function filladdr(){
    var nameElement=document.getElementById("name");
    var name=nameElement.value;
    var echo = new dojo.rpc.JsonService("/EchoService?smd");
    echo.echo(name).addCallback(fillmsg);
  }

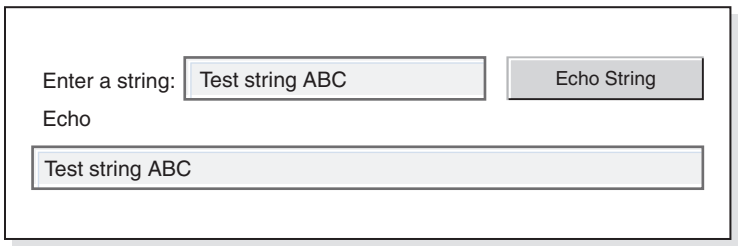
  function fillmsg(result){
    var line=document.getElementById("line1");
    line.value=result;
  }
</script>
</head>
<body>
Enter a string: <input id="name" type="text">
<input type="submit" value="Echo String" onClick="filladdr()"><br>
<p>Echo </p><input id="line1" type="text" size="50"><br><br>
</body>
</html>
```

The URI passed into the dojo.rpc.JsonService constructor "/EchoService?smd" contains the query string "smd" on the end of the URI specified in the <binding.http> definition in the composite. The query string "smd" on the end of the URI is required when using Dojo clients.

Results

The HTML output for the example output shows two text boxes and a "submit" button. When a user enters text in the first box and clicks the submit button, the following steps take place:

1. The JavaScript code in the filladdr() method obtains the value that was entered in the first text box.
2. The filladdr() method instantiates a dojo.rpc.JsonService object pointed to the URI "/EchoService?smd".
3. The JavaScript code runs the "echo(String)" method on the JsonService object, causing a JSON-RPC request to be sent to "/EchoService?smd".
4. The SCA run time handles the URI request by running the EchoComponentImpl.echo(String) method. The result is returned to the client as an HTTP response.
5. The web client runs the designated callback method, "fillmsg(result)", with the value returned from the service.
6. The JavaScript code in the fillmsg(result) method updates the second text box to contain the text returned from the service invocation.



What to do next

Consider the supported data types for the JSON conversion. Parameters for JSON-RPC requests are sent to the server in JSON format, and must be transformed by the SCA run time for use in the Java implementation. The response to the client is also in JSON format, so the SCA run time converts the value returned from the EchoComponentImpl.echo() method back into JSON. For example, echo("Testing...") might submit the following data to the server:

```
{"params":["Testing..."],"method":"echo","id":1}
```

The Java method `EchoComponentImpl.echo(String message)` is invoked with the String parameter `"Testing..."` and returns the String object `"echo: Testing..."`. The JSON response returned to the web client might look like:

```
{"id":1,"result":"echo: Testing..."}
```

Table 90. Supported data types for JSON conversions. Conversion enables the Web client and Java implementation to use the data.

Data type				
Primitive Type	<==>	JSON	<==>	Primitive Type
Array of Primitive Type	<==>	JSON	<==>	Array of Primitive Type
Java bean	<==>	JSON	<==>	Java bean
List	<==>	JSON	<==>	List
Map	<==>	JSON	<==>	Map
Set	<==>	JSON	<==>	Set

Securing services exposed by HTTP bindings

You can use an HTTP binding with a wire format of JSON-RPC securely in a Service Component Architecture (SCA) application. Use intents to secure services that are exposed by the HTTP binding to remote web browser clients.

Before you begin

JSON-RPC is a remote procedure call (RPC) protocol encoded in the JavaScript Object Notation (JSON) format.

For information about using HTTP bindings in this product, refer to “Using HTTP bindings in SCA applications” on page 812.

Enable administrative and application security, if not done so already. To enforce intents to secure services that are exposed by an HTTP binding, administrative and application security must be enabled.

transition: In Version 8.0, the default value for the web authentication property `webAuthReq` is `persisting`, which enables credential persistence that allows login information to be available to unprotected web clients and enables additional access to user information. You must set the `webAuthReq` property to `lazy` to prevent unprotected web clients additional access to user information through persisting credentials. For more information, see Security hardening features enablement and migration. You can set `webAuthReq` to lazy on the administrative console Web security - General settings page:

1. Click **Security** > **Global security** > **Authentication** > **web and SIP security** > **General settings**.
2. Select **Authenticate only when the URI is protected**, which enables lazy authentication.
3. Click **Apply**.

For more information, see Web authentication settings.

About this task

Use the HTTP binding to secure services. To secure services, configure the `requires` attributes on the `binding.http` element.

Procedure

1. Configure security for the HTTP binding service in an SCA composite definition.

   You can secure services that are exposed over an HTTP binding using intents. The following three intents are valid options for the `requires` attribute on the `binding.http` element:

authentication.transport
Requires any client invoking the service to provide valid authentication information.

confidentiality.transport
Requires any client invoking the service to do so over a secure transport that provides confidentiality of the transport.

integrity.transport
Requires any client invoking the service to do so over a secure transport that provides integrity of the transport.

Edit a composite definition that exposes a Java service over the HTTP binding so that the exposed service requires a client to authenticate and communicate over a secure transport; for example:

```
<composite>
  <service name="EchoService" promote="EchoComponent">
    <interface.java interface="echo.Echo"/>
    <tuscany:binding.http uri="/EchoService" requires="authentication.transport confidentiality.transport"/>
    <tuscany:wireFormat.jsonrpc/>
    </tuscany:binding.http>
  </service>

  <component name="EchoComponent">
    <implementation.java class="echo.EchoComponentImpl"/>
  </component>
</composite>
```

For information about authorization policy, refer to topics on SCA authorization and security identity policies.

2. Invoke a secure service that is exposed over an HTTP binding from a web browser.

   You can access the service directly from a JavaServer Pages (JSP) file or HTML page using the Dojo toolkit application programming interfaces from a web browser.

   If the service requires confidentiality or integrity, use the HTTPS protocol. If the service requires authentication, configure the client application to prompt the user for valid user name and password. If the default product settings enable single sign-on (SSO) and the user has authenticated previously, these credentials are automatically propagated in the request to the service.

What to do next

Test the service security.

Using Widget implementation in JavaScript with HTTP bindings

The JavaScript code in an HTML file can use Service Component Architecture (SCA) references that are defined in a Tuscany Widget implementation. Use Widget implementation to work with data in JavaScript Object Notation (JSON) format that an SCA service returns in JavaScript.

Before you begin

You can use the HTTP binding with a wire format of JSON-RPC to expose SCA services for consumption by remote web browser clients. JSON-RPC is a remote procedure call (RPC) protocol encoded in the JSON format.

About this task

An SCA component can define SCA references for use in JavaScript code. Use Tuscany Widget implementation to define the references. The implementation supports references that use an HTTP binding with a wire format of JSON-RPC, and does not support the definition of SCA services.

The SCA composite that uses the Widget implementation must be deployed inside a web application archive (WAR) file.

Procedure

1. Configure a Widget implementation in an SCA composite definition.

Create an SCA composite definition file for a component that uses Tuscany `implementation.widget`. For example:

```
<composite>
  <component name="Store">
    <tuscany:implementation.widget location="ui/store.html"/>
      <reference name="catalog">
        <tuscany:binding.http uri="/Catalog"/>
          <tuscany:wireFormat.jsonrpc/>
        </tuscany:binding.http>
      </reference>
  </component>
</composite>
```

This example defines a Store component that uses Tuscany `implementation.widget` in an HTML file at `ui/store.html`.

2. Create the HTML file specified in the SCA composite definition for the Widget implementation.

   In the HTML file, define required script elements such as the following:

```
<script type="text/javascript" src="/Store/store.js"></script>
```

   The script `src` attribute points to a JavaScript file that the product dynamically generates to connect the SCA references to their associated services. Specify the uniform resource identifier (URI) in the format */SCA_component_name/modified_implementation.widget_location_attribute*; for example, `/Store/store.js`. The modified location attribute is the location attribute without a leading path and with a file extension of `.js`.

3. Define the SCA reference in JavaScript in the HTML file.

   In the HTML file, define an SCA reference. For example:

```
//@Reference
var catalog = new tuscany.sca.Reference("catalog");
```

4. Add JavaScript code that uses the reference to the HTML file.

   The code used for this example resembles:

```
<script>

  function init() {
    catalog.get().addCallback(catalog_getResponse);
  }

  function catalog_getResponse(items,exception) {
    if(exception){
      alert(exception.message);
      return;
    }
    var catalog = "";
    for (var i=0; i < items.length; i++) {
      var item = items[i].name + ' - ' + items[i].price;
      catalog += '<input name="items" type="checkbox" value="' +
        item + '">' + item + '<br>';
    }
    document.getElementById('catalog').innerHTML=catalog;
  }

</script>
```

   In this example code, the `init` method calls the `get` method on the `catalog` reference. The result is sent to the callback method `callback_getResponse()`. The callback method adds check box elements to the HTML for each item returned from the catalog `get` method.

5. Add the user interface to the HTML file, as needed.

   The `ui/store.html` file used for this example might use the following user interface:

```
<html>
<body onload="init()">
<h1>Store</h1>
   <h2>Catalog</h2>
   <form name="catalogForm">
      <div id="catalog"></div>
      <br>
      <input type="button" onClick="addToCart()" value="Add to Cart">
   </form>
</body>
</html>
```

What to do next

Deploy your SCA component in an application.

When using the Widget implementation, HTTP binding references must be deployed on the same server or cluster as the HTTP binding services that they reference. This limitation is a result of browser limitations on cross-domain JavaScript invocation. If your application defines the reference and service in separate servers or clusters, use a proxy server so that the Widget implementation resource that contains the reference and the HTTP binding service are both accessed using the same HTTP domain.

To resolve HTTP binding references, either use a target attribute, @target, on the reference or specify the URI attribute on the `binding.http` element. For more information, see the topic on resolving SCA references.

For more examples, see the topic on using Widget implementation in JavaScript with Atom or HTTP bindings.

Using Widget implementation in JavaScript with Atom or HTTP bindings

You can use Tuscany Widget implementation to define Service Component Architecture (SCA) references for use in JavaScript code. Use Widget implementation to work with data that an SCA service returns in JavaScript. The data can be in Atom collections or in JavaScript Object Notation (JSON) format.

Before you begin

You can use an Atom binding in an SCA application to expose collections of data as an Atom feed or to reference existing external Atom feeds. If you are unfamiliar with the Atom protocol, refer to documentation on the Atom Syndication Format, an XML-based document format that describes web feeds, and the Atom Publishing Protocol, a protocol for publishing and updating web resources.

You can use the HTTP binding with a wire format of JSON-RPC to expose SCA services for consumption by remote web browser clients. JSON-RPC is a remote procedure call (RPC) protocol encoded in the JSON format.

About this task

An SCA component can define SCA references for use in JavaScript code. Use Tuscany Widget implementation to define the references. The implementation supports references that use an Atom binding or an HTTP binding with a wire format of JSON-RPC, and does not support the definition of SCA services. The implementation also supports the definition of SCA properties.

The SCA composite that uses the Widget implementation must be deployed inside a web application archive (WAR) file.

Procedure

1. Configure a Widget implementation in an SCA composite definition.

   Create an SCA composite definition file for a component that uses Tuscany `implementation.widget`. For example:

```
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
           xmlns:tuscany="http://tuscany.apache.org/xmlns/sca/1.0"
           targetNamespace="http://store" name="storeWidget">
  <component name="Store">
    <tuscany:implementation.widget location="ui/store.html"/>
 </component>
</composite>
```

This example defines a Store component that uses Tuscany `implementation.widget` in an HTML file at `ui/store.html`. The `implementation.widget` definition is located in the `"http://tuscany.apache.org/xmlns/sca/1.0"` namespace, rather than the `"http://www.osoa.org/xmlns/sca/1.0"` namespace that most SCA artifacts use.

2. Add SCA reference definitions to the SCA composite definition.

   Define one or more references that use an Atom binding or an HTTP binding. An SCA reference that uses an Atom binding resembles:

   ```
   <reference name="shoppingCart">
       <tuscany:binding.atom uri="/ShoppingCart/Cart"/>
   </reference>
   ```

   An SCA reference that uses the HTTP binding with a wire format of JSON-RPC resembles:

   ```
   <reference name="catalog">
       <tuscany:binding.http uri="/Catalog"/>
         <tuscany:wireFormat.jsonrpc/>
       </tuscany:binding.http>
   </reference>
   ```

   For more information on the Atom binding references, see the topics on using Atom bindings. For more information on HTTP binding references, see the topics on using HTTP bindings.

3. Add SCA property definitions to the SCA composite definition.

   You can define one or more properties in the SCA composite definition file. For example:

   ```
   <property name="currency">USD</property>
   ```

4. Add the SCA composite definition to the WAR file.

   Save the SCA composite definition in the `META-INF/sca-deployables/default.composite` file in the WAR file.

   For the example in this topic, the complete composite file is as follows:

   ```
   <composite xmlns="http://www.osoa.org/xmlns/sca/1.0"
              xmlns:tuscany="http://tuscany.apache.org/xmlns/sca/1.0"
              targetNamespace="http://store" name="storeWidget">
     <component name="Store">
       <tuscany:implementation.widget location="ui/store.html"/>

         <reference name="shoppingCart">
             <tuscany:binding.atom uri="/ShoppingCart/Cart"/>
         </reference>
         <reference name="shoppingTotal">
             <tuscany:binding.http uri="/ShoppingCart/Total">
               <tuscany:wireFormat.jsonrpc/>
             </tuscany:binding.http>
         </reference>
         <reference name="catalog">
             <tuscany:binding.http uri="/Catalog"/>
               <tuscany:wireFormat.jsonrpc/>
             </tuscany:binding.http>
         </reference>

         <property name="currency">USD</property>

     </component>
   </composite>
   ```

5. Create the HTML file specified in the SCA composite definition for the Widget implementation and add it to the WAR file.

   In the HTML file, define the SCA references and properties and define required script elements as described in topics on using Atom bindings or HTTP bindings. The `ui/store.html` file used for this example resembles:

   ```
   <html>
   <head>
   <title>Store</title>
   ```

```
<script type="text/JavaScript" src="../dojo/dojo.js"></script>
<script type="text/javascript>>
     dojo.registerModulePath("tuscany", "/Store/tuscany");
     dojo.require("tuscany.AtomService");
     dojo.require("dojo.rpc.JsonService");
</script>
<script type="text/JavaScript" src="/Store/store.js"></script>
<script language="JavaScript">

  //@Reference
  var catalog = new tuscany.sca.Reference("catalog");

  //@Reference
  var shoppingCart = new tuscany.sca.Reference("shoppingCart");

  //@Property
  var currency = new tuscany.sca.Property("currency");

  var catalogItems;

  function catalog_getResponse(items,exception) {
    var catalog = "";
    for (var i=0; i < items.length; i++) {
      var item = items[i].name + ' - ' + items[i].price;
      catalog += '<input name="items" type="checkbox" value="' +
        item + '">' + item + '<br>';
    }
    document.getElementById('catalog').innerHTML=catalog;
    catalogItems = items;
  }

  function shoppingCart_getResponse(feed) {
    if (feed != null) {
       var entries = feed.getElementsByTagName("entry");
       var list = "";
       for (var i=0; i < entries.length; i++) {
         var content =
           entries[i].getElementsByTagName("content")[0];
         var name =
           content.getElementsByTagName("name")[0].firstChild.nodeValue;
         var price =
           content.getElementsByTagName("price")[0].firstChild.nodeValue;
         list += name + ' - ' + price + '<br>';
       }
     }
     document.getElementById("shoppingCart").innerHTML = list;
   }

   function shoppingCart_postResponse(entry) {
     shoppingCart.get("").addCallback(shoppingCart_getResponse);
   }

   function addToCart() {
     var items  = document.catalogForm.items;
     var j = 0;
     for (var i=0; i < items.length; i++) {
       if (items[i].checked) {
         var entry =
           '<entry xmlns="http://www.w3.org/2005/Atom"><title>item<content
           type="text/xml">' + '<Item xmlns="http://services/">' + '<name xmlns="">'
           + catalogItems[i].name + '</name>' + '<price xmlns="">' +
           catalogItems[i].price + '</price>' + '</item>' + '</content></entry>';

         shoppingCart.post(entry).addCallback(shoppingCart_postResponse);
         items[i].checked = false;
       }
     }
```

```
    }

    function init() {
      catalog.get().addCallback(catalog_getResponse);
      shoppingCart.get("").addCallback(shoppingCart_getResponse);
    }
</script>
</head>

<body onload="init()">
<h1>Store</h1>
 <div id="store">
   <h2>Catalog</h2>
   <form name="catalogForm">
      <div id="catalog"></div>
      <br>
      <input type="button" onClick="addToCart()" value="Add to Cart">
   </form>
   <br>
   <h2>Your Shopping Cart</h2>
   <form name="shoppingCartForm">
      <div id="shoppingCart"></div>
      <br>
      <div id="total"></div>
      <br>
   </form>
 </div>
</body>
</html>
```

What to do next

Deploy your SCA component in an application.

Resolving SCA references

During application assembly or deployment, a reference (a service dependency) is typically resolved to an actual deployed SCA service.

About this task

You can specify the target endpoint of a Service Component Architecture (SCA) reference in any of the following ways:

- Using the @target attribute on the reference element in order to target a reference to a component service within the domain
- For OASIS composites, using the @target attribute of the `binding.ws` element to target a web service reference to an SCA web service within the domain
- Using the @uri attribute of the binding element to specify a binding-specific endpoint

Using the @target attribute on the reference element

Use this option when the target service is another SCA service that is in the same domain as the client component, or rather, the component with the reference.

This @target attribute is supported for `binding.sca` for both OSOA and OASIS composites. In an OSOA composite, you can optionally include a `binding.sca` element within a reference element that uses the @target attribute. In an OASIS composite, you cannot include a `binding.sca` element within a reference element that uses the @target attribute.

The @target attribute is supported for the following bindings for OSOA composites only:
- binding.ws
- binding.atom

- binding.http
- binding.json

When a reference uses the @target attribute, the client does not need to know the endpoint address of a service. It is determined during run time. Also, the @target attribute does not need to be updated when the target service is deployed to a new server with a different address.

If you use this approach, remember that you must use bindings of the same type, meaning that the reference must share a common binding with the service it is targeting.

Using the @target attribute on the binding.ws element

Use this option to wire an SCA web service reference to an SCA web service within the same domain.

This option is supported for OASIS composites only.

Using a binding-specific endpoint

You must resolve an SCA reference using a binding-specific endpoint if you invoke non-SCA services over non-default bindings or if you have compatible SCA services that are hosted in another domain.

In general, obtain the binding-specific endpoint from the service provider.

If your target service is another SCA service, see the documentation for configuring the particular SCA binding to learn more about which binding-specific endpoint is used for a given service deployment over a particular binding.

Procedure

1. Determine from the service provider whether the service that you are consuming is an SCA service within the same domain as your client.
2. Determine the binding that your client uses to consume this service.

   If the target service is an SCA service, the binding that you use is based on the bindings over which the service is exposed. If the service is not an SCA service, the binding depends on the technology over which the service is provided. For example, services offered over SOAP/HTTP use the SCA web services binding.
3. If the SCA service is hosted in the same domain as your client, use the @target attribute to resolve a reference to a component service within the domain.

   The following examples demonstrate using the @target attribute. The syntax for the `<reference>` element is the same for the different SCA binding types.

   - SCA default binding

     Target component

     ```
     <component name="TargetComponent">
       <service name="BankService"/>
     </component>
     ```

     Client component

     ```
     <component name="ClientComponent">
       <reference name="myReference" target="TargetComponent"/>
     </component>
     ```

   - SCA web service binding

     Target component

     ```
     <component name="TargetComponent">
       <service name="BankService">
         <interface.wsdl ....>
         <binding.ws/>
       </service>
     </component>
     ```

     Client component (OSOA example)

```
<component name="ClientComponent">
  <reference name="myReference" target="TargetComponent">
    <interface.wsdl ....>
    <binding.ws/>  <!-- The client does not have to specify endpoint details. -->
  </reference>
</component>
```

Client component (OASIS example)

```
<component name="ClientComponent">
  <reference name="myReference">
    <interface.wsdl ....>
    <binding.ws target="TargetComponent"/>
  </reference>
</component>
```

- SCA Atom binding

  Target component

  ```
  <component name="NewsServiceComponent">
    <service name="NewsService">
      <t:binding.atom uri="/newsService"/>
    </service>
  </component>
  ```

  Client component

  ```
  <component name="NewsComponent">
    <reference name="newsServiceRef" target="NewsServiceComponent/NewsService">
      <t:binding.atom/> <!-- The client does not need to specify endpoint details -->
    </reference>
  </component>
  ```

- SCA HTTP binding

  Target component

  ```
  <component name="Catalog">
    <service name="Catalog">
      <t:binding.http>
        <t:wireFormat.jsonrpc/>
      </t:binding.http>
    </service>
  </component>
  ```

  Client component

  ```
  <component name="Store">
     <t:implementation.widget location="store.html"/>
     <reference name="catalog" target="Catalog/Catalog">
        <t:binding.http/> <!-- The client does not need to specify endpoint details -->
           <t:wireFormat.jsonrpc/>
        </t:binding.http>
     </reference>
  </component>
  ```

4. Resolve the SCA reference by using a binding-specific endpoint if you are invoking non-SCA services over non-default binding or if you have compatible SCA services that are hosted in another domain.

   The following examples demonstrate using the binding-specific endpoint for the client component:

   - SCA web service client component

     ```
     <component name="ClientComponent">
       <reference name="myReference">
           <!-- The exact URL is obtained from a service provider. -->
         <binding.ws uri="http://www.mybank.com:9080/MyBank/AccountService/services>
       </reference>
     </component>
     ```

   - SCA `binding.atom` client component

     ```
     <component name="Aggregator">
       <reference name="atomFeed1">
         <t:binding.atom
           uri="http://www.ibm.com/developerworks/views/webservices/rss/libraryview.jsp"/>
       </reference>
     </component>
     ```

   - SCA `binding.http` client component

```
<component name="Store">
  <reference name="catalog">
    <t:binding.http uri="/catalog">
      <t:wireFormat.jsonrpc/>
    </t:binding.http>
  </reference>
</component>
```

See the documentation for configuring the particular SCA binding to learn more about binding-specific endpoint resolution for these SCA binding types.

Results

You have identified your SCA client's reference to a target service that it will consume.

Routing HTTP requests to an SCA service when using an external web server

If you are using an external web server to route requests to an SCA service that is exposed over the SCA web services, Atom or HTTP binding, you must define the endpoints of the SCA service to the Web Server HTTP plug-in.

About this task

Requests to services that are exposed over the SCA binding that use the proxy server type that is provided with WebSphere Application Server are routed over the specified proxy by default.

However, if your configuration uses an external web server with the HTTP plug-in for WebSphere Application Server and you want requests to services that are exposed over the SCA binding to route through the external web server, you must define the endpoints for the SCA service by adding the service URL patterns to the `plugin-cfg.xml` file for the Application Server.

Procedure

1. Obtain the URL patterns for each service.

   You can obtain the URL patterns in one of the following ways:

   - Use the message, which is located in the server log file, that indicates the web application is successfully created.

     During service startup, for each service that is exposed over an SCA binding, a dynamic web application is created and configured with the URI of the service. This process is described as an informational message within the server log file as shown in the following example.

     In the following example message, the helloworldws composition unit contains the AsyncTranslatorService service, which is exposed over the SCA web service binding. This message provides the necessary context root and URL pattern for the service, which you must add to the `plugin-cfg.xml` file.

```
/AsynchTranslatorComponent/AsynchTranslatorService/*

[[11/18/08 10:10:52:156 EST] 00000070 servlet I com.ibm.ws.webcontainer.servlet.ServletWrapper init
SRVE0242I: [helloworldws]
[/AsynchTranslatorComponent/AsynchTranslatorService]
[SCA_WS_BINDING_IMPL_CLASS_PLACEHOLDER]: Initialization successful.
[11/18/08 10:10:52:156 EST] 00000070 WASAxis2Exten I
WSWS7037I: The /* URL pattern was configured for the SCA_WS_BINDING_IMPL_CLASS_PLACEHOLDER servlet located
in the SCAWSBindSERV_AsynchTranslatorComponent_AsynchTranslatorService.war web module.
```

   - Use the `warinfo.props` WebSphere configuration repository file.

     For each composition unit that has at least one service or reference exposed over the binding, a single `warinfo.props` file is generated during deployment. This file contains configuration information for each dynamic web application that starts during the server startup process.

     The `warinfo.props` file is located in, for example, the *profile_root*`\SOAAppSrv01\config\cells\cell1\cus\helloworldws\cver\BASE\meta\warinfo.props` directory.

The file contains an entry for each dynamic web application. For example:

```
#
#Tue Nov 18 10:10:37 EST 2008
SCAWSBindSERV_AsynchTranslatorComponent_
AsynchTranslatorService.war=AsynchTranslatorComponent/
AsynchTranslatorService\:default_host\:false\:false\:false
```

The value immediately following the `war=` and ending prior to the `\:` is the context root for the web application. In this example, the context root is **AsynchTranslatorComponent/ AsynchTranslatorService**.

2. Add the values for each dynamic web application to the `plugin-cfg.xml` file.

   After obtaining all of the entries from each of the services that you want to define to the proxy server, add the values to the `plugin-cfg.xml` file. It is important that you add the URI to the specific UriGroup that contains a server and hosts the proxied service because multiple UriGroups might exist. If this process is not done correctly, an HTTP 404 message results.

   In the following example, see the **AsynchTranslatorComponent/AsynchTranslatorService** entry that has been added to the list of URI patterns:

```
<UriGroup Name="default_host_Cluster2_URIs">
? <Uri AffinityCookie="JSESSIONID"
AffinityURLIdentifier="jsessionid"
Name="/IBM_WS_SYS_RESPONSESERVLET/*" />
?  <Uri AffinityCookie="JSESSIONID"
AffinityURLIdentifier="jsessionid"
Name="/IBM_WS_SYS_RESPONSESERVLET/*.jsp" />
?  <Uri AffinityCookie="JSESSIONID"
AffinityURLIdentifier="jsessionid"
Name="/IBM_WS_SYS_RESPONSESERVLET/*.jsv" />
?  <Uri AffinityCookie="JSESSIONID"
AffinityURLIdentifier="jsessionid"
Name="/IBM_WS_SYS_RESPONSESERVLET/*.jsw" />
?  <Uri AffinityCookie="JSESSIONID"
AffinityURLIdentifier="jsessionid"
Name="/IBM_WS_SYS_RESPONSESERVLET/j_security_check" />
?  <Uri AffinityCookie="JSESSIONID"
AffinityURLIdentifier="jsessionid"
Name="/IBM_WS_SYS_RESPONSESERVLET/ibm_security_logout" />

?  <Uri AffinityCookie="JSESSIONID"
AffinityURLIdentifier="jsessionid"
Name="/AsynchTranslatorComponent/AsynchTranslatorService/*" /> </UriGroup>
```

Results

You have configured the endpoints for SCA services to route requests through an external web server configured with the HTTP plug-in for WebSphere Application Server

Interoperability between Open SCA client services and WebSphere Process Server SCA modules

Support for Service Component Architecture (SCA) provides a simple, yet powerful programming model for constructing applications based on the Open SCA specifications. The SCA modules of WebSphere Process Server use import and export bindings to interoperate with Open SCA services.

An Open SCA application invokes WebSphere Process Server SCA applications using an export binding. An Open SCA application receives a call from a WebSphere Process Server SCA application using an import binding.

When building an Open SCA service client which will invoke WebSphere Process Server SCA module services, start with an existing WSDL file for all supported bindings except Enterprise JavaBeans (EJB) bindings.

Generate Java interfaces from the Web Services Description Language (WSDL) file. Do not port modules from WebSphere Process Server SCA to Open SCA and do not port modules from Open SCA to WebSphere Process Server SCA.

In general, Java artifacts are not reusable across WebSphere Process Server SCA modules and Open SCA applications, even when one artifact invokes the other over a common WSDL interface. You must use appropriate tooling to separately generate, from the WSDL interface, the Java interfaces and classes that are used in the Open SCA applications and the Java interfaces and classes that are used in the WebSphere Process Server SCA modules. For Open SCA applications, use the **wsimport** command-line tool or Rational Application Developer with SCA function. For WebSphere Process Server SCA modules, use a tool such as WebSphere Integration Developer.

Bindings that support interoperability between Open SCA client services and WebSphere Process Server SCA modules

Currently, four bindings support interoperability between Open SCA client services and WebSphere Process Server SCA modules:

- SCA binding
- EJB binding
- Web service binding
- JMS binding

SCA binding

When configuring a reference to a WebSphere Process Server SCA module export over SCA binding the following restrictions apply:

- Only synchronous invocations of request-response (two-way) operations are supported.
- All components or modules must be in the same WebSphere Application Server cell definition. The SCA binding is not supported across the cell.
- Both the Open SCA component and the WebSphere Process Server SCA module must use a WSDL interface that meets the following requirements:
  - Web Services Description Language (WSDL) Version 1.1
  - WS-I Basic Profile Version 1.1
  - Simple SOAP Binding Profile 1.0 standards
  - Document literal style

Constructing a URI for a WebSphere Process Server SCA module export over SCA binding

WebSphere Process Server SCA module export is exposed using a uniform resource indicator (URI) that is constructed as follows:

module_name/export_name

The *module_name* and *export_name* variables are defined in the WebSphere Process Server application. You can view the values from either WebSphere Integration Developer or from the administrative console.

Specify this URI as the reference target URI or as the URI in the `binding.sca` element in the `.composite` file. For example, for a WebSphere Process Server module named `HelloWorldModule` and a WebSphere Process Server export named `/test/sca/ClassicHelloWorld`, the `.composite` file resembles the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0" autowire="false"
       name="HelloWorldClientComposite" targetNamespace="http://sca.test">
  <component name="HelloWorldClientComponent">
    <implementation.java class="test.sca.open.OpenHelloWorldClient"/>
    <reference name="classicHWReference" target="HelloWorldModule/test/sca/ClassicHelloWorld">
      <interface.wsdl interface="http://sca.test#wsdl.interface(HelloWorldInterface)"/>
      <binding.sca/>
    </reference>
  </component>
</composite>
```

or:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0" autowire="false"
       name="HelloWorldClientComposite" targetNamespace="http://sca.test">
  <component name="HelloWorldClientComponent">
```

```
    <implementation.java class="test.sca.open.OpenHelloWorldClient"/>
    <reference name="classicHWReference">
      <interface.wsdl interface="http://sca.test#wsdl.interface(HelloWorldInterface)"/>
      <binding.sca uri="HelloWorldModule/test/sca/ClassicHelloWorld"//>
    </reference>
  </component>
</composite>
```

EJB binding

When configuring a reference to a WebSphere Process Server SCA module export over an EJB binding, the following restrictions apply:

- Only synchronous invocations are supported.
- Only EJB 3.x protocol is supported.
- Both the Open SCA component and WebSphere Process Server SCA module must use a Java interface that conforms to the EJB 3.x programming model.

Web service (JAX-WS) binding

When configuring a reference to a WebSphere Process Server SCA module over a Web service binding, the following features are supported:

- Asynchronous (one-way) and synchronous (request or response) invocations
- The SOAP1.1/HTTP or SOAP1.2/HTTP protocols
- Web Services Atomic Transaction and Web Services Security qualities of service

When configuring a reference to a WebSphere Process Server SCA module over a Web service binding, the following restrictions apply:

- Callback is not supported for non-SCA services like WebSphere Process Server SCA export modules.
- Both the Open SCA component and the WebSphere Process Server SCA module must use a WSDL interface that meets the following requirements:
  - Web Services Description Language (WSDL) Version 1.1
  - WS-I Basic Profile Version 1.1
  - Simple SOAP Binding Profile 1.0 standards
  - Document literal style

JMS binding

When configuring a reference to a WebSphere Process Server SCA module over a JMS binding, the following features are supported:

- Asynchronous (one-way) and synchronous (request or response) invocations
- JMS provider platform messaging (JMS binding)
- JMS provider WebSphere MQ (WebSphere MQ JMS binding)

When configuring a reference to a WebSphere Process Server SCA module over a JMS binding, the following restrictions apply:

- When using `commonj.sdo.DataObject` as a parameter type in Java, `wireFormat.jmsObject` is not supported. Although both the SCA and WebSphere Process Server application Java programming models support the use of the same Java-serializable type, `commonj.sdo.DataObject`, and `wireFormat.jmsObject` results in Java serialization, the `commonj.sdo.DataObject` interface is backed by different implementations in each of the two environments. Thus, this wire format is not an interoperable option. Instead, use an XML wire format, such as `wireFormat.jmsTextXML` or `wireFormat.jmsBytesXML`, or use `wireFormat.jmsdefault`.
- Callback is not supported.

Data types

Business graphs are not interoperable across any SCA bindings and, therefore, are not supported in interfaces used to interoperate with SCA.

Creating wire format handlers

You can use a wire format handler to transform data between a Service Component Architecture (SCA) application and the application binding.

Before you begin

This topic assumes that you have an SCA application with a specified binding. The product supports wire format handling for a Java Message Service (JMS) binding.

Unless otherwise specified, the information in this topic pertains to both OSOA and OASIS applications.

About this task

You can implement a wire format handler that converts data between an application wire format and a JMS Message wire format that is used by the JMS destination of a JMS binding.

Creating a wire format handler consists of two main steps:

1. Implement a Java interface that defines the wire format handler.
2. Configure the wire format handler in the composite definition file of the SCA application.

Procedure

1. Implement the wire format handler interface.

   The wire format handler provides function that transforms one form (source) to another. The result of a transformation is mapped into either object source or JMS message source. The wire format handler must implement the WireFormatHandler interface, which has methods that map into the two source types.

   See the following example wire format handler interface:

```
package com.ibm.websphere.soa.sca.wireformat;

public interface WireFormatHandler {

    /**
  * Transform.
  *
  * @param source
  *            the source
  *
  * @return the object
  *
  * @throws WireFormatHandlerException
  *             the wire format handler exception
  */
    public Object transform(Object source)
        throws WireFormatHandlerException;

    /**
  * Sets the wire format context.
  *
  * @param ctx
  *            the new wire format context
  */
    public void setWireFormatContext(WireFormatContext ctx);

    /**
  * Gets the wire format context.
  *
  * @return the wire format context
  */
    public WireFormatContext getWireFormatContext();}
```

In the `public Object transform` method implementation, the wire format handler transforms data from the source object to a target object. If an error occurs during the transformation, the data handler implementation throws a WireFormatHandlerException.

The `public void setWireFormatContext` method implementation sets the runtime context of the wire format handler. The `public WireFormatContext getWireFormatContext` method implementation gets the runtime context of the wire format handler. Even if you do not intend to use the context object, you must implement these methods.

The wire format context contains runtime contextual information passed from the caller to the wire format handler. The WireFormatContext interface specifies the runtime context of the wire format handler. Each wire format handler implementation must implement the `setWireFormatContext` method of the WireFormatContext interface.

The WireFormatContext class provides a java.util.Map interface where you can set property key and value pairs in the context. The WireFormatContext interface also provides several methods to extract useful information about the current context such as component and service names, invocation types, and the ability to mark exceptions. Refer to the Java documentation for the com.ibm.websphere.soa.sca.wireformat.WireFormatContext interface for a complete list of methods.

2. Configure the wire format handler in the SCA composite definition file.

   Configuring a wire format handler consists of specifying the configuration properties at authoring time and then accessing the configuration properties at run time. Update the composite definition file of your SCA composite to instruct the component to use the wire format handler class; for example:

   OSOA

```
xmlns:fep="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"

<component name="Account">
  <implementation.java class="helloworld.AccountComponent"/>
  <service name="Account">
    <binding.jms>
      <destination ...>
      <response>
        ...
      </response>
      <fep:wireFormat.jmsCustom class="helloworld.custom.FirstWFH"/>
    </binding.jms>
  </service>
</component>
```

   OASIS

```
xmlns:fep="http://www.ibm.com/xmlns/prod/websphere/sca/1.1"

<component name="Account">
  <implementation.java class="helloworld.AccountComponent"/>
  <service name="Account">
    <binding.jms>
      <fep:wireFormat.jmsCustom class="helloworld.custom.FirstWFH"/>
      <destination ...>
      <response>
        ...
      </response>
    </binding.jms>
  </service>
</component>
```

What to do next

Deploy your SCA application and test its behavior.

Wire format handler errors

A wire format handler can transform data between a Service Component Architecture (SCA) application and the application binding. This topic discusses the different types of exceptions and errors that can result at run time in an SCA application that uses wire format handlers. The product supports wire format handling for a Java Message Service (JMS) binding.

The information in this topic pertains to both OSOA and OASIS applications.
- Business exceptions
- Runtime exceptions
- Service and reference exceptions
- Exception handling from a wire format handler

Business exceptions

Business exceptions are business errors or exceptions that occur during processing.

A business exception is a checked exception. It inherits from the Exception class. Client code must handle a checked exception in a catch clause or with a throws clause.

When a business exception occurs, a checked exception object results from the service business exception in the SCA application. The object calls the wire format handler that is configured on the service.

Runtime exceptions

Runtime exceptions are exceptions that occur in the SCA application from processing of a request. Runtime exceptions do not correspond to business exceptions. Unlike business exceptions, runtime exceptions are not defined on the interface.

You can propagate runtime exceptions to the client application so that the client application handles the exceptions. For example, if a client sends a request to create a customer to an SCA application and an authorization error occurs during processing of this request, the SCA component throws a runtime exception. This runtime exception must be propagated back to the calling client so it can act on the authorization request. You can use a wire format handler configured on the reference to propagate runtime exceptions back to the calling client application.

Service and reference exceptions

To handle both business exceptions and runtime exceptions, you can set up exception handling on the application bindings. Handling exceptions on either the reference or service on a binding is optional.

You likely create exception wire format handlers for the most common errors that occur at run time in your application:
- When the exception thrown by the SCA application service must be transformed to a value the client can understand.
- When the incoming exception received on a reference must be transformed to a value the client code can understand.

Exception handling from a wire format handler

An exception handler is a wire format handler. Business and runtime exception handling is done from the wire format handler An exception wire format handler transforms specific exceptions into objects that can be understood by the client application.

Both service and reference bindings can use an exception wire format handler. You can configure an exception wire format handler to do the following:
- Handle runtime exceptions that are received from external applications (reference)
- Send runtime exceptions that have occurred in your SCA application to the external applications (service)

On the service implementation of a wire format handler, the implementation can examine the WireFormatContext.INVOCATION value from the context to find that an exception was thrown. The wire format handler might handle normal invocations and exceptions differently. See the following sample code:

```
public Message transformIntoJMSMessage(Session session, Object source)
   throws JMSException, WireFormatHandlerException {

   WireFormatContext.INVOCATION invocationType =
      (WireFormatContext.INVOCATION) context.get(WireFormatContext.INVOCATION_TYPE);

   if (invocationType == WireFormatContext.INVOCATION.TYPE_EXCEPTION) {
      return handleException(session, source);
   } else if (invocationType == WireFormatContext.INVOCATION.TYPE_RESPONSE) {
      return handleResponse(session, source);
   } else {
      throw new WireFormatHandlerException("Unexpected Invocation Type.");
   }
}
```

On the reference implementation of a wire format handler, the implementation must determine at run time if the incoming response is of type fault. The WireFormatContext.INVOCATION value must be initially set to TYPE_RESPONSE. The implementation examines incoming messages. When an incoming message is an exception rather than a normal response, the implementation must set the invocation type to TYPE_EXCEPTION and throw an appropriate exception. See the following code sample:

```
// On Reference-side, this is for an incoming response
public Object transformFromJMSMessage(Message source)
  throws WireFormatHandlerException {

  ObjectMessage msg = null;
  Object payload = null;
  Object[] payloadArray = null;
  Integer payloadInt = null;
  Object payloadItem = null;

  try {
    msg = (ObjectMessage)source;
  } catch (ClassCastException cce) {
      throw new WireFormatHandlerException("Did not receive ObjectMessage", cce);
  }
  try {
    payload = msg.getObject();
  } catch (JMSException e) {
      throw new WireFormatHandlerException("Cannot get Object from message using getObject()", e);
  }

  if (payload instanceof Integer) {
    // Expected type returned
    payloadInt  = (Integer)payload;
    Integer code = new Integer(0);
    Integer one = new Integer(1);
    code = payloadInt + one;
    return code;
  } else {
    // Response is some type of exception...

    // Change the response type to Exception
    context.put(WireFormatContext.INVOCATION_TYPE, WireFormatContext.INVOCATION.TYPE_EXCEPTION);

    if (payload instanceof Throwable) {
      Throwable thw = (Throwable) payload;

      ////////////////////////////////////////////////////
      // TO DO: Map to checked business exception and throw it
      ////////////////////////////////////////////////////

    } else {
      return new ServiceRuntimeException(((Throwable) payload).getMessage());
      // Unchecked
    }
```

```
  } else {
    throw new WireFormatHandlerException("Unexpected Object returned: " + payload);
    // Unexpected or unknown object returned.
    }
  }
}
```

Interoperating between SCA OASIS and OSOA composites

Service Component Architecture (SCA) applications are based on either the Open SOA Collaboration (OSOA) Version 1.0 SCA specifications or the OASIS SCA Version 1.1 specifications. You cannot mix OSOA and OASIS SCA artifacts, such as `.composite` files or `sca-contribution.xml` files, within the same asset. However, you can wire OASIS and OSOA SCA components together when both SCA composites are running in a single product cell.

Before you begin

For information about the differences between OSOA and OASIS specifications and about the differences between OSOA and OASIS in SCA applications, see the SCA overview topic.

About this task

This topic describes how you might wire OSOA and OASIS components together so that the components, although in separate SCA applications, can interoperate while both applications are running in the same product cell. The procedure provides a simple example that shows how to wire an OASIS component reference to an OSOA component service.

When wiring components for interoperation between OSOA and OASIS in SCA applications, consider the following restrictions:

- OSOA and OASIS components must interoperate over `@Remotable` interfaces. Local interfaces cannot be used and result in an exception error.
- Interfaces must be annotated in a way consistent with the run time in which they are deployed.
  - For an OASIS component to reference an OSOA component, the OASIS reference type must contain OASIS annotations, such as `org.oasisopen.sca.annotation.Remotable`.
  - For an OSOA component to reference an OASIS component, the OSOA reference type must contain OSOA annotations, such as `org.osoa.sca.annotations.Remotable`.
- For a reference in an OASIS component to target an OSOA component, the uniform resource identifier (URI) form must be `component` or `component/service`. The `component/service/binding` URI form is not supported.
- OASIS interfaces marked with the `asyncInvocation` intent cannot interoperate with OSOA services.
- The product does not perform interface matching between OASIS and OSOA services. Incompatible interfaces result in a runtime exception.
- The product does not perform policy matching between OASIS and OSOA services. Incompatible policies result in a runtime exception.

Procedure

1. Create an OSOA SCA application.
   a. Define an OSOA composite with a single component for the application.

```
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0" name="InteropOSOARemote">
   <component name="HelloWorldService">
      <implementation.java class="interop.osoa.HelloWorldServiceImpl"/>
      <service name="HelloWorld"/>
   </component>
</composite>
```

   b. Create a service interface that has a Java interface marked as remotable. The `@Remotable` annotation comes from the OSOA annotations package.

```
package interop.osoa;

import org.osoa.sca.annotations.Remotable;

@Remotable
interface HelloWorld {
   public String sayHello(String text);
}
```

c. Create a service implementation.

   For this example, the service implementation adds the string "Hello " to the start of the text that it is sent, and then returns the modified text:

```
package interop.osoa;

public class HelloWorldServiceImpl implements HelloWorld {
   public String sayHello(String text) {
      return "Hello " + text;
   }
}
```

2. Create an OASIS SCA application and wire a component reference to the service that is defined in the OSOA application.

   a. Define an OASIS composite with a single component and with a reference to the service in the OSOA application.

```
<composite xmlns="http://docs.oasis-open.org/ns/opencsa/sca/200912" name="InteropOASIS">
   <component name="HelloWorldClient">
      <implementation.java class="interop.oasis.HelloWorldClientImpl"/>
      <service name="HelloWorld"/>
      <reference name="helloWorldOSOA" target="HelloWorldService"/>
   </component>
</composite>
```

   b. Create a reference interface that has a Java interface marked as remotable.

      The reference interface is compatible with the HelloWorld service interface that is defined in the OSOA application but it is a different Java interface. The reference interface is in a different Java package; the @Remotable annotation comes from the OASIS annotations package.

```
package interop.oasis;

import org.oasisopen.sca.annotation.Remotable;

@Remotable
interface HelloWorld {
   public String sayHello(String text);
}
```

   c. Create a service implementation that implements the HelloWorld interface and uses a reference to the OSOA version of the component.

      For this example, the reference determines the text to return to the caller.

```
package interop.oasis;

import org.oasisopen.sca.annotation.Reference;

public class HelloWorldClientImpl implements HelloWorld {

   @Reference
   protected HelloWorld helloWorldOSOA;

   public String sayHello(String text) {
      return helloWorldOSOA.sayHello(text);
   }
}
```

3. Deploy the SCA applications into the same, or separate, business-level applications in the same cell.

   For OSOA, an sca-contribution.xml file is not required if there is only one default.composite file in the Java archive (JAR). An sca-contribution.xml file can reside in the META-INF/ directory or in a subdirectory.

   For OASIS, an sca-contribution.xml file is required and must reside in the META-INF/ directory, and not in a subdirectory.

What to do next

To test the applications, you can call the HelloWorld service of the OASIS component (the HelloWorldClient component in step 2) and have the service return the string that it retrieves from the OSOA component (the HelloWorldService component in step 1).

Using existing Java EE modules and components as SCA implementations

You can use the Service Component Architecture (SCA) programming model to invoke business services in Java Platform, Enterprise Edition (Java EE) components.

About this task

The SCA programming model supports Java EE integration. You can expose Enterprise JavaBeans (EJB) stateless session beans as SCA services. You can take advantage of SCA annotations to enable the Java EE components, such as session beans, message driven beans, or web components to consume SCA services. You also can rewire EJB references to SCA services. Thus, you can enable an existing Java EE component so that it is recognized as an SCA component and so that the component can participate in an SCA composite.

Procedure

1. Use non-SCA enhanced Java EE applications as SCA component implementations.
2. Use SCA enhanced Java EE applications as SCA component implementations.

   For this step, create an `application.composite` file. Then, determine the Java EE component type that you want to consume SCA services. Depending on the Java EE component type, use SCA annotations:

   - Use SCA annotations with web modules.
   - Use SCA annotations with session beans.
   - Use SCA annotations with message-driven beans.

   If your application uses security, specify security roles and runAs identity in the Java EE application implementation instead of in the composite. Authorization policy is enforced by the implementation.
3. Rewire EJB references to SCA references.
4. Deploy an SCA composite using a Java EE application as a component implementation.

   You can deploy an SCA composite that uses an `implementation.jee` defining a Java EE application as a component implementation. Deploy the SCA composite that uses the application as a component implementation along with the enterprise archive (EAR) file. Add the SCA composite and Java EE application as composition units of a business-level application.

   a. Import the EAR file as an asset.
   b. Import the SCA composite Java archive (JAR) file as an asset.
   c. Create an empty business-level application.
   d. Add the EAR file asset to the business-level application.
   e. Add the SCA composite asset to the business-level application. Map the SCA composite to the same target server as the EAR file.
   f. If you are rewiring EJB references, set the starting weight of the EAR file to a greater value than the starting weight of the SCA composite. The SCA composite then starts before the EAR file.

   When deploying an SCA JAR contribution that has a deployable SCA composite with `implementation.jee` for one or more of its SCA components, ensure that the following requirements are met:

   - Deploy the SCA deployable composite and all the Java EE applications used for the SCA component implementation in the same business-level application.

- Add all the Java EE applications referenced by the `archive` attribute of the `implementation.jee` directive to the business-level application before adding the SCA deployable composite.
- Map all the deployed components of an SCA business-level application to the same target server or cluster.
- When using an SCA enhanced EAR file that requires injection of values for SCA references, properties, context or component names in Java EE modules such as stateless session beans, servlets, or JSP files, the deployed SCA asset must start before the Java EE asset. If necessary, set the weights of the composition units so that the deployed SCA asset starts before the Java EE asset.
- If you update Java EE composition units, deploy the SCA composition unit again to apply the changes in the SCA component that uses Java EE implementation.

5. Start the business-level application.

Results

You now have defined and deployed Java EE components to take advantage of the SCA programming model. The SCA composite and the EAR file are deployed and started, and the Java EE application is able to participate in the SCA domain.

Invoke the EJB services exposed as SCA services using the SCA programming model.

Example

The product provides the HelloJee sample to show how to use SCA annotations within Java EE components so that these components can consume SCA services.

This sample uses the `HelloJeeEar.ear`, `HelloJeeEnhancedEar.ear`, and `HelloJeeSca.jar` SCA sample files. To download HelloJee sample files from a product website:

1. Go to the **Samples, Version 8.5** information center.
2. On the **Downloads** tab, click **FTP** or **HTTP** in the **Service Component Architecture** section.
3. In the authentication window, click **OK**.
4. From the **SCA.zip** compressed file, download prebuilt `HelloJeeEar.ear`, `HelloJeeEnhancedEar.ear`, and `HelloJeeSca.jar` files in the `SCA/installableApps` directory.

   If you want to build your own deployable files, download the `SCA/HelloJee` directory and follow instructions in `SCA/HelloJee/documentation/readme.html` to build the files.

Briefly, to deploy the HelloJee sample, do the following:

1. Import as assets the `HelloJeeEar.ear`, `HelloJeeEnhancedEar.ear`, and `HelloJeeSca.jar` files.
2. Create a business-level application named `HelloJeeBla`.
3. Add the `HelloJeeEar.ear` and `HelloJeeEnhancedEar.ear` assets to the business-level application.
4. Add the `HelloJeeSca.jar` asset to the business-level application. When adding the asset, ensure that it is targeted to the same server or node as the EAR files added in step 3. If you are adding the JAR file using the administrative console, ensure that components HelloJeeEnhancedComponent and HelloJeeComponent are listed on the Set Java EE composition unit relationships page. Also ensure that HelloJeeEnhancedComponent associates with the HelloJeeEnhancedEar composition unit and HelloJeeComponent associates with the HelloJeeEar composition unit.
5. Start the business-level application.
6. Run the sample application. Open a web browser on a URL that accesses a sample. The following URLs use `localhost` for host name and `9080` for port number. Use the host name and `WC_defaulthost` port number that is correct for your installation.
   - Access the non-SCA enhanced EJB as is: `http://localhost:9080/HelloJeeWeb/JeeEjbClient`

- Access the non-SCA enhanced EJB as an SCA service: `http://localhost:9080/HelloJeeWeb/JeeScaClient`
- Access the SCA enhanced EJB as is: `http://localhost:9080/HelloJeeEnhancedWeb/JeeEEjbClient`
- Access the SCA enhanced EJB service or reference as an SCA service or reference and demonstrate SCA annotations: `http://localhost:9080/HelloJeeEnhancedWeb/JeeEScaClient`

Using non-SCA enhanced Java EE applications as SCA component implementations

You can use an existing Java Platform, Enterprise Edition (Java EE) application as a Service Component Architecture (SCA) component without requiring SCA annotations or composite files.

Before you begin

Identify the Java EE application that contains business logic in Enterprise JavaBeans (EJB) or web modules to enable in the SCA environment.

A Java EE application is also called an enterprise application or enterprise archive (EAR) file.

About this task

The SCA programming model supports Java EE integration. You can expose EJB stateless session beans as SCA services by enabling an existing enterprise application module to be recognized as an SCA component and participate in an SCA composite.

You can use an enterprise application as an SCA component implementation, without requiring any SCA annotations or composite files in the application. Such an application is denoted as a non-SCA enhanced enterprise application.

The EJB business interfaces of stateless session beans configured in EJB modules are exposed as SCA services. The EJB business interfaces of EJB references configured in EJB and web modules are exposed as SCA references.

The component type of a non-SCA enhanced enterprise application is defined as follows:

- Each EJB 3.x session bean business interface with unqualified name `intf` of a session bean with mapped name `mname` translates into a service by the name `mname_intf`.
- The service interface that is derived from the business interface of an EJB 3.x session bean consists of all methods of the EJB business interface.
- The service interface is remotable if it is derived from a remote business interface. Each EJB 3.x remote reference of each session bean within the enterprise application is exposed as an SCA reference. If the remote reference has the name `ref` and the name of the session bean is `beanname`, the SCA reference name is `beanname_ref`. Services thus derived can be invoked or wired to like an SCA service.

Procedure

1. Create a component in an SCA composite definition. Specify the `implementation.jee` component type and set the `archive` attribute to the name of the asset object.

   For example, the composite definition for a `implementation.jee` component named `ImplJeeComponent` that uses the `MyJEE.ear` archive resembles the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<composite xmlns="http://www.osoa.org/xmlns/sca/1.0"; autowire="false"
    name="ImplJeeSCAComposite"
    targetNamespace="' class='inlinelink' target="_blank">http://jee">
  <component name="ImplJeeComponent">
    <implementation.jee archive="MyJEE.ear"/>
  </component>
</composite>
```

2. Optional: Write client code that looks up and invokes a derived SCA service.

   A client can look up and invoke a derived SCA service. For example, suppose the `ImplJeeComponent` component has a stateless session bean named `Bean1` with a remote interface `Intf1` in an EJB module in the enterprise application. Invoke the service with code such as the following:

   ```
   CompositeContext compositeContext = CurrentCompositeContext.getContext();
   Intf1 myEjb = compositeContext.getService(Intf1.class, "ImplJeeComponent/Bean1_Intf1");
   retStr = ejb.myOperation();
   ```

3. Optional: Define a reference to a derived service in an SCA component composite. Use the injected value of a matching @Reference SCA annotation to invoke an EJB service as an SCA service.

   Instead of writing client code to look up and invoke the derived SCA server (step 2), you can define a reference to the derived service in an SCA component composite. An SCA service in a component can use the injected value of a matching @Reference SCA annotation to invoke the EJB service as a SCA service.

   For example, the `ImplJeeComponent` component might invoke an EJB service as a SCA service using the following code. The SCA component reference code resembles:

   ```
   <reference name="MyRef" target="ImplJeeComponent/Bean1_Intf1>
   ```

   The SCA service code resembles:

   ```
   @Reference public Intf1 MyRef;
   .....
   String retStr = MyRef.myOperation();
   ....
   ```

Results

The enterprise application is available as an SCA component type. Any SCA component can refer to the derived services.

What to do next

Deploy the enterprise application and the SCA composite that uses the application as composition units of the same business-level application. You can use the administrative console or wsadmin commands to create the business-level application and add the enterprise application and the SCA composite as composition units.

The product provides the HelloJee sample. The sample has a non-SCA enhanced EJB. The Example section in the Using existing Java EE modules and components as SCA implementations topic summarizes how to deploy the HelloJee sample and access the non-SCA enhanced EJB.

Using SCA enhanced Java EE applications as SCA component implementations

You can use an existing Java Platform, Enterprise Edition (Java EE) application as a Service Component Architecture (SCA) component after enhancing the application. Define an SCA composite that has components with `implementation.ejb` and `implementation.web` component types which refer to Enterprise JavaBeans (EJB) and web modules within the Java EE application, and then promote services and references.

Before you begin

Identify the Java EE application that contains business logic in EJB or web modules to enable in the SCA environment.

A Java EE application is also called an enterprise application or enterprise archive (EAR) file.

About this task

The SCA programming model supports Java EE integration. You can expose EJB stateless session beans as SCA services by enabling an existing enterprise application module to be recognized as an SCA component and participate in an SCA composite. You can rewire the SCA services over different bindings. You can rewire EJB references in EJB and web modules to SCA references. Also, you can use SCA annotations to enable Java EE components such as stateless session beans, message driven beans, servlets, listeners, filters, and JavaServer Pages (JSP) files to consume SCA services and properties.

Define a composite in a file named `application.composite` and place the file in the enterprise application `META-INF` directory.

Procedure

1. Create a file named `application.composite` that defines components with component types of web and EJB modules of the enterprise application. Save the file to the enterprise application `META-INF` directory.

   Use the `implementation.web` element to declare a service component that is implemented by the web component. The component contains information for the annotations. To configure a web component implementation, use the following schema:

   ```
   <implementation.web web-uri="web_module_name"/>
   ```

   Use the `implementation.ejb` element to declare a service component that is implemented by a session bean component. To configure an EJB component implementation, use the following schema:

   ```
   <implementation.ejb ejb-link="EJB_module_name"/>
   ```

   The components can contain one or more supported elements, such as `<service>`, `<reference>`, and `<property>` elements. In the composite definition, promote the services and references to be available in the SCA component using the enterprise application as the component type.

   An example `application.composite` file for an enterprise application named `MyEAR.ear` follows. The file contains an EJB module named `myEJB.jar` with a bean named `MyBean` and a remote business interface named `MyRemoteIntf`. The file also contains a Web module named `myWeb.war`.

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <composite xmlns="http://www.osoa.org/xmlns/sca/1.0"; autowire="false" name="MyComposite"
           targetNamespace="' class='inlinelink' target="_blank">http://jee">

     <service name="MyBean_MyRemoteIntf" promote="MyEJBComponent/MyBean_MyRemoteIntf"/>
     <reference name="MySCAReference1" promote="MyEJBComponent/MySCAReference1"/>
     <reference name="MySCAReference2" promote="MyWebComponent/MySCAReference2"/>

     <component name="MyEJBComponent">
       <implementation.ejb ejb-link="MyEJB.jar#MyBean"/>
       <service name="MyBean_MyRemoteIntf">
         <interface.java ... />
       </service>
       <reference name="MySCAReference1" target="MySCAComponent1">
     </component>

     <component name="MyWebComponent">
       <implementation.web web-uri="MyWeb.war"/>
       <reference name="MySCAReference2" target="MySCAComponent2">
     </component>
   </composite>
   ```

2. Create a component in an SCA composite definition that has the `implementation.jee` component type and the `archive` attribute set to the name of the enterprise application asset object.

   For the example enterprise application `MyEAR.ear`, create a component such as the following:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <composite xmlns="http://www.osoa.org/xmlns/sca/1.0"; autowire="false" name="ImplJeeSCAComposite"
         targetNamespace="' class='inlinelink' target="_blank">http://jee">
     <component name="ImplJeeComponent">
       <implementation.jee archive="MyEAR.ear"/>
     </component>
   </composite>
   ```

3. Inject the promoted references into @Reference annotations in the EJB and web modules. Also, rewire the promoted service, and reference the service from other SCA components.

   For information about using a composite file to support annotations, refer to the following topics:
   - Using SCA annotations with web modules
   - Using SCA annotations with session beans
   - Using SCA annotations with message-driven beans
4. Using a client or an SCA service, invoke the promoted EJB as an SCA service.

Results

The enterprise application is available as an SCA component type. Any SCA component can refer to the promoted services. Java EE modules can access SCA services and properties using SCA annotations. You can rewire the services and reference them like any other SCA service.

What to do next

Deploy the enterprise application and the SCA composite that uses the application as composition units of the same business-level application. You can use the administrative console or wsadmin commands to create the business-level application and add the enterprise application and the SCA composite as composition units.

The product provides the HelloJee sample. The sample has an SCA enhanced EJB. The Example section in the Using existing Java EE modules and components as SCA implementations topic summarizes how to deploy the HelloJee sample and access the SCA enhanced EJB.

Using SCA annotations with web modules

Use Java annotations for Service Component Architecture (SCA) to identify existing Java Platform, Enterprise Edition (Java EE) components, such as web modules, as SCA components that are a part of an SCA composite.

Before you begin

Identify and obtain the web module that represents your business logic that you want to enable within an SCA environment.

About this task

The SCA programming model supports Java EE integration. As a result, you can take advantage of SCA annotations to enable Java EE web components such as servlets, filters, and event listeners to consume SCA services. By using Java annotations that apply to SCA, you can enable existing web modules to be recognized as an SCA component and participate in an SCA composite.

Web modules can participate in SCA assembly as the implementation type of a component that does not offer services, even though you can configure or wire the component to other services. You can configure a web module with annotations to acquire references to services that are wired to the component by the SCA assembly. You can also use annotations when you want to obtain the value of a property using the @Property annotation, to inject a handle to the SCA component context using the @Context annotation or to obtain the component name using the @ComponentName annotation.

For a list of supported annotations for web modules, see the SCA specifications and APIs documentation.

You can also obtain SCA references in JavaServer Pages (JSP) files by using SCA JSP tag libraries. The following example illustrates how annotations are used within a JSP tag handler:

```
<%@ taglib uri="http://www.osoa.org/sca/sca_jsp.tld" prefix="sca" %>
<sca:reference name="service" type="test.MyService"  />
<% service.sayHello(); %>
```

Procedure

1. Add SCA annotations to the components that you want within a web module. Based on your needs, use the supported annotations to inject SCA information into your web module.
2. Define a component in the `application.composite` file in the `META-INF` directory.

   The `implementation.web` element is used to declare a service component that is implemented by the web component. The component contains information for the annotations. To configure this component implementation, use the following schema:

   ```
   <implementation.web web-uri="<module name>"/>
   ```

   For example, you can define a component in the EAR `META-INF/application.composite` file as follows:

```
<component name="WebAnnotationTestServletComponent">
   <implementation.web web-uri="SCA_JEE_InjectionWeb.war"/>
   <reference name="getServerDateReference" target="GetServerDateServiceComponent">
       <interface.java interface="sca.injection.test.GetServerDateService"/>
   </reference>
</component>
```

   The following example illustrates a servlet in the web application archive (WAR) module using SCA annotations:

```
 public class WebAnnotationTestServlet extends HttpServlet {
     @Reference GetServerDateService getServerDateReference;
 }
```

   The following example illustrates a JSP using SCA annotations by importing the SCA tag library:

```
<%@ page language="java" contentType="text/html; charset=ISO-8859-1"
pageEncoding="ISO-8859-1"%>
<%@ taglib uri="http://www.osoa.org/sca/sca_jsp.tld" prefix="sca" %>

<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN
" "http://www.w3.org/TR/html4/loose.dtd">

<sca:reference name="getServerDateReference"
type="sca.injection.test.GetServerDateService" />
<html>
   <head>
    <meta http-equiv="Content-Type" content="text/html; charset=ISO-8859-1">
    <title>TESTING SCA ANNOTATION IN JSP</title>
   </head>
   <body>
   <h2> Reference Annotation in JSP: </h2>
     GetServerDateService.getString returns : <%=getServerDateReference.getString() %>
   </body>
</html>
```

Results

You now have SCA-enabled Java EE web modules that take advantage of the SCA programming model.

What to do next

Deploy the components to a business-level application.

Using SCA annotations with session beans

Use Java annotations for Service Component Architecture (SCA) to identify existing Java Platform, Enterprise Edition (Java EE) components, such as session beans, as SCA components that are a part of an SCA composite.

Before you begin

Identify and obtain the session beans that represent your business logic that you want to enable within an SCA environment.

About this task

The SCA programming model supports Java EE integration. As a result, you can take advantage of SCA annotations to enable Java EE web components such as session beans to consume SCA services. By using Java annotations that apply to SCA, you can enable existing session beans to be recognized as an SCA component and participate in an SCA composite. Within Java EE environments, sessions beans encapsulate business logic to manage security, transactions, and remotable interfaces. Because service components within SCA environments play a similar role, you can take advantage of the capability to use session beans as a service component implementation in a Java EE environment.

Any session bean that serves as the implementation type of an SCA service component can use annotations to obtain an interface to the SCA services that are wired to the component by the SCA assembly. You can also use annotations when you want to obtain the value of a property using the @Property annotation, to inject a handle to the SCA component context using the @Context annotation or to obtain the component name using the @ComponentName annotation. When using SCA annotations, you must apply the injection using annotations after the session bean instance is created, but before invoking business methods on the bean instance.

For a list of supported annotations for session beans, see the SCA specifications and APIs documentation.

Procedure

1. Add SCA annotations to the components that you want within your session beans to enable the component to be recognized as an SCA component. Based on your needs, use the supported annotations to inject SCA information such as context or component name into your session beans.
2. Edit the `application.composite` in the `META-INF` directory of the Java EE JAR file.

   Define a component within the `application.composite` file whose implementation is defined by an `implementation.ejb` element and specifies a session bean within the module. You can define multiple components, each with an `implementation.ejb` link that points to a session bean.

   Because message-driven beans and session beans are enterprise beans, you can uniquely refer to both bean types in an ejb-link element.

   The `implementation.ejb` element is used to declare a service component that is implemented by the session bean component. The component contains information for the annotations. To configure this component implementation, use the following schema:

   ```
   <implementation.ejb ejb-link="<ejb_link_name>"/>
   ```

   The enterprise bean that serves as the component implementation is uniquely identified by the *<ejb_link_name>* attribute. The format of the *<ejb_link_name>* attribute is identical to the format of the ejb-link element in a Java EE deployment descriptor.

   If the Java EE archive that contains the composite file is an application enterprise archive (EAR) file, multiple session beans might have the same name. In this case, the value of the ejb-link element must be composed of a path name. The path name specifies the ejb-jar that contains the referenced enterprise bean with the value of the ejb-name of the referenced enterprise bean appended and separated from the path name with the # symbol. The path name is relative to the root of the EAR file. For the case where the Java EE archive is a JAR file for the Enterprise JavaBeans (EJB) module, omit the path name.

   For example, you can have a JAR module that has the following component defined in the `application.composite` file:

```
<component name="AnnotationTest">
    <implementation.ejb ejb-link="SCA_JEE_Injection.jar#AnnotationTest"/>
        <property name="property" type="xsd:string">Right</property>

    <reference name="getServerDateReference" target="GetServerDateServiceComponent">
    <interface.java interface="sca.injection.test.GetServerDateService"/>
    </reference>

</component>
```

In this example, the session bean, AnnotationTest, is consuming an SCA service exposed by the GetServerDataServiceComponent reference.

The AnnotationTest session bean includes the @Property, @Reference, @ComponentName, and @Context annotations:

```
import javax.ejb.Stateless;

import org.osoa.sca.ComponentContext;
import org.osoa.sca.annotations.ComponentName;
import org.osoa.sca.annotations.Context;
import org.osoa.sca.annotations.Property;
import org.osoa.sca.annotations.Reference;

import sca.injection.test.GetServerDateService;
/**
* Session Bean implementation class AnnotationTest
*/
@Stateless
public class AnnotationTest implements AnnotationTestRemote, AnnotationTestLocal {

@Context protected ComponentContext myContext;
@ComponentName String myCompName;
@Property protected String property;
@Reference GetServerDateService getServerDateReference;

@Reference
GetServerDateService referenceDefault;

/**
* Default constructor.
*/
public AnnotationTest() {
// TODO Auto-generated constructor stub
}

public String getServString(){
GetServerDateService svc = myContext.getService(GetServerDateService.class, "getServerDateReference");
return svc.getString();
}

public String getProperty(){
return property;
}
public String getComponentName(){
return myCompName;
}
public String getReferenceDefault() {
if ( referenceDefault == null )
return null;
else
return referenceDefault.getString();
}

}
```

Results

You now have SCA-enabled Java EE session beans that take advantage of the SCA programming model.

What to do next

Deploy the components to a business-level application.

Using SCA annotations with message-driven beans

Use Java annotations for Service Component Architecture (SCA) to identify existing Java Platform, Enterprise Edition (Java EE) components, such as message-driven beans, as SCA components that are a part of an SCA composite.

Before you begin

Identify and obtain the message-driven beans that represent your business logic that you want to enable within an SCA environment.

About this task

The SCA programming model supports Java EE integration. As a result, you can take advantage of SCA annotations to enable Java EE web components such as message-driven beans to consume SCA services. By using Java annotations that apply to SCA, you can enable existing message-driven beans to be recognized as an SCA component and participate in an SCA composite.

Message-driven beans can only participate in SCA assembly as the implementation type of a component that does not offer services, even though you can configure or wire the component to other services. Because of the association with endpoints that are not controlled by SCA such as Java Message Service (JMS), do not instantiate message-driven beans arbitrarily. You must not use a message-driven bean as a service component implementation more than one time within the SCA assembly of the application package.

You can configure a message-driven bean that is defined as an implementation type of an SCA component with annotations in order to obtain references to services that are wired to the component by the SCA assembly by using the @Reference annotation. You can also use annotations when you want to obtain the value of a property using the @Property annotation, to inject a handle to the SCA component context using the @Context annotation or to obtain the component name using the @ComponentName annotation.

For a list of supported annotations for message-driven beans, see the SCA specifications and APIs documentation.

Procedure

1. Add SCA annotations to the components that you want within your message-driven beans. Based on your needs, use the supported annotations to inject SCA information into your message-driven beans.
2. Edit the `application.composite` in the META-INF directory of the Java EE JAR file.

   Define a component within the `application.composite` whose implementation is defined by an `implementation.ejb` element and specifies a message-driven bean within the module. You can define multiple components, each with an `implementation.ejb` link that points to a message-driven bean.

   Because message-driven beans and session beans are enterprise beans, you can uniquely refer to both bean types in an ejb-link element.

   The `implementation.ejb` element is used to declare a service component that is implemented by the message-driven bean component. The component contains information for the annotations. To configure this component implementation, use the following schema:

   ```
   <implementation.ejb ejb-link="<ejb_link_name>"/>
   ```

   The enterprise bean that serves as the component implementation is uniquely identified by the *<ejb_link_name>* attribute. The format of the *<ejb_link_name>* attribute is identical to the format of the ejb-link element in a Java EE deployment descriptor.

   If the Java EE archive that contains the composite file is an application enterprise archive (EAR) file, it is possible that multiple message-driven beans have the same name. In this case, the value of the ejb-link element must be composed of a path name specifying the ejb-jar that contains the referenced enterprise bean with the ejb-name of the referenced enterprise bean appended and separated from the

path name with the # symbol. The path name is relative to the root of the EAR file. For the case where the Java EE archive is a JAR file for the Enterprise JavaBeans (EJB) module, omit the path name.

For example, you can have a JAR module that has the following component defined in the `application.composite`:

```
<component name="AnnotationTest">
     <implementation.ejb ejb-link="SCA_JEE_Injection.jar#AnnotationTest"/>
                <property name="property" type="xsd:string">Right</property>

      <reference name="getServerDateReference" target="GetServerDateServiceComponent">
     <interface.java interface="sca.injection.test.GetServerDateService"/>
      </reference>

</component>
```

In the following example, the message-driven bean, AnnotationTestMDB, is consuming an SCA service exposed by the GetServerDataServiceComponent reference. The AnnotationTestMDB message driven bean includes the @Property and @Reference annotations.

```
@MessageDriven
public class AnnotationTestMDB implements MessageListener {

//Property Annotations
@Property protected String property;

//Reference Annotation
@Reference protected GetServerDateService getServerDateReference;

/**
* Default constructor.
*/
public AnnotationTestMDB() {
// TODO Auto-generated constructor stub
}

private static final String JMSCF_JNDI_NAME = "jms/AnnotationQueueFactory";
private static final String JMSResponseQ_JNDI_NAME = "jms/AnnotationResponseQueue";
/**
* @see MessageListener#onMessage(Message)
*/
public void onMessage(Message message) {
String strDefaultReference = null;

System.out.println("Inside onMessage()");
try {
System.out.println("onMessage: " + "Exercising annotations");
if ( getServerDateReference != null)
strDefaultReference = getServerDateReference.getString();
}
catch (RuntimeException e) {
strError = "Error - Failed WebAnnotationTestServlet.service()!";
e.printStackTrace();
}

if (strError != null){
System.out.println("onMessage: " + "Encountered an error while annotation work");
outSB.append("@FINALERROR" + strError);
} else {
System.out.println("onMessage: " + "Annotations successful: now creating reply message");
outSB.append("@PropertyDefault:" + propertyDefault);
outSB.append("@ReferenceDefault:" + strDefaultReference);
}
}
}
```

Results

You now have SCA-enabled Java EE message-driven beans to take advantage of the SCA programming model.

What to do next

Deploy the components to a business-level application.

SCA annotations

By using Java annotations that apply to Service Component Architecture (SCA), you can enable an existing Java Platform, Enterprise Edition (Java EE) component to be recognized as an SCA component and participate in an SCA composite.

The SCA programming model supports Java EE integration. As a result, you can take advantage of SCA annotations to enable the Java EE components, such as session beans, message driven beans, or web components to consume SCA services.

The target for annotations applies for these Java objects:

- Types such as a Java class, enum or interface
- Methods
- Fields representing local instance variables within a Java class
- Parameters within a Java method

Annotations supported by SCA are listed in the following table:

Table 91. SCA annotations. The annotations enable Java EE components.

Annotation class	Annotation	Properties
`org.osoa.sca.annotations.ComponentName.class`	The **@ComponentName** annotation specifies the injection of a component name.	• Annotation target: Method or field • There are no properties on the @ComponentName annotation.
`org.osoa.sca.annotations.Context.class`	The **@Context** annotation specifies to inject SCA context into a service component instance. When you inject a composite context for the component, the type of context is defined by the type of the Java class field or type of the setter method input argument. Specify the type as either ComponentContext or RequestContext.	• Annotation target: Method or field • There are no properties on the @Context annotation.
`org.osoa.sca.annotations.Property.class`	The **@Property** annotation specifies to inject configuration properties from service component configuration. You can inject a simple Java type or a complex Java type. The type of the property injected is defined by the type of the Java class field or type of the setter method input argument. You can use this annotation on protected or public fields, on setter methods, or on a constructor method.	• Annotation target: Method or field • Properties: **- name** The name of the property. The default is the name of the field of the Java class. This property is optional. (String) **- required** Specifies whether injection is required. The default value is `false`. This property is optional. (Boolean)
`org.osoa.sca.annotations.Reference.class`	The **@Reference** annotation specifies the injection of a service reference. The interface of the service injected is defined by the type of the Java class field or the type of the setter method input parameter.	• Annotation target: Method or field • Properties: **- name** The name of the property. The default is the name of the field of the Java class. This property is optional. (String) **- required** Specifies whether injection is required. The default value is `false`. This property is optional. (Boolean)

Rewiring EJB references to SCA references

You can rewire an Enterprise JavaBeans (EJB) reference to a Service Component Architecture (SCA) reference that provides the same named operations. The rewiring does not require a change to existing code.

Before you begin

Identify the Java Platform, Enterprise Edition (Java EE) application that contains business logic in EJB or web modules to enable in the SCA environment. A Java EE application is also called an enterprise application or enterprise archive (EAR) file.

Identify the SCA components and services to replace the EJB references in EJB and web modules.

About this task

The SCA programming model supports Java EE integration. You can rewire EJB references to SCA references without changing existing code that uses the EJB reference. Thus, you can use the SCA programming model without changing the implementation code.

Procedure

1. Create a file named `application.composite` that defines components with component types of web and EJB modules of the enterprise application. Save the file to the enterprise application `META-INF` directory.

   Use the `implementation.web` element to declare a service component that is implemented by the web component. The component contains information for the annotations. To configure a web component implementation, use the following schema:

```
<implementation.web web-uri="web_module_name"/>
```

   Use the `implementation.ejb` element to declare a service component that is implemented by a session bean component. To configure an EJB component implementation, use the following schema:

```
<implementation.ejb ejb-link="EJB_module_name"/>
```

   To rewire an EJB reference to an SCA service in an SCA component, add a `<reference>` element to the `jee` module component. For example, to rewire an EJB reference named `MyEJBRef` to an SCA service named `MySCASvc` in an SCA component named `MyComponent`, the `<reference>` element resembles the following:

```
<reference name="MyEJBRef" target="MyComponent/MySCASvc">
  <interface.java .... />
</reference>
```

   The reference names must match the name of the EJB reference. The contract of operations supported must also match. Because references must be promoted in the composite, the names of the references must be unique. After the EJB reference is promoted, all matching instances of the EJB reference in the module are rewired to the SCA service.

2. Create a component in an SCA composite definition that has the `implementation.jee` component type and the `archive` attribute set to the name of the enterprise application asset object.

   For an enterprise application named `MyEAR.ear`, create a component such as the following:

```
<component name="ImplJeeComponent">
  <implementation.jee archive="MyEAR.ear"/>
</component>
```

Results

The EJB references are rewired to SCA references enabling Java EE modules to use SCA features without changing its implementation.

What to do next

Deploy the enterprise application and the SCA composite that uses the application as composition units of the same business-level application. You can use the administrative console or wsadmin commands to create the business-level application and add the enterprise application and the SCA composite as composition units.

Using OSGi applications as SCA component implementations

You can use an OSGi application as a Service Component Architecture (SCA) component.

Before you begin

Identify the OSGi application to use as an SCA component. An OSGi application is a collection of OSGi bundles that use the Blueprint component model to expose or consume services. An OSGi application contains an application manifest that declares the following services:

- Services that the application provides that can be accessed from outside the application
- Services that the application wants to consume from outside the application

You can use SCA to provide service bindings for these services.

About this task

To provide service bindings using SCA, do the following:

1. Modify an OSGi application to provide or use remote services.
2. Write an SCA composite definition that uses an OSGi application as a component implementation, and provide bindings for its remote services.

An OSGi application declares external services in the Application-ImportService and Application-ExportService statements of its application manifest, which is provided in the `META-INF/APPLICATION.MF` file of the enterprise bundle archive (EBA). The Application-ExportService statement declares remote services that are provided by the OSGi application. The Application-ImportService statement declares services on which the OSGi application depends. All services specified in the application manifest are remotable.

Procedure

1. Create an `implementation.osgiapp` component in an SCA composite definition.

   Specify the `implementation.osgiapp` component type and set `applicationSymbolicName` and `applicationVersion` to values that match the `Application-SymbolicName` and `Application-Version` attributes in the application manifest.

   For example, suppose the OSGi application manifest, the `META-INF/APPLICATION.MF` file, contains the following headers:

   ```
   Application-SymbolicName: helloworldApp
   Application-Version: 1.0.0
   ```

   Configure a component that references these headers in an SCA composite definition; for example:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <composite
     xmlns="http://www.osoa.org/xmlns/sca/1.0"
     xmlns:scafp="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
     targetNamespace="http://www.example.com"
     name="HelloWorldComposite">
       <component name="HelloWorldComponent">
           <scafp:implementation.osgiapp
              applicationSymbolicName="helloworldApp"
              applicationVersion="1.0.0"/>
       </component></composite>
   ```

The `implementation.osgiapp` element requires the use of an XML namespace prefix that is associated with the `"http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"` namespace.

The `applicationVersion` attribute is optional. You can add it to ensure that a particular version of an OSGi application is used.

2. Identify Blueprint services to be made available remotely.
   a. Edit the Application-ExportService header in the OSGi application manifest so that it identifies one or more service interfaces to be exported.

      The following example header specifies that Blueprint services which implement and export the `example.HelloWorld` interface are to be made available outside the application.

      ```
      Application-ExportService: example.HelloWorld
      ```

      An example of a Blueprint component with such a service follows:

      ```
      <blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0">
      <bean id="helloWorldComponent" class="example.HelloWorldImpl"
        <service id="helloWorld" ref="helloWorldComponent"
           interface="example.HelloWorld">
         <service-properties>
           <entry key="service.exported.interfaces" value="*"/>
         </service-properties>
        </service>
      </blueprint>
      ```

      The Blueprint service must specify the `service.exported.interfaces` property to identify which of its interfaces are to be exposed remotely. The value can be an asterisk (`*`) to indicate that all of its interfaces are available remotely, or it can be a particular interface name.

   b. Configure an SCA service that corresponds to each remotable Blueprint service in the component.

      Use the Blueprint service `id` value for the SCA service name. If a Blueprint service does not have an `id` value, use the bean `id` value instead. If more than one interface is defined for the Blueprint service, for the first service interface SCA Service name use the Blueprint `id` value. For the second and later services, use the *`Blueprint id_ fully qualified interface name`* value for the SCA service name in the order of interfaces defined in the `blueprint.xml` file.

      For example, add the `helloWorld` service that is shown in the Blueprint component from step 2a to the SCA composite definition from step 1:

      ```
      <?xml version="1.0" encoding="UTF-8"?>
       <composite
        xmlns="http://www.osoa.org/xmlns/sca/1.0"
        xmlns:scafp="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
        targetNamespace="http://www.example.com"
        name="HelloWorldComposite">
          <component name="HelloWorldComponent">
              <scafp:implementation.osgiapp
                 applicationSymbolicName="helloworldApp"
                 applicationVersion="1.0.0"/>
              <service name="helloWorld">
                  <binding.sca>
              </service>
          </component>
      </composite>
      ```

      The example uses `binding.sca` for the service binding. The service can be made available over one or more of the other bindings that SCA supports, except the EJB 2.x service binding.

      The SCA service element is not required. If it is not specified, the service is made available over `binding.sca` by default.

3. Identify services to be provided from outside the OSGi application.
   a. Edit the Application-ImportService header in the OSGi application manifest so that it identifies one or more service interfaces to be imported.

      The following example header specifies that the `example.Greeting` service interface be imported:

      ```
      Application-ImportService: example.Greeting
      ```

A Blueprint reference explicitly requests an imported service by filtering for the `service.imported` property. Remote services use pass-by-value semantics instead of pass-by-reference semantics for local services within the application. The following example shows a Blueprint component with such a reference:

```
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0">
  <bean id="helloWorldComponent" class="example.HelloWorldImpl"
    <property name="greetingList" ref="greetingRef"/>
  </bean>
  <service id="helloWorld" ref="helloWorldComponent"
     interface="example.HelloWorld">
   <service-properties>
     <entry key="service.exported.interfaces" value="*"/>
   </service-properties>
  </service>
  <reference-list id="greetingRef" interface="example.Greeting"
     filter="(&amp;(service.imported=*))"/>
</blueprint>
```

b. Configure an SCA reference that corresponds to each imported service in the component.

Use the fully qualified interface name for the SCA reference name.

For example, add the `example.Greeting` reference that is shown in the Blueprint component from step 3 to the SCA composite definition from step 2:

```
<?xml version="1.0" encoding="UTF-8"?>
 <composite
  xmlns="http://www.osoa.org/xmlns/sca/1.0"
  xmlns:scafp="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
  targetNamespace="http://www.example.com"
  name="HelloWorldComposite">
    <component name="HelloWorldComponent">
        <scafp:implementation.osgiapp
           applicationSymbolicName="helloworldApp"
           applicationVersion="1.0.0"/>
        <service name="helloWorld">
            <binding.sca>
        </service>
        <reference name="example.Greeting">
            <binding.sca uri="MyGreetingComponent">
        </reference>
    </component>
</composite>
```

The example uses `binding.sca` for the reference binding. The reference can use one or more of the other bindings that SCA supports.

An SCA reference for an `implementation.osgiapp` component implicitly has 0-to-many for the multiplicity attribute (`multiplicity='0..n'`). This means you can wire the reference to 0, 1, or multiple services depending upon the requirements of the application. As to the multiplicity attribute:

- A blueprint `reference-list` element selects multiple services. The blueprint implementation cannot make any assumptions about the order of the services in the reference list compared to the order of bindings in the composite definition.
- A blueprint `reference` element selects a single service. If the SCA reference provides more than one binding, the selection of which binding is used is unspecified. If the SCA reference does not provide any bindings, the dependency is unsatisfied. If the reference is mandatory, the bean might not start.

You can override the multiplicity attribute on the SCA reference, setting 1-to-many (`'1..n'`) or 1-to-1 (`'1..1'`), to ensure that a particular number of bindings is specified.

Results

The OSGi application is defined as an SCA component.

What to do next

Deploy the OSGi application and the SCA composite that uses the application as composition units of the same business-level application. You can use the administrative console or wsadmin commands to create

a business-level application, import the EBA file and SCA composite as assets, and then add the EBA and SCA assets as composition units to the business-level application.

SCA programming model support in OSGi applications

This topic describes the features of the Service Component Architecture (SCA) programming model that can be used with OSGi applications.

- Annotations
- Authorization policy
- Mapping of Blueprint transaction metadata to SCA service and reference transaction intents
- Using intents in an OSGi application
- Interface definition
- Custom wire format and operation selector
- Service Data Objects (SDO) version 2.1.1 with OSGi applications

Annotations

The following annotations from the org.osoa.sca.annotations package are supported within the interface classes in an OSGi application:

- @OneWay
- @Remotable

  When an OSGi application is used as an SCA component, its service and reference interfaces are automatically treated as remotable. The @Remotable annotation is not required. However, if you want to use the same Java source interface in other contexts, it might need to contain the @Remotable annotation:

  – If you copy the interface to the SCA asset and specify it in an `interface.java` element for an `implementation.osgiapp` service or reference, the interface must contain the @Remotable annotation. Otherwise, an interface incompatibility error occurs.

  – If you wire `implementation.java` and `implementation.osgiapp` components to each other, the interface must contain the @Remotable annotation. Otherwise, the `implementation.java` component considers the interface to be local and an interface incompatibility error occurs.

No annotations from the org.osoa.sca.annotations package are supported within the implementation classes in an OSGi application.

Authorization policy

You can attach an SCA policy set containing authorization policy statements to an `implementation.osgiapp` component. The policy set applies to all services of the component. It applies only when the services are started through SCA service bindings, and not when the OSGi application internally uses its services.

SCA does not support the use of the org.osoa.sca.annotations.PolicySet annotation or the annotations in the javax.annotation.security package in Blueprint implementation classes.

The configuration of role-based security for SCA components is independent of the configuration of role-based security for a Web application bundle (WAB). In other words, the roles and role mappings used for SCA components and for WABs are separate.

Mapping of Blueprint transaction metadata to SCA service and reference transaction intents

Use the transaction metadata in the Blueprint component definition to define the transactional environment of an `implementation.osgiapp` component

You can use the propagatesTransaction, suspendsTransaction, transactedOneWay, and exactlyOnce intents with the services and references of an `implementation.osgiapp` component. Use the correct intents for the transaction metadata in the Blueprint component definition. SCA does not detect mismatches. The following table shows valid combinations of Blueprint transaction metadata and transaction intents.

Table 92. Valid combinations of transaction intents in OSGi applications. Use valid transaction intents for services and references of an `implementation.osgiapp` component.

Transaction definition in Blueprint component	**Valid service intents**	**Valid reference intents**
Required	• propagatesTransaction • transactedOneWay • exactlyOnce	• propagatesTransaction • suspendsTransaction • transactedOneWay
Mandatory	• propagatesTransaction • transactedOneWay • exactlyOnce	• propagatesTransaction • suspendsTransaction • transactedOneWay
RequiresNew	suspendsTransaction	• propagatesTransaction • suspendsTransaction • transactedOneWay
Supports	propagatesTransaction	• propagatesTransaction • suspendsTransaction
NotSupported	suspendsTransaction	
Never		

The managedTransaction.global, managedTransaction.local, and noManagedTransaction intents do not apply for `implementation.osgiapp` components.

Not all service bindings support all intents. For information about each intent, consult the SCA Transaction Policy specification.

The SCA run time does not effect the propagatesTransaction or suspendsTransaction behavior on an SCA service. Use the correct transaction definition in the Blueprint component to achieve the wanted behavior. The main purpose of using an intent is to document a requirement to use a binding that supports it.

Using intents in an OSGi application

A Blueprint service can require a policy intent by using the `service.exported.intents` service property as shown in the following example:

```
<service ref="componentImplementation"
   interface="example.MyTransactionalServiceInterface">
   <service-properties>
      <entry key="service.exported.intents" value="propagatesTransaction"/>
   </service-properties>
</service>
```

Using the `service.exported.intents` property has the same effect as putting the intent in the SCA service definition.

The Application-ImportService header in the OSGi application manifest can filter for a particular policy intent on an imported service:

```
Application-ImportService: example.Greeting;filter="(&(service.intents=propagatesTransaction))"
```

If the SCA reference does not provide the intent, no services are imported.

Interface definition

It is not required to specify an interface element on a component service or component reference. You can specify an interface to enforce a given contract with the implementation. In this case, the interface must be compatible with the implementation as stated in the SCA specification. The SCA run time cannot validate that the interfaces are compatible until the business-level application is started.

If you specify an `interface.java` or `interface.wsdl` element, it must refer to a Java class or WSDL file that is packaged in the SCA asset, or that is imported from a shared asset.

Custom wire format and operation selector

The JMS binding enables you to provide classes that customize its function. The classes can provide:

- A wire format handler that transforms data between the application interface and a JMS Message
- A custom operation selector to determine the operation name from a JMS Message

You can package these classes in a bundle within the enterprise bundle archive (EBA). This is necessary to have access to Java packages inside the EBA bundles. For example, if a wire format handler needs to transform the content of a JMS Message into user-defined types defined within the EBA, the handler must be packaged in the EBA. To indicate that the handler is packaged in the EBA, you must use the `deferLoad` attribute; for example:

```
<composite
  xmlns="http://www.osoa.org/xmlns/sca/1.0"
  xmlns:scafp="http://www.ibm.com/xmlns/prod/websphere/sca/1.0/2007/06"
  targetNamespace="http://www.example.com"
  name="MyOSGiComposite">
    <component name="MyOSGiComponent">
      <scafp:implementation.osgiapp ...>
        <service name="MyOSGiService">
          <binding.jms>
            <activationSpec ...>
              <scafp:wireFormat.jmsCustom
                      class="example.WireHandler" deferLoad="true"/>
              <scafp:operationSelector.jmsCustom
                      class="example.OpSelector" deferLoad=="true"/>
          </binding.jms>
        </service>
    </component>
</composite>
```

Service Data Objects (SDO) version 2.1.1 with OSGi applications

You can use Service Data Objects version 2.1.1 over SCA default, Web service, JMS and HTTP bindings for an `implementation.osgiapp` component service. Package schema definition (XSD) files in an SCA asset, or import XSD files from a shared asset.

The following limitations apply when you use SDO with an `implementation.osgiapp` component:

- You must invoke the OSGi application over a supported SCA service binding, such as an SCA default, Web service, JMS or HTTP binding. In particular, you cannot use the SDO functionality in your OSGi application when you access the OSGi application over HTTP using the Web container access path that you typically use to access OSGi application code packaged in an OSGi Web application bundle (WAB).
- The product does not support the injection of the SCA-managed default HelperContext object using annotation. However, you can implement an application programming interface (API), which uses the commonj.sdo.helper.SDO class, to access the default HelperContext object. For more information about the HelperContext object, see the documentation about accessing default HelperContext objects in SCA applications
- You cannot use SDO in an OSGi application that is accessed over the SCA service bindings `binding.atom` or `binding.ejb`.

Note: If your application previously used SDO version 1.0.0, change the Import-Package to:

```
Import-Package: commonj.sdo;version="[2.0.0,3.0.0)"
```

Using Spring 2.5.5 containers in SCA applications

You can use the Service Component Architecture (SCA) programming model to invoke beans that follow the Java 2 Platform, Standard Edition (J2SE) programming model in a Spring 2.5.5 container. The product supports components implemented with Spring Framework that use `<implementation.spring>` in composite definitions.

Before you begin

Before you start the procedure in this topic, do the following:

1. Become familiar with the SCA Spring Component Implementation 1.0.0 specification and Spring 2.5.5 programming. You must use Spring 2.5.5 for the SCA composite component implementation. The product does not support other levels of Spring.

   The product only supports the Spring Framework using the J2SE programming model. Local Java Naming and Directory Interface (JNDI) lookups are not supported, thus the product does not support the Spring Framework using the Java Platform, Enterprise Edition (Java EE) 5 programming model. Any attempts by a Spring container to perform a local JNDI lookup fail.
2. Decide whether to use `implementation.spring` or `implementation.jee` for your Spring application.

   The procedure in this topic discusses using `implementation.spring` in an SCA component implementation. If a Spring application is, in fact, a specialized Java EE application, instead of using `implementation.spring`, you can use `implementation.jee` to define the SCA component implementation and enable the Spring application to be part of an SCA component.

   For example, if a Spring application is packaged in a web module (WAR), then you can use an enterprise archive (EAR) that contains the WAR file as a component implementation using `implementation.jee`. The Spring application works like before and the Java EE context is not affected. Spring beans are not available in an SCA domain; however, other modules that are compatible with `implementation.jee` within the EAR file can participate in SCA.

   For information on deploying a Spring application with `implementation.jee`, see the topic on using existing Java EE modules and components as SCA implementations.
3. If you decide to use `implementation.spring` and you want beans in your Spring application to perform JNDI lookups, set `com.ibm.websphere.naming.WsnInitialContextFactory` as a property for the beans.

   You can use globally defined JNDI resources, such as databases and connection factories, in a Spring bean definition with `implementation.spring`. However, you must set a Spring JNDI template bean that has been configured to reference the WebSphere initial context factory, `com.ibm.websphere.naming.WsnInitialContextFactory`, as a property for beans performing JNDI lookups. For example, the following bean definitions specify that the `myJndiResource` bean use the WebSphere initial context factory:

```
<bean id="myJndiResource" class="org.springframework.jndi.JndiObjectFactoryBean">
  <property name="jndiName" value="jdbc/myJndiResource"/>
  <property name="lookupOnStartup" value="true"/>
  <property name="cache" value="true"/>
  <property name="jndiTemplate" ref="wasJndiTemplate"/>
</bean>

<bean id="wasJndiTemplate" class="org.springframework.jndi.JndiTemplate">
  <property name="environment">
    <props>
      <prop key="java.naming.factory.initial">com.ibm.websphere.naming.WsnInitialContextFactory</prop>
    </props>
  </property>
</bean>
```

The SCA container for implementation.spring does not run in a Java EE container, so it does not have access to the Java EE local JNDI namespace. By specifying that your Spring beans use the WebSphere initial context factory, you can prevent java:comp/ext from being prepended to the JNDI name during lookup.

About this task

You can use a Spring application context as an implementation within an SCA composite component. Define the implementation using Spring 2.5.5. A Spring application context provides a complete composite, exposing services and using references using SCA.

A component that uses Spring for an implementation can wire SCA services and references without introducing SCA metadata into the Spring configuration. Generally, the Spring context knows little about the SCA environment.

Procedure

1. Define a component implementation that uses the Spring Framework in a composite definition.

   The Spring component implementation in a composite definition has the following format:

   ```
   <implementation.spring location="targetURI"/>
   ```

   The location attribute of the element specifies the target uniform resource indicator (URI) of a directory, or the fully qualified path that contains the Spring application context files.

   There are two ways that you can specify the target URI in the location attribute:

   - Specify a fully qualified path:

     ```
     <implementation.spring location="./spring/application-context.xml"/>
     ```

   - Specify a directory:

     ```
     <implementation.spring location="./spring"/>
     ```

     The target URI specifies the resource as a directory, here named spring, that has all the Spring-related files. To point to one application context, a META-INF/MANIFEST.MF file in that directory must contain a Spring-Context header of the format Spring-Context: *path*, where *path* is a relative path with respect to the location URI. For example:

     ```
     Spring-Context: META-INF/spring/application-context.xml
     ```

     If the META-INF/MANIFEST.MF file does not exist or does not contain the Spring-Context header, then the product builds an application context using the application-context.xml file in the META-INF/spring directory. If the META-INF/spring/application-context.xml file does not exist, then the application does not deploy.

2. Optional: Override implicit mapping of Spring resource to SCA resources.

   By default, SCA implicitly maps Spring resources to SCA resources as follows:

   - Each <bean/> becomes <sca:service/>.
   - Each unresolved <property/> becomes <sca:reference/> if typed by an interface.
   - Each unresolved <property/> becomes <sca:property/> if not typed by an interface.

   You can override this default mapping by using the SCA XML extensions in the Spring context to create explicit declarations. You typically do this to enable the Spring container to decorate the bean using, for example, Spring Aspect-Oriented Programming (AOP). The SCA XML extensions are defined as follows:

   - <sca:service/> defines each service exposed by the context.
   - <sca:reference/> defines each reference exposed by the context.
   - <sca:property/> defines each property exposed by the context.<sca:property/> must be a bean class and not a primitive type.

   For example, the properties checkingAccountService, calculatorService, and stockQuoteService defined in the following Spring configuration are declared explicitly as SCA beans in a Spring application context using the <sca:reference> element:

```
<beans>
  <bean id="AccountServiceBean" class="bigbank.account.AccountServiceImpl">
    <property name="calculatorService" ref="calculatorService"/>
    <property name="stockQuoteService" ref="stockQuoteService"/>
    <property name="checkingAccountService" ref="checkingAccountService"/>
    <!-- Some implicit references and properties follow. A property with a reference
         not satisifed * within the Spring application context. -->
    <property name="savingsAccountService" ref="savingsAccountService"/>
    <property name="stockAccountService" ref="stockAccountService"/>
    <property name="currency" value="EURO"/>
  </bean>
  <sca:reference name="checkingAccountService" type="bigbank.account.checking.CheckingAccountService"/>
  <ca:reference name="calculatorService" type="bigbank.calculator.CalculatorService"/>
  <sca:reference name="stockQuoteService" type="bigbank.stockquote.StockQuoteService"/>
</beans>
```

3. If you completed step 2, to use the SCA XML extensions you must add the SCA schema to the application context.

   Add the SCA schema, `http://www.osoa.org/xmlns/sca/1.0/spring-sca.xsd` , to the application context. Specify a Spring application context that defines the SCA schema namespace and makes the Spring application aware of the SCA-related beans; for example:

```
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xmlns:sca="http://www.springframework.org/schema/sca"
       xsi:schemaLocation="
         http://www.springframework.org/schema/beans
         http://www.springframework.org/schema/beans/spring-beans.xsd
         http://www.springframework.org/schema/sca
         http://www.osoa.org/xmlns/sca/1.0/spring-sca.xsd">
  <sca:service name="StockQuoteService"
       type="bigbank.stockquote.StockQuoteService" target="StockQuoteServiceBean"/>
  <bean id="StockQuoteServiceBean" class="bigbank.stockquote.StockQuoteImpl">
  </bean>
</beans>
```

   For more information about defining an application context, see the reference documentation provided by the Spring source community. For more information about the SCA schema, see the SCA Spring Implementation specification.

4. Package the SCA application context file in your service Java archive (JAR) file at the location specified in your composite definition.

   For example, package the SCA application context file in a Spring service JAR file is named `helloworld-spring.jar`.

5. Create a Spring runtime JAR file that contains Spring and product SCA runtime files.

   Because the Spring runtime binary files are not shipped with the product, you must create an asset that contains three Spring framework JAR files and one product JAR file. Create the asset as follows:

   a. If you do not have the Spring 2.5.5 framework binary files, go to Spring Community Downloads at `http://www.springsource.com/download/community?project=` and download `spring-framework-2.5.5.zip`.

      After you download the compressed `.zip` file, extract it to a temporary directory.

   b. Create an empty directory; for example, `C:\SpringAsset`.

   c. Copy the Spring 2.5.5 framework binary files `spring-beans.jar`, `spring-context.jar`, and `spring-core.jar` to the empty directory.

      If the Spring application requires transaction support, copy all the Spring JAR files into the empty directory. The AspectJ Weaver library files are also required for transaction support.

   d. Copy the *app_server_root*`/optionalLibraries/sca/SCA-implementation-spring-runtime-1.0.1.jar` file to the same directory in which you placed the three Spring JAR files.

      Note: If you install a product maintenance package, update the `SpringSharedLibAsset.jar` with the newer version of the *app_server_root*`/optionalLibraries/sca/SCA-implementation-spring-runtime-1.0.1.jar` file.

e. Create a JAR file named `SpringSharedLibAsset.jar` that contains the four JAR files you placed in the `C:\SpringAsset` directory.

   For example, at a command prompt, enter the following commands:

   1) `cd C:\SpringAsset`
   2) `jar –cvf SpringSharedLibAsset.jar *.jar`

   For performances reasons, the JAR file must be named `SpringSharedLibAsset.jar`.

f. Verify that the `SpringSharedLibAsset.jar` file contains all four JAR files in the root directory.

6. Import the Spring runtime JAR file as an asset.

   To import `SpringSharedLibAsset.jar` as an asset using a wsadmin Jython command, enter the following command:

   ```
   AdminTask.importAsset('-source SpringSharedLibAsset.jar -storageType FULL')
   ```

   You can also use the administrative console.

7. Import the Spring service JAR file as an asset with a dependency on the Spring runtime asset.

   Suppose that your Spring service JAR file is named `helloworld-spring.jar`. Import your Spring service JAR file, `helloworld-spring.jar`, and create a dependency on the Spring runtime asset, `SpringSharedLibAsset.jar`. The dependency enables the product to access the necessary Spring classes. You can import the Spring service JAR file using the following wsadmin Jython command:

   ```
   AdminTask.importAsset('-source helloworld-spring.jar -storageType FULL -AssetOptions
    [[ helloworld-spring.jar helloworld-spring.jar "" "" "" spec=zip assetname=SpringSharedLibAsset.jar
    "" false]]')
   ```

   Alternatively, you can use the administrative console to import the asset with a dependency:

   a. On the administrative console, click **Applications** > **Application Types** > **Assets**.
   b. On the Assets page, click **Import**.
   c. On the Upload asset page, specify the full path name of the service JAR file and click **Next**.
   d. On the Select options for importing an asset page, specify a dependency.
      1) Click **Manage Relationships**. The button is near the bottom of the page. The product detects asset relationships automatically by matching the dependencies defined in the JAR manifest with the assets that are already imported into the administrative domain.
      2) Select your Spring runtime JAR file, such as `SpringSharedLibAsset.jar`, click **>>** to move the JAR file to the **Selected** list.
      3) Click **OK**.

         Under **Current asset relationships**, the asset name is shown; for example:

         ```
         WebSphere:assetname=SpringSharedLibAsset.jar
         ```

      4) Click **Next**.
   e. Click **Finish**.
   f. After the product imports the asset, click **Save**.

Results

The Spring runtime JAR file and Spring service JAR file are imported assets available for use in a business-level application. The Spring service JAR asset has a dependency on the Spring runtime asset.

What to do next

Add the JAR assets that you created to an SCA business-level application.

To learn about Spring implementation features that the product supports but which are not defined in the SCA Spring Implementation specification, see "Additional Spring component implementation features."

Additional Spring component implementation features

The product supports Spring implementation features that are not defined in the Service Component Architecture (SCA) Spring Implementation specification.

The product supports the following features:

- Constructor injection

  The product supports the injection of SCA references and properties within Spring bean constructors. Define `<constructor-arg>` elements that specify the appropriate type of the SCA references or properties to use. If the elements do not specify the `type` attribute, then at least specify the index attribute. The product only supports constructor injection when the Spring bean has a single constructor.

- Using the ClassPathXmlApplicationContext bean definition

  When the ClassPathXMLApplicationContext bean definition is in an application context, only the beans and properties defined in the top-level application context can be mapped, either explicitly or implicitly, to SCA resources.

  The product does not support using a FileSystemXMLApplicationContext definition to load an application context file.

- `<import>` elements in application context files

  The product supports use of `<import>` elements in application context files. Each `<import>` element points to an application context XML file; for example:

```
<bean>
  <import resource="services.xml"/>
  <import resource="resources/messageSource.xml"/>
  <import resource="/resources/themeSource.xml"/>
  <bean id="bean1" class="..."/>
  <bean id="bean2" class="..."/>
</beans>
```

Chapter 20. Developing Scheduler service

This page provides a starting point for finding information about the scheduler service, a WebSphere programming extension responsible for starting actions at specific times or intervals.

Schedulers are persistent and transactional timer services that run Enterprise JavaBeans methods or send Java Message Service messages using any Java Message Service messages using any Java Platform, Enterprise Edition (Java EE) server application.

The scheduler service helps minimize IT costs and increase application speed and responsiveness by maximizing utilization of existing computing resources.

The scheduler service provides the ability to reliably process workloads using parallel processing and schedule resource-intensive tasks to process during low traffic off-hours.

Developing and scheduling tasks

To develop and schedule tasks, use a configured scheduler.

Procedure

1. Look up a configured scheduler. Refer to the Accessing schedules topic. Each configured scheduler is available from two different programming models:
   - A Java Platform, Enterprise Edition (Java EE) server application, such as a servlet or Enterprise JavaBeans (EJB) component, can use the Scheduler API. Schedulers are accessed by looking them up using a Java Naming and Directory Interface (JNDI) name or resource reference.
   - Java Management Extensions (JMX) applications, such as wsadmin scripts, can use the Scheduler API using WASScheduler MBeans.
2. Develop the task.

   The Scheduler API supports different implementations of the TaskInfo interface, each of which can be used to schedule a particular type of work. Refer to the Developing a task that calls a session bean topic and Develop a task that sends a Java Message Service (JMS) message topic for details. The task object that is referenced in the Develop a task that sends a Java Message Service (JMS) message topic can send a JMS message to either a queue or a topic.

   Attention: Creating and manipulating scheduled tasks through the Scheduler interface is only supported from within the EJB container or Web container (Enterprise beans or servlets). Looking up and using a configured scheduler from a Java EE application client container is not supported.
3. Receive scheduler notifications. A notification sink is set on a task in order to receive the notification events that are generated by a scheduler when it performs an operation on the task.
4. Use custom calendars. You can assign a UserCalendar session bean to a task that allows schedulers to use custom and predefined date algorithms to determine when a task should run. Refer to the UserCalendar interface topic for details.
5. Submit tasks to a scheduler. After a TaskInfo object has been created, it can be submitted to the scheduler for task creation by calling the Scheduler.create() method.
6. Manage tasks with a scheduler.
7. Secure tasks with a scheduler.

Example

You can use the SIMPLE and CRON calendars from any Java EE application. This example illustrates the process.

- Using default scheduler calendars

Using default scheduler calendars. The following code examples illustrates how to use connections correctly and incorrectly.

Using default scheduler calendars involves looking up the default UserCalendarHome Enterprise JavaBeans (EJB) home object, creating the UserCalendar bean and calling the applyDelta() method. For details on the applyDelta method as well as the syntax for the SIMPLE and CRON calendars, see UserCalendar interface topic.

```
import java.util.Date;
import javax.naming.InitialContext;
import javax.rmi.PortableRemoteObject;
import com.ibm.websphere.scheduler.UserCalendar;
import com.ibm.websphere.scheduler.UserCalendarHome;

// Create an initial context
InitialContext ctx = new InitialContext();

// Lookup and narrow the default UserCalendar home.
UserCalendarHome defaultCalHome=(UserCalendarHome)
 PortableRemoteObject.narrow(ctx.lookup(
      UserCalendarHome.DEFAULT_CALENDAR_JNDI_NAME),
    UserCalendarHome.class);

// Create the default UserCalendar instance.
UserCalendar defaultCal = defaultCalHome.create();

// Calculate a date using CRON based on the current
// date and time.  Return the next date that is
// Saturday at 2AM
Date newDate =
    defaultCal.applyDelta(new Date(),
        "CRON", "0 0 2 ? * SAT");
```

Accessing schedulers

Each configured scheduler is available using the Scheduler API from a Java Platform, Enterprise Edition (Java EE) server application, such as a servlet or Enterprise JavaBeans (EJB) module. Use a Java Naming and Directory Interface (JNDI). name or resource reference to access schedulers. Each scheduler is also available using the Java™ Management Extensions (JMX) API, using its associated WASScheduler MBean.

About this task

Scheduler and WASScheduler interfaces are the starting point for all scheduler activities. Each scheduler is independent and allows task life cycle operations, such as creating new tasks.

Procedure

1. Locate schedulers using the javax.naming.Context.lookup() method from a Java EE server application, such as a servlet or EJB module like the following example:

   ```
   //lookup the scheduler to be used
   import com.ibm.websphere.scheduler.Scheduler;
   import javax.naming.InitialContext;
   Scheduler scheduler = (Scheduler)new InitialContext.lookup("java:comp/env/sched/MyScheduler");
   ```

2. Use wsadmin to locate a WASScheduler MBean using JACL scripting:

   ```
   set jndiName sched/MyScheduler

   # Map the JNDI name to the mbean name.  The mbean name is
   # formed by replacing the / in the JNDI namewith . and prepending
   # Scheduler_
   regsub -all {/} $jndiName "." jndiName
   set mbeanName Scheduler_$jndiName
   ```

```
puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
puts $sched
```

Results

The scheduler is now available to use from a Java EE server application or from a JMX API client. To create a task see the topics, Developing a task that calls a session bean or Developing a task that sends a JMS message.

Developing a task that calls a session bean

The Scheduler API and WASScheduler MBean API support different implementations of the TaskInfo interface, each of which can be used to schedule a particular type of work. This topic describes how to create a task to call a method on a TaskHandler session bean.

About this task

To create a task to call a method on a TaskHandler session bean, use these steps.

Procedure

1. Create a new enterprise application with an Enterprise JavaBeans (EJB) module. This application hosts the TaskHandler EJB module.
2. Create a stateless session bean in the EJB Module that implements the process() method in the com.ibm.websphere.scheduler.TaskHandler remote interface. Place the business logic you want created in the process() method. The process() method is called when the task runs. The Home and Remote interfaces must be set as follows in the deployment descriptor bean:
   - com.ibm.websphere.scheduler.TaskHandlerHome
   - com.ibm.websphere.scheduler.TaskHandler
3. Create an instance of the BeanTaskInfo interface by using the following example factory method. Using a JavaServer Pages (JSP) file, servlet or EJB component, create the instance as shown in the following code example. This code should coexist in the same application as the previously created TaskHandler EJB module:

   ```
   // Assume that a scheduler has already been looked-up in JNDI.
   BeanTaskInfo taskInfo = (BeanTaskInfo) scheduler.createTaskInfo(BeanTaskInfo.class)
   ```

   You can also use the wsadmin tool to create the instance as shown in the following JACL scripting example:

   ```
   set taskHandlerHomeJNDIName ejb/MyTaskHandler

   # Map the JNDI name to the mbean name.  The mbean name is formed by replacing the / in the jndi name
   # with . and prepending Scheduler_
   regsub -all {/} $jndiName "." jndiName
   set mbeanName Scheduler_$jndiName

   puts "Looking-up Scheduler MBean $mbeanName"
   set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
   puts $sched

   # Get the ObjectName format of the Scheduler MBean
   set schedO [$AdminControl makeObjectName $sched]

   # Create a BeanTaskInfo object using invoke_jmx
   puts "Creating BeanTaskInfo"
   set params [java::new {java.lang.Object[]} 1]
   $params set 0 [java::field com.ibm.websphere.scheduler.BeanTaskInfo class]

   set sigs [java::new {java.lang.String[]} 1]
   $sigs set 0 java.lang.Class
   ```

```
set ti [$AdminControl invoke_jmx $schedO createTaskInfo $params $sigs]
set bti [java::cast com.ibm.websphere.scheduler.BeanTaskInfo  $ti]
puts "Created the BeanTaskInfo object: $bti"
```

Important: Creating a BeanTaskInfo object does not add the task to the persistent store. Rather, it creates a placeholder for the necessary data. The task is not added to the persistent store until the create() method is called on a Scheduler, as described in the Submitting tasks to schedulers topic.

4. Set parameters on the BeanTaskInfo object. These parameters define which session bean is called and when. The TaskInfo interface contains various set() methods that you can use to control execution of the task, including when the task runs and what work the task does when it runs.

   The BeanTaskInfo interface requires that the TaskHandler Java™ Naming and Directory Interface (JNDI) name or TaskHandlerHome is set using the setTaskHandler method. If using the WASScheduler MBean API to set the task handler, then the JNDI name must be the fully-qualified global JNDI name.

   The TaskInfo interface specifies additional control points, as documented in the API documentation. Set parameters using the TaskInfo interface API method as shown in the following code example:

```
//create a date object which represents 30 seconds from now
java.util.Date startDate = new java.util.Date(System.currentTimeMillis()+30000);

//find the session bean to be called when the task starts
Object o = new InitialContext().lookup("java:comp/env/ejb/MyTaskHandlerHome");
TaskHandlerHome home = (TaskHandlerHome)javax.rmi.PortableRemoteObject.narrow(o,TaskHandlerHome.class);

//now set the start time and task handler to be called in the task info
taskInfo.setTaskHandler(home);
taskInfo.setStartTime(startDate);
```

   You can also set parameters using the following JACL scripting example:

```
# Setup the task
puts "Setting up the task..."
# Set the startTime if you want the task to run at a specific time, for example:
$bti setStartTime [java::new {java.util.Date long} [java::call System currentTimeMillis]]

# Set the StartTimeInterval so the task runs in 30 seconds from now
$bti setStartTimeInterval 30seconds

# Set JNDI name of the EJB which will get called when the task runs.  Since there is no
# application J2EE Context when the task is created by the MBean, this must be a
# global JNDI name.
$bti setTaskHandler $taskHandlerHomeJNDIName

# Do not purge the task when it's complete
$bti setAutoPurge false

# Set the name of the task.  This can be any string value.
$bti setName Created_by_MBean

# If the task needs to run with specific authorization you can set the tasks Authentication Alias
# Authentication aliases are created using the Admin Console.
# $bti setAuthenticationAlias {myRealm/myAlias}

puts "Task setup completed."
```

Results

A BeanTaskInfo object has been created that contains all of the relevant data to call an EJB method.

What to do next

Submit the task to a scheduler for creation.

Developing a task that sends a Java Message Service message

The Scheduler API and WASScheduler MBean API support different implementations of the TaskInfo interface, each of which can be used to schedule a particular type of work. This topic describes how to create a task that sends a Java Message Service (JMS) message to a queue or topic.

About this task

To create a task that sends a Java Message Service (JMS) message to a queue or topic, use these steps.

Procedure

1. Create an instance of the MessageTaskInfo interface using the Scheduler.createTaskInfo() factory method. Using a JavaServer Pages (JSP) file, servlet or EJB container, create the instance as shown in the following code example:

```
//lookup the scheduler to be used
Scheduler scheduler = (Scheduler)new InitialContext.lookup("java:comp/env/Scheduler");

MessageTaskInfo taskInfo = (MessageTaskInfo) scheduler.createTaskInfo(MessageTaskInfo.class);
```

   You can also use the wsadmin tool, create the instance as shown in the following JACL scripting example:

```
# Sample create a task using MessageTaskInfo task type
# Call this mbean with the following parameters:
#    <scheduler jndiName>     = JNDI name of the scheduler resource,
#                               for example scheduler/myScheduler
#    <JNDI name of the QCF>   = The global JNDI name of the Queue Connection Factory.
#    <JNDI name of the Queue> = The global JNDI name of the Queue destination

set jndiName [lindex $argv 0]
set jndiName_QCF [lindex $argv 1]
set jndiName_Q [lindex $argv 2]

# Map the JNDI name to the mbean name.  The mbean name is formed by replacing the / in the jndi name
# with . and prepending Scheduler_
regsub -all {/} $jndiName "." jndiName
set mbeanName Scheduler_$jndiName

puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
puts $sched

# Get the ObjectName format of the Scheduler MBean
set schedO [$AdminControl makeObjectName $sched]

# Create a MessageTaskInfo object using invoke_jmx
puts "Creating MessageTaskInfo"
set params [java::new {java.lang.Object[]} 1]
$params set 0 [java::field com.ibm.websphere.scheduler.MessageTaskInfo class]

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 java.lang.Class

set ti [$AdminControl invoke_jmx $schedO createTaskInfo $params $sigs]
set mti [java::cast com.ibm.websphere.scheduler.MessageTaskInfo  $ti]
puts "Created the MessageTaskInfo object: $mti"
```

   Attention: Creating a MessageTaskInfo object does not add the task to the persistent store. Rather, it creates a placeholder for the necessary data. The task is not added to the persistent store until the create() method is called on a Scheduler, as described in the Submitting a task to a scheduler topic.

2. Set parameters on the MessageTaskInfo object. The TaskInfo interface contains various set() methods that can be used to control execution of the task, including when the task runs and what work the task does when it starts.

The TaskInfo interface specifies additional behavior settings, as documented in the API documentation. Using a JavaServer Pages (JSP) file, servlet or EJB container, create the instance as shown in the following code example:

```
//create a date object which represents 30 seconds from now
java.util.Date startDate = new java.util.Date(System.currentTimeMillis()+30000);

//now set the start time and the JNDI names for the queue connection factory and the queue
taskInfo.setConnectionFactoryJndiName("jms/MyQueueConnectionFactory");
taskInfo.setDestination("jms/MyQueue");
taskInfo.setStartTime(startDate);
```

You can also use the wsadmin tool, to create the instance as shown in the following JACL scripting example:

```
# Setup the task
puts "Setting up the task..."
# Set the startTime if you want the task to run at a specific time, for example:
$mti setStartTime [java::new {java.util.Date long} [java::call System currentTimeMillis]]

# Set the StartTimeInterval so the task runs in 30 seconds from now
$mti setStartTimeInterval 30seconds

# Set the global JNDI name of the QCF & Queue to send the message to.
$mti setConnectionFactoryJndiName $jndiName_QCF
$mti setDestinationJndiName $jndiName_Q

# Set the message
$mti setMessageData "Test Message"

# Do not purge the task when it's complete
$mti setAutoPurge false

# Set the name of the task.  This can be any string value.
$mti setName Created_by_MBean

# If the task needs to run with specific authorization you can set the tasks Authentication Alias
# Authentication aliases are created using the Admin Console.
# $mti setAuthenticationAlias {myRealm/myAlias}

puts "Task setup completed."
```

Results

A MessageTaskInfo object has been created that contains all of the relevant data for a task that sends a JMS message.

What to do next

Submit the task to a scheduler for creation, as described in the Submitting a task to a scheduler topic.

Scheduling long-running tasks

The default behavior of the scheduler is designed to run business logic that runs for a short period of time. In version 6.0.2 and later, two API methods on the com.ibm.websphere.scheduler.TaskInfo interface help avoid some of the problems that can occur when running tasks for an extended time.

About this task

The TaskInfo.setQOS method supports tasks with both a transactional and non-transactional quality of service. When running tasks that run for long periods, you can use the TaskInfo.QOS_ATLEASTONCE quality of service to run the task without a global transaction. This process prevents various timeout issues

that can occur when resources are held by a long-running transaction. See the Transactions and schedulers topic for details on the TaskInfo.setQOS method and how it can be used.

Using the TaskInfo.setExpectedDuration method, the scheduler can to adjust timeout values, as appropriate, for a given task for all qualities of service. The application server attempts to adjust various run-time parameters to accommodate the estimated run time of the task.

Procedure

1. When you assemble the TaskInfo object with the Scheduler API or the WASScheduler MBean, use the following methods on the TaskInfo interface:
   a. Set the quality of service.
      1) If the task must be transactional, use the setQOS method with the QOS_ONLYONCE constant, which is the default, if not set.
      2) If the task does not need to be transactional, use the setQOS method with the QOS_ATLEASTONCE constant.
   b. Set the expected duration.
      1) Use the setExpectedDuration method to set the expected duration of the task in seconds.
2. Schedule the task using the Scheduler.create method.

What to do next

View the Access schedulers topic.

Receiving scheduler notifications

Various notification events are generated by a scheduler when it performs an operation on a task. These notifications events are described in this topic.

About this task

The notification events generated by a scheduler when it performs a task include:

Scheduled
A task has been scheduled.

Purged
A task has been permanently deleted from the persistent store.

Suspended
A task was suspended.

Resumed
A task was resumed.

Complete
A task has run completely. If it was a repeating task, all repeats have been performed.

Cancelled
A task has been cancelled. It will not run again.

Firing A task is prepared to run.

Fired A task completed successfully.

Fire failed
A task could not run successfully.

To receive notification events, call the setNotificationSink() method on the TaskInfo interface before creating the task. The setNotificationSink() method enables you to specify the session bean that is to act as the callback, and a mask that restricts which events are generated.

Procedure

1. Create a NotificationSink session bean. Create a stateless session bean that implements the handleEvent() method in the com.ibm.websphere.scheduler.NotificationSink remote interface. The handleEvent() method is called when the notification is fired. The Home and Remote interfaces can be set as follows in the bean's deployment descriptor:

   ```
   com.ibm.websphere.scheduler.NotificationSinkHome
   com.ibm.websphere.scheduler.NotificationSink
   ```

   The NotificationSink interface defines the following method:

   ```
   public void handleEvent(TaskNotificationInfo task) throws java.rmi.RemoteException;
   ```

2. Specify the notification sink session bean prior to submitting the task to the Scheduler using the TaskInfo interface API setNotificationSink() method.

   If using the WASScheduler MBean API to set the notification sink, then the Java™ Naming and Directory Interface (JNDI) name must be the fully-qualified global JNDI name. Using a JavaServer Pages (JSP) file, servlet or Enterprise JavaBeans (EJB) component, look up and set the notification sink on a task as shown in the following code example:

   ```
   TaskInfo taskInfo = ...
   Object o = new InitialContext().lookup("java:comp/env/ejb/NotificationSink");
   NotificationSinkHome home = (NotificationSinkHome )javax.rmi.PortableRemoteObject.narrow
   (o,NotificationSinkHome.class);
   taskInfo.setNotificationSink(home,TaskNotificationInfo.ALL_EVENTS);
   ```

   You can also use the wsadmin tool to set the notification sink callback session bean as shown in the following JACL scripting example:

   ```
   # Use the NotificationSinkHome's Global JNDI name
   # Assume that a TaskInfo was already created...
   $taskInfo setNotificationSink "ejb/MyNotificationSink"
   ```

3. Specify the event mask. The event mask is specified as an integer bitmap. You can either use an individual mask such as TaskNotificationInfo.CREATED to receive specific events, TaskNotificationInfo.ALL_EVENTS to receive all events or a combination of specific events. If you use Java, your script might look like the following example:

   ```
   int eventMask = TaskNotificationInfo.FIRED | TaskNotificationInfo.COMPLETE;
   taskInfo.setNotificationSink(home,eventMask);
   ```

   If you use JACL, your script might look like the following example:

   ```
   # Set the event mask based on two event constants.
   set eventmask [expr [java::field com.ibm.websphere.scheduler.TaskNotificationInfo FIRED] +
    [java::field com.ibm.websphere.scheduler.TaskNotificationInfo COMPLETE]]

   # Set our Notification Sink based on our global JNDI name AND event mask.
   # Note:  We need to use the full method signature here since the
   # method resolver can't always detect the right method.
   $taskInfo {setNotificationSink String int} "ejb/MyNotificationSink" $eventmask
   ```

Results

A notification sink bean is now set on a TaskInfo object and can now be submitted to a scheduler using the create method.

Submitting a task to a scheduler

This topic describes the process of submitting a task to a configured scheduler.

Before you begin

This task assumes that you have already configured a scheduler and created and configured a TaskInfo object that calls a session bean or sends a Java Messaging Service (JMS) message.

About this task

Once you have developed a TaskInfo object that contains all relevant data for a task, submit the task to a scheduler for creation. When the task is created, the scheduler runs it.

Procedure

Create the task. After you configure TaskInfo, submit it to the appropriate scheduler, using the Scheduler API create method.

```
// Create the TaskInfo using the Scheduler that you already looked up and print out the Task ID
TaskStatus ts = scheduler.create(taskInfo);
System.out.println("Task created with id: " + ts.getTaskId()"
```

You can also create the task using the wsadmin tool as shown in the following JACL scripting example:

```
# Create the TaskInfo using the WASScheduler MBean that you previously located and print out the Task ID
puts "Creating the task..."

set params [java::new {java.lang.Object[]} 1]
$params set 0 $taskInfo

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 com.ibm.websphere.scheduler.TaskInfo

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $schedO
 create $params $sigs]]

puts "Task Created.  TaskID= [$taskStatus getTaskId]"

puts $taskStatus
```

When the call to the create() method is complete, the task exists in the persistent store and is run at the time specified in the TaskInfo object. If a global transactional context is present on the thread, and the create() transaction rolls back or is aborted, the task does not run.
The TaskStatus object, which has been returned by the call to the create() method, contains information about the state of the task, as well as the task ID. The task ID is the unique identifier for this task, and is required if the task is to be suspended, resumed, cancelled, and so on, at a later time.

Tip: The TaskStatus object is only a snapshot of the current state of the task. Use the Scheduler.getStatus() method to receive the current state when needed.

Task management methods using a scheduler

The scheduler provides several task management methods.

When a task is created by calling the create() method on a scheduler, a TaskStatus object is returned to the caller. The TaskStatus object contains the task ID, which is a unique identifier. The Scheduler API and WASScheduler MBean define several additional methods that pertain to the management of tasks, each of which accepts the task ID as a parameter. The following task management methods are defined:

suspend()
: Suspends a task. The task does not run until it has been resumed.

resume()
: Resumes a previously suspended task.

cancel()
: Cancels a task. The task is not run and cannot be resumed.

purge()
: Permanently deletes a cancelled task from the persistent store.

getStatus()
: Returns the current status of the task.

Use the following API example to create and cancel a task:

```
//Create the task.
TaskInfo taskInfo = ...
TaskStatus status = scheduler.create(taskInfo);

//Get the task ID
String taskId = status.getTaskId();

//Cancel the task. Specify the purgeAlso flag so that the task does not remain in the persistent store
scheduler.cancel(taskId,true);
```

Use the following example JACL script operations in the wsadmin tool to create and cancel a task:

```
set jndiName sched/MyScheduler

# Map the JNDI name to the mbean name.  The mbean name is
# formed by replacing the / in the jndi name with . and prepending
# Scheduler_
regsub -all {/} $jndiName "." jndiName
set mbeanName Scheduler_$jndiName

puts "Looking-up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]
puts $sched

# Get the ObjectName format of the Scheduler MBean
set schedO [$AdminControl makeObjectName $sched]

# Create a TaskInfo object...
# (Some code excluded...)
set params [java::new {java.lang.Object[]} 1]
$params set 0 $taskInfo

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 com.ibm.websphere.scheduler.TaskInfo

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $schedO
 create $params $sigs]]

set taskID [$taskStatus getTaskId]
puts "Task Created.  TaskID= $taskID"

# Cancel the task using the Task ID from the TaskStatus object returned during create.
set params [java::new {java.lang.Object[]} 1]
$params set 0 false

set sigs [java::new {java.lang.String[]} 1]
$sigs set 0 java.lang.boolean

set taskStatus [java::cast com.ibm.websphere.scheduler.TaskStatus [$AdminControl invoke_jmx $schedO
 cancel $params $sigs]]
```

Transactionality. All methods of the Scheduler API are transactional. If a global transactional context is present, it is used to perform the operation. If an unexpected exception is thrown, the transaction is marked to roll back, and the caller must handle it appropriately. If an expected or declared exception is thrown, the transaction remains intact and the caller must choose to roll back or to commit the transaction. If the transaction is rolled back at some point, all scheduler operations performed within the transaction are also rolled back.

If a local transactional context is present, it is suspended and a new global transactional context begins. Likewise, if no transactional context is active, a global transactional context begins. In both cases, if an unexpected exception is thrown, the transaction rolls back. If a declared exception is thrown, the transaction is committed.

If another thread is concurrently modifying the task in question, a TaskPending exception is thrown. This is because schedulers lock the database optimistically. The calling application can then retry the operation.

Task management functions may block if the task is currently running. Because the scheduler guarantees that each task will run only once, the task must be locked for the duration of a running task. Likewise, if a task is changed using one of the management functions but the global transaction is not committed, any other management functions issued from another transaction for that task will be blocked.

A stateless session bean task's TaskHandler.process() method can change it's own state. However, the task must be running within the same transaction as the scheduler. Therefore, a running task can only modify itself if it is using the Required or Mandatory container managed transaction types. If the Requires New transaction type is specified on the process() method, all management functions will deadlock.

All methods defined by the Scheduler API are described in the API documentation.

Identifying tasks that are currently running

When a task runs, the task database record is locked until the task completes. This topic describes how to determine whether or not a task is running.

About this task

Prior to version 6.0.2, all tasks ran in a single global transaction. This process not only prevented the task from running more than once successfully, but it also blocked all attempts at reading the state of the task, since each task used read-committed transaction isolation.

There are two methods for determining whether a task is running:

1. **NotificationSink**

   A NotificationSink EJB can be set on the task using the setNotificationSink method on the TaskInfo object. The NotificationSink bean can then log the life cycle of the task to a separate database record in a custom table. This would result in a history log of the task that can be queried independently from the scheduler. This solution works for all versions of the scheduler service. See the Receiving Scheduler Notifications topic for details.
2. **Delayed Execution and Uncommitted Read**

   In Version 6.0.2 and later, two behaviors enable the scheduler find and retrieve API methods, such as getTask, getTaskStatus or findTasksByName, to see the current state of the task without blocking. To see the current state of the task, including its uncommitted running state, complete the following steps:

Procedure

1. Enable read-uncommitted transaction isolation for the scheduler read methods to prevent these methods from blocking while a task is running. To set the default transaction isolation for read methods, see the Configuring scheduler default transaction isolation topic for read operation details.

   Important: If the scheduler database does not support uncommitted reads, such as Oracle, it might not be possible to determine if a task is running unless you use the QOS_ATLEASTONCE quality of service.
2. Use the TaskInfo.EXECUTION_DELAYEDUPDATE option on the TaskInfo.setTaskExecutionOptions method to force the scheduler to write the TaskStatus.RUNNING state to the task when that task starts running.

Stopping tasks that are failing

The scheduler runs tasks in a global transactional context, by default. If a task is failing due to a configuration problem or application error, the scheduler attempts to retry the task until the scheduler failure threshold is reached. This topic describes how to stop the tasks that are failing.

Before you begin

The default scheduler failure threshold is `10` and can be configured using the taskFailureThreshold scheduler custom property. To configure this custom property, in the administrative console click **Resources** > **Schedulers** > ***scheduler_name*** and click **Custom Properties**. Valid values are non-negative integers, that is, integers greater than `0`.

About this task

When the task reaches the failure threshold, the scheduler stops running the task until the scheduler daemon is restarted using the WASScheduler MBean, the scheduler fails over to another server, or until the scheduler is resumed using the resume method on the Scheduler API or WASScheduler MBean.

Procedure

1. Cancel or suspend a transactional (QOS_ONLYONCE) task that is continually failing. This action can be difficult if the scheduler has not yet reached the failure threshold. The cancel and suspend Scheduler API methods or WASScheduler MBean operations block until the task fails or the method times out, while waiting for a database lock and throws a TaskPending exception. If this occurs, then the application can retry the cancel or suspend operation until it completes.
2. Alternatively, stop the scheduler daemon using the stopDaemon operation on the WASScheduler MBean to avoid running the task multiple times, and run the cancel or suspend operation while it is stopped. While the daemon is stopped, the scheduler does not run tasks. However, all MBean operations and API methods are still available.

Scheduler tasks and Java EE context

When a task is created using the Scheduler API create() method, the Java Platform, Enterprise Edition (Java EE) thread context of the creator is stored with the scheduled task. When the task runs, the original Java EE thread context is reapplied to the thread before calling the customer TaskInfo instance.

The scheduler service utilizes the asynchronous beans deferred start mechanism to propagate Java EE service context information to a task when it runs. The amount of service context information that is propagated is controlled by the Service Context settings on the WorkManager configuration object that schedulers reference. For example, security and internationalization service contexts can be enabled. See the Using asynchronous beans topic for details on how to configure the Application Server to propagate these service contexts.

Transactions and schedulers

The scheduler runs a task in a single global transaction, by default. You can use the QOS_ONLYONCE or QOS_ATLEASTONCE quality of service to specify whether the task runs as a single unit of work once or as independent transactions.

Transaction behavior when running a task

Because the scheduler runs a task in a single global transaction, by default, the transaction is open until the task completes or fails. The resources involved in that transaction are subject to various timeouts and the thread of the task could be identified as hung if the task runs for a long period of time that can span many minutes or hours.

QOS_ONLYONCE

Scheduled tasks execute only one time successfully when using the QOS_ONLYONCE quality of service. This action is accomplished by grouping all of the work done in the task as a single unit of work. When each task fires, the following events occur in a single global transactional context:

1. The context of the application that created the task is applied to the thread.
2. A global transactional context is started.

3. The next fire time and start-by time are calculated using the UserCalendar bean or the DefaultUserCalendar.

   Important: If using the TaskInfo.setTaskExcecutionOptions method with the TaskInfo.EXECUTION_DELAYEDUPDATE option, this step will occur after the record is updated.
4. The task database task record is updated in the database with the state of the next task or deleted if the task is complete and the task's auto-purge setting is true.
5. The task database record is updated in the database with the state of the next task or deleted if the task is complete and the task's auto-purge setting is true. If the EXECUTION_DELAYEDUPDATE option is used, the database will not reflect the next state of the task, but the current state with the TaskStatus.RUNNING state set.
6. If the NotificationSink bean is set, a FIRING notification is fired.
7. The BeanTaskInfo or MessageTaskInfo object starts.
8. If the task fails and the NotificationSink bean is set, a FIRE_FAILED notification is fired on a separate transaction.
9. If the task's NotificationSink bean is set, then the various notifications are fired as required.
10. If the EXECUTION_DELAYEDUPDATE option is used for the task, the database will be updated a second time with the next state of the task.
11. The global transaction is committed.

Because all events belonging to a task are executed in a single global transactional context, consider the following points in order to avoid transaction-related errors:

- Each resource participating in the task transaction must be two-phase XA capable.

  This includes the Java Database Connectivity (JDBC) datasource that is configured for the scheduler, any Java Messaging Service (JMS) services used by the MessageTaskInfo objects, and any resources used within any of the UserCalendar, TaskHandler, or NotificationSink beans that have a transaction setting of "Required".
- One resource can be single-phase, if last participant support is enabled for the application that created the transaction. Enable last participant support using an assembly tool. You can also enable last participant support through the administrative console. See the Last participant support extension settings topic for details.

All unexpected exceptions are logged to the activity log and all events participating in the task global transaction are rolled back. This includes changes to the task database record, which force the task to be executed again when the scheduler daemon polls the database during the next poll cycle. The UserCalendar, TaskHandler, and NotificationSink beans can choose not to participate in the global transaction by configuring the bean transaction setting to "Requires new".

QOS_ATLEASTONCE

Scheduled tasks that use the QOS_ATLEASTONCE quality of service do not have a single transactional context. In this case, each calendar calculation, event notification and database update occurs in an independent transaction:

1. The context of the application that created the task is applied to the thread.
2. The task’s database record is updated with the RUNNING state of the task.
3. UserCalendar, NotificationSink beans are called.
4. The BeanTaskInfo or MessageTaskInfo is started.
5. Result notifications are sent.
6. The database is updated with the next state of the task, if the task has not been changed since the RUNNING state was written.

If a failure happens after the RUNNING state is written to the database and before the result is written, then the task may run more than one time.

When using QOS_ATLEASTONCE, all NotificationSink, UserCalendar and TaskHandler beans must not mandate a transaction (TX_MANDATORY), since there is no global transaction available when the task runs. The EJB components use "Required" or "Requires new" container managed transaction or a bean managed transaction.

Transaction behavior when using the Scheduler API methods or WASScheduler MBean operations

All Scheduler interface methods participate in a single global transactional context. If a global transactional context is already present on the thread when the create(), suspend(), resume(), cancel(), and purge() methods are executed, then the existing global transaction is used. Otherwise, a new global transaction begins.

If the method participates in the global transaction of the caller and an unexpected error occurs, then the transaction is marked to roll back. If the exception is a declared exception, then the exception is resubmitted to the caller, and the transaction is left alone for the caller to commit or roll back.

If the method starts its own global transaction and any exception occurs, then the transaction is rolled back, and the exception is resubmitted to the caller.

Scheduler task user authorization

The scheduler service uses the asynchronous beans deferred start mechanism to propagate Java Platform, Enterprise Edition (Java EE) service context information to a task when it runs. If you plan to secure your application using the JAAS security context of the administrative security mechanism built into WebSphere Application Server, create each task with the correct credentials on the thread.

Tasks run with specified security credentials using the following methods:

- Using the Java Authentication and Authorization Service (JAAS) security context on the thread at the time the task was created. See the Deferred start and security topic in the Asynchronous beans section of the information center.
- Using the setAuthenticationAlias method on the TaskInfo object.
- Using a specified security identity on a BeanTaskInfo task TaskHandler EJB method.

The scheduler service utilizes the asynchronous beans deferred start mechanism to propagate Java EE service context information to a task when it runs. The amount of service context information that is propagated is controlled by the Service Context settings on the WorkManager configuration object that schedulers reference. For example, security and internationalization service contexts can be enabled. See the Using asynchronous beans topic for details on how to configure the Application Server to propagate these service contexts.

Java Authentication and Authorization Service Security context

If you intend to secure your application using the JAAS security context of the administrative security mechanism built into WebSphere Application Server, create each task with the correct credentials on the thread. Once each task has the correct credentials, you can disable and re-enable administrative security without causing any security problems. If you do not set the security context when the scheduler task is created and you later enable security in the target application, a security exception or error message might display, such as SECJ0053E. You might also see this error if two or more schedulers on different servers are accessing the same tables (a clustered or redundant scheduler) and the security settings are different.

The JAAS security context is not set if any of the follow conditions are true:

- Administrative security is disabled.
- Security context policies are disabled on the configured WorkManager for the associated scheduler configuration.

- A credential is not set on the thread. For example, the enterprise bean or servlet that is used to create the scheduled task is not secured, or the task was created with a WASScheduler MBean.

If any of the previously mentioned conditions are true when you create your task and you need to enable security on your application server or application, you must complete the following steps for each task:

1. Find the task using the Scheduler API find or get methods.
2. Cancel the task using the Scheduler.cancel() API.
3. Recreate the task using the Scheduler.create() method with security enabled. Submitting a task that was retrieved from the scheduler using the find or get methods will automatically generate a new task ID.

Security order of precedence

As previously noted, there are three ways of verifying that a task will run with the correct user credentials. In addition, each TaskInfo implementation may have its own way of supplying user information, which may override the standard mechanisms. If multiple methods are used, refer to the following lists to determine which security mechanism is going to be employed.

BeanTaskInfo

1. TaskHandler security identity set on the process() method of the Enterprise Java Bean file
2. Authentication Alias set with the setAuthenticationAlias method on the TaskInfo interface
3. JAAS security context

MessageTaskInfo

1. Authentication Alias set with the setAuthenticationAlias method on the TaskInfo interface
2. The setUsername and setPassword methods on the MessageTaskInfo interface. See the Deprecated features article for more information.

Securing scheduler tasks

Scheduled tasks are protected using application isolation and administrative roles. This topic describes how to secure scheduler tasks.

About this task

If a task is created using a Java Platform, Enterprise Edition (Java EE) server application, only applications with the same name can access those tasks. Tasks created with a WASScheduler MBean using the AdminClient interface or scripting are not part of a J2EE application and have access to all tasks regardless of the application with which they were created. Tasks created with a WASScheduler MBean are only accessible from the WASScheduler MBean API and are not accessible from the Scheduler API.

If the Use Administration Roles attribute is enabled on a scheduler and administrative security is enabled on the Application Server, all Scheduler API methods and WASScheduler MBean API operations enforce access based on the WebSphere Administration Roles. If either of these attributes are disabled, then all API methods are fully accessible by all users.

Procedure

1. Enable security for all application servers.
2. Manage schedulers.

Scheduler configuration or topology

The scheduler uses a database to persist information concerning which tasks to run and when. Errors might occur when changing the application server topology or when changing the application or server configuration. When you change the configuration or topology, carefully consider how this action affects the scheduler.

Restricting security

If you created tasks with an application server while security is disabled, and you later decide to enable security, then the scheduler might have difficulty running tasks. When you create a task, the security context of the application thread is automatically stored with the task. If security is not stored with the task (see Scheduler task user authorization), and you later enable security on the server or application where the task is to run, then the following errors might be logged:

```
SECJ0053E: Authorization failed for /UNAUTHENTICATED while invoking (Home)com/ibm/websphere/scheduler
/TaskHandler create:2 securityName: /UNAUTHENTICATED;accessID: UNAUTHENTICATED is not granted any of
the required roles: MySecurityRole
```

Before you enable security on the server or application, determine if any tasks might be adversely affected. If so, use the Scheduler API or WASScheduler MBean to cancel the tasks and recreate them after you configure security.

Application server topology changes

The scheduler stores javax.ejb.HomeHandle objects for TaskHandler, NotificationSink and UserCalendar *homes* when the task is created. When you run the task later, these home handles are reinflated and used to access the Enterprise JavaBeans (EJB) component home. When the home handle references an EJB on a single-server environment, the home handles have affinity to that server. When the home handle references an EJB component on a cluster, then the home handles have affinity to the cluster.

If the application server or the Workload Managed (WLM) cluster that a home handle is referencing is not available, then the scheduler fails to run the task, and the following error is logged:

```
SCHD0063E: A task with ID 123 failed to run on Scheduler MyScheduler (sched/MyScheduler) because of
an exception: {cause of failure}
```

If you upgrade the application server to a cluster, or if the Object Request Broker (ORB) ORB_LISTENER_ADDRESS is not set to a fixed port number (see Configuring Inbound Transports), then the task might also fail, since the information stored within the home handle does not have the appropriate information to find the desired server.

Upgrading to a scheduler cluster

A scheduler cluster (not to be confused with a WLM cluster) is a collection of scheduler configurations on different application servers that share the same Java Naming and Directory Interface (JNDI) name, Java Database Connectivity (JDBC) data source and table prefix. If you upgrade a stand-alone scheduler to a clustered scheduler, then the application and any associated resources that the application requires must be available. If this is not the case, the scheduled task fails to run and error messages might be logged:

```
SCHD0103W: The Scheduler MyScheduler (sched/MyScheduler) was unable to run task 123 because the
application or module is unavailable: MyTaskHandlerEJB
```

To avoid issues with application availability and achieve optimal results, use the same servers in a scheduler cluster as those used in a WLM cluster.

Reusing scheduler tables

When changing any topology, moving from development to production environments, or making any configuration changes that make the environment more restrictive, you might get optimal results if you use

a different set of scheduler tables. Reusing scheduler tables that have scheduled tasks from previous releases without careful planning might cause problems:

- EJB components running on unexpected application servers.
- Tasks failing to run due to invalid or missing security credentials.
- Tasks failing to run due to invalid or missing Java Platform, Enterprise Edition (Java EE) context information.

Diagnosing such problems is challenging and requires analyzing logs on all servers that have a scheduler installed and configured. When the problem tasks are located, the tasks can be cancelled using the Scheduler APIs, or the tables can be dropped and recreated.

Scheduler interface

Use the `com.ibm.websphere.scheduler.Scheduler` Java object (in the Java™ Naming and Directory Interface (JNDI) namespace for the scheduler configuration) to find a reference to a scheduler and work with tasks.

A `com.ibm.websphere.scheduler.Scheduler` Java object exists in the JNDI namespace for each scheduler configuration. A reference to a scheduler can be obtained by performing a lookup on the JNDI name; however, the lookup is valid only from the server process where the scheduler instance exists. Once a reference has been obtained, tasks can be created, suspended, cancelled, and so on, if the caller has access to the scheduler instance.

For details, see Interface Scheduler in the API documentation.

Task creation
: The task is created in the persistent store using the global transactional context of the caller, if present. See the topic, “Transactions and schedulers” on page 868, for more details. Since this is a transactional operation, the task cannot be run or modified from another thread until the current transaction commits.

Task modification
: Tasks that have been created can be modified with the suspend(), resume(), cancel(), and purge() methods. These methods take a Task Identifier string as a parameter, which is generated by the create() method and can be found in the TaskStatus object. If a task is currently running or being modified by another thread, an operation that attempts to modify the state of the task might block on the attempt. Tasks can only be modified by the same application (EAR file) that was used to create the task.

Task execution
: Tasks are run in the thread pool specified by the configuration's work manager. If multiple schedulers are configured to share the same database tables, the scheduler is clustered and the tasks found in the table can be run on any of the schedulers, whether or not they are in the same server, node, or cell.

Task lookup
: Tasks can be located using the Name property that was assigned at creation time. This is useful when you need to modify a group of tasks and tracking individual task ID's is not convenient.

TaskInfo interface

TaskInfo objects contain the information to create a task. Several implementations of this class exist, one for each type of task that can run.

Available TaskInfo implementations include:

BeanTaskInfo
: Calls a stateless session bean.

MessageTaskInfo
: Sends a Java™ Messaging Service (JMS) message to a queue or publishes a message to a topic. For details, see the Interface TaskInfo in the API documentation.

After a TaskInfo object is created, it can be submitted to the scheduler for task creation by calling the Scheduler.create() method.

For details about the TaskInfo interface, see the API documentation .

TaskHandler interface

A task handler is a user-defined stateless session bean that is called by tasks created using a BeanTaskInfo object.

A task handler bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as Rational Application Developer:

```
com.ibm.websphere.scheduler.TaskHandlerHome
com.ibm.websphere.scheduler.TaskHandler
```

The bean itself needs to implement the process() method defined in the remote interface. For details, see the Interface TaskHandler in the API documentation.

Once an EJB is created and available within an enterprise application, it can be called by a BeanTaskInfo task when it runs. See the Developing a task that calls a session bean topic for details.

When a task is created using a BeanTaskInfo object, the process() method on the TaskHandler session bean is called whenever the task runs. Because the TaskStatus object for the task is passed as a parameter to the process() method, the task handler determines different types of information about the task, such as when it will fire next, the number of repeats remaining, its name and its ID.

The process() method can also change its own state. However, the task must be running within the same transaction as the scheduler. Therefore, a running task can only modify itself if it is using the **Required** or **Mandatory** container managed transaction types. If the **Requires New** transaction type is specified on the process()method, all management functions deadlock.

NotificationSink interface

A notification sink is a user-defined stateless session bean that is called when the task changes state.

A notification sink bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as Rational Application Developer:

```
com.ibm.websphere.scheduler.NotificationSinkHome
com.ibm.websphere.scheduler.NotificationSink
```

The bean itself needs to implement the handleEvent() method defined in the remote interface. For details, see the Interface NotificationSink section of the API documentation and the Receiving scheduler notifications topic.

A NotificationSink provides an event notification callback on a task-by-task basis. A notification sink is set on the TaskInfo interface, using the setNotificationSink() method. If a notification sink is not specified on a task, all notifications are lost; however, the status of a task can be determined by calling the getStatus() method from the Scheduler interface. A notification callback is made for each of the following events:

- Scheduled
- Suspended
- Resumed
- Fired
- Firing
- Fire Failed
- Complete
- Purged

UserCalendar interface

A user calendar is a user-defined stateless session bean that is called by tasks when they need to calculate date-related values.

A user calendar bean uses the following home and remote interfaces, which are defined in the deployment descriptor using an assembly tool, such as Rational Application Developer:

```
com.ibm.websphere.scheduler.UserCalendarHome
com.ibm.websphere.scheduler.UserCalendar
```

The bean itself needs to implement the applyDelta(), validate(), and getCalendarNames() methods defined in the remote interface. For details, see the Interface UserCalendar in the API documentation.

User calendars are used to calculate time intervals, such as the time between task runs. A user calendar takes a java.util.Date object, applies the interval string and returns the resulting java.util.Date.

User calendars are set with the setUserCalendar() method on the TaskInfo interface and called by the scheduler run-time code when a delta calculation is necessary.

The following methods on the TaskInfo interface specify delta strings that use the user calendar for calculation:

- setStartTimeInterval
- setStartByInterval
- setRepeatInterval

Default user calendar

If a user calendar has not been specified using the TaskInfo.setUserCalendar() method, a default user calendar is used. The default calendar allows for simple delta specifications, such as seconds, minutes, hours, days, and months. See the API documentation for details on the default calendar. The default user calendar also provides a CRON-like syntax for calculating absolute times versus time deltas.

Calendar identifiers

A single user calendar can contain logic for multiple calendars. A calendar specifier string determines which calendar is used. For example, a calendar bean might be implemented to recognize the interval *day*. However, the identifier also recognizes two calendar implementations: *standard* (for a standard calendar day) and *business* (for a business day).

Internationalization and time zones

Scheduler makes use of the java.util.Date class when storing and processing dates. Internally, this class saves the time as milliseconds since the Epoch, Greenwich Mean Time. Since the Date is not converted to local time until converted to a string, the scheduler respects the time zone where the date was created.

Writing user calendars

Because the user calendar is a stateless session bean, the same Java Platform, Enterprise Edition (Java EE) programming model available to other session beans is available to the user calendar as well.

Chapter 21. Developing security

Secure specific types of applications, such as applications that include portlets, SIP servlets, enterprise beans, web services. Find security information that focuses on specific concerns, such as messaging, transaction support, naming and directory, data access.

Developing extensions to the WebSphere security infrastructure

WebSphere Application Server provides various plug points so that you can extend the security infrastructure. Extending this security infrastructure involves several activities including: Developing custom user registries, developing applications that use programmatic security, and customizing web application login forms.

About this task

The following topics are covered in this section:

Procedure

- Developing custom user registries
- Developing applications that use programmatic security
- Customizing web application login forms
- Customizing application login forms with Java Authentication and Authorization Service (JAAS)
- Securing transports with Java Secure Sockets Extension (JSSE) and Java Cryptography Extension (JCE) programming interfaces
- Implementing tokens for security attribute propagation
- Implementing a custom authentication provider using JASPI

Developing stand-alone custom registries

This development provides considerable flexibility in adapting WebSphere Application Server security to various environments where some notion of a user registry, other than LDAP or Local OS, already exists in the operational environment.

Before you begin

WebSphere Application Server security supports the use of stand-alone custom registries in addition to the local operating system registry, stand-alone Lightweight Directory Access Protocol (LDAP) registries, and federated repositories for authentication and authorization purposes. A stand-alone custom-implemented registry uses the UserRegistry Java interface as provided by WebSphere Application Server. A stand-alone custom-implemented registry can support virtually any type or notion of an accounts repository from a relational database, flat file, and so on.

Implementing a stand-alone custom registry is a software development effort. Implement the methods that are defined in the com.ibm.websphere.security.UserRegistry interface to make calls to the appropriate registry to obtain user and group information. The interface defines a general set of methods for encapsulating a wide variety of registries. You can configure a stand-alone custom registry as the selected repository when configuring WebSphere Application Server security on the Global security panel.

In WebSphere Application Server Version 8.5, make sure that your implementation of the stand-alone custom registry does not depend on any WebSphere Application Server components such as data sources, Enterprise JavaBeans (EJB) and Java Naming and Directory Interface (JNDI). You can not have this dependency because security is initialized and enabled prior to most of the other WebSphere Application Server components during startup. If your previous implementation used these components,

make a change that eliminates the dependency. For example, if your previous implementation used data sources to connect to a database, instead use the JDBC java.sql.DriverManager interface to connect to the database.

Note: The user registry is used in controllers and servants. There is an increased risk of integrity exposure in that configuration if the registry implementation is not secured.

If your previous implementation uses data sources to connect to a database, change the implementation to use Java database connectivity (JDBC) connections.

Procedure

1. Implement all the methods in the interface except for the CreateCredential method, which is implemented by WebSphere Application Server.
2. Build your implementation.

   To compile your code, you need the *app_server_root*/plugins/com.ibm.ws.runtime.jar and the *app_server_root*/plugins/com.ibm.ws.security.crypto.jar files in your class path. For example:

   ```
   app_server_root\java\bin\javac -classpath
   app_server_root\plugins\com.ibm.ws.runtime.jar:
   app_server_root\plugins\com.ibm.ws.security.crypto.jar your_implementation_file.java
   ```
3. Copy the class files that are generated in the previous step to the product class path.

   The preferred location is the following directory:

   - *%install_root%*\lib\ext

   directory. Copy these class files to all of the product process class paths.
4. To configure your implementation using the administrative console, follow the steps in topics about configuring stand-alone custom registries. This step is required to implement custom user registries.

Example

Viewing stand-alone custom registries.

Use these links to view registry examples.

A *stand-alone custom registry* is a customer-implemented registry that implements the UserRegistry Java interface, as provided by WebSphere Application Server. A custom-implemented registry can support virtually any type or form of an accounts repository from a relational database, flat file, and so on. The custom registry provides considerable flexibility in adapting WebSphere Application Server security to various environments where some form of a registry, other than a federated repository, Lightweight Directory Access Protocol (LDAP) registry, or local operating system registry, already exist in the operational environment.

What to do next

If you enable security, make sure that you complete the remaining steps:

1. Save and synchronize the configuration and restart all of the servers.
2. Try accessing some J2EE resources to verify that the custom registry implementation is correct.

Result.java file

This module is used by user registries in WebSphere Application Server when calling the getUsers and getGroups methods. The user registries use this method to set the list of users and groups and to indicate if more users and groups in the user registry exist than requested.

// (C) COPYRIGHT International Business Machines Corp. 1997, 2005
//  All Rights Reserved * Licensed Materials - Property of IBM
//
```

```
package com.ibm.websphere.security;

import java.util.List;

public class Result implements java.io.Serializable {
    /**
      Default constructor
    */
    public Result() {
    }

    /**
       Returns the list of users and groups
       @return the list of users and groups
    */
    public List getList() {
      return list;
    }

    /**
       indicates if there are more users and groups in the registry
    */
    public boolean hasMore() {
      return more;
    }
    /**
       Set the flag to indicate that there are more users and groups
       in the registry to true
    */
    public void setHasMore() {
      more = true;
    }

    /*
      Set the list of users and groups
      @param list   list of users/groups
    */
    public void setList(List list) {
      this.list = list;
    }

    private boolean more = false;
    private List list;
}
```

UserRegistry.java files

The following file is a custom property that is used with a custom user registry.

For more information, see Configuring stand-alone custom registries.

```

import com.ibm.websphere.security.cred.WSCredential;

/**
 * Implementing this interface enables WebSphere Application Server Security
 * to use custom registries. This interface extends java.rmi.Remote because the
 * registry can be in a remote process.
 *
 * Implementation of this interface must provide implementations for:
*
* initialize(java.util.Properties)
* checkPassword(String,String)
* mapCertificate(X509Certificate[])
* getRealm
* getUsers(String,int)
* getUserDisplayName(String)
* getUniqueUserId(String)
* getUserSecurityName(String)
* isValidUser(String)
* getGroups(String,int)
* getGroupDisplayName(String)
* getUniqueGroupId(String)
* getUniqueGroupIds(String)
```

```
* getGroupSecurityName(String)
* isValidGroup(String)
* getGroupsForUser(String)
* getUsersForGroup(String,int)
* createCredential(String)
**/

public interface UserRegistry extends java.rmi.Remote
{

  /**
   * Initializes the registry. This method is called when creating the
   * registry.
   *
   * @param props the registry-specific properties with which to
   *               initialize the  custom registry
   * @exception CustomRegistryException
   *                    if there is any registry specific problem
   * @exception RemoteException
   *    as this extends java.rmi.Remote
   **/
   public void initialize(java.util.Properties props)
      throws CustomRegistryException,
             RemoteException;
  /**
   * Checks the password of the user. This method is called to authenticate a
   * user when the user's name and password are given.
   *
   * @param userSecurityName the name of the user
   * @param password the password of the user
   * @return a valid userSecurityName. Normally this is
   *   the name of same user whose password was checked but if the
   *  implementation wants to return any other valid
   *  userSecurityName in the registry it can do so
   * @exception CheckPasswordFailedException if userSecurityName/
   *  password combination does not exist in the registry
   * @exception CustomRegistryException if there is any registry specific
   *            problem
   * @exception RemoteException as this extends java.rmi.Remote
   **/
   public String checkPassword(String userSecurityName, String password)
      throws PasswordCheckFailedException,
             CustomRegistryException,
             RemoteException;

  /**
   * Maps a certificate (of X509 format) to a valid user in the registry.
   * This is used to map the name in the certificate supplied by a browser
   * to a valid userSecurityName in the registry
   *
   * @param cert the X509 certificate chain
   * @return the mapped name of the user userSecurityName
   * @exception CertificateMapNotSupportedException if the particular
   *            certificate is not supported.
   * @exception CertificateMapFailedException if the mapping of the
   *            certificate fails.
   * @exception CustomRegistryException if there is any registry specific
   *            problem
   * @exception RemoteException as this extends java.rmi.Remote
   **/
   public String mapCertificate(X509Certificate[] cert)
      throws CertificateMapNotSupportedException,
             CertificateMapFailedException,
             CustomRegistryException,
             RemoteException;

  /**
   * Returns the realm of the registry.
   *
   * @return the realm. The realm is a registry-specific string indicating
   *            the realm or domain for which this registry
   *            applies.  For example, for OS400 or AIX this would be the
   *            host name of the system whose user registry this object
   *            represents.
   *            If null is returned by this method realm defaults to the
   *            value of "customRealm". It is recommended that you use
   *            your own value for realm.
   * @exception CustomRegistryException if there is any registry specific
   *            problem
   * @exception RemoteException as this extends java.rmi.Remote
   **/
   public String getRealm()
      throws CustomRegistryException,
             RemoteException;

  /**
   * Gets a list of users that match a pattern in the registry.
   * The maximum number of users returned is defined by the limit
   * argument.
   * This method is called by administrative console and by scripting (command
```

```
 * line) to make available the users in the registry for adding them (users)
 * to roles.
 *
 * @parameter pattern the pattern to match. (For example., a* will match all
 *   userSecurityNames starting with a)
 * @parameter limit the maximum number of users that should be returned.
 *  This is very useful in situations where there are thousands of
 *            users in the registry and getting all of them at once is not
 *            practical. A value of 0 implies get all the users and hence
 *            must be used with care.
 * @return a Result object that contains the list of users
 *   requested and a flag to indicate if more users exist.
 * @exception CustomRegistryException if there is any registry specific
 *            problem
 * @exception RemoteException as this extends java.rmi.Remote
 **/
 public Result getUsers(String pattern, int limit)
    throws CustomRegistryException,
           RemoteException;

/**
 * Returns the display name for the user specified by userSecurityName.
 *
 * This method is called only when the user information displays
 * (information purposes only, for example, in the administrative console) and not used
 * in the actual authentication or authorization purposes. If there are no
 * display names in the registry return null or empty string.
 *
 * In WebSphere Application Server Version 4.0 custom registry, if you had a display
 * name for the user and  if it was different from the security name, the display name
 * was returned for the EJB methods getCallerPrincipal() and the servlet methods
 * getUserPrincipal() and  getRemoteUser().
 * In WebSphere Application Server Version 6.0 for the same methods the security
 * name is returned by default. This is the recommended way as the display name
 * is not unique and might create security holes.
 *
 * See the documentation for more information.
 *
 * @parameter userSecurityName the name of the user.
 * @return the display name for the user. The display name
 *   is a registry-specific string that represents a descriptive, not
 *  necessarily unique, name for a user. If a display name does
 *            not exist return null or empty string.
 * @exception EntryNotFoundException if userSecurityName does not exist.
 * @exception CustomRegistryException if there is any registry specific
 *            problem
 * @exception RemoteException as this extends java.rmi.Remote

             CustomRegistryException,
             RemoteException;
}
```

Developing a custom SAF EJB role mapper

WebSphere Application Server for z/OS allows an installation to map Java Platform, Enterprise Edition (Java EE) role names to SAF EJBRole profile names.

Before you begin

WebSphere Application Server for z/OS supports the use of a custom SAF EJB role mapper. The custom SAF EJB role mapper allows an installation to map J2EE role names to SAF EJBRole profile names. Without the SAF EJB role mapper, you must deploy an application by using a role in the deployment descriptor of a component that is identical to the name of an EJBROLE class profile. The security administrator defines EJBROLE profiles and provides the permission to these profiles to SAF users or groups.

Using SAF EJBROLE class profiles can conflict with the standard Java EE role naming conventions. Java EE role names are Unicode strings of any length. RACF® class profiles are restricted to 240 characters in length and cannot be defined if these profiles contain any white spaces or extended code page characters.

If a Java EE role name for an installation conflicts with these RACF restrictions, an installation can use the SAF EJB role mapper exit to map the desired Java EE role name to an acceptable class profile name.

The custom SAF role mapper is a Java-based exit to replace the EJBROLE class profile construction algorithm. The custom SAF role mapper is called to generate a profile for authorization and delegation requests. The role mapper passes the name of the application and the name of the role then passes back the appropriate class profile name. Information about the server name, cell name, and the SAF profile prefix (previously referred to as the z/OS security domain) is provided to the implementation during initialization.

You can set the com.ibm.websphere.security.SAF.RoleMapper custom property on the z/OS SAF authorization panel in the administrative console. You also can enable the role mapper by setting the custom property com.ibm.websphere.security.SAF.RoleMapper to the name of the class that is to be given control.

Procedure

1. Build your custom SAF role mapper. The SAFRoleMapper example (below) can be used as a reference.

```
public class SAFRoleMapperImpl1 {
 String domainPrefix = null;

 public void initialize(Properties context) {
  domainPrefix = context.get(SAFRoleMapper.DOMAIN_NAME);
 }

 public String getProfileNameFromRole(String app, String role) {
  String profile = app + "." + role;
  if (domainPrefix != null) {
   profile = domainPrefix + "." + profile;
  }
  profile = profile.replaceAll("\\%", "#");
  profile = profile.replaceAll("\\&", "#");
  profile = profile.replaceAll("\\*", "#");
  profile = profile.replaceAll("\\s","#");

  return profile;
 }
}
```

2. Click **Security > Global security > z/OS SAF authorization** and enable the role mapper by providing the name of the class that you want to give control in the **SAF profile mapper** field. You also can set this property as a custom property by entering `com.ibm.websphere.security.SAF.RoleMapper` as the name and providing the name of the class in the value field.
3. Click **Security > Global security > External authorization providers** and select the **System Authorization Facility (SAF) authorization** option to enable SAF as the authorization provider. After you select this option, click **z/OS SAF authorization** under Related items to configure the SAF authorization options.

   You also can set this property as a custom property by entering `com.ibm.websphere.security.SAF.authorization` as the name and `true` as the value.

Implementing custom password encryption

WebSphere Application Server supports the use of custom password encryption.

Before you begin

An installation can implement any password encryption algorithm it chooses.

About this task

Complete the following steps to implement custom password encryption:

Procedure

1. Build your custom password encryption class. An example of a custom password encryption class follows.

```
// CustomPasswordEncryption
// Encryption and decryption functions
public interface CustomPasswordEncryption {
    public EncryptedInfo encrypt(byte[] clearText) throws PasswordEncryptException;
    public byte[] decrypt(EncryptedInfo cipherTextInfo) throws PasswordEncryptException;
    public void initialize(HashMap initParameters);
};
// Encapsulation of cipher text and label
public class EncryptedInfo {
```

```
    public EncryptedInfo(byte[] bytes, String keyAlias);
    public byte[] getEncryptedBytes();
    public String getKeyAlias();
};
```

2. If you need to custom encode passwords in property files, manually edit the PropFilePasswordEncoder.sh or PropFilePasswordEncoder.bat file.
   a. Use a file editor to open the PropFilePasswordEncoder.sh or PropFilePasswordEncoder.bat file.
   b. Locate the following lines near the end of the file:

```
"%JAVA_HOME%/bin/java" -Dcmd.properties.file=%TMPJAVAPROPFILE%
"-Dwas.install.root=%WAS_HOME%" com.ibm.ws.bootstrap.WSLauncher
com.ibm.ws.security.util.PropFilePasswordEncoder %1 %2
```

   c. Add following lines to the call.

      These custom properties will be passed to the command so that PropFilePasswordEncoder will look for custom encoding classes and utilize it.

```
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=true
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionClass=(customEncoding class file)
```

   The updated lines should look like the following lines:

```
"%JAVA_HOME%/bin/java" -Dcmd.properties.file=%TMPJAVAPROPFILE%
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=true
-Dcom.ibm.wsspi.security.crypto.customPasswordEncryptionClass=(customEncoding class file)
"-Dwas.install.root=%WAS_HOME%" com.ibm.ws.bootstrap.WSLauncher
com.ibm.ws.security.util.PropFilePasswordEncoder %1 %2
```

3. Enable custom password encryption.
   a. Set the custom property **com.ibm.wsspi.security.crypto.customPasswordEncryptionClass** to the name of the class that is to be given control.
   b. Enable the function. Set the custom property, **com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled** to `true`.

Results

Custom password encryption at the installation is complete.

Developing applications that use programmatic security

For some applications, declarative security is not sufficient to express the security model of the application. Use this topic to develop applications that use programmatic security.

About this task

IBM WebSphere Application Server provides security components that provide or collaborate with other services to provide authentication, authorization, delegation, and data protection. WebSphere Application Server also supports the security features that are described in the Java Platform, Enterprise Edition (Java EE) specification. An application goes through three stages before it is ready to run:

- Development
- Assembly
- Deployment

Most of the security for an application is configured during the assembly stage. The security that is configured during the assembly stage is called *declarative security* because the security is *declared* or *defined* in the deployment descriptors. The declarative security is enforced by the security runtime. For some applications, declarative security is not sufficient to express the security model of the application. For these applications, you can use *programmatic security*.

Procedure

1. Develop secure web applications. For more information, see “Developing with programmatic security APIs for web applications” on page 909.

2. Develop servlet filters for form login processing. For more information, see “Developing servlet filters for form login processing” on page 924.
3. Develop form login pages. For more information, see “Customizing web application login” on page 921.
4. Develop enterprise bean component applications. For more information, see “Developing with programmatic APIs for EJB applications” on page 917.
5. Develop with Java Authentication and Authorization Service to log in programmatically.

   For more information, see topics about developing programmatic logins with the Java Authentication and Authorization Service.
6. Develop your own Java EE security mapping module.

   For more information, see topics about configuring programmatic logins for Java Authentication and Authorization Service.
7. Develop custom user registries. For more information, see “Developing stand-alone custom registries” on page 877.
8. Develop a custom interceptor for trust associations.

Protecting system resources and APIs (Java 2 security) for developing applications

Java 2 security is a programming model that is very pervasive and has a huge impact on application development.

Before you begin

Java 2 security is orthogonal to Java Platform, Enterprise Edition (Java EE) role-based security; you can disable or enable it independently of administrative security.

However, it does provide an extra level of access control protection on top of the Java EE role-based authorization. It particularly addresses the protection of system resources and application programming interfaces (API). Administrators need to consider the benefits against the risks of disabling Java 2 security.

The following recommendations are provided to help enable Java 2 security in a test or production environment:

1. Make sure the application is developed with the Java 2 security programming model. Developers have to know whether or not the APIs that are used in the applications are protected by Java 2 security. It is very important that the required permissions for the APIs used are declared in the policy file (`was.policy`), or the application fails to run when Java 2 security is enabled. Developers can reference the website for Development Kit APIs that are protected by Java 2 security. See the Programming model and decisions section of the Security: Resources for Learning topic to visit this website.
2. Make sure that migrated applications from previous releases are given the required permissions. Because Java 2 security is not supported or partially supported in previous WebSphere Application Server releases, applications developed prior to Version 5 most likely are not using the Java 2 security programming model. No easy way to find out all the required permissions for the application is available. The following are activities you can perform to determine the extra permissions that are required by an application:
   - Code review and code inspection
   - Application documentation review
   - Sandbox testing of migrated enterprise applications with Java 2 security enabled in a preproduction environment. Enable tracing in WebSphere Java 2 security manager to help determine the missing permissions in the application policy file. The trace specification is: `com.ibm.ws.security.core.SecurityManager=all=enabled`.
   - Use the com.ibm.websphere.java2secman.norethrow system property to aid debugging. Do not use this property in a production environment.

The default permission set for applications is the recommended permission set that is defined in the J2EE 1.3 Specification. The default is declared in the *app_server_root*/`profiles/`*profile_name*`/config/cells/`

cell_name/nodes/*node_name*/app.policy policy file with permissions defined in the Development Kit (*JAVA_HOME*/jre/lib/security/java.policy) policy file that grant permissions to everyone. However, applications are denied permissions that are declared in the profiles/*profile_name*/config/cells/*cell_name*/filter.policy file. Permissions that are declared in the *filter.policy* file are filtered for applications during the permission check.

Define the required permissions for an application in a was.policy file and embed the was.policy file in the application enterprise archive (EAR) file as *YOURAPP.ear/META-INF/was.policy*, see "Configuring Java 2 security policy files" on page 890 for details.

The following steps describe how to enforce Java 2 security on the cell level for WebSphere Application Server, Network Deployment and the server level for WebSphere Application Server, Express

Procedure

1. Click **Security > Global security**. The Global security panel is displayed.
2. Select the **Use Java 2 security to restrict application access to local resources** option.
3. Click **OK** or **Apply**.
4. Click **Save** to save the changes.
5. Restart the server for the changes to take effect.

Results

Java 2 security is enabled and enforced for the servers. Java 2 security permission is selected when a Java 2 security protected API is called.

When to use Java 2 security

1. Enable protection on system resources, for example when opening or listening to a socket connection, reading or writing to operating system file systems, reading or writing Java virtual machine system properties, and so on.
2. Prevent application code from calling destructive APIs, for example, calling the System.exit method brings down the application server.
3. Prevent application code from obtaining privileged information (passwords) or gaining extra privileges (obtaining server credentials).

What to do next

You can enforce Java 2 security on the server level for WebSphere Application Server, Network Deployment by completing the following steps.

Note: Changes to Java 2 security settings on the server level override the settings on the cell level.

1. Click **Servers > Application servers >** *server_name*.
2. Under Security, click **Server security**.
3. Select the **Security settings for this server override cell settings** option.
4. Select the **Use Java 2 security to restrict application access to local resources** option.
5. Click **OK** or **Apply**.
6. Click **Save** to save the changes.
7. Restart the server for the changes to take effect.

The Java 2 security manager is enhanced to dump the Java 2 security permissions that are granted to all classes on the call stack when an application is denied access to a resource. The java.security.AccessControlException exception is created. However, this tracing capability is disabled by default. You can enable this capability by specifying the server trace service with the com.ibm.ws.security.core.SecurityManager=all=enabled trace specification. When the exception is

created, the trace dump provides hints to determine whether the application is missing permissions or the product runtime code or the third-party libraries that are used are not properly marked as `privileged` when accessing Java 2 security-protected resources.

Using PolicyTool to edit policy files for Java 2 security:

Use the **PolicyTool** utility to update policy files.

Before you begin

Java 2 security uses several policy files to determine the granted permission for each Java program. The Java Development Kit provides the **PolicyTool** tool to edit these policy files. This tool is recommended for editing any policy file to verify the syntax of its contents. Syntax errors in the policy file cause an AccessControlException exception when the application runs, including the server start. Identifying the cause of this exception is not easy because the user might not be familiar with the resource that has an access violation. Be careful when you edit these policy files.

To use the **PolicyTool** utility with WebSphere Application Server for z/OS, choose one of the following two options:

- Copy the policy files to another platform such as Microsoft Windows and modify the files. To use this option, you must issue the FTP command to transfer the files to the other platform, invoke the **PolicyTool**, and transfer the updated files back to the z/OS system in binary mode.
- Invoke the **PolicyTool** that is supplied with the Software Development Kit (SDK) installed on your z/OS system.

Procedure

1. Invoke the **PolicyTool** that is supplied with the Software Development Kit (SDK) installed on your z/OS system.
   a. Export the display to an Xwindows-enabled device. For example, in Open MVS™ (OMVS), type `export DISPLAY=<IP_address_of_the_Xwindows_device>:0.0`
   b. Enable the z/OS system to access the display of the Xwindows-enabled device. For example, on AIX® systems, type `xhost + address_of_the_MVS_system`.
   c. Convert the policy file to the Extended Binary Coded Decimal Interchange Code (EBCDIC) format.
   d. Invoke the **PolicyTool** on OMVS by typing `$JAVA_HOME/policytool`. The *JAVA_HOME* variable represents the directory in which the SDK is installed.
2. Click **File** > **Open**.
3. Navigate the directory tree in the **Open** window to pick up the policy file that you need to update. After selecting the policy file, click **Open**. The code base entries are listed in the window.
4. Create or modify the code base entry.
   a. Modify the existing code base entry by double-clicking the code base, or click the code base and click **Edit Policy Entry**. The Policy Entry window opens with the permission list defined for the selected code base.
   b. Create a new code base entry by clicking **Add Policy Entry**.

      The Policy Entry window opens. At the code base column, enter the code base information as a URL format.

      For example, you can enter:

```
app_server_root/InstalledApps/testcase.ear
```

      where the *app_server_root* variable represents your installation location.
5. Modify or add the permission specification.

a. Modify the permission specification by double-clicking the entry that you want to modify, or by selecting the permission and clicking **Edit Permission**. The Permissions window opens with the selected permission information.
b. Add a new permission by clicking **Add Permission**. The Permissions window opens. In the Permissions window are four rows for Permission, Target Name, Actions, and Signed By.

6. Select the permission from the Permission list. The selected permission displays. After a permission is selected, the Target Name, Actions, and Signed By fields automatically show the valid choices or they enable text input in the right text input area.
   a. Select **Target Name** from the list, or enter the target name in the right text input area.
   b. Select **Actions** from the list.
   c. Input **Signed By** if it is needed.

      Important: The Signed By keyword is not supported in the following policy files: `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the Signed By keyword is supported in the following policy files: `#java.policy`, `server.policy`, and `client.policy` files. The Java Authentication and Authorization Service (JAAS) is not supported in the `app.policy`, `spi.policy`, `library.policy`, `was.policy`, and `filter.policy` files. However, the JAAS principal keyword is supported in a JAAS policy file when it is specified by the java.security.auth.policy Java virtual machine (JVM) system property.
7. Click **OK** to close the Permissions window. Modified permission entries of the specified code base display.
8. Click **Done** to close the window. Modified code base entries are listed. Repeat the previous steps until you complete editing.
9. Click **File** > **Save** after you finish editing the file.
10. Convert the policy file back from the EBCDIC format to the ASCII format.

Results

A policy file is updated. If any policy files need editing, use the **PolicyTool** utility. Do not edit the policy file manually. Syntax errors in the policy files can potentially cause application servers or enterprise applications to not start or function incorrectly. For the changes in the updated policy file to take effect, restart the Java processes.

Configuring Java 2 security policy files:

Users can configure Java 2 security policy files so that the required permission is granted for the specified WebSphere Application Server enterprise application.

Before you begin

Java 2 security uses several policy files to determine the permissions for each Java programs.

See the Java 2 security policy files topic for the list of available policy files that are supported by WebSphere Application Server.

Two types of policy files are supported by WebSphere Application Server: dynamic policy files and static policy files. Static policy files provide the default permissions. Dynamic policy files provide application permissions. Six dynamic policy files are provided:

Table 93. Dynamic policy files. This table lists the dynamic policy files.

Policy file name	Description
app.policy	Contains default permissions for all of the enterprise applications in the cell. **Note:** Updates to the app.policy file only apply to the enterprise applications on the node to which the app.policy file belongs.
was.policy	Contains application-specific permissions for an WebSphere Application Server enterprise application. This file is packaged in an enterprise archive (EAR) file.
ra.xml	Contains connector application specific permissions for a WebSphere Application Server enterprise application. This file is packaged in a resource adapter archive (RAR) file.
spi.policy	Contains permissions for Service Provider Interface (SPI) or third-party resources that are embedded in WebSphere Application Server. The default contents grant everything. Update this file carefully when the cell requires more protection against SPI in the cell. This file is applied to all of the SPIs that are defined in the resources.xml file.
library.policy	Contains permissions for the shared library of enterprise applications.
filter.policy	Contains the list of permissions that require filtering from the was.policy file and the app.policy file in the cell. This filtering mechanism only applies to the was.policy and app.policy files.

In WebSphere Application Server, applications must have the appropriate thread permissions specified in the was.policy or app.policy file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a java.security.AccessControlException exception. The app.policy file applies to a specified node. If you change the permissions in one app.policy file, you must incorporate the new thread policy in the same file on the remaining nodes. Also, if you add the thread permissions to the app.policy file, you must restart WebSphere Application Server to enforce the new permissions. However, if you add the permissions to the was.policy file for a specific application, you do not need to restart WebSphere Application Server. An administrator must add the following code to a was.policy or app.policy file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
  permission java.lang.RuntimePermission "stopThread";
  permission java.lang.RuntimePermission "modifyThread";
  permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

Important: The Signed By keyword is not supported in the following policy files: app.policy, spi.policy, library.policy, was.policy, and filter.policy files. However, the Signed By keyword is supported in the following policy files:java.policy, server.policy, and client.policy files. The Java Authentication and Authorization Service (JAAS) is not supported in the app.policy, spi.policy, library.policy, was.policy, and filter.policy files. However, the JAAS principal keyword is supported in a JAAS policy file when it is specified by the java.security.auth.policy Java virtual machine (JVM) system property. You can statically set the authorization policy files in java.security.auth.policy with auth.policy.url.n=*URL*, where *URL* is the location of the authorization policy.

Procedure

1. Identify the policy file to update.
   - If the permission is required by an application, update the static policy file. Refer to “Configuring static policy files in Java 2 security” on page 903.
   - If the permission is required by all of the WebSphere Application Server enterprise applications in the node, refer to “spi.policy file permissions” on page 899.
   - If the permission is required only by specific WebSphere Application Server enterprise applications and the permission is required only by connector, update the ra.xml file. Refer to Refer to the Assembling resource adapter (connector) modules article for more information. Otherwise, update the was.policy file. Refer to “Configuring the was.policy file for Java 2 security” on page 896 and “Adding the was.policy file to applications for Java 2 security” on page 901.

- If the permission is required by shared libraries, refer to “library.policy file permissions” on page 900.
- If the permission is required by SPI libraries, refer to “spi.policy file permissions” on page 899.

Tip: Pick up the policy file with the smallest scope. You can avoid giving an extra permission to the Java programs and protect the resources. You can update the `ra.xml` file or the `was.policy` file rather than the `app.policy` file. Use specific component symbols ($(ejbcomponent), ${webComponent},${connectorComponent} and ${jars}) than ${application} symbols. Update dynamic policy files, rather than static policy files.

Add any permission that you never want granted to the WebSphere Application Server enterprise application in the cell to the `filter.policy` file. Refer to “filter.policy file permissions” on page 894.

2. Restart the WebSphere Application Server enterprise application.

Results

The required permission is granted for the specified WebSphere Application Server enterprise application.

app.policy file permissions:

Java 2 security uses several policy files to determine the granted permissions for each Java program. The union of the permissions that are contained in these following files is applied to the WebSphere Application Server enterprise application. This union determines the granted permissions.

For the list of available policy files that are supported by WebSphere Application Server, see the topic about Java 2 security policy files. The `app.policy` file is a default policy file that is shared by all of the WebSphere Application Server enterprise applications. The union of the permissions that are contained in the following files is applied to the WebSphere Application Server enterprise application:

- Any policy file that is specified in the policy.url.* properties in the `java.security` file.
- The `app.policy` files, which are managed by configuration and file replication services.
- The `server.policy` file.
- The `java.policy` file.
- The application `was.policy` file.
- The permission specification of the `ra.xml` file.
- The shared library, which is the `library.policy` file.

Changes made in these files are replicated to other nodes in the WebSphere Application Server, Network Deployment cell.

In WebSphere Application Server, applications that manipulate threads must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a java.security.AccessControlException exception. If an administrator adds thread permissions to the `app.policy` file, the permission change requires a restart of the WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
  permission java.lang.RuntimePermission "stopThread";
  permission java.lang.RuntimePermission "modifyThread";
  permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

Important: The Signed By and the Java Authentication and Authorization Service (JAAS) principal keywords are not supported in the `app.policy` file. However, the Signed By keyword is supported in the following files: `java.policy`, `server.policy`, and the `client.policy` files. The JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically

set the authorization policy files in the java.security.auth.policy property with auth.policy.url.n=URL where URL is the location of the authorization policy.

If the default permissions for enterprise applications (the union of the permissions that is defined in the java.policy file, the server.policy file and the app.policy file) are enough; no action is required. The default app.policy file is used automatically. If a specific change is required to all of the enterprise applications in the cell, update the app.policy file. Syntax errors in the policy files cause start failures in the application servers. Edit these policy files carefully.

Note: Updates to the app.policy file only apply to the enterprise applications on the node to which the app.policy file belongs.

To extract the policy file, use a command prompt to enter the following command on one line using the appropriate variable values for your environment:

```
wsadmin> set obj [$AdminConfig extract  cells/cell_name/node/node_name/app.policy /temp/test/app.policy]
```

Edit the extracted app.policy file with the Policy Tool. For more information, see "Using PolicyTool to edit policy files for Java 2 security" on page 889. Changes to the app.policy file are local for the node.

To check in the policy file, use a command prompt to enter the following command on one line using the appropriate variable values for your environment:

```
wsadmin> $AdminConfig checkin cells/cell_name/nodes/node_name/app.policy  temp/test/app.policy $obj
```

Table 94. Symbols used to associate permission lists to a specific type of resource. Several product-reserved symbols are defined to associate the permission lists to a specific type of resource.

Symbol	Meaning
file:${application}	Permissions apply to all resources within the application
file:${jars}	Permissions apply to all utility Java archive (JAR) files within the application
file:${ejbComponent}	Permissions apply to enterprise bean resources within the application
file:${webComponent}	Permissions apply to web resources within the application
file:${connectorComponent}	Permissions apply to connector resources both within the application and within stand-alone connector resources.

Table 95. Symbols provided to specify the path and name for the java.io.FilePermission permission. Five embedded symbols are provided to specify the path and name for the java.io.FilePermission permission. These symbols enable flexible permission specifications. The absolute file path is fixed after the installation of the application.

Symbol	Meaning
${app.installed.path}	Path where the application is installed
${was.module.path}	Path where the module is installed
${current.cell.name}	Current cell name
${current.node.name}	Current node name
${current.server.name}	Current server name

Tip: You cannot use the ${was.module.path} in the ${application} entry.

The app.policy file supplied by WebSphere Application Server is located in the *profile_root*/config/cells/cell_name/nodes/node_name/app.policy, which contains the following default permissions:

Attention: In the following code sample, the first two lines that are related to java.io.FilePermission permission are split into two lines for illustrative purposes only.

```
grant codeBase "file:${application}" {
  // The following are required by JavaMail
  permission java.io.FilePermission "${was.install.root}${/}lib${/}activation-impl.jar", "read";
  permission java.io.FilePermission "${was.install.root}${/}lib${/}mail-impl.jar", "read";
};

grant codeBase "file:${jars}" {
```

```
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${connectorComponent}" {
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${webComponent}" {
  permission java.io.FilePermission "${was.module.path}${/}-", "read, write";
  permission java.lang.RuntimePermission "loadLibrary.*";
  permission java.lang.RuntimePermission "queuePrintJob";
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

grant codeBase "file:${ejbComponent}" {
  permission java.lang.RuntimePermission "queuePrintJob";
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};
```

If all of the WebSphere Application Server enterprise applications in a cell require permissions that are not defined as defaults in the `java.policy` file, the `server.policy` file and the `app.policy` file, then update the `app.policy` file. The symptom of a missing permission is the `java.security.AccessControlException` exception.

Note: Updates to the app.policy file only apply to the enterprise applications on the node to which the app.policy file belongs.

When a Java program receives this exception and adding this permission is justified, add a permission to the `server.policy` file, for example:

The previous permission information lines are split for the illustration. You actually enter the permission on one line.

To decide whether to add a permission, refer to the AccessControlException topic.

Restart all WebSphere Application Server enterprise applications to ensure that the updated `app.policy` file takes effect.

filter.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program. Java 2 security policy filtering is only in effect when Java 2 security is enabled.

Before modifying the `filter.policy` file, you must start the wsadmin tool.

Refer to “Protecting system resources and APIs (Java 2 security) for developing applications” on page 887. The filtering policy defined in the `filter.policy` file is cell wide. The `filter.policy` file is the only policy file that is used when restricting the permission instead of granting permission. The permissions that are listed in the filter policy file are filtered out from the `app.policy` file and the `was.policy` file. Permissions that are defined in the other policy files are not affected by the `filter.policy` file.

When a permission is filtered out, an audit message is logged. However, if the permissions that are defined in the `app.policy` file and the `was.policy` file are compound permissions like the java.security.AllPermission permission, for example, the permission is not removed. A warning message is logged. If the Issue Permission Warning flag is enabled (default) and if the `app.policy` file and the `was.policy` file contain custom permissions (non-Java API permission, the permission package name begins with characters other than `java` or `javax`), a warning message is logged and the permission is not removed. You can change the value of the `Warn if applications are granted custom permissions` option on the Global security panel. It is not recommended that you use the `AllPermission` permission for the enterprise application.

Some default permissions that are defined in the `filter.policy` file. These permissions are the minimal ones that are recommended by the product. If more permissions are added to the `filter.policy` file, certain operations can fail for enterprise applications. Add permissions to the `filter.policy` file carefully.

You cannot use the Policy Tool to edit the `filter.policy` file. Editing must be completed in a text editor. Be careful and verify that no syntax errors exist in the `filter.policy` file. If any syntax errors exist in the `filter.policy` file, the file is not loaded by the product security runtime, which implies that filtering is disabled.

To extract the `filter.policy` file, enter the following command using information from your environment:

```
set obj [$AdminConfig extract cells/cell_name/filter.policy /temp/test/filter.policy]
```

To check in the policy file, enter the following command using information from your environment:

```
$AdminConfig checkin cells/cell_name/filter.policy /temp/test/filter.policy $obj
```

An updated `filter.policy` file is applied to all of the WebSphere Application Server enterprise applications after the servers are restarted. The `filter.policy` file is managed by configuration and file replication services.

Changes made in the file are replicated to other nodes in the cell.

The `filter.policy` file that is supplied by WebSphere Application Server resides at: *app_server_root*/`profiles/profile_name/config/cells/cell_name/filter.policy`.

This fill contains these permissions as defaults:

```
filterMask {
permission java.lang.RuntimePermission "exitVM";
permission java.lang.RuntimePermission "setSecurityManager";
permission java.security.SecurityPermission "setPolicy";
permission javax.security.auth.AuthPermission "setLoginConfiguration"; };
runtimeFilterMask {
permission java.lang.RuntimePermission "exitVM";
permission java.lang.RuntimePermission "setSecurityManager";
permission java.security.SecurityPermission "setPolicy";
permission javax.security.auth.AuthPermission "setLoginConfiguration"; };
```

The permissions that are defined in `filterMask` filter are for static policy filtering. The security runtime tries to remove the permissions from applications during application startup. Compound permissions are not removed, but are issued with a warning, and application deployment is stopped if applications contain permissions that are defined in the `filterMask` filter, and if scripting is used. The runtimeFilterMask filter defines permissions that are used by the security runtime to deny access to those permissions to application thread. Do not add more permissions to the runtimeFilterMask filter. Application start failure or incorrect functioning might result. Be careful when adding more permissions to the runtimeFilterMask filter. Usually, you only need to add permissions to the `filterMask` stanza.

WebSphere Application Server relies on the filter policy file to restrict or disallow certain permissions that can compromise the integrity of the system. For instance, WebSphere Application Server considers the exitVM and setSecurityManager permissions as those permissions that most applications never have. If these permissions are granted, the following scenarios are possible:

exitVM
A servlet, JavaServer Pages (JSP) file, enterprise bean, or other library that is used by the aforementioned might call the System.exit API and cause the entire WebSphere Application Server process to terminate.

setSecurityManager
An application might install its own security manager and either grant more permissions or bypass the default policy that the WebSphere Application Server security manager enforces.

Important: In application code, do not use the setSecurityManager permission to set a security manager. When an application uses the setSecurityManager permission, a conflict exists with the internal security manager within WebSphere Application Server. If you must set a security manager in an application for Remote Method Invocation (RMI) purposes, you also must select the Use Java 2 security to restrict application access to local resources option on the Global security panel within the WebSphere Application Server administrative console. WebSphere Application Server then registers a security manager, which the application code can verify is registered by using the System.getSecurityManager application programming interface (API).

For the updated `filter.policy` file to take effect, restart related Java processes.

Configuring the was.policy file for Java 2 security:

You should update the `was.policy` file if the application has specific resources to access.

Before you begin

Java 2 security uses several policy files to determine the granted permission for each Java program. The `was.policy` file is an application-specific policy file for WebSphere Application Server enterprise applications. This file is embedded in the `META-INF/was.policy` enterprise archive (.EAR) file. The `was.policy` file is located in:

profile_root`/config/cells/`*cell_name*`/applications/`
ear_file_name`/deployments/`*application_name*`/META-INF/was.policy`

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server Version 6.1.

The union of the permissions that are contained in the following files is applied to the WebSphere Application Server enterprise application:

- Any policy file that is specified in the policy.url.* properties in the `java.security` file.
- The `app.policy` files, which are managed by configuration and file replication services.
- The `server.policy` file.
- The `java.policy` file.
- The application `was.policy` file.
- The permission specification of the `ra.xml` file.
- The shared library, which is the `library.policy` file.

Changes made in these files are replicated to other nodes in the cell.

Table 96. Symbols defined to associate permission lists to a specific type of resource. Several product-reserved symbols are defined to associate the permission lists to a specific type of resource.

Symbol	Definition
file:${application}	Permissions apply to all resources used within the application.
file:${jars}	Permissions apply to all utility Java archive (JAR) files within the application

Table 96. Symbols defined to associate permission lists to a specific type of resource (continued). Several product-reserved symbols are defined to associate the permission lists to a specific type of resource.

Symbol	Definition
file:${ejbComponent}	Permissions apply to enterprise bean resources within the application
file:${webComponent}	Permissions apply to web resources within the application
file:${connectorComponent}	Permissions apply to connector resources within the application

In WebSphere Application Server, applications that manipulate threads must have the appropriate thread permissions specified in the `was.policy` or `app.policy` file. Without the thread permissions specified, the application cannot manipulate threads and WebSphere Application Server creates a java.security.AccessControlException exception. If you add the permissions to the `was.policy` file for a specific application, you do not need to restart WebSphere Application Server. An administrator must add the following code to a `was.policy` or `app.policy` file for an application to manipulate threads:

```
grant codeBase "file:${application}" {
  permission java.lang.RuntimePermission "stopThread";
  permission java.lang.RuntimePermission "modifyThread";
  permission java.lang.RuntimePermission "modifyThreadGroup";
};
```

An administrator can add the thread permissions to the `app.policy` file, but the permission change requires a restart of WebSphere Application Server.

Important: The Signed By and the Java Authentication and Authorization Service (JAAS) principal keywords are not supported in the `was.policy` file. The Signed By keyword is supported in the `java.policy`, `server.policy`, and `client.policy` policy file. The JAAS principal keyword is supported in a JAAS policy file when it is specified by the `java.security.auth.policy` Java virtual machine (JVM) system property. You can statically set the authorization policy files in the `java.security.auth.policy` file with the `auth.policy.url.n=`*URL*, where *URL* is the location of the authorization policy.

Other than these blocks, you can specify the module name for granular settings. For example,

```
grant codeBase "file:DefaultWebApplication.war" {
  permission java.security.SecurityPermission "printIdentity";
};

grant codeBase "file:IncCMP11.jar" {
  permission java.io.FilePermission
      "${user.install.root}${/}bin${/}DefaultDB${/}-",
      "read,write,delete";
};
```

Table 97. Embedded symbols provided to specify the path and name for the java.io.FilePermission permission. Five embedded symbols are provided to specify the path and name for the java.io.FilePermission permission. These symbols enable flexible permission specification. The absolute file path is fixed after the application is installed.

Symbol	Definition
${app.installed.path}	Path where the application is installed
${was.module.path}	Path where the module is installed
${current.cell.name}	Current® cell name
${current.node.name}	Current node name
${current.server.name}	Current server name

About this task

If the default permissions for the enterprise application are enough, an action is not required. The default permissions are a union of the permissions that are defined in the `java.policy` file, the `server.policy` file, and the `app.policy` file. If an application has specific resources to access, update the `was.policy` file. The first two steps assume that you are creating a new policy file.

Tip: Syntax errors in the policy files cause the application server to fail. Use care when editing these policy files.

Procedure

1. Create or edit a new `was.policy` file by using the PolicyTool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 889.
2. Package the `was.policy` file into the enterprise archive (EAR) file.

   For more information, see “Adding the was.policy file to applications for Java 2 security” on page 901.The following instructions describe how to import a `was.policy` file.

   a. Import the EAR file into an assembly tool.

   b. Open the Project Navigator view.

   c. Expand the EAR file and click **META-INF**. You might find a `was.policy` file in the META-INF directory. If you want to delete the file, right-click the file name and select **Delete**.

   d. At the bottom of the Project Navigator view, click **J2EE Hierarchy**.

   e. Import the `was.policy` file by right-clicking the **Modules** directory within the deployment descriptor and by clicking **Import > Import > File system**.

   f. Click **Next**.

   g. Enter the path name to the `was.policy` file in the **From directory** field or click **Browse** to locate the file.

   h. Verify that the path directory that is listed in the **Into directory** field lists the correct `META-INF` directory.

   i. Click **Finish**.

   j. To validate the EAR file, right-click the EAR file, which contains the Modules directory, and click **Run Validation**.

   k. To save the new EAR file, right-click the EAR file, and click **Export > Export EAR file**. If you do not save the revised EAR file, the EAR file will contain the new `was.policy` file. However, if the workspace becomes corrupted, you might lose the revised EAR file.

   l. To generate deployment code, right-click the EAR file and click **Generate Deployment Code**.
3. Update an existing installed application, if one already exists. Modify the `was.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 889.

   a. Extract the policy file. Enter the following command from a command prompt:

```
wsadmin> set obj [$AdminConfig extract profiles/profile_name/cells/cell_name
/application/ear_file_name/deployments/application_name
/META_INF/was.policy c:/temp/test/was.policy]
```

   Enter the three previous lines as one continuous line. They are display here for illustration only.

   b. Edit the extracted `was.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 889.

   c. Check in the policy file. Enter the following at a command prompt:

```
wsadmin> $AdminConfig checkin profiles/profile_name/cells/cell_name/application/
ear_file_name/deployments/application_name/META_INF/was.policy
c:/temp/test/was.policy $obj
```

   Enter the three previous lines as one continuous line. They are display here for illustration only.

Results

The updated `was.policy` file is applied to the application after the application restarts.

Example

```
java.security.AccessControlException: access denied (java.io.FilePermission
${was.install.root}/java/ext/mail.jar read)
```

If an application must access a specific resource that is not defined as a default in the java.policy file, the server.policy file, and the app.policy, delete the was.policy file for that application. The symptom of the missing permission is the java.security.AccessControlException exception. The missing permission is listed in the exception data:

Note: Examples that appear below are split into several lines for illustration only. You actually enter the permission on one line.

```
java.security.AccessControlException: access denied (java.io.FilePermission
${was.install.root}/java/ext/mail.jar read)
```

When a Java program receives this exception and adding this permission is justified, add the following permission to the was.policy file:

```
grant codeBase "file:user_client_installed_location" {
  permission java.io.FilePermission
"${was.install.root}$(/)java$(/)jre$(/)lib$(/)ext$(/)mail.jar", "read";
};
```

To determine whether to add a permission, see Access control exception for Java 2 security.

What to do next

Restart all applications for the updated app.policy file to take effect.

spi.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server Version 6.0.x, see Java 2 security policy files.

Because the default permission for the Service Provider Interface (SPI) is the AllPermission permission, the only reason to update the spi.policy file is a restricted SPI permission. When a change in the spi.policy is required, complete the following steps.

Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully.

Important: Do not place the codebase keyword or any other keyword after the filterMask and runtimeFilterMask keywords. The Signed By and the Java Authentication and Authorization Service (JAAS) Principal keywords are not supported in the spi.policy file. The Signed By keyword is supported in the java.policy, server.policy, and client.policy policy files. The JAAS Principal keyword is supported in a JAAS policy file that is specified by the java.security.auth.policy Java virtual machine (JVM) system property. You can statically set the authorization policy files in java.security.auth.policy with auth.policy.url.n=URL, where URL is the location of the authorization policy.

To extract the filter.policy file, enter the following command using information from your environment:

set obj [$AdminConfig extract profiles/profile_name/cells/cell_name/nodes/node_name/spi.policy c:/temp/test/spi.policy]

Edit the file using the Policy Tool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 889.

To check in the policy file, enter the following command using information from your environment:

The updated spi.policy is applied to the Service Provider Interface (SPI) libraries after the Java process is restarted.

$AdminConfig checkin profiles/profile_name/cells/cell_name/nodes/node_name/spi.policy c:/temp/test/spi.policy $obj

Examples

The spi.policy file is the template for SPIs or third-party resources embedded in the product. Examples of SPIs are Java Message Services (JMS) (MQSeries) and Java database connectivity (JDBC) drivers. They are specified in the resources.xml file. The dynamic policy grants the permissions that are defined in the spi.policy file to the class paths defined in the resources.xml file. The union of the permission that is contained in the java.policy file and the spi.policy file are applied to the SPI libraries. The spi.policy files are managed by configuration and file replication services.

Changes made in these files are replicated to other nodes in the cell.

You can find the spi.policy file that is supplied by WebSphere Application Server in the following location: *app_server_root*/profiles/profile_name/config/cells/cell_name/nodes/node_name/spi.policy. This file contains the following default permission:

```
grant {
  permission java.security.AllPermission;
};
```

Restart the related Java processes for the changes in the spi.policy file to become effective.

library.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see Java 2 security policy files.

The library.policy file is the template for shared libraries (Java library classes). Multiple enterprise applications can define and use shared libraries. Refer to Managing shared libraries for information on how to define and manage the shared libraries.

If the default permissions for a shared library (union of the permissions defined in the java.policy file, the app.policy file and the library.policy file) are enough, no action is required. The default library policy is picked up automatically. If a specific change is required to share a library in the cell, update the library.policy file.

Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully.

Important: Do not place the codebase keyword or any other keyword after the grant keyword. The Signed By keyword and the Java Authentication and Authorization Service (JAAS) Principal keyword are not supported in the library.policy file. The Signed By keyword is supported in the java.policy, the server.policy, and the client.policy policy files. The JAAS Principal keyword is supported in a JAAS policy file when it is specified by the Java virtual machine (JVM) system property, java.security.auth.policy. You can statically set the authorization policy files in the java.security.auth.policy file with auth.policy.url.n=URL where URL is the location of the authorization policy.

To extract the policy file, use a command prompt to enter the following command using the appropriate variable values for your environment:The previous two lines were split onto two lines for illustrative purposes only.

wsadmin> set obj [$AdminConfig extract cells/cell_name/nodes/
node_name/library.policy /temp/test/library.policy]

Edit the extracted `library.policy` file with the Policy Tool. For more information, see “Using PolicyTool to edit policy files for Java 2 security” on page 889.

To check in the policy file, use a command prompt to enter the following command using the appropriate variable values for your environment:An updated `library.policy` is applied to shared libraries after the servers restart.

wsadmin> $AdminConfig checkin cells/cell_name/nodes/node_name/library.policy
temp/test/library.policy $obj

Example

The union of the permission that is contained in the `java.policy` file, the `app.policy` file, and the `library.policy` file are applied to the shared libraries. The `library.policy` file is managed by configuration and file replication services.

Changes made in the file are replicated to other nodes in the cell.

The `library.policy` file are supplied by WebSphere Application Server resides at: *app_server_root*/`config/cells/cell_name/nodes/node_name/` directory. The file contains an empty permission entry as a default. For example:

```
grant {
  };
```

If the shared library in a cell requires permissions that are not defined as defaults in the`java.policy` file, the `app.policy` file and the `library.policy` file, update the `library.policy` file. The missing permission causes the java.security.AccessControlException exception. The missing permission is listed in the exception data.

When a Java program receives this exception and adding this permission is justified, add a permission to the `library.policy` file.

To decide whether to add a permission, refer to Access control exception for Java 2 security.

Restart the related Java processes for the changes in the `library.policy` file to become effective.

Adding the was.policy file to applications for Java 2 security:

An application might need a `was.policy` file if it accesses resources that require more permissions than those granted in the default `app.policy` file.

About this task

When Java 2 security is enabled for a WebSphere Application Server, all the applications that run on WebSphere Application Server undergo a security check before accessing system resources. An application might need a `was.policy` file if it accesses resources that require more permissions than those granted in the default `app.policy` file. By default, the product security reads an `app.policy` file that is located in each node and grants the permissions in the `app.policy` file to all the applications. Include any additional required permissions in the `was.policy` file. The `was.policy` file is only required if an application requires additional permissions.

The default policy file for all applications is specified in the app.policy file. This file is provided by the product security, is common to all applications, and you do not change this file. Add any new permissions that are required for an application in the was.policy file.

The app.policy file supplied by WebSphere Application Server resides at *app_server_root*/config/cells/profile/profile_name/config/*cell_name*/nodes/*node_name*/app.policy. The contents of the app.policy file are presented in the following example:

Attention: In the following code sample, the two permissions that are required by JavaMail are split onto two lines for illustration only. You actually enter the permission on one line.

```
// The following permissions apply to all the components under the application.

grant codeBase "file:${application}" {
   // The following are required by JavaMail

  permission java.io.FilePermission "
        ${was.install.root}${/}lib${/}activation-impl.jar",
"read";

  permission java.io.FilePermission "
        ${was.install.root}${/}lib${/}mail-impl.jar","read";

  };
   // The following permissions apply to all utility .jar files  (other
   //  than enterprise beans JAR files) in the application.
grant codeBase "file:${jars}" {
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to connector resources within the application
grant codeBase "file:${connectorComponent}" {
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to all the web modules (.war files)
// within the application.
grant codeBase "file:${webComponent}" {
  permission java.io.FilePermission "${was.module.path}${/}-", "read, write";
       //  where "was.module.path" is the path where the web module is
       //  installed. Refer to Dynamic policy concepts for other symbols.
  permission java.lang.RuntimePermission "loadLibrary.*";
  permission java.lang.RuntimePermission "queuePrintJob";
  permission java.net.SocketPermission "*", "connect";
  permission java.util.PropertyPermission "*", "read";
};

// The following permissions apply to all the EJB modules within the application.
grant codeBase "file:${ejbComponent}" {
 permission java.lang.RuntimePermission "queuePrintJob";
 permission java.net.SocketPermission "*", "connect";
 permission java.util.PropertyPermission "*", "read";
};
```

If additional permissions are required for an application or for one or more modules of an application, use the was.policy file for that application. For example, use codeBase of ${application} and add required permissions to grant additional permissions to the entire application. Similarly, use codeBase of ${webComponent} and ${ejbComponent} to grant additional permissions to all the web modules and all the enterprise bean modules in the application. You can assign additional permissions to each module (.war file or .jar file), as shown in the following example.

This example illustrates adding extra permissions for an application in the was.policy file:

Attention: In the following code sample, the permission for the EJB module was split onto two lines for illustration only. You actually enter the permission on one line.

```
// grant additional permissions to a web module
grant codeBase " file:aWebModule.war" {
 permission java.security.SecurityPermission "printIdentity";
};

// grant additional permission to an EJB module
grant codeBase "file:aEJBModule.jar"  {
    permission java.io.FilePermission "
```

```
      ${user.install.root}${/}bin${/}DefaultDB${/}-", "read,write,delete";
   // where, ${user.install.root} is the system property whose value is
   // located in the app_server_root directory.
};
```

To use a `was.policy` file for your application, perform the following steps:

Procedure

1. Create a `was.policy` file using the policy tool. For more information on using the policy tool, see “Using PolicyTool to edit policy files for Java 2 security” on page 889.
2. Add the required permissions in the `was.policy` file using the policy tool.
3. Place the `was.policy` file in the application enterprise archive (EAR) file under the `META-INF` directory. Update the application EAR file with the newly created `was.policy` file by using the **jar** command.
4. Verify that the `was.policy` file is inserted and start an assembly tool.

   Note: An assembly tool is not available. Use an assembly tool on another platform such as Linux Intel or Windows.
5. Verify that the `was.policy` file in the application is syntactically correct. In an assembly tool, right-click the enterprise application module and click **Run Validation**.

Results

An application EAR file is now ready to run when Java 2 security is enabled.

Example

This step is required for applications to run properly when Java 2 security is enabled. If the `was.policy` file is not created and it does not contain required permissions, the application might not access system resources.

The symptom of the missing permissions is the java.security.AccessControlException exception. The missing permission is listed in the exception data, for example,

```
java.security.AccessControlException: access denied (java.io.FilePermission
${was.install.root}/java/ext/mail.jar read)
```

When an application program receives this exception and adding this permission is justified, include the permission in the `was.policy` file, for example,

```
grant codeBase "file:user_client_installed_location" {
  permission java.io.FilePermission
"${was.install.root}$(/)java$(/)jre$(/)lib$(/)ext$(/)mail.jar", "read";
};
```

The previous permission information lines are split for the illustration. Enter the permission on one line.

What to do next

Install the application.

Configuring static policy files in Java 2 security:

By configuring the static policy files, the required permission will be granted for all of the Java programs.

Before you begin

Java 2 security uses several policy files to determine the granted permission for each Java program.

See the topic about Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server.

Two types of policy files are supported by WebSphere Application Server: dynamic policy files and static policy files. Static policy files provide the default permissions. Dynamic policy files provide application permissions.

Table 98. Policy Files. This table lists the policy files.

Policy file name	Description
`java.policy`	Contains default permissions for all of the Java programs on the node. This file seldom changes.
`server.policy`	Contains default permissions for all of the WebSphere Application Server programs on the node. This file is rarely updated.
`client.policy`	Contains default permissions for all of the applets and client containers on the node.

The static policy file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not get replicated to the other machine.

Procedure

1. Identify the policy file to update.
   - If the permission is required only by an application, update the dynamic policy file. Refer to "Configuring Java 2 security policy files" on page 890.
   - If the permission is required only by applets and client containers, update the `client.policy` file. Refer to "client.policy file permissions" on page 907.
   - If the permission is required only by WebSphere Application Server (servers, agents, managers and application servers), update the `server.policy` file. Refer to "server.policy file permissions" on page 906.
   - If the permission is required by all of the Java programs running on the Java virtual machine (JVM), update the `java.policy` file. Refer to "java.policy file permissions."
2. Stop and restart WebSphere Application Server.

Results

The required permission is granted for all of the Java programs that run with the restarted JVM.

Example

If Java programs on a node require permissions, the policy file needs updating. If the Java program that required the permission is not part of an enterprise application, update the static policy file. The missing permission results in the creation of the java.security.AccessControlException exception. The missing permission is listed in the exception data.

For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
C:/WAS_HOME/lib/mail-impl.jar read)
```

When a Java program receives this exception and adding this permission is justified, add a permission to an adequate policy file.

For example:

```
grant codeBase "file:user_client_installed_location" {
  permission java.io.FilePermission
  "C:/WAS_HOME/lib/mail-impl.jar",
  "read";
};
```

To decide whether to add a permission, refer to Access control exception for Java 2 security.

java.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server.

The `java.policy` file is a global default policy file that is shared by all of the Java programs that run in the Java virtual machine (JVM) on the node. A change to the `java.policy` file is local for the node. The default Java policy is picked up automatically. Syntax errors in the policy files cause the application server to fail. An updated `java.policy` file is applied to all the Java programs that run in all the JVMs on the local node. Restart the programs for the updates to take effect. Modifying this file is not recommended. If a specific change is required to some of the Java programs on a node and the `java.policy` file requires updating, carefully modify the `java.policy` file with the policy tool. For more information, see "Using PolicyTool to edit policy files for Java 2 security" on page 889.

Default permissions for the `java.policy` file

The `java.policy` file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not get replicated to the other machine. The `java.policy` file that is supplied by WebSphere Application Server is located at `install_root/java/jre/lib/security/java.policy`. This file contains these default permissions.

```
// Standard extensions get all permissions by default
grant codeBase "file:${java.home}/lib/ext/*" {
        permission java.security.AllPermission;
};
// default permissions granted to all domains
grant {
        // Allows any thread to stop itself using the java.lang.Thread.stop()
        // method that takes no argument.
        // Note that this permission is granted by default only to remain
        // backwards compatible.
        // It is strongly recommended that you either remove this permission
        // from this policy file or further restrict it to code sources
        // that you specify, because Thread.stop() is potentially unsafe.
        // See "http://java.sun.com/notes" for more information.
        // permission java.lang.RuntimePermission "stopThread";

        // allows anyone to listen on un-privileged ports
        permission java.net.SocketPermission "localhost:1024-", "listen";

        // "standard" properties that can be read by anyone

        permission java.util.PropertyPermission "java.version", "read";
        permission java.util.PropertyPermission "java.vendor", "read";
        permission java.util.PropertyPermission "java.vendor.url", "read";
        permission java.util.PropertyPermission "java.class.version", "read";
        permission java.util.PropertyPermission "os.name", "read";
        permission java.util.PropertyPermission "os.version", "read";
        permission java.util.PropertyPermission "os.arch", "read";
        permission java.util.PropertyPermission "file.separator", "read";
        permission java.util.PropertyPermission "path.separator", "read";
        permission java.util.PropertyPermission "line.separator", "read";

        permission java.util.PropertyPermission "java.specification.version", "read";
        permission java.util.PropertyPermission "java.specification.vendor", "read";
        permission java.util.PropertyPermission "java.specification.name", "read";

        permission java.util.PropertyPermission "java.vm.specification.version","read";
        permission java.util.PropertyPermission "java.vm.specification.vendor","read";
        permission java.util.PropertyPermission "java.vm.specification.name", "read";
        permission java.util.PropertyPermission "java.vm.version", "read";
        permission java.util.PropertyPermission "java.vm.vendor", "read";
        permission java.util.PropertyPermission "java.vm.name", "read";
       };
```

If some Java programs on a node require permissions that are not defined as defaults in the `java.policy` file, consider updating the `java.policy` file. Most of the time, other policy files are updated instead of the `java.policy` file. The missing permission causes the creation of the , java.security.AccessControlException exception. The missing permission is listed in the exception data.

For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar read)
```

The previous two lines are one continuous line.

When a Java program receives this exception and adding this permission is justified, add a permission to the `java.policy` file.

For example:

```
grant codeBase "file:user_client_installed_location" {
permission java.io.FilePermission
"C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar", "read"; };
```

To decide whether to add a permission, refer to Access control exception for Java 2 security.

Restart all of the Java processes for the updated `java.policy` file to take effect.

server.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

See Java 2 security policy files for the list of available policy files that are supported by WebSphere Application Server.

The `server.policy` file is a default policy file that is shared by all of the WebSphere Application Servers on a node. The `server.policy` file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not replicate to the other machine.

If the default permissions for a server (the union of the permissions that is defined in the `java.policy` file and the `server.policy` file) are enough, no action is required. The default server policy is picked up automatically. If a specific change is required to some of the server programs on a node, update the `server.policy` file with the Policy Tool. Refer to the “Using PolicyTool to edit policy files for Java 2 security” on page 889 topic to edit policy files. Changes to the `server.policy` file are local for the node. Syntax errors in the policy files cause the application server to fail. Edit these policy files carefully. An updated `server.policy` file is applied to all the server programs on the local node. Restart the servers for the updates to take effect.

If you want to add permissions to an application, use the `app.policy` file and the `was.policy` file.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the `app.policy` file belongs.

When you do need to modify the `server.policy` file, locate this file at: *profile_root*`/properties/server.policy`. This file contains these default permissions:

```
// Allow to use sun tools
grant codeBase "file:${java.home}/lib/tools.jar" {
permission java.security.AllPermission;
};

// Allow the WebSphere deploy tool all permissions
grant codeBase "file:${was.install.root}/deploytool/-" {
permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/plugins/-" {
permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/classes/-" {
permission java.security.AllPermission;
};
```

```
grant codeBase "file:${was.install.root}/lib/-" {
permission java.security.AllPermission;
};

grant codeBase "file:${smpe.install.root}/lib/-" {
permission java.security.AllPermission;
};

grant codeBase "file:${smpe.install.root}/-" {
permission java.security.AllPermission;
};

// Allow to use TAM
grant codeBase "file:${was.install.root}/tivoli/tam/PD.jar" {
permission java.security.AllPermission;
};
```

If some server programs on a node require permissions that are not defined as defaults in the `server.policy` file and the `server.policy` file, update the `server.policy` file. The missing permission creates the java.security.AccessControlException exception. The missing permission is listed in the exception data.

For example:

```
java.security.AccessControlException: access denied (java.io.FilePermission
C:\WebSphere\AppServer\java\jre\lib\ext\mail-impl.jar read)
```

The previous two lines are split into two lines for illustrative purposes only.

When a Java program receives this exception and adding this permission is justified, add a permission to the `server.policy` file.

For example:

```
grant codeBase "file:user_client_installed_location" {
permission java.io.FilePermission
"C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar", "read"; };
```

To decide whether to add a permission, refer to Access control exception for Java 2 security.

Restart all of the Java processes for the updated `server.policy` file to take effect.

client.policy file permissions:

Java 2 security uses several policy files to determine the granted permission for each Java program.

For the list of available policy files that are supported by WebSphere Application Server, see Java 2 security policy files.

- The `client.policy` file is a default policy file that is shared by all of the WebSphere Application Server client containers and applets on a node.
- The union of the permissions that is contained in the `java.policy` file and the `client.policy` file are given to all of the client containers for WebSphere Application Server and applets running on the node.
- The `client.policy` file is not a configuration file that is managed by the repository and the file replication service. Changes to this file are local and do not replicate to the other machine.
- The `client.policy` file supplied by WebSphere Application Server is located in the *profile_root*`/properties/client.policy`.
- If the default permissions for a client (union of the permissions defined in the `java.policy` file and the `client.policy` file) are enough, no action is required. The default client policy is picked up automatically.

- If a specific change is required to some of the client containers and applets on a node, modify the `client.policy` file with the Policy Tool. Refer to “Using PolicyTool to edit policy files for Java 2 security” on page 889, to edit policy files. Changes to the `client.policy` file are local for the node.

This file contains these default permissions:

```
grant codeBase "file:${was.install.root}/java/ext/*" {
  permission java.security.AllPermission;
};

// JDK classes
grant codeBase "file:${was.install.root}/java/ext/-" {
  permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/java/tools/ibmtools.jar" {
  permission java.security.AllPermission;
};
grant codeBase "file:/QIBM/ProdData/Java400/jdk14/lib/tools.jar" {
  permission java.security.AllPermission;
};

// WebSphere system classes
grant codeBase "file:${was.install.root}/lib/-" {
  permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/plugins/-" {
  permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/classes/-" {
  permission java.security.AllPermission;
};
grant codeBase "file:${was.install.root}/installedConnectors/-" {
  permission java.security.AllPermission;
};
grant codeBase "file:${user.install.root}/installedConnectors/-" {
  permission java.security.AllPermission;
};

grant codeBase "file:${was.install.root}/installedChannels/-" {
  permission java.security.AllPermission;
};

// J2EE 1.4 permissions for client container applications
// in $WAS_HOME/installedApps
grant codeBase "file:${user.install.root}/installedApps/-" {
  //Application client permissions
  permission java.awt.AWTPermission "accessClipboard";
  permission java.awt.AWTPermission "accessEventQueue";
  permission java.awt.AWTPermission "showWindowWithoutWarningBanner";
  permission java.lang.RuntimePermission "exitVM";
  permission java.lang.RuntimePermission "loadLibrary";
  permission java.lang.RuntimePermission "queuePrintJob";
  permission java.net.SocketPermission "*", "connect";
  permission java.net.SocketPermission "localhost:1024-", "accept,listen";
  permission java.io.FilePermission "*", "read,write";
  permission java.util.PropertyPermission "*", "read";

};

// J2EE 1.4 permissions for client container - expanded ear file code base
grant codeBase "file:${com.ibm.websphere.client.applicationclient.archivedir}/-" {
  permission java.awt.AWTPermission "accessClipboard";
  permission java.awt.AWTPermission "accessEventQueue";
  permission java.awt.AWTPermission "showWindowWithoutWarningBanner";
  permission java.lang.RuntimePermission "exitVM";
  permission java.lang.RuntimePermission "loadLibrary";
  permission java.lang.RuntimePermission "queuePrintJob";
  permission java.net.SocketPermission "*", "connect";
```

```
  permission java.net.SocketPermission "localhost:1024-", "accept,listen";
  permission java.io.FilePermission "*", "read,write";
  permission java.util.PropertyPermission "*", "read";
};
```

All of the client containers and applets on the local node are granted the updated permissions when they start. If some client containers or applets on a node require permissions that are not defined as defaults in the `java.policy` file and the default `client.policy` file, update the `client.policy` file. The missing permission creates the java.security.AccessControlException exception. The missing permission is listed in the exception data, for example,

```
java.security.AccessControlException: access denied (java.io.FilePermission
C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar read)
```

The previous two lines of the example are one continuous line, but presented as such for illustrative purposes only.

When a client program receives this exception and adding this permission is justified, add a permission to the `client.policy` file, for example:

```
grant codebase "file:user_client_installed_location" {permission
 java.io.FilePermission "C:\WebSphere\AppServer\java\jre\lib\ext\mail.jar", "read"; };
```

To decide whether to add a permission, refer to Access control exception for Java 2 security.

If you update the policy file, you must restart the browser and any client applications.

Developing with programmatic security APIs for web applications

Use this information to programmatically secure APIs for web applications.

Before you begin

Programmatic security is used by security-aware applications when declarative security alone is not sufficient to express the security model of the application.

The authenticate, login, logout, getRemoteUser, isUserInRole and getAuthType servlet security methods are methods of the javax.servlet.http.HttpServletRequest interface. For more detailed information about these servlet security methods, read the Servlet security methods article.

Note:

> The logout, login, and authenticate APIs are new for Java Servlet 3.0 in this release of WebSphere Application Server.

You can configure several options for web authentication that determine how the web client interacts with protected and unprotected Uniform Resource Identifiers (URI). Also, you can specify whether WebSphere Application Server challenges the web client for basic authentication information if the certificate authentication for the HTTPS client fails. For more information, see the Selecting an authentication mechanism article.

You can enable a login module to indicate which principal class is returned by these calls. Refer to the topic about mapping a registry principal to a System Authorization Facility user ID using a Java Authentication and Authorization Services login module for more information.

When the isUserInRole method is used, declare a security-role-ref element in the deployment descriptor with a role-name subelement containing the role name that is passed to this method, or use the @DeclareRoles annotation. Because actual roles are created during the assembly stage of the application, you can use a logical role as the role name and provide enough hints to the assembler in the description of the security-role-ref element to link that role to the actual role. During assembly, the assembler creates

a role-link subelement to link the role name to the actual role. Creation of a security-role-ref element is possible if an assembly tool, such as Rational Application Developer, is used. You also can create the security-role-ref element during assembly stage using an assembly tool.

Procedure

1. Add the required security methods in the servlet code.
2. Create a security-role-ref element with the **role-name** field. If a security-role-ref element is not created during development, make sure it is created during the assembly stage.

Results

A programmatically secured servlet application.

Example

These steps are required to secure an application programmatically. This action is particularly useful when a web application needs to access external resources and wants to control the access to external resources using its own authorization table (external-resource to remote-user mapping). In this case, use the getUserPrincipal or the getRemoteUser methods to get the remote user, then the application can consult its own authorization table to perform authorization. The remote user information also can help retrieve the corresponding user information from an external source such as a database or from an enterprise bean. You can use the isUserInRole method in a similar way.

After development, you can create a security-role-ref element:

```
<security-role-ref>
   <description>Provide hints to assembler for linking this role
                name to an actual role here<\description>
   <role-name>Mgr<\role-name>
</security-role-ref>
```

During assembly, the assembler creates a role-link element:

```
<security-role-ref>
   <description>Hints provided by developer to map the role
               name to the role-link</description>
   <role-name>Mgr</role-name>
   <role-link>Manager</role-link>
</security-role-ref>
```

You can add programmatic servlet security methods inside any servlet doGet, doPost, doPut, and doDelete service methods. The following example depicts using a programmatic security API:

```
public void doGet(HttpServletRequest request,
HttpServletResponse response) {

   ....
   // to logoff the current user
  request.logout();

   // to login with a new user
   request.login("bob","bobpwd")

   // to get remote user using getUserPrincipal()
   java.security.Principal principal = request.getUserPrincipal();
   String remoteUser = principal.getName();

   // to get remote user using getRemoteUser()
   remoteUser = request.getRemoteUser();

   // to check if remote user is granted Mgr role
   boolean isMgr = request.isUserInRole("Mgr");

   // use the above information in any way as needed by
   // the application
   ....

}
```

You can programmatic login with a user ID and password inside any servlet doGet, doPost, doPut, and doDelete service methods. The following example depicts using a programmatic login/logout API:

```
public void doGet(HttpServletRequest request,
HttpServletResponse response) {

   ....
   // to logout the current user. If you are not already authenticate, then no need to call the logout() method.
   request.logout();

   // to login with a new user
   request.login("utle","mypwd")

   // the user utle subject now set on the thread and the LTPA SSO cookie is set in the response
   ....

}
```

You can programmatic authenticate with a different identity inside any servlet doGet, doPost, doPut, and doDelete service methods. In this example, if the web servlet is configured to use basicAuth, the web server returns a response code 401, the login prompt is displayed, and you can enter the user ID and password to authenticate. The following example depicts using a programmatic login/logout API:

```
public void doGet(HttpServletRequest request,
HttpServletResponse response) {

   ....
   // to logout the current user. If you are not already authenticate, then no need to call the logout() method.

   // to login with a new user
   request.authenticate(response);

   // the new user subject now set on the thread and the LTPA SSO cookie is set in the response
   ....

}
```

When developing Servlet 3.0 modules, the value of the rolename argument in isCallerInRole method can be defined using Java annotations instead of declaring a security-role-ref elements in the deployment descriptor.

```
@javax.annotation.security.DeclareRoles("Mgr")
public void doGet(HttpServletRequest request,
HttpServletResponse response) {

   ....

   // to get remote user using getUserPrincipal()
   java.security.Principal principal = request.getUserPrincipal();
   String remoteUser = principal.getName();

   // to get remote user using getRemoteUser()
   remoteUser = request.getRemoteUser();

   // to check if remote user is granted Mgr role
   boolean isMgr = request.isUserInRole("Mgr");

   // use the above information in any way as needed by
   // the application
   ....

}
```

The following example depicts a web application or servlet using the programmatic security model.

This example illustrates one use and not necessarily the only use of the programmatic security model. The application can use the information that is returned by the getUserPrincipal, isUserInRole, and the getRemoteUser methods in any other way that is meaningful to that application. Use the declarative security model whenever possible.

File : HelloServlet.java

```
public class HelloServlet extends javax.servlet.http.HttpServlet {

 public void doPost(
  javax.servlet.http.HttpServletRequest request,
  javax.servlet.http.HttpServletResponse response)
  throws javax.servlet.ServletException, java.io.IOException {
 }
public void doGet(
```

```
  javax.servlet.http.HttpServletRequest request,
  javax.servlet.http.HttpServletResponse response)
  throws javax.servlet.ServletException, java.io.IOException {

        String s = "Hello";

        // get remote user using getUserPrincipal()
        java.security.Principal principal = request.getUserPrincipal();
        String remoteUserName = "";
        if( principal != null )
          remoteUserName = principal.getName();
// get remote user using getRemoteUser()
        String remoteUser = request.getRemoteUser();

        // check if remote user is granted Mgr role
        boolean isMgr = request.isUserInRole("Mgr");

        // display Hello username for managers and bob.
        if ( isMgr || remoteUserName.equals("bob") )
            s = "Hello " + remoteUserName;

   String message =  "<html> \n" +
              "<head><title>Hello Servlet</title></head>\n" +
         "<body> /n +"
    "<h1> "  +s+ </h1>/n " +
  byte[] bytes = message.getBytes();

  // displays "Hello" for ordinary users
        // and displays "Hello username" for managers and "bob".
        response.getOutputStream().write(bytes);
 }

}
```

After developing the servlet, you can create a security role reference for the HelloServlet servlet as shown in the following example:

```
<security-role-ref>
     <description> </description>
     <role-name>Mgr</role-name>
</security-role-ref>
```

What to do next

After developing an application, use an assembly tool to create roles and to link the actual roles to role names in the security-role-ref elements. See the information about securing web applications using an assembly tool.

Servlet security methods:

The authenticate, login, logout, getRemoteUser, isUserInRole and getAuthType servlet security methods are methods of the javax.servlet.http.HttpServletRequest interface.

authenticate

Note: The authenticate, login and logout servlet security methods are new for Java Servlet 3.0 in this release of WebSphere Application Server.

The authenticate method authenticates a user by using the WebSphere Application Server container login mechanism configured for the servlet context.

The syntax of the authenticate method is as follows:

```
boolean authenticate(HttpServletResponse response))
```

The previous example uses the following element:

response
The HttpServletResponse associated with the HttpServletRequest.

The authenticate method returns `true` when authentication has been established or authentication is successful.

The authenticate method returns `false` if authentication is incomplete and the underlying login mechanism has committed, in the response, the message and HTTP status code to be returned to the user.

A java.io.IOException occurs if an error occurs while writing the response.

A ServletException occurs if the authentication failed, and the caller is responsible for handling the error (for example, the underlying login mechanism did not establish the message and the HTTP status code to be returned to the user).

Note: When the authenticate method is called, be aware of the following:

- WebSphere Application Server returns `HTTP 401` code to a client.
- The method depends on the WebSphere Application Server container login mechanism that is configured for the servlet context. For example, if you have a form login defined for this servlet, it prompts for a user name and password. The client sends the user ID and password to WebSphere Application Server for authentication.

Important: Make sure that the authenticate method returns `true` before using the new subject to call another service. For example:

```
Boolean authResultTrue = req.authenticate(response);
  if (!authResultTrue) {
 return;
} else {
 // Use the new invocation subject to call other services.
       }
```

login

The login method authenticates a user to the WebSphere Application Server with a user ID and password. If authentication is successful, it creates a user subject on the thread and Lightweight Third Party Authentication (LTPA) cookies (if single sign-on (SSO) is enabled).

The syntax of the login method is as follows:

```
login(java.lang.String username, java.lang.String password)
```

The previous example uses the following elements:

username
The string value that corresponds to the login identifier of the user.

password
The password of the user.

A ServletException occurs if the configured login mechanism does not support username and password authentication, if an identity had already been authenticated (prior to the call to login), or if validation of the provided username and password fails.

Note: You can set the security custom property com.ibm.websphere.security.webAlwaysLogin to `true` and it will authenticate to the WebSphere application with the username and password, even if it is already authenticated.

For more information about modifying security custom properties, read the Modifying an existing custom property in a global security configuration or in a security domain configuration article.

Note: The login method always uses the user ID and password to authenticate to the WebSphere application server and even the SSO information that is present in the HttpServletRequest.

Note: The authenticate and login methods set the invocation subject to the new subject. If the caller subject is null, it then sets the caller subject to the new subject. If the caller subject is not null, then the caller subject is not set to the new subject.

Since the authenticate and login methods set the invocation subject to the new subject, the RunAs defined by the run-As attribute in deployment descriptor, security annotation or dynamic annotation is ignored.

logout

The logout method logs the user out of the WebSphere Application Server and invalidates the HTTP session. During this process, WebSphere Application Server completes the following processes:

- Clears the LTPA cookies if SSO is enabled
- Invalidates the HTTP session
- Removes the user from the authentication cache
- Removes the user subject from the thread
- Clears the caller and invocation subjects
- Sets the authentication type to `null`

After logging out, access to a protected web resource requires re-authentication and the getUserPrincipal, getRemoteUser and getAuthType methods return `null`.

The syntax of the logout method is as follows:

```
logout()
```

A ServletException occurs if the logout fails.

Audit event types for the authenticate, login and logout methods

To audit authenticate, login and logout methods, you must create or extend some audit event type files. These event type are not part of the default event type files.

Table 99. Audit event types for the authenticate, login, and logout methods.

The audit event types required for the authenticate, login, and logout methods are:

Method	Audit event name	Audit outcome of the event
authenticate/login	SECURITY_AUTHN	SUCCESS and or FAILURE
logout	SECURITY_AUTHN_TERMINATE	SUCCESS
logout	SECURITY_AUTHN_TERMINATE	FAILURE

isUserInRole

(String role name): Returns `true` if the remote user is granted the specified security role. If the remote user is not granted the specified role, or if no user is authenticated, it returns `false`.

getRemoteUser

The getRemoteUser method returns the login of the user that makes the request if the user has been authenticated. If the user has not been authenticated, the getRemoteUser method returns `null`.

getAuthType

The getAuthType method returns the name of the authentication scheme that is used to protect the servlet. If the servlet is not protected, the getAuthType method returns `null`.

The authentication schemes used are:

FORM when form-based authentication is used

BASIC
when basic authentication is used.

CLIENT_CERT
when client certificate authentication is used.

Note:

For both the getRemoteUser and getAuthType methods, the data that is returned depends upon whether security is enabled in the application server where the servlet is deployed. The following possibilities exist:

- If application security is enabled and a servlet is protected, then the getRemoteUser method returns the login and the getAuthType method returns the configured authentication scheme.
- If application security is not enabled, both methods return `null`.

Web authentication settings:

Use this page to specify the web authentication settings that are associated with a web client.

To view this administrative console page, complete the following steps:

1. Click **Security** > **Global security**.
2. Under Authentication, expand `Web and SIP security` and click `General settings`.

You can override the global Web authentication settings that you select on this panel by specifying one or more of the following system properties for the controller and the servant. Complete the following steps to specify one of these system properties for the controller:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Server infrastructure, click **Java and Process Management** > **Process definition**.
3. Under Additional properties, click **Java Virtual Machine** > **Custom properties** > **New**

Complete the following steps to specify one of these system properties for the servant:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Server infrastructure, click **Java and Process Management** > **Process definition**.
3. Under Additional properties, click **Java Virtual Machine** > **Custom properties** > **New**

Table 100. Web authentication system property values. This table lists the web authentication system property values.

Property name	Value	Explanation
com.ibm.wsspi.security.web.webAuthReq	lazy	This value is equivalent to the `Authenticate only when the URI is protected` option. **Note:** You can set webAuthReq differently through the administrative console or scripting when using a global or a security domain, but the global level always takes precedence.
com.ibm.wsspi.security.web.webAuthReq	persisting	This value is equivalent to the `Use available authentication data when an unprotected URI is accessed` option.
com.ibm.wsspi.security.web.webAuthReq	always	This value is equivalent to the `Authenticate when any URI is accessed` option.
com.ibm.wsspi.security.web.failOverToBasicAuth	true	This value is equivalent to the `Default to basic authentication when certificate authentication for the HTTPS client fails` option.

Authenticate only when the URI is protected:

The application server challenges the web client to provide authentication data when the web client accesses a Uniform Resource Identifier (URI) that is protected by a Java 2 Platform, Enterprise Edition (J2EE) role. The authenticated identity is available only when the web client accesses a protected URI.

This option is the default J2EE web authentication behavior that is also available in previous releases of WebSphere Application Server.

Note: When you select this option, the administrative console login page is missing images. You might encounter the following error in the administrative console: “CWLAA6003: Could not display the portlet, the portlet may not be started. Check the error logs”.

The missing images and the error message are a side-effect of this option. The images do not display because the URIs for the images now need authentication, which requires you to log in. You can ignore this error message.

Information	**Value**
Default:	Enabled

Use available authentication data when an unprotected URI is accessed:

The web client can access validated authenticated data that it previously could not access. This option enables the web client to call the getRemoteUser, isUserInRole, and getUserPrincipal methods to retrieve an authenticated identity from an unprotected URI.

When you select this option with the `Authenticate only when the URI is protected` option, the web client can use authenticated data when the URI is protected or not protected.

When this option is selected and Form-based authentication is being used, a WASPostParam cookie is generated during the authentication procedure of the HTTP POST request even if the target URL is unprotected. A WASPOSTParam cookie is a temporary cookie used to store HTTP POST parameters. This results in the Web client being sent the unnecessary cookie with an HTTP response. This might cause unexpected behavior when the size of the cookie is larger than the browser limit. To avoid this behavior, a custom property, com.ibm.websphere.security.util.postParamMaxCookieSize can be set to cause the security code to stop generating the cookie if the maximum size is reached.

Important: This option does not challenge the web client to provide authenticated data if the web client accesses an unprotected URI without authenticated data.

Information	**Value**
Default:	Enabled

Authenticate when any URI is accessed:

The web client must provide authentication data regardless of whether the URI is protected.

Information	**Value**
Default:	Disabled

Default to basic authentication when certificate authentication for the HTTPS client fails:

When the required HTTPS client certificate authentication fails, the application server uses the basic authentication method to challenge the web client to provide a user ID and password.

The HTTP client certification authentication that is performed by the application server security is different from the client authentication that is performed by the web server plug-in. If you configure the web server plug-in for mutual authentication and client authentication fails, the following situations will occur:

- The web server produces a error and the web request is not processed by application server security.
- The application server cannot fail over to basic authentication.

Information	Value
Default:	Disabled

Developing with programmatic APIs for EJB applications

Use this topic to programmatically secure your Enterprise JavaBeans (EJB) applications.

About this task

Programmatic security is used by security-aware applications when declarative security alone is not sufficient to express the security model of the application. The javax.ejb.EJBContext application programming interface (API) provides two methods whereby the bean provider can access security information about the enterprise bean caller.

- **IsCallerInRole**(String rolename): Returns `true` if the bean caller is granted the security role that is specified by role name. If the caller is not granted the specified role, or if the caller is not authenticated, it returns `false`. If the specified role is granted Everyone access, it always returns `true`.
- **getCallerPrincipal**: Returns the java.security. Principal object that contains the bean caller name. If the caller is not authenticated, it returns a principal that contains an unauthorized name.

You can enable a login module to indicate which principal class is returned by these calls.

When the isCallerInRole method is used, declare a security-role-ref element in the deployment descriptor with a role-name that is subelement containing the role name that is passed to this method. Because actual roles are created during the assembly stage of the application, you can use a logical role as the role name and provide enough hints to the assembler in the description of the security-role-ref element to link that role to an actual role. During assembly, the assembler creates a role-link subelement to link the role-name to the actual role. Creation of a security-role-ref element is possible if an assembly tool such as Rational Application Developer is used. You also can create the security-role-ref element during the assembly stage using an assembly tool.

Procedure

1. Add the required security methods in the EJB module code.
2. Create a security-role-ref element with a role-name field for all the role names used in the isCallerInRole method. If a security-role-ref element is not created during development, make sure it is created during the assembly stage.

Results

Performing the previous steps result in a programmatically secured EJB application.

Example

Hard coding security policies in applications is strongly discouraged. The Java Platform, Enterprise Edition (Java EE) security model capabilities of declaratively specifying security policies is encouraged wherever possible. Use these APIs to develop security-aware EJB applications.

Using Java EE security model capabilities to specify security policies declaratively is useful when an EJB application wants to access external resources and wants to control the access to these external resources using its own authorization table (external-resource to user mapping). In this case, use the

getCallerPrincipal method to get the caller identity and then the application can consult its own authorization table to perform authorization. The caller identification also can help retrieve the corresponding user information from an external source, such as database or from another enterprise bean. You can use the isCallerInRole method in a similar way.

After development, you can create a security-role-ref element:

```
<security-role-ref>
<description>Provide hints to assembler for linking this role-name to
actual role here<\description>
<role-name>Mgr<\role-name>
</security-role-ref>
```

During assembly, the assembler creates a role-link element:

```
<security-role-ref>
<description>Hints provided by developer to map role-name to role-link</description>
<role-name>Mgr</role-name>
<role-link>Manager</role-link>
</security-role-ref>
```

You can add programmatic EJB component security methods for example isCallerInRole and getCallerPrincipal, inside any business methods of an enterprise bean. The following example of programmatic security APIs includes a session bean:

```
public class aSessionBean implements SessionBean {

       .....

       // SessionContext extends EJBContext. If it is entity bean use EntityContext
       javax.ejb.SessionContext context;

       // The following method will be called by the EJB container
       // automatically
       public void setSessionContext(javax.ejb.SessionContext ctx) {
              context = ctx; // save the session bean's context
       }

       ....

       private  void aBusinessMethod()  {
       ....

       // to get  bean's caller using getCallerPrincipal()
       java.security.Principal principal = context.getCallerPrincipal();
       String  callerId= principal.getName();

       // to check if  bean's caller is granted Mgr role
       boolean isMgr = context.isCallerInRole("Mgr");

       // use the above information in any way as needed by the
       //application

       ....
       }

       ....
}
```

When developing EJB 3.x modules, the value of the rolename argument in isCallerInRole method can be defined using Java annotations instead of declaring a security-role-ref elements in the deployment descriptor.

```
@javax.annotation.security.DeclareRoles("Mgr")
@Stateless           // annotation is used to indicate a session bean
public class aSessionBean implements MyBusinessInterface { //you don't have to extend sessionbean interface
```

```
        .....
        // SessionContext extends EJBContext. In EJB 3.0 use Resource annotation to inject context
    @Resource
        javax.ejb.SessionContext context;       }

       ....

       private  void aBusinessMethod()  {
       ....

       // to get  bean's caller using getCallerPrincipal()
       java.security.Principal principal = context.getCallerPrincipal();
       String  callerId= principal.getName();

       // to check if  bean's caller is granted Mgr role
       boolean isMgr = context.isCallerInRole("Mgr");

       // use the above information in any way as needed by the
       //application

       ....
       }

       ....
}
```

What to do next

After developing an application, use an assembly tool to create roles and to link the actual roles to role names in the security-role-ref elements. See the information about securing web applications using an assembly tool.

Example: Enterprise bean application code:

The following Enterprise JavaBeans (EJB) component example illustrates the use of the isCallerInRole and the getCallerPrincipal methods in an EJB module.

Using declarative security is recommended. The following example is one way of using the isCallerInRole and the getCallerPrincipal methods. The application can use this result in any way that is suitable.

A remote interface

```
File : Hello.java

package tests;
import java.rmi.RemoteException;
/**
 * Remote interface for Enterprise Bean: Hello
 */
public interface Hello extends javax.ejb.EJBObject {
      public abstract String getMessage()throws RemoteException;
     public abstract void setMessage(String s)throws RemoteException;
}
```

A home interface

```
File : HelloHome.java
package tests;
/**
 * Home interface for Enterprise Bean: Hello
 */
public interface HelloHome extends javax.ejb.EJBHome {
 /**
  * Creates a default instance of Session Bean: Hello
  */
 public tests.Hello create() throws javax.ejb.CreateException,
  java.rmi.RemoteException;
}
```

A bean implementation

File : HelloBean.java

```
package tests;
/**
 * Bean implementation class for Enterprise Bean: Hello
 */
public class HelloBean implements javax.ejb.SessionBean {
 private javax.ejb.SessionContext mySessionCtx;
 /**
  * getSessionContext
  */
 public javax.ejb.SessionContext getSessionContext() {
  return mySessionCtx;
 }
 /**
  * setSessionContext
  */
 public void setSessionContext(javax.ejb.SessionContext ctx) {
  mySessionCtx = ctx;
 }
 /**
  * ejbActivate
  */
 public void ejbActivate() {
 }
 /**
  * ejbCreate
  */
 public void ejbCreate() throws javax.ejb.CreateException {
 }
 /**
  * ejbPassivate
  */
 public void ejbPassivate() {
 }
 /**
  * ejbRemove
  */
 public void ejbRemove() {
 }

 public java.lang.String message;

      //business methods

      // all users can call getMessage()
      public String getMessage() {
          return message;
      }

      // all users can call setMessage() but only few users can set new message.
      public void setMessage(String s) {

        // get  bean's caller using getCallerPrincipal()
        java.security.Principal principal = mySessionCtx.getCallerPrincipal();
        java.lang.String  callerId= principal.getName();

        // check if  bean's caller is granted Mgr role
        boolean isMgr = mySessionCtx.isCallerInRole("Mgr");

        // only set supplied message if caller is "bob" or caller is granted Mgr role
        if ( isMgr || callerId.equals("bob") )
            message = s;
        else
            message = "Hello";
      }

}
```

After the development of the entity bean, create a security role reference in the deployment descriptor under the session bean, Hello:

```
<security-role-ref>
     <description>Only Managers can call setMessage() on this bean (Hello)</description>
     <role-name>Mgr</role-name>
</security-role-ref>
```

For an explanation of how to create a <security-role-ref> element, see Securing enterprise bean applications. Use the information under Map security-role-ref and role-name to role-link to create the element.

Customizing web application login

You can create a form login page and an error page to authenticate a user.

Before you begin

A web client or a browser can authenticate a user to a Web server using one of the following mechanisms:

- **HTTP basic authentication**: A web server requests the Web client to authenticate and the web client passes a user ID and a password in the HTTP header.
- **HTTPS client authentication**: This mechanism requires a user (web client) to possess a public key certificate. The web client sends the certificate to a web server that requests the client certificates. This authentication mechanism is strong and uses the Hypertext Transfer Protocol with Secure Sockets Layer (HTTPS) protocol.
- **Form-based Authentication**: A developer controls the look and feel of the login screens using this authentication mechanism.

The Hypertext Transfer Protocol (HTTP) basic authentication transmits a user password from the web client to the web server in simple base64 encoding. Form-based authentication transmits a user password from the browser to the web server in plain text. Therefore, both HTTP basic authentication and form-based authentication are not very secure unless the HTTPS protocol is used.

The web application deployment descriptor contains information about which authentication mechanism to use. When form-based authentication is used, the deployment descriptor also contains entries for login and error pages. A login page can be either an HTML page or a JavaServer Pages (JSP) file. This login page is displayed on the web client side when a secured resource (servlet, JSP file, HTML page) is accessed from the application. On authentication failure, an error page is displayed. You can write login and error pages to suit the application needs and control the look and feel of these pages. During assembly of the application, an assembler can set the authentication mechanism for the application and set the login and error pages in the deployment descriptor.

Form login uses the servlet sendRedirect method, which has several implications for the user. The sendRedirect method is used twice during form login:

- The sendRedirect method initially displays the form login page in the web browser. It later redirects the web browser back to the originally requested protected page. The sendRedirect(String URL) method tells the web browser to use the HTTP GET request to get the page that is specified in the web address. If HTTP POST is the first request to a protected servlet or JavaServer Pages (JSP) file, and no previous authentication or login occurred, then HTTP POST is not delivered to the requested page. However, HTTP GET is delivered because form login uses the sendRedirect method, which behaves as an HTTP GET request that tries to display a requested page after a login occurs.
- Using HTTP POST, you might experience a scenario where an unprotected HTML form collects data from users and then posts this data to protected servlets or JSP files for processing, but the users are not logged in for the resource. To avoid this scenario, structure your web application or permissions so that users are forced to use a form login page before the application performs any HTTP POST actions to protected servlets or JSP files.

Procedure

1. Create a form login page with the required look and feel, including the required elements to perform form-based authentication.
2. Create an error page. You can program error pages to retry authentication or to display an appropriate error message.
3. Place the login page and error page in the web application archive (`.war`) file relative to the top directory. For example, if the login page is configured as `/login.html` in the deployment descriptor, place it in the top directory of the WAR file. An assembler can also perform this step using the assembly tool.
4. Create a form logout page and insert it to the application only when the web application requires a form-based authentication mechanism.

   By default the URL to the logout page should point to the host to which the request was made or its domain. Otherwise, a generic logout page is displayed. If you need to point this URL to a different host, then you need to set the com.ibm.websphere.security.logoutExitPageDomainList property in the `security.xml` file with a list of URLs that are allowed for the logout page. You can choose to allow any logout exit page to be used by setting the com.ibm.websphere.security.allowAnyLogoutExitPageHost property to a value of `true`. Setting this property to `true` might open your systems to a potential URL redirect attacks.

Example: Form login

You can use the WebSphere Application Server login facilities to implement and configure form login procedures. Use the following technologies for WebSphere Application Server and Java Platform, Enterprise Edition (Java EE) login functionality:

- Java EE form-based login
- Java EE servlet filter with login
- IBM extension: form-based login

The form login sample is part of the Technology Samples package. For more information on how to access the form login sample, see Accessing the samples.

Form login usage

For the authentication to proceed appropriately, the action of the login form must always have the j_security_check action. The following example shows how to code the form into the HTML page:

```
<form method="POST" action="j_security_check">
<input type="text" name="j_username">
<input type="text" name="j_password">
<\form>
```

Use the **j_username** input field to get the user name, and use the **j_password** input field to get the user password.

On receiving a request from a web client, the web server sends the configured form page to the client and preserves the original request. When the web server receives the completed form page from the web client, the server extracts the user name and password from the form and authenticates the user. On successful authentication, the web server redirects the call to the original request. If authentication fails, the web server redirects the call to the configured error page.

The following example depicts a login page in HTML (`login.html`):

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
<META HTTP-EQUIV = "Pragma" CONTENT="no-cache">
<title> Security FVT Login Page </title>
<body>
<h2>Form Login</h2>
<FORM METHOD=POST ACTION="j_security_check">
<p>
<font size="2"> <strong> Enter user ID and password: </strong></font>
```

```
<BR>
<strong> User ID</strong> <input type="text" size="20" name="j_username">
<strong> Password </strong>  <input type="password" size="20" name="j_password">
<BR>
<BR>
<font size="2">  <strong> And then click this button: </strong></font>
<input type="submit" name="login" value="Login">
</p>

</form>
</body>
</html>
```

The following example depicts an error page in a JSP file:

```
<!DOCTYPE HTML PUBLIC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
<head><title>A Form login authentication failure occurred</head></title>
<body>
<H1><B>A Form login authentication failure occurred</H1></B>
<P>Authentication may fail for one of many reasons. Some possibilities include:
<OL>
<LI>The user-id or password may be entered incorrectly; either misspelled or the
wrong case was used.
<LI>The user-id or password does not exist, has expired, or has been disabled.
</OL>
</P>
</body>
</html>
```

After an assembler configures the web application to use form-based authentication, the deployment descriptor contains the login configuration as shown:

```
<login-config id="LoginConfig_1">
<auth-method>FORM<auth-method>
<realm-name>Example Form-Based Authentication Area</realm-name>
<form-login-config id="FormLoginConfig_1">
<form-login-page>/login.html</form-login-page>
<form-error-page>/error.jsp</form-error-page>
</form-login-config>
</login-config>
```

A sample web application archive (WAR) file directory structure that shows login and error pages for the previous login configuration follows:

```
META-INF
     META-INF/MANIFEST.MF
     login.html
     error.jsp
     WEB-INF/
     WEB-INF/classes/
     WEB-INF/classes/aServlet.class
```

Form logout

Form logout is a mechanism to log out without having to close all Web-browser sessions. After logging out of the form logout mechanism, access to a protected web resource requires re-authentication. This feature is not required by J2EE specifications, but it is provided as an additional feature in WebSphere Application Server security.

Suppose that you want to log out after logging into a web application and perform some actions. A form logout works in the following manner:

1. The logout-form URI is specified in the web browser and loads the form.
2. The user clicks **Submit** on the form to log out.
3. The WebSphere Application Server security code logs the user out. During this process, the Application Server completes the following processes:
   a. Clears the Lightweight Third Party Authentication (LTPA) / single sign-on (SSO) cookies
   b. Invalidates the HTTP session
   c. Removes the user from the authentication cache
4. Upon logout, the user is redirected to a logout exit page.

Form logout does not require any attributes in a deployment descriptor. The form-logout page is an HTML or a JavaServer Pages (JSP) file that is included with the web application. The form-logout page is like

most HTML forms except that like the form-login page, the form-logout page has a special post action. This post action is recognized by the web container, which dispatches the post action to a special internal form-logout servlet. The post action in the form-logout page must be `ibm_security_logout`.

You can specify a logout-exit page in the logout form and the exit page can represent an HTML or a JSP file within the same web application to which the user is redirected after logging out. Additionally, the logout-exit page permits a fully qualified URL in the form of `http://hostname:port/URL`. The logout-exit page is specified as a parameter in the form-logout page. If no logout-exit page is specified, a default logout HTML message is returned to the user.

Here is a sample form logout HTML form. This form configures the logout-exit page to redirect the user back to the login page after logout.

```
<!DOCTYPE HTML PUBliC "-//W3C/DTD HTML 4.0 Transitional//EN">
<html>
  <META HTTP-EQUIV = "Pragma" CONTENT="no-cache">
  <title>Logout Page </title>
  <body>
  <h2>Sample Form Logout</h2>
      <FORM METHOD=POST ACTION="ibm_security_logout" NAME="logout">
      <p>
      <BR>
      <BR>
      <font size="2"><strong> Click this button to log out: </strong></font>
      <input type="submit" name="logout" value="Logout">
      <INPUT TYPE="HIDDEN" name="logoutExitPage" VALUE="/login.html">
      </p>
      </form>
  </body>
</html>
```

What to do next

After developing login and error pages, add them to the Web application. Use the assembly tool to configure an authentication mechanism and insert the developed login page and error page in the deployment descriptor of the application.

Developing servlet filters for form login processing

You can control the look and feel of the login screen using the form-based login mechanism. In form-based login, you specify a login page that is used to retrieve the user ID and password information. You also can specify an error page that displays when authentication fails.

About this task

If additional authentication or additional processing is required before and after authentication, servlet filters are an option. Servlet filters can dynamically intercept requests and responses to transform or to use the information that is contained in the requests or responses. One or more servlet filters can be attached to a servlet or to a group of servlets. Servlet filters also can attach to JavaServer Pages (JSP) files and HTML pages. All of the attached servlet filters are called before the servlet is invoked.

Both form-based login and servlet filters are supported by any servlet Version 2.3 specification-complaint web container. The form login servlet performs the authentication and servlet filters perform additional authentication, auditing, or logging information.

To perform pre-login and post-login actions using servlet filters, configure these filters for either form login page support or for the /j_security_check URL. The j_security_check is posted by a form login page with the j_username parameter that contains the user name and the j_password parameter that contains the password. A servlet filter can use the user name parameter and password information to perform more authentication or other special needs.

Procedure

1. A servlet filter implements the javax.servlet.Filter class. Implement three methods in the filter class:

- **init(javax.servlet.FilterConfig cfg)**. This method is called by the container once, when the servlet filter is placed into service. The FilterConfig passed to this method contains the init-parameters of the servlet filter. Specify the init-parameters for a servlet filter during configuration using the assembly tool.
- **destroy**. This method is called by the container when the servlet filter is taken out of a service.
- **doFilter(ServletRequest req, ServletResponse res, FilterChain chain)**. This method is called by the container for every servlet request that maps to this filter before invoking the servlet. The FilterChain chain that is passed to this method can be used to invoke the next filter in the chain of filters. The original requested servlet runs when the last filter in the chain calls the chain.doFilter method. Therefore, all filters call the chain.doFilter method for the original servlet to run after filtering. If an additional authentication check is implemented in the filter code and results in failure, the original servlet does not run. The chain.doFilter method is not called and can be redirected to some other error page.

2. If a servlet maps to many servlet filters, servlet filters are called in the order that is listed in the `web.xml` deployment descriptor of the application. Place the servlet filter class file in the `WEB-INF/classes` directory of the application.

Example

An example of a servlet filter.

This login filter can map to the /j_security_check URL to perform pre-login and post-login actions.

```
import javax.servlet.*;
     public class LoginFilter implements Filter {
     protected FilterConfig filterConfig;
     // Called once when this filter is instantiated.
     // If mapped to j_security_check, called
     // very first time j_security_check is invoked.
     public void init(FilterConfig filterConfig) throws ServletException {
        this.filterConfig = filterConfig;
        }
     public void destroy() {
        this.filterConfig = null;
        }
      // Called for every request that is mapped to this filter.
     // If mapped to j_security_check,
     // called for every  j_security_check action
     public void doFilter(ServletRequest request,
     ServletResponse response, FilterChain chain)
         throws java.io.IOException, ServletException   {
         // perform pre-login action here
         chain.doFilter(request, response);
         // calls the next filter in chain.
         // j_security_check if this filter is
         // mapped to j_security_check.
        // perform post-login action here.
                 }
       }
```

Using servlet filters to perform pre-login and post-login processing during form login

This example illustrates one way that the servlet filters can perform pre-login and post-login processing during form login.

```
Servlet filter source code: LoginFilter.java
/**
 * A servlet filter example: This example filters j_security_check and
 * performs pre-login action to determine if the user trying to log in
 * is in the revoked list. If the user is on the revoked list, an error is
 * sent back to the browser.
 *
 * This filter reads the revoked list file name from the FilterConfig
 * passed in the init() method. It reads the revoked user list file and
 * creates a revokedUsers list.
 *
 * When the doFilter method is called, the user logging in is checked
 * to make sure that the user is not on the revoked Users list.
 *
 */

import javax.servlet.*;
import javax.servlet.http.*;
```

```
import java.io.*;

public class LoginFilter implements Filter {

   protected FilterConfig filterConfig;

   java.util.List revokeList;

   /**
    * init() : init() method called when the filter is instantiated.
    * This filter is instantiated the first time j_security_check is
    * invoked for the application (When a protected servlet in the
    * application is accessed).
    */
   public void init(FilterConfig filterConfig) throws ServletException {
      this.filterConfig = filterConfig;

      // read revoked user list
      revokeList = new java.util.ArrayList();
      readConfig();
   }

   /**
    * destroy() : destroy() method called when the filter is taken
    * out of service.
    */
   public void destroy() {
      this.filterConfig = null;
      revokeList = null;
   }

   /**
    * doFilter() : doFilter() method called before the servlet to
    * which this filter is mapped is invoked. Since this filter is
    * mapped to j_security_check,this method is called before
    * j_security_check action is posted.
    */
   public void doFilter(ServletRequest request, ServletResponse response,
FilterChain chain) throws java.io.IOException, ServletException {

      HttpServletRequest req = (HttpServletRequest)request;
      HttpServletResponse res = (HttpServletResponse)response;

      // pre login action

      // get username
      String username = req.getParameter("j_username");

      // if user is in revoked list send error
      if ( revokeList.contains(username) ) {
      res.sendError(javax.servlet.http.HttpServletResponse.SC_UNAUTHORIZED);
      return;
      }

      // call next filter in the chain : let j_security_check authenticate
      // user
      chain.doFilter(request, response);

      // post login action

   }

   /**
    * readConfig() : Reads revoked user list file and creates a revoked
    * user list.
    */
   private void readConfig() {
      if ( filterConfig != null ) {

         // get the revoked user list file and open it.
         BufferedReader in;
         try {
               String filename = filterConfig.getInitParameter("RevokedUsers");
               in = new BufferedReader( new FileReader(filename));
         } catch ( FileNotFoundException fnfe) {
               return;
         }

         // read all the revoked users and add to revokeList.
         String userName;
         try {
               while ( (userName = in.readLine()) != null )
                   revokeList.add(userName);
         } catch (IOException ioe) {
         }

      }
```

```
   }

}
```

Important: In the previous code sample, the line that begins `public void doFilter(ServletRequest request` is broken into two lines for illustrative purposes only. The `public void doFilter(ServletRequest request` line and the line after it are one continuous line.

An example of the `web.xml` file that shows the LoginFilter filter configured and mapped to the j_security_check URL:

```
<filter id="Filter_1">
    <filter-name>LoginFilter</filter-name>
    <filter-class>LoginFilter</filter-class>
         <description>Performs pre-login and post-login operation</description>
    <init-param>
    <param-name>RevokedUsers</param-name>
    <param-value>c:\WebSphere\AppServer\installedApps\
                          <app-name>\revokedUsers.lst</param-value>
    </init-param>
</filter-id>

<filter-mapping>
 <filter-name>LoginFilter</filter-name>
     <url-pattern>/j_security_check</url-pattern>
</filter-mapping>
```

An example of a revoked user list file:

```
user1
cn=user1,o=ibm,c=us
user99
cn=user99,o=ibm,c=us
```

Configuring servlet filters for form login processing:

IBM Rational Application Developer or an assembly tool can configure the servlet filters. Two steps are involved in configuring a servlet filter.

Procedure

1. Name the servlet filter and assign the corresponding implementation class to the servlet filter.

   Optionally, assign initialization parameters that get passed to the init method of the servlet filter.After configuring the servlet filter, the `web.xml` application deployment descriptor contains a servlet filter configuration similar to the following example:

```
<filter id="Filter_1">
   <filter-name>LoginFilter</filter-name>
   <filter-class>LoginFilter</filter-class>
   <description>Performs pre-login and post-login
        operation</description>
   <init-param>// optional
     <param-name>ParameterName</param-name>
     <param-value>ParameterName</param-value>
   </init-param>
</filter>
```

2. Map the servlet filter to a URL or a servlet.

   After mapping the servlet filter to a URL or a servlet, the `web.xml` application deployment descriptor contains servlet mapping similar to the following example:

```
<filter-mapping>
   <filter-name>LoginFilter</filter-name>
   <url-pattern>/j_security_check</url-pattern>
               // can be servlet <servlet>servletName</servlet>
</filter-mapping>
```

Example

You can use servlet filters to replace the CustomLoginServlet servlet, and to perform additional authentication, auditing, and logging.

The WebSphere Application Server Samples provide a form login sample that demonstrates how to use the WebSphere Application Server login facilities to implement and configure form login procedures. The sample integrates the following technologies to demonstrate the WebSphere Application Server and Java Platform, Enterprise Edition (Java EE) login functionality:

- Java EE form-based login
- Java EE servlet filter with login
- IBM extension: form-based login

The form login sample is part of the Technology Samples package.

Note: If you install the application server on a z/OS system in which program control is enabled, when you log into a form-based web application you might receive the following error message in the system log file:

```
ICH420I PROGRAM BBORSMCT FROM LIBRARY WAS.SBBOLD2 CAUSED THE ENVIRONMENT TO BECOME UNCONTROLLED.
BPXP014I ENVIRONMENT MUST BE CONTROLLED FOR DAEMON (BPX.DAEMON)
PROCESSING.
```

Although program control is enabled on the z/OS system, the program control extended control bits for the application server's native modules will not be enabled. To prevent or resolve this problem enable the program control bits for all of the native load modules in the SMP/E HTTP Server file system (HFS).

1. Add the necessary attributes to the modules:

```
cd SMPE_ROOT/usr/lpp/install_root/V7R0/lib/modules
extattr +p *
```

2. Add the attributes to the *.so files and bbo* files in the lib directory:

```
cd SMPE_ROOT/usr/lpp/install_root/V7R0/lib
extattr +p *.so
extattr +p bbo*
```

Secure transports with JSSE and JCE programming interfaces

This topic provides detailed information about transport security using Java Secure Socket Extension (JSSE) and Java Cryptography Extension (JCE) programming interfaces. Within this topic, there is a description of the IBM version of the Java Cryptography Extension Federal Information Processing Standard (IBMJCEFIPS).

Java Secure Socket Extension

Java Secure Socket Extension (JSSE) provides the transport security for WebSphere Application Server. JSSE provides the application programming interface (API) framework and the implementation of the APIs for Secure Sockets Layer (SSL) and Transport Layer Security (TLS) protocols, including functionality for data encryption, message integrity, and authentication.

JSSE APIs are integrated into the Java 2 SDK, Standard Edition (J2SDK), Version 5. The API package for JSSE APIs is `javax.net.ssl.*`. Documentation for using JSSE APIs can be found in the J2SE 6 API documentation that is located at `http://java.sun.com/javase/6/docs/technotes/guides/security/jsse/JSSERefGuide.html`.

Several JSSE providers ship with the Java 2 SDK Version 5 that comes with WebSphere Application Server. The IBMJSSE provider is used in previous WebSphere Application Server releases. Associated with the IBMJSSE provider is the IBMJSSEFIPS provider, which is used when FIPS is enabled on the server. Both of these providers do not work with the Java Message Service (JMS) and HTTP transports in WebSphere Application Server Version 8.5. These transports take advantage of the J2SDK Verison 5 network input/output (NIO) asynchronous channels.

For more information on the new IBMJSSE2 provider, please review the documentation located at `http://www.ibm.com/developerworks/java/jdk/security/60/`.

Customizing Java Secure Socket Extension

You can customize a number of aspects of JSSE by plugging in different implementations of Cryptography Package Provider, X509Certificate and HTTPS protocols, or specifying different default keystore files, key manager factories, and trust manager factories. The following table summarizes which aspects can be customized, what the defaults are, and which mechanisms are used to provide customization.

Table 101. Customizable items. You can customize the following key aspects:

Customizable item	Default	How to customize
X509Certificate	X509Certificate implementation from IBM	The cert.provider.x509v1 security property
HTTPS protocol	Implementation from IBM	The java.protocol.handler.pkgs system property
Cryptography Package Provider	IBMJSSE2	A security.provider.n= line in security properties file. See description.
Default keystore	None	The * javax.net.ssl.keyStore system property
Default truststore	jssecacerts, if it exists. Otherwise, cacerts	The * javax.net.ssl.trustStore system property
Default key manager factory	IbmX509	The ssl.KeyManagerFactory.algorithm security property
Default trust manager factory	IbmX509	The ssl.TrustManagerFactory.algorithm security property

For aspects that you can customize by setting a system property, statically set the system property by using the `-D` option of the Java command. You can set the system property using the administrative console, or set the system property dynamically by calling the java.lang.System.setProperty method in your code: System.setProperty(propertyName,"propertyValue").

For aspects that you can customize by setting a Java security property, statically specify a security property value in the `java.security` properties file. The security property is propertyName=propertyValue. Dynamically set the Java security property by calling the java.security.Security.setProperty method in your code.

The `java.security` properties file is located in the following directory:

app_server_root/`properties` directory.

Application Programming Interface

The JSSE provides a standard application programming interface (API) that is available in packages of the `javax.net` file, `javax.net.ssl` file, and the `javax.security.cert` file. The APIs cover:

- Sockets and SSL sockets
- Factories to create the sockets and SSL sockets
- Secure socket context that acts as a factory for secure socket factories
- Key and trust manager interfaces
- Secure HTTP URL connection classes
- Public key certificate API

Samples using Java Secure Socket Extension

The Java Secure Socket Extension (JSSE) also provides samples to demonstrate its functionality. The Java Secure Socket Extension (JSSE) also provides samples to demonstrate its functionality. You can access the samples in the following location:

Version 1.6

1. Access the http://www.ibm.com/developerworks/java/jdk/security/ website.
2. Click Java 1.6.
3. Click `jssedocs_samples.zip` in the Java Secure Socket Extension (JSSE) Guide section.

Table 102. Extracted files. This table lists the following extracted files:

Files	Description
ClientJsse.java	Demonstrates a simple client and server interaction using JSSE. All enabled cipher suites are used.
OldServerJsse.java	Back-level samples
ServerPKCS12Jsse.java	Demonstrates a simple client and server interaction using JSSE with the PKCS12 keystore file. All enabled cipher suites are used.
ClientPKCS12Jsse.java	Demonstrates a simple client and server interaction using JSSE with the PKCS12 keystore file. All enabled cipher suites are used.
UseHttps.java	Demonstrates accessing an SSL or non-SSL web server using the Java protocol handler of the com.ibm.net.ssl.www.protocol class. The URL is specified with the `http` or `https` prefix. The HTML that is returned from this site is displayed.

See more instructions in the source code. Follow these instructions before you run the samples.

Permissions for Java 2 security

You might need the following permissions to run an application with JSSE: This list is for reference only.
- java.util.PropertyPermission "java.protocol.handler.pkgs", "write"
- java.lang.RuntimePermission "writeFileDescriptor"
- java.lang.RuntimePermission "readFileDescriptor"
- java.lang.RuntimePermission "accessClassInPackage.sun.security.x509"
- java.io.FilePermission "${user.install.root}${/}etc${/}.keystore", "read"
- java.io.FilePermission "${user.install.root}${/}etc${/}.truststore", "read"

For the IBMJSSE provider:
- java.security.SecurityPermission "putProviderProperty.IBMJSSE"
- java.security.SecurityPermission "insertProvider.IBMJSSE"

For the SUNJSSE provider:
- java.security.SecurityPermission "putProviderProperty.SunJSSE"
- java.security.SecurityPermission "insertProvider.SunJSSE"

Debugging

By configuring through the javax.net.debug system property, JSSE provides the following dynamic debug tracing: `-Djavax.net.debug=true`.

A value of `true` turns on the trace facility. Use the administrative console to set the system property for debugging the application server.

Documentation

See the Security: Resources for learning topic for documentation references to JSSE.

JCE

Java Cryptography Extension (JCE) provides cryptographic, key and hash algorithms for WebSphere Application Server. JCE provides a framework and implementations for encryption, key generation, key agreement, and Message Authentication Code (MAC) algorithms. Support for encryption includes symmetric, asymmetric, block and stream ciphers.

IBMJCE

The IBM version of the Java Cryptography Extension (IBMJCE) is an implementation of the JCE cryptographic service provider that is used in WebSphere Application Server. The IBMJCE is similar to SunJCE, except that the IBMJCE offers more algorithms:
- Cipher algorithm (AES, DES, TripleDES, PBEs, Blowfish, and so on)

- Signature algorithm (SHA1withRSA, MD5withRSA, SHA1withDSA)
- Message digest algorithm (MD5, MD2, SHA1, SHA-256, SHA-384, SHA-512)
- Message authentication code (HmacSHA1, HmacMD5)
- Key agreement algorithm (DiffieHellman)
- Random number generation algorithm (IBMSecureRandom, SHA1PRNG)
- Key store (JKS, JCEKS, PKCS12, JCERACFKS [z/OS only])

The IBMJCE belongs to the com.ibm.crypto.provider.* packages.

For further information, see the information on JCE on the following website: http://www.ibm.com/developerworks/java/jdk/security/60/.

IBMJCEFIPS

The IBM version of the Java Cryptography Extension Federal Information Processing Standard (IBMJCEFIPS) is an implementation of the JCE cryptographic service provider that is used in WebSphere Application Server. The IBMJCEFIPS service provider implements the following:

- Signature algorithms (SHA1withDSA, SHA1withRSA)
- Cipher algorithms (AES, TripleDES, RSA)
- Key agreement algorithm (DiffieHellman)
- Key (pair) generator (DSA, AES, TripleDES, HmacSHA1, RSA, DiffieHellman)
- Message authentication code (MAC) (HmacSHA1)
- Message digest (MD5, SHA-1, SHA-256, SHA-384, SHA-512)
- Algorithm parameter generator (DiffieHellman, DSA)
- Algorithm parameter (AES, DiffieHellman, DES, TripleDES, DSA)
- Key factory (DiffieHellman, DSA, RSA)
- Secret key factory (AES, TripleDES)
- Certificate (X.509)
- Secure random (IBMSecureRandom)

Application Programming Interface

Java Cryptography Extension (JCE) has a provider-based architecture. Providers can be plugged into the JCE framework by implementing the APIs that are defined by the JCE. The JCE APIs cover:

- Symmetric bulk encryption, such as DES, RC2, and IDEA
- Symmetric stream encryption, such as RC4
- Asymmetric encryption, such as RSA
- Password-based encryption (PBE)
- Key agreement
- Message authentication codes

Samples using Java Cryptography Extension

There are samples located on the `http://www.ibm.com/developerworks/java/jdk/security/` website in the `jceDocs_samples.zip` file. Unzip the file and locate the following samples in the `jceDocs/samples` directory:

Table 103. Samples using Java Cryptography Extension. This table describes samples using Java Cryptography Extension.

File	Description
SampleDSASignature.java	Demonstrates how to generate a pair of DSA keys (a public key and a private key) and use the key to digitally sign a message using the SHA1withDSA algorithm
SampleMarsCrypto.java	Demonstrates how to generate a Mars secret key, and how to do Mars encryption and decryption

Table 103. Samples using Java Cryptography Extension (continued). This table describes samples using Java Cryptography Extension.

File	Description
SampleMessageDigests.java	Demonstrates how to use the message digest for MD2 and MD5 algorithms
SampleRSACrypto.java	Demonstrates how to generate an RSA key pair, and how to do RSA encryption and decryption
SampleRSASignatures.java	Demonstrates how to generate a pair of RSA keys (a public key and a private key) and use the key to digitally sign a message using the SHA1withRSA algorithm
SampleX509Verification.java	Demonstrates how to verify X509 certificates

Documentation

Refer to the Security: Resources for learning topic for documentation on JCE.

Using System Authorization Facility keyrings with Java Secure Sockets Extension

WebSphere Application Server for z/OS customers running server W50100*x* or later, with Java Development Kit 1.3 level SR20 or later, can modify their WebSphere Application Server systems to use System Authorization Facility (SAF) for Java Secure Sockets Extension (JSSE) as well as Secure Sockets Layer (SSL), which eliminates the need to maintain duplicate certificates in the hierarchical file system (HFS).

Before you begin

WebSphere Application Server for z/OS running at maintenance levels before W502000 stored digital certificate information in two different places because of the following Software Development Kit (SDK) restrictions:

- JSSE used digital certificates stored in hierarchical file system files
- SSL used digital certificate information stored in the SAF database

Systems customized at W502000 or above use the single SAF digital certificate repository by default, and do not need the modifications described below.

About this task

WebSphere Application Server for z/OS customers running server W50100x or later, with Java Development Kit 1.3 level SR20 or later, can modify their WebSphere Application Server systems to use SAF for JSSE as well as SSL (eliminating the need to maintain duplicate certificates in the HFS). The instructions below describe how to enable this support.

Note: Systems that are customized at maintenance levels at or after W502000 use the single (SAF digital certificate repository by default, and these systems do not need the modifications described below.

To use SAF certificates with JSSE:

Procedure

1. Update the Java Management Extensions (JMX) connector settings to indicate the SAF keyring names for the node.
   a. Log in to the administrative console using an identity with administrator authority.
   b. Click **Servers > Application servers >** *server_name*.
   c. Under Server infrastructure, click **Administration > Administration services**.
   d. Under Additional properties, click **JMX connectors**.
   e. On the JMX Connectors panel, click **SOAPConnector**.

f. Under Additional Properties, click **Custom Properties**.

g. On the Custom properties page, click **sslConfig**.

h. On the sslConfig page, look at the Value field. Verify that this field says *node_name/DefaultSSLSettings*, where *nodename* represents the node name where the application server resides. Record the node name for a subsequent step.

i. Select ***node_name*/RACFJSSESettings** from the list next to the Value field, where *node_name* is the same as the node name that you previously recorded.

j. Click **OK**. The Custom Properties page appears with a message indicating that changes are made to your local configuration. Do not click **Save** because additional changes that are required.

2. Click **Servers > Application servers** and repeat the previous substeps for each of the other application servers in the cell.

3. Update the Java Management Extensions (JMX) connector settings to indicate the SAF keyring names for the deployment manager node.

a. Click **System administration > Deployment manager**.

b. Under Additional properties, click **Administration services > JMX Connectors**.

c. On the JMX Connectors panel, click **SOAPConnector**.

d. Under Additional properties, click **Custom properties**.

e. On the Custom properties page, click **sslConfig**.

f. On the sslConfig page, look at the Value field. This field displays *dmnode/DefaultSSLSettings*, where *dmnode* represents the deployment manager node name. Record the node name for a subsequent step.

g. Select **dmnode/RACFJSSESettings** from the list next to the Value field, where **dmnode** represents the Deployment Manager node name.

h. Click **OK**. After a short time the Custom Properties page appears with a message at the top indicating that changes have been made to your local configuration. Do not click **Save** at this point because there are additional changes that are required.

4. Update the Java Management Extensions (JMX) connector settings to indicate the SAF keyring names for the node agent.

a. Click **System administration > Node agents >** *Node_name*. Record the node agent name for the next step.

b. Under Additional properties, click **Administration services > JMX Connectors**.

c. On the JMX Connectors panel, click **SOAPConnector**.

d. Under Additional properties, click **Custom properties**.

e. On the Custom properties page, click **sslConfig**.

f. On the sslConfig page, look at the Value field. This field displays *nodename/DefaultSSLSettings*, where *nodename* is the node name where the node agent resides. Record the node name for a subsequent step.

g. Select **nodename/RACFJSSESettings** from the list next to the Value field, where **nodename** is the node name that you previously recorded.

h. Click **OK**. The Custom Properties page is displayed with a message indicating that changes have been made to the local configuration. Do not click **Save** at this point because additional changes are required.

5. Click **System administration > Node agents** and repeat the previous substeps for each of the other node agents servers in the cell.

6. Click **Save** when the `Changes have been made to your local configuration. Click Save to apply changes to the master configuration` message is displayed.

7. On the Save page, select the **Synchronize changes with Nodes** option and click **Save**. After the changes are saved, the administrative console returns to the home page.

8. Update the soap.client.props file in the *profile_root*/properties directory to indicate the SAF keyring names that are appropriate for your configuration. The soap.client.props file is used by the wsadmin.sh script and is located in the application server or deployment manager (user.install.root)/properties file. The purpose of the soap.client.props file is to specify the values used by SOAP clients such as wsadmin.sh. In a cell configured before WebSphere Application Server for z/OS maintenance level W502000, the soap.client.props file indicates the names of the Java key stores used by JSSE. Once your cell is using SAF keyrings for JSSE administration, verify that SAF keyrings are being used for SOAP clients.

   The soap.client.props file is used by the wsadmin.sh script.

   Changes to wsadmin client SAF keyrings require updates to the soap.client.props file and the creation of a keyring for administrators. Specify the following values:

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.keyStoreType=JCERACFKS
com.ibm.ssl.keyStore=safkeyring:///yourkeyringName
com.ibm.ssl.keyStorePassword=password
com.ibm.ssl.trustStoreType=JCERACFKS
com.ibm.ssl.trustStore=safkeyring:///yourKeyringName
com.ibm.ssl.trustStorePassword=password
```

   =

   The password value specified does not represent a real password because you can use any string. Replace the string yourKeyringName with your administrative SAF keyring. The keyring name used by all WebSphere administrators and the administrative started task user ID (default WSADMSH) must be the same. Additionally, a keyring must be created for each user that uses the wsadmin.sh file with the SOAP connector when using SAF keyrings and security is enabled. (A keyring is created by the customization process for your initial administrative user ID, such as WSADMIN.)

   A description of how to create keyrings for administrative users in SAF is described in SSL considerations for WebSphere Application Server administrators.

9. Recycle the cell.

Configuring Federal Information Processing Standard Java Secure Socket Extension files

Use this topic to configure Federal Information Processing Standard Java Secure Socket Extension files.

About this task

In WebSphere Application Server, the Java Secure Socket Extension (JSSE) provider used is the IBMJSSE2 provider. This provider delegates encryption and signature functions to the Java Cryptography Extension (JCE) provider. Consequently, IBMJSSE2 does not need to be Federal Information Processing Standard (FIPS)-approved because it does not perform cryptography. However, the JCE provider requires FIPS-approval.

WebSphere Application Server provides a FIPS-approved IBMJCEFIPS provider that IBMJSSE2 can utilize. The IBMJCEFIPS provider that is shipped in WebSphere Application Server Version 8.5 supports the following SSL ciphers:

- SSL_RSA_WITH_AES_128_CBC_SHA
- SSL_RSA_WITH_3DES_EDE_CBC_SHA
- SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA
- SSL_DHE_RSA_WITH_AES_128_CBC_SHA
- SSL_DHE_RSA_WITH_3DES_EDE_CBC_SHA
- SSL_DHE_DSS_WITH_AES_128_CBC_SHA
- SSL_DHE_DSS_WITH_3DES_EDE_CBC_SHA

Even though the IBMJSSEFIPS provider is still present, the runtime does not use this provider. If IBMJSSEFIPS is specified as a contextProvider, WebSphere Application Server automatically defaults to the IBMJSSE2 provider (with the IBMJCEFIPS provider) for supporting FIPS. When enabling the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option on the server SSL certificate and key management panel, the runtime always uses IBMJSSE2, despite the contextProvider that you specify for SSL (IBMJSSE, IBMJSSE2 or IBMJSSEFIPS). Also, because FIPS requires the SSL protocol be TLS, the runtime always uses TLS when FIPS is enabled, regardless of the SSL protocol setting in the SSL repertoire. This simplifies the FIPS configuration in Version 8.5 because an administrator needs to enable only the **Use the United States Federal Information Processing Standard (FIPS) algorithms** option on the server SSL certificate and key management panel to enable all transports using SSL.

Procedure

1. Click **Security > SSL certificate and key management > Manage FIPS**.
2. Select the **Enable FIPS 140-2** option and click **Apply**. This option makes IBMJSSE2 and IBMJCEFIPS the active providers.
3. Accommodate Java clients that must access enterprise beans.

   Change the `com.ibm.security.useFIPS` property value from `false` to `true` in the *profile_root*`/properties/ssl.client.props` file.
4. Ensure that the com.ibm.ssl.protocol property within the *profile_root*`/properties/ssl.client.props` file is set to TLS.
5. Ensure that the `java.security` file includes the provider.

What to do next

After completing these steps, a FIPS-approved JSSE or JCE provider offers increased encryption capabilities. However, when you use FIPS-approved providers:

- By default, Microsoft Internet Explorer might not have TLS enabled. To enable TLS, open the Internet Explorer browser and click **Tools > Internet Options**. On the Advanced tab, select the Use TLS 1.0 option.

  Note: Netscape Version 4.7.*x* and earlier versions might not support TLS.
- If you have an administrative client that uses a SOAP connector and you enable FIPS, add the following line to the *profile_root*`/properties/soap.client.props` file:

  `com.ibm.ssl.contextProvider=IBMJSSEFIPS`
- When you select the **Use the Federal Information Processing Standard (FIPS)** option on the SSL certificate and key management panel, the Lightweight Third-Party Authentication (LTPA) token format is not backwards-compatible with previous releases of WebSphere Application Server. However, you can import the LTPA keys from a previous version of the application server.

Note: When enabling FIPS, you cannot configure cryptographic token devices in the SSL repertoires. IBMJSSE2 must use IBMJCEFIPS when utilizing cryptographic services for FIPS.

The following FIPS 140-2 approved cryptographic providers that are the only devices that are supported with the FIPS option:

- IBMJCEFIPS (certificate 376)
- IBM Cryptography for C (ICC) (certificate 384)

The relevant certificates are listed on the NIST website: Cryptographic Module Validation Program FIPS 140-1 and FIPS 140-2 Pre-validation List

To unconfigure the FIPS provider, reverse the changes that you made in the previous steps. After you reverse the changes, verify that you have made the following changes to the `sas.client.props`, `soap.client.props`, and `java.security` files:

- In the `ssl.client.props` file, you must change the `com.ibm.security.useFIPS` value to `false`.
- In the `java.security` file, you must change the FIPS provider to a non-FIPS provider.

  If you are using the IBM SDK `java.security` file, you must change the first provider to a non-FIPS provider as shown in the following example:

```
#security.provider.1=com.ibm.crypto.fips.provider.IBMJCEFIPS
security.provider.1=com.ibm.crypto.provider.IBMJCE
security.provider.2=com.ibm.jsse.IBMJSSEProvider
security.provider.3=com.ibm.jsse2.IBMJSSEProvider2
security.provider.4=com.ibm.security.jgss.IBMJGSSProvider
security.provider.5=com.ibm.security.cert.IBMCertPath
#security.provider.6=com.ibm.crypto.pkcs11.provider.IBMPKCS11
```

  If you are using the Sun JDK `java.security` file, you must change the third provider to a non-FIPS provider as shown in the following example:

```
security.provider.1=sun.security.provider.Sun
security.provider.2=com.ibm.security.jgss.IBMJGSSProvider
security.provider.3=com.ibm.crypto.fips.provider.IBMJCEFIPS
security.provider.4=com.ibm.crypto.provider.IBMJCE
security.provider.5=com.ibm.jsse.IBMJSSEProvider
security.provider.6=com.ibm.jsse2.IBMJSSEProvider2
security.provider.7=com.ibm.security.cert.IBMCertPath
#security.provider.8=com.ibm.crypto.pkcs11.provider.IBMPKCS11
```

When you use the FIPS provider, the IBM Software Development Kit (SDK) might issue an error message that refers to a bad certificate. Although this error message can result from a multitude of reasons, review your security configuration and consider one of the following actions:

- Reduce the cipher suite level to Medium, if your cipher suite level is currently Strong.

  Note: You can change the cipher suite level for different levels of your environment such as the node or server level. Limit the change to the level of your environment where the change is necessary.

  To change the cipher suite, see the cipher suite groups information within the quality of protection settings documentation. If you change the cipher suite level to Medium, save and synchronize the changes. If the **Dynamically update the run time when SSL configuration changes occur** option is selected, you do not need to restart the server. However, if the option is not selected, you must restart the server for the changes to be effective. The **Dynamically update the run time when SSL configuration changes occur** option is available within the administrative console on the SSL certificate and key management panel. To access the panel, click **Security** > **SSL certificate and key management**.
- Install security level 3 FMID JCPT3A1 for the z/OS operating system.

  Security Level 3 FMID JCPT3A1 is the z/OS operating system implementation of the FIPS 140-2 approved cryptographic providers.

WebSphere Application Server security standards configurations

WebSphere Application Server can be configured to work with various security standards, which are typically used to meet security requirements required by the government.

Note: WebSphere Application Server integrates cryptographic modules, which include Java Secure Socket Extension (JSSE) and Java Cryptography Extension (JCE). Most of the requirements in the standards are handled in the JSSE and JCE, which must undergo the certification process to meet government standards. WebSphere Application Server must be configured to run with the JSSE and JCE enabled for a particular standard, and now supports the FIPS 140-2, SP800-131 and Suite B security standards.

- **FIPS 140-2** are Federal Information Processing Standards (FIPS) that specify requirements on cryptographic modules. WebSphere Application Server has been able to configure using this standard the longest. Many users can be configured to use this level, but might be required to move up to the newer SP800-131 or Suite B standard.

  See The National Institute of Standards and Technology web site for more information about the 140-2 standard.

To configure FIPS 140-2, see the topic “Configuring Federal Information Processing Standard Java Secure Socket Extension files”.

- **SP800-131** is a requirement originated by the National Institute of Standards and Technology (NIST) which requires longer key lengths and stronger cryptography. The specification also provides a transition configuration to enable users to move to a strict enforcement of SP800-131. The transition configuration also enables users to run with a mixture of settings from both FIPS140-2 and SP800-131. SP800-131 can be run in two modes, `transition` and `strict`.

  Strict enforcement of SP800-131 requirements on WebSphere Application server includes the following:

  – The use of the TLSv1.2 protocol for the Secure Sockets Layer (SSL) context.
  – Certificates must have a minimum length of 2048. Elliptical Curve (EC) certificate require a minimum size of 244-bit curves.
  – Certificates must be signed with a signature algorithm of SHA256, SHA384, or SHA512. Valid signatureAlgorithms include:
    - SHA256withRSA
    - SHA384withRSA
    - SHA512withRSA
    - SHA256withECDSA
    - SHA384withECDSA
    - SHA512withECDSA
  – SP800-131 approved Cipher suites

  See The National Institute of Standards and Technology web site for more details about the SP800-131 standard.

  See the topic “Transitioning WebSphere Application Server to the SP800-131 security standard” for information on how to transition WebSphere Application Server to the SP800-131 strict standard. See the topic “Configuring WebSphere Application Server for SP800-131 standard strict mode” for information on how to configure SP800-131.

- **Suite B** is a requirement originated by the National Security Agency (NSA) to specify a cryptographic interoperability strategy. This standard is similar to SP800-131 with some tighter restrictions. Suite B can run in 2 modes: 128-bit or 192-bit. If using 192-bit mode, users must apply the unrestricted policy file to the JDK so that the stronger cipher required for the 192-bit mode can be used.

  See the topic "Configuring WebSphere Application Server for the Suite B security standard" for information on to configure Suite B.

  Suite B requirements on WebSphere Application Server includes the following:

  – The use of the TLSv1.2 protocol for the SSL Context
  – Suite B approved Cipher suites
  – Certificates:
    - 128 bit mode certificates must be signed with SHA256withECDSA
    - 192 bit mode certificates must be signed with SHA384withECDSA
  – Ciphers:
    - SSL_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
    - SSL_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384.

Properties used to enable the Security Standards

The IBM virtual machine for Java (JVM) runs in a given security mode based on system properties. WebSphere Application Server sets these system properties based on security configuration settings. The security configuration can be set up through the administrative console or through scripting admin tasks. If an application sets these properties directly it can affect WebSphere Application Server SSL communication.

Table 104. JVM system properties to enable the security standard

Security standard	System property to enable	Valid values
FIPS 140-2	com.ibm.jsse2.usefipsprovider	`true` or `false`
SP800-131	com.ibm.jsse2.sp800-131	`transition` or `strict`
Suite B	com.ibm.jsse2.suiteB	128 or 192

WebSphere Application Server configuration clears out all of these properties if they are set, then sets them to how the security configuration is specified. WebSphere Application Server enables the security standard based on the custom properties set in the security configuration.

WebSphere Application Server security custom properties to enable the security standard

Table 105. WebSphere Application Server security custom properties to enable the security standard

Security standard	Security custom properties	JVM system property
FIPS 140-2	com.ibm.security.useFips=true com.ibm.websphere.security.FIPSLevel=FIPS140-2	com.ibm.jsse2.usefipsprovider=true
SP800-131- transition	com.ibm.security.useFips=true com.ibm.websphere.security.FIPSLevel=transition	com.ibm.jsse2.sp800-131=transition
SP800-131 – strict	com.ibm.security.useFips=true com.ibm.websphere.security.FIPSLevel=SP800-131	com.ibm.jsse2.sp800-131=strict
Suite B 128	com.ibm.security.useFips=true com.ibm.websphere.security.suiteB=128	com.ibm.jsse2.suiteB=128
Suite B 192	com.ibm.security.useFips=true com.ibm.websphere.security.suiteB=192	com.ibm.jsse2.suiteB=192

Convert certificates

Use this page to convert certificates to the selected security standard. All certificates in keystores associated with an Secure Socket Layer (SSL) configuration are converted.

To view this administrative console page, click **Security > SSL certificate and key management > Manage FIPS > Convert certificates**.

Algorithm: Specifies the signature algorithm used to convert the certificate to the selected security standard.

The following choices are available:

Strict Select for the strict enforcement of the SP800-131 standard.

Strict enforcement of SP800-131 requirements on WebSphere Application Server includes the following:

- The use of the TLSv1.2 protocol for the Secure Sockets Layer (SSL) context.
- Certificates must have a minimum length of 2048. Elliptical Curve (EC) certificate require a minimum size of 244-bit curves.
- Certificates must be signed with a signature algorithm of SHA256, SHA384, or SHA512. Valid signatureAlgorithms include:
  - SHA256withRSA
  - SHA384withRSA
  - SHA512withRSA
  - SHA256withECDSA
  - SHA384withECDSA
  - SHA512withECDSA

- SP800-131 approved Cipher suites

Suite B with 128 bit keys
This requirement places some tighter restrictions on the SP800-131 specification. 128-bit mode certificates must be signed with SHA256withECDSA.

Suite B with 192 bit keys
192 bit mode certificates must be signed with SHA384withECDSA.

To run in 192-bit mode, the unrestricted policy files must be in place on the JDK.

New certificate key size: Specifies the key size to use when converting the certificates.

The valid values are 512, 1024, 2048, 4096 and 8192. The default value is 2048.

Note: Elliptical Curve signature algorithms require specific sizes, so you must provide a size.

Certificates that can not be converted: Lists the certificates that are not compliant with the specified security standard and cannot be converted.

If certificates show up listed in this box, the server is unable to convert the certificates for you. You must replace these certificates with ones that meet Suite B requirements. Reasons why the server cannot convert the certificates might include:

- The certificate was created by a Certificate Authority (CA).
- The certificate is in a read-only keystore.

Manage FIPS

Use this page to disable Federal Information Processing Standards (FIPS) or to enable security standards that are required by the government.

WebSphere Application Server integrates cryptographic modules, which include Java Secure Socket Extension (JSSE) and Java Cryptography Extension (JCE). JSSE and JCE must undergo the certification process to meet government standards, and WebSphere Application Server must be configured to use them as specified by the standards.

To view this administrative console page, click **Security > SSL certificate and key management > Manage FIPS**.

Disable FIPS: Select to disable FIPS, which is the default.

Data type:	Default:	Range:
Boolean	Enabled	Enabled or Disabled

Enable FIPS 140-2: Select to enable FIPS 140-2. This option makes IBMJSSE2 and IBMJCEFIPS the active providers.

Federal Information Processing Standards (FIPS) specifies requirements on cryptographic modules. WebSphere Application Server has been able to configure using the FIPS 140-2 standard the longest. Many users can be configured to use this level, but might be required to move up to the newer SP800-131 or Suite B standard.

Data type:	Default:	Range:
Boolean	Enabled	Enabled or Disabled

Enable SP800-131: Select to enable SP800-131.

SP800-131 is a requirement originated by the National Institute of Standards and Technology (NIST) which requires longer key lengths and stronger cryptography. The specification also provides a transition configuration to enable users to move to a strict enforcement of SP800-131. The transition configuration also enables users to run with a mixture of settings from both FIPS140-2 and SP800-131. SP800-131 can be run in two modes, `transition` and `strict`.

Data type:	Default:	Range:
Boolean	Enabled	Enabled or Disabled

Enable Suite B: Accept 128 bit keys: Select to specify that suite B cryptography is used, and is configured to accept a 128-bit key size. Keystore certificate algorithms require Elliptical curve (EC) cryptography.

Data type:	Default:	Range:
Boolean	Enabled	Enabled or Disabled

Enable Suite B: Accept 192-bit keys: Select to specify that suite B cryptography is used, and is configured to accept a 192-bit key size. Keystore certificate algorithms require Elliptical curve (EC) cryptography.

Suite B can run in 2 modes: 128-bit or 192-bit. If using 192-bit mode, you must apply the unrestricted policy file to the JDK so that the stronger cipher required for the 192-bit mode can be used.

Data type:	Default:	Range:
Boolean	Enabled	Enabled or Disabled

Convert certificates: Select to convert certificates to the selected security standard. All certificates in keystores associated with an Secure Socket Layer (SSL) configuration are converted.

Configuring WebSphere Application Server for the Suite B security standard

You can configure WebSphere Application Server to use the new Suite B security standard.

Before you begin

Read the “WebSphere Application Server security standards configurations” topic for more background information regarding security standards.

About this task

The National Security Agency (NSA) created a cryptographic interoperability strategy called Suite B. It places specific requirements on the National Institute of Standards and Technology (NIST) SP800-131 standard.

Suite B requirements:

WebSphere Application Server must be compliant with the following Suite B requirements:

- SSL configuration must use the TLSv1.2 protocol.
- The com.ibm.jsse.suiteb system property must be set to 128 or 192.
- Certificates running in 128-bit mode must be created with the SHA256withECDSA signature algorithm. Certificates running in 192-bit mode must be created with the SHA384withECDSA signature algorithm.

  Note: To run in 192-bit mode, the unrestricted policy files must be in place on the JDK.

- Suite B approved cipher suites must be used.

To configure the server for the Suite B standard:

Procedure

1. Click **Security > SSL certificate and key management > Manage FIPS** To run in a Suite B mode, all of the certificates used for SSL on the server must be converted to certificates that comply with Suite B requirements.
2. To convert certificates, under Related Items click **Convert Certificates**.
3. Select the radio button labeled **128-bit or 192-bit** in the Algorithm box.

   Note: Elliptical Curve signature algorithms require specific sizes, so you must provide a size.
4. Click **Apply/Save**. If no certificates show up in the box labeled **Certificates that can not be converted**, then you can enable the standard.

   If certificates show up listed in the box labeled **Certificates that can not be converted**, the server is unable to convert the certificates for you. You must replace these certificates with ones that meet Suite B requirements. Reasons why the server cannot convert the certificates might include:
   - The certificate was created by a Certificate Authority (CA).
   - The certificate is in a read-only keystore.

   After certificates are converted to meet the Suite B specifications, follow the remaining steps to enable the Suite B standard.
5. Click **SSL certificate and key management > Manage FIPS**.
6. Select the **Suite B: Accept 128 bit key** for 128-bit mode or the **Suite B: Accept 192 bit key** for 192-bit mode.
7. Click **Apply/Save**.
8. Restart the servers and manually sync the nodes for the Suite B standard to take effect.

   When these changes are applied and the server is restarted, the SSL configurations on the server is modified to use the TLSv1.2 protocol, and the com.ibm.jsse.suiteb system property is set to the desired Suite B mode. The SSL configuration uses the appropriate SSL ciphers for the standard.

   There are wsadmin tasks also available that can enable the Suite B standard using scripting. :
   - Check the status of certificates for the security standard by using the listCertStatusForSecurityStandard task.
   - Convert certificates for the security standard by using the convertCertForSecurityStandard task.
   - Enable the security standard by using the enableFips task.
   - To see the security standard setting, use the getFipsInfo task.
9. Once the server is configured for SP800-131 strict mode, the `ssl.client.props` file must be modified so that administrative clients are running in SP800-131 strict mode. They are unable to make a SSL connection to the server with the change. Edit the `ssl.client.props` file by doing the following:
   a. Modify com.ibm.security.useFIPS to be set to `true`.
   b. Add the com.ibm.jsse.suiteb property, and set it to 128 or 192.
   c. Change the com.ibm.ssl.protocol property to TLSv1.2.

What to do next

The Suite B standard requires that the SSL connection use the TLSv1.2 protocol. For a browser to access the administrative console or an application, the browser must support and first be configured to use the TLSv1.2 protocol.

Note: When enabling the security standards on a Network Deployed, the node and deployment manager can be in an incompatible protocol state. Since configuring the security standard requires the server

to be restarted, it is recommended that all node agents and servers be stopped, leaving the deployment manager running. Once the configuration changes are made through the console, restart the deployment manager.

Manually sync the nodes with syncNode, and start the node agents and servers. To use syncNode, you might need to update the `ssl.client.props` file to communicate with the deployment manager.

Transitioning WebSphere Application Server to the SP800-131 security standard

The National Institute of Standards and Technology (NIST) Special Publications 800-131 standard strengthens algorithms and increases the key lengths to improve security. The standard also provides for a transition period to move to the new standard. You can configure WebSphere Application Server for SP800-131 standard transition mode.

Before you begin

Read the "WebSphere Application Server security standards configurations" topic for more background information regarding security standards.

About this task

The transition period enables a user to run in a mixed environment of settings not supported under the standard along with those that are supported. The NIST SP800-131 standard requires that users be configured for strict enforcement of the standard by a specific timeframe. See The National Institute of Standards and Technology web site for more details.

The transition options can be very useful when trying to get to `strict` SP800-131. The servers can accept a mixture old settings and new requirements. For example. they can convert certificates but continue to use the TLS protocol.

WebSphere Application Server can be configured to run SP800-131 in a `transition` mode or a `strict` mode. For information on how to configure strict mode. read the Configuring WebSphere Application Server for strict mode SP800-131 security standard topic.

To run in the SP800-131 transition mode, the server must be in a specific configuration setting as well. Other strict requirements can be include as wanted.

- The com.ibm.jsse2.sp800-131 system property must be set to `transition` for the JSSE to run in the transition mode.
- The SSL configuration protocols must be one of the TLS settings. Valid values include TLS, TLSv1, TLSv1.1, and TLSv1.2.

Procedure

1. Click **Security > SSL certificate and key management > Manage FIPS**.
2. Select the **Enable SP800-131** radio button.
3. Select the **Transition** radio button.
4. You have the choice to change the protocols in SSL configuration to TLSv1.2 by optionally selecting the **Update the SSL configuration to require TLSv1.2** box. If you do not select this box, all SSL configurations are set to TLS.
5. Click **Apply/Save**.
6. Restart the servers.

When these changes are applied, and the server is restarted, all of the SSL configuration on the server are modified to use the TLS or TLSv1.2 protocol, and the com.ibm.jsse2.sp800-131 system property is set to `transition`. The SSL configuration uses the appropriate SSL ciphers for the standard.

Before you can move to the strict mode certificate, the protocol in the configuration must meet the strict requirements.

You can go to directly to the SSL configuration and set protocols to TLSv1.2 by doing the following:

7. Click **Security > SSL certificate and key management > SSL Configurations**.
8. Select a SSL configuration from the collection panel.
9. Under Related Items, select **Quality of protection (QoP)**.
10. Select **TLSv1.2** from the pull-down box labeled Protocol
11. Click **Apply/Save**. To change the SSL protocol using scripting, the modifySSLConfig task can also be used.

    Certificates must have a minimum size of 2048 (244 if an Elliptical Curve certificate), and signed with SHA256, SHA384, or SHA512. You can create new ones on the console and replace the old one, or import certificates that meet the standards requirements.

    There are a number of options you can use to replace certificates.

    - Use the Convert Certificate panel. This panel converts all certificates to meet the standard specified.
      a. Click **Security > SSL certificate and key management > Manage FIPS > Convert Certificate**

         Note: If there are any certificates in the box labeled **Certificates** that can not be converted, then a certificate can not be converted using this option.
      b. Select the **Strict** radio button and choose which signatureAlgorithm to use when creating the new certificates from the pull-down box.
      c. Select the size of the certificate from the pull-down box labeled **New Certificate Key Size**. Note that Elliptical Curve signature algorithms require a specific size, so there is no need to provide a size.
      d. Click **Apply/Save**.

         The convertCertForSecurityStandard scripting task can also be used to convert all certificates to meet a specified standard.
    - Use the personal certificate panels to create new certificates and replace a certificate that does not meet the requirements by doing the following:
      a. Click **Security > SSL certificate and key management > Key stores and certificates**.
      b. Select a keystore from the collection panel.
      c. Select **Personal Certificate**.
         1) From the pull-down list on the Create button, select **Self-Signed Certificate**.
         2) Fill in an alias for the certificate. Select a signature algorithm for the certificate that is signed with SHA256, SHA384, or SHA512. Choose a size that is 2048 or greater. Note that Elliptical Curve signature algorithms require a specific size, so there is no need to specify a size.
         3) Click **Apply/Save**.
         4) Go back to the Personal certificate collection panel and select the certificate that does not meet the standard. Click **Replace**.
         5) On the Replace panel, select the certificate created that meets the standard from the pull-down list in the box labeled **Replace with**.
         6) Select **Delete old certificate** after replacement, and **Delete old signer boxes**.
         7) Click **Apply/Save**.

Note: To replace chained certificates, a root certificate must be created that meets the standard. Follow the previous navigation path to the root certificate in the defaultRootStore, then create a chained certificate with that new root certificate.

The createSelfSigneCertificate scripting task can also be used to create self-signed certificate. The replaceCertificate scripting task can also be used to replace the new certificate for the old one.

- Use the personal certificate panels to import certificates and to replace the certificate that does not meet the requirements. Some certificate come from external sources such as a Certificate Authority (CA).
  a. Click **Security > SSL certificate and key management > Key stores and certificates**.
  b. Select a keystore from the collection panel.
  c. Select **Personal Certificate**.
     1) Select **Import Certificate**.
     2) Fill in the information needed to access the certificate in an existing keystore file.
     3) Click **Apply/Save**.
     4) Go back to the Personal certificate collection panel and select the certificate that does not meet the standard. Click the **Replace** button.
     5) On the Replace panel, select the certificate created that meets the standard from the pull-down list in the box labeled **Replace with**. Select **Delete old certificate after replacement** and **Delete old signer boxes**.
     6) Click **Apply/Save**.

        The importCertificate scripting task can also be used to import a certificate. The replaceCertificate scripting task can also be used to replace the new certificate for the old one.

12. To enable strict SP800-131, click **Security > SSL certificate and key management > Manage FIPS**.
13. Click the **Enable SP800-131**.
14. Click the **Strict**.
15. Click **Apply/Save**.
16. Restart your servers and manually sync your nodes for the changes to take effect.
17. Configure the client `ssl.client.props` file for the transition mode SP800-131 standard. Once the server is configured for SP800-131 transition mode, the `ssl.client.props` file might need to modified so that the admin client can connect to the server.

    Edit the `ssl.client.props` file. Change the com.ibm.ssl.protocol property to match the protocol the server is using.
18. Configure the `client ssl.client.props` file for strict mode SP800-131 standard. Once the server is configured for SP800-131 strict mode, the `ssl.client.props` file must be modified so that the admin client is running in SP800-131 strict mode. It is not able to make a SSL connection to the server without the change.

    Edit the `ssl.client.props` file as follows:
    a. Modify the com.ibm.security.useFIPS to be set to`true`.
    b. Add the com.ibm.websphere.security.FIPSLevel=SP800-131 just below the useFips property.
    c. Change the com.ibm.ssl.protocol property to TLSv1.2

What to do next

The browser used to access the administrative console or an application must use a protocol that is compatible with the server. If the server is running in a transition mode, the browser must be set to use the protocol that matches the server. The SP800-131 standard requires that the SSL connection use the TLSv1.2 protocol, so the browser must support TLSv1.2 and use it to access the administrative console.

Configuring WebSphere Application Server for SP800-131 standard strict mode

You can configure WebSphere Application Server to use the SP800-131 standard strict mode.

Before you begin

Read the “WebSphere Application Server security standards configurations” topic for more background information regarding security standards.

About this task

The National Institute of Standards and Technology (NIST) Special Publications (SP) 800-131 standard strengthens algorithms and increases the key lengths to improve security. The standard also provides for a transition period to move to the new standard. The transition period enables a user to run in a mixed environment of settings not supported under the standard along with those that are supported. The NIST SP800-131 standard requires that users be configured for strict enforcement of the standard by a specific timeframe. See The National Institute of Standards and Technology web site for more details.

WebSphere Application Server can be configured to run SP800-131 in a `transition` mode or a `strict` mode. For instructions on how to configure transition mode, read the topic “Transitioning WebSphere Application Server to the SP800-131 Security Standard”.

To run in strict mode, there are several changes necessary to the server configuration:

- Secure Sockets Layer (SSL) configuration must use the TLSv1.2 protocol.
- The com.ibm.jsse2.sp800-131 system property must be set to `strict` for the JSSE to run in a strict SP800-131 mode.
- Certificates used for SSL communication must have a minimum length of 2048, and for Elliptical Curve (EC) certificates they must have a minimum length of 244.
- Certificates must be signed with a signature algorithm of SHA256, SHA384, or SHA512.
- SP800-131 approved cipher suites must be used.

.

Procedure

1. Click **Security > SSL certificate and key management > Manage FIPS** To run in a strict SP800-131 mode, all of the certificates used for SSL on the server must be converted to certificates that comply with the SP800-131 requirements.
2. To convert certificates, under Related Items, click **Convert Certificates**.
3. Select the radio button marked **Strict**, and choose which signatureAlgorithm to use when creating the new certificates from the pull-down box.
4. Select the size of the certificate from the pull-down box labeled **New Certificate Key Size**.

   Note: If you choose an Elliptical Curve signature algorithm, they require specific sizes; you are not able to fill in a size. The correct size is used instead.
5. If no certificates are displayed in the box labeled **Certificates that can not be converted**, click **Apply/Save**.
6. If certificates are displayed in the box labeled **Certificates that can not be converted**, the server is unable to convert the certificate for you. You must replace these certificates with ones that meet SP800-131 requirements. Reasons why the server can not convert a certificate for you include:
   - The certificate was created by a Certificate Authority (CA)
   - The certificate is in a read only keystore

Once certificates are converted to meet the SP800-131 specification, perform the following steps to enable SP800-131 strict mode.

7. Click **SSL certificate and key management > Manage FIPS**.
8. Enable the radio button labeled **Enable SP800-131**.
9. Enable the radio button labeled **Strict**.
10. Click **Apply/Save**.
11. Restart the servers and manually sync the nodes for the SP800-131 strict mode to take effect.

    When these changes are applied, and the server is restarted, all of the SSL configuration on the server are modified to use the TLSv1.2 protocol and the com.ibm.jsse2.sp800-131 system property is set to `strict`. The SSL configuration uses the appropriate SSL ciphers for the standard.

    There are several wsadmin tasks that can be used to enable strict SP800-131 using scripting

    - Check the status of certificates for the security standard by using the listCertStatusForSecurityStandard task.
    - Convert certificates for the security standard by using the convertCertForSecurityStandard task.
    - Enable the security standard by using the enableFips task.
    - To see the security standard setting, use the getFipsInfo task.
12. Once the server is configured for SP800-131 strict mode, the `ssl.client.props` file must be modified so that the admininstrative client is running in SP800-131 strict mode. They are not able to make a SSL connection to the server without the change.

    Edit the `ssl.client.props` file by doing the following:

    a. Modify com.ibm.security.useFIPS to be set to `true`.
    b. Add com.ibm.websphere.security.FIPSLevel=SP800-131 just below the useFips property.
    c. Change the com.ibm.ssl.protocol property to TLSv1.2.

What to do next

The SP800-131 standard strict mode requires that the SSL connection use the TLSv1.2 protocol. For a browser to access the administrative console or an application, the browser must support and first be configured to use the TLSv1.2 protocol.

gotcha: When enabling the security standards on a Network Deployment version of the product, the node and deployment manager can be in an incompatible protocol state. Since configuring the security standard requires the server to be restarted, it is recommended that all node agents and servers be stopped, leaving the deployment manager running. Once the configuration changes are made through the console, restart the deployment manager.

Manually sync the nodes with syncNode, and start the node agents and servers. To use syncNode, you might need to update the `ssl.client.props` file to communicate with the deployment manager.

Implementing tokens for security attribute propagation

As part of an extensible architecture, WebSphere Application Server enables you to implement your own tokens in which to propagate security attributes.

About this task

The following topics are covered in this section:

Procedure

- Implementing a custom propagation token
- Implementing a custom authorization token
- Implementing a custom a single sign-on token

- Implementing a custom authentication token
- Propagating a custom Java serializable object

Implementing a custom propagation token for security attribute propagation

This topic explains how you might create your own propagation token implementation, which is set on the running thread and propagated downstream.

About this task

The default propagation token usually is sufficient for propagating attributes that are not user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread by plugging in a custom login module into the inbound system login configurations. This task also might include encryption and decryption.

To implement a custom propagation token, you must complete the following steps:

Procedure

1. Write a custom implementation of the PropagationToken interface. Many different methods are available for implementing the PropagationToken interface. However, make sure that the methods that are required by the PropagationToken interface and the token interface are fully implemented.

   After you implement this interface, you can place it in the *app_server_root*/classes directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the server.policy file so that it has the required permissions for the server code.

   Tip: All of the token types that are defined by the propagation framework have similar interfaces. The token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the propagation token, might extend the abstract class and then most of the work is complete.

   To see an implementation of the propagation token, see “Example: com.ibm.wsspi.security.token.PropagationToken implementation” on page 948.
2. Add and receive the custom propagation token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. You also can add the implementation from an application. However, to deserialize the information, you need to plug in a custom login module, which is discussed in “Propagating a custom Java serializable object for security attribute propagation” on page 975. The WSSecurityPropagationHelper class has APIs that are used to set a propagation token on the thread and to retrieve the token from the thread to make updates.

   The code sample in “Example: Custom propagation token login module” on page 952 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback callback contains propagation data. If the callback does not contain propagation data, initialize a new custom propagation token implementation and set it on the thread. If the callback contains propagation data, look for your specific custom propagation token TokenHolder instance, convert the byte array back into your custom PropagationToken object, and set it back on the thread. The code sample shows both instances.

   You can add attributes any time your custom propagation token is added to the thread. If you add attributes between requests and the getUniqueId method changes, the Common Secure Interoperability Version 2 (CSIv2) client session is invalidated so that it can send the new information

downstream. Adding attributes between requests can affect performance. In many cases, you want the downstream requests to receive the new propagation token information.

To add the custom propagation token to the thread, call the WSSecurityPropagationHelper.addPropagationToken method. This call requires the WebSphereRuntimePerMission "setPropagationToken" Java 2 Security permission.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module for receiving serialized versions of your custom propagation token You can also add this login module to any of the application logins where you might want to generate your custom propagation token on the thread during the login. Alternatively, you can generate the custom PropagationToken implementation from within your application. However, to deserialize it, you need to add the implementation to the system login modules.

Results

After completing these steps, you have implemented a custom PropagationToken.

Example: com.ibm.wsspi.security.token.PropagationToken implementation:

Use this file to see an example of a propagation token implementation. The following sample code does not extend an abstract class, but implements the com.ibm.wsspi.security.token.PropagationToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

For information on how to implement a custom propagation token, see “Implementing a custom propagation token for security attribute propagation” on page 947.

Example: Custom propagation token login module:

This example shows how to determine if the login is an initial login or a propagation login.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
        Map sharedState, Map options)
 {
  // (For more information on what to do during initialization, see
     // Developing custom login modules for a system login configuration for JAAS.)
 }

 public boolean login() throws LoginException
 {
  // (For more information on what to do during login, see
     // Developing custom login modules for a system login configuration for JAAS.)

  // Handles the WSTokenHolderCallback to see if this is an initial
     // or propagation login.
  Callback callbacks[] = new Callback[1];
  callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

  try
  {
   callbackHandler.handle(callbacks);
  }
  catch (Exception e)
  {
   // handle exception
  }

  // Receives the ArrayList of TokenHolder objects (the serialized tokens)
  List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

  if (authzTokenList != null)
  {
   // Iterates through the list looking for your custom token
   for (int i=0; i<authzTokenList.size(); i++)
   {
    TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

    // Looks for the name and version of your custom PropagationToken implementation
    if (tokenHolder.getName().equals("
              com.ibm.websphere.security.token.CustomPropagationTokenImpl") &&
        tokenHolder.getVersion() == 1)
    {
     // Passes the bytes into your custom PropagationToken constructor
            //  to deserialize
     customPropToken = new
      com.ibm.websphere.security.token.CustomPropagationTokenImpl(tokenHolder.
                 getBytes());

    }
   }
  }
  else // This is not a propagation login. Create a new instance of
          // your PropagationToken implementation
  {
   // Adds a new custom propagation token. This is an initial login
   customPropToken = new com.ibm.websphere.security.token.CustomPropagationTokenImpl();

   // Adds any initial attributes
   if (customPropToken != null)
   {
    customPropToken.addAttribute("key1", "value1");
    customPropToken.addAttribute("key1", "value2");
    customPropToken.addAttribute("key2", "value1");
    customPropToken.addAttribute("key3", "something different");
   }
  }

  // Note: You can add the token to the thread during commit in case
     // something happens during the login.
 }

 public boolean commit() throws LoginException
 {
  // For more information on what to do during commit, see
     // Developing custom login modules for a system login configuration for JAAS.
  if (customPropToken != null)
  {
```

```
   // Sets the propagation token on the thread
   try
   {

    System.out.println(tc, "*** ADDED MY CUSTOM PROPAGATION TOKEN TO THE THREAD ***");
    // Prints out the values in the deserialized propagation token
    java.util.Enumeration keys = customPropToken.getAttributeNames();
    while (keys.hasMoreElements())
    {
     String key = (String) keys.nextElement();
     String[] list = (String[]) customPropToken.getAttributes(key);
     for (int k=0; k<list.length; k++)
     System.out.println("Key/Value: " + key + "/" + list[k]);
    }

    // This sets it on the thread using getName() + getVersion() as the key
    com.ibm.wsspi.security.token.WSSecurityPropagationHelper.addPropagationToken(
              customPropToken);
   }
   catch (Exception e)
   {
    // Handles exception
   }

   // Now you can verify that you have set it properly by trying to get
       // it back from the thread and print the values.
   try
   {
    // This gets the PropagationToken from the thread using getName()
          // and getVersion() parameters.
    com.ibm.wsspi.security.token.PropagationToken tempPropagationToken =
     com.ibm.wsspi.security.token.WSSecurityPropagationHelper.getPropagationToken
      ("com.ibm.websphere.security.token.CustomPropagationTokenImpl", 1);

    if  (tempPropagationToken != null)
    {
     System.out.println(tc, "*** RECEIVED MY CUSTOM PROPAGATION
               TOKEN FROM THE THREAD ***");
     // Prints out the values in the deserialized propagation token
     java.util.Enumeration keys = tempPropagationToken.getAttributeNames();
     while (keys.hasMoreElements())
     {
      String key = (String) keys.nextElement();
      String[] list = (String[]) tempPropagationToken.getAttributes(key);
      for (int k=0; k<list.length; k++)
      System.out.println("Key/Value: " + key + "/" + list[k]);
     }
    }
   }
   catch (Exception e)
   {
    // Handles exception
   }
  }
 }

 // Defines your login module variables
 com.ibm.wsspi.security.token.PropagationToken customPropToken = null;

}
```

Implementing a custom authorization token for security attribute propagation

This task explains how you might create your own AuthorizationToken implementation, which is set in the login Subject and propagated downstream.

About this task

The default AuthorizationToken usually is sufficient for propagating attributes that are user-specific. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread. This task also might include encryption and decryption.
- Affect the overall uniqueness of the Subject using the getUniqueID() application programming interface (API).

To implement a custom authorization token, you must complete the following steps:

Procedure

1. Write a custom implementation of the AuthorizationToken interface. There are many different methods for implementing the AuthorizationToken interface. However, make sure that the methods required by the AuthorizationToken interface and the token interface are fully implemented.

   After you implement this interface, you can place it in the *app_server_root*/classes directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the server.policy file so that it has the necessary permissions that are needed by the server code.

   Tip: All of the token types defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the AuthorizationToken, might extend the abstract class and then most of the work is completed.

   To see an implementation of AuthorizationToken, see "Example: com.ibm.wsspi.security.token.AuthorizationToken implementation"

2. Add and receive the custom AuthorizationToken during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, in order to deserialize the information, you must plug in a custom login module, which is discussed in "Propagating a custom Java serializable object for security attribute propagation" on page 975. After the object is instantiated in the login module, you can add the object to the Subject during the commit() method.

   If you only want to add information to the Subject to get propagated, see "Propagating a custom Java serializable object for security attribute propagation" on page 975. If you want to ensure that the information is propagated, want to do you own custom serialization, or want to specify the uniqueness for Subject caching purposes, then consider writing your own AuthorizationToken implementation.

   The code sample in "Example: custom AuthorizationToken login module" on page 958 shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback contains propagation data. If the callback does not contain propagation data, initialize a new custom AuthorizationToken implementation and set it into the Subject. If the callback contains propagation data, look for your specific custom AuthorizationToken TokenHolder instance, convert the byte[] back into your custom AuthorizationToken object, and set it back into the Subject. The code sample shows both instances.

   You can make your AuthorizationToken read-only in the commit phase of the login module. If you do not make the token read-only, then attributes can be added within your applications.

3. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule for receiving serialized versions of your custom authorization token.

   Because this login module relies on information in the sharedState added by the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule, add this login module after com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule. For information on how to add your custom login module to the existing login configurations, see Developing custom login modules for a system login configuration for JAAS.

Results

After completing these steps, you have implemented a custom AuthorizationToken.

Example: com.ibm.wsspi.security.token.AuthorizationToken implementation:

Use this file to see an example of a AuthorizationToken implementation. The following sample code does not extend an abstract class, but rather implements the com.ibm.wsspi.security.token.AuthorizationToken

interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if there are considerable differences between how you handle the various token implementations.

For information on how to implement a custom AuthorizationToken, see “Implementing a custom authorization token for security attribute propagation” on page 953.

 java.util.Map _sharedState = null;
}
```

Implementing a custom single sign-on token for security attribute propagation

You can create your own single sign-on token implementation. The single sign-on token implementation is set in the login Subject and added to the HTTP response as an HTTP cookie.

About this task

The cookie name is the concatenation of the SingleSignonToken.getName application programming interface (API) and the SingleSignonToken.getVersion API. There is no delimiter. When you add a single sign-on token to the Subject, it also gets propagated horizontally and downstream in case the Subject is used for other web requests. You must deserialize your custom single sign-on token when you receive it from a propagation login. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. Encrypt the information because it is out to the HTTP response and is available on the Internet. You must deserialize or decrypt the bytes at the target and add that information back into the Subject.
- Affect the overall uniqueness of the Subject using the getUniqueID API.

To implement a custom single sign-on token, complete the following steps:

Procedure

1. Write a custom implementation of the SingleSignonToken interface.

   Many different methods are available for implementing the SingleSignonToken interface. However, make sure the methods that are required by the SingleSignonToken interface and the token interface are fully implemented.

   After you implement this interface, you can place it in the *app_server_root*/classes directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the server.policy file so that it has the required permissions for the server code.

   Tip: All of the token types that are defined by the propagation framework have similar interfaces. Basically, the token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the single sign-on token, might extend the abstract class and then most of the work is complete.

   To see an implementation of the single sign-on token, see “Example: A com.ibm.wsspi.security.token.SingleSignonToken implementation” on page 961

2. Add and receive the custom single sign-on token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system

login configurations. However, to deserialize the information, you need to plug in a custom login module, which is discussed in a subsequent step. After the object is instantiated in the login module, you can add it to the Subject during the commit method.

The code sample in “Example: A custom single sign-on token login module” on page 965, shows how to determine if the login is an initial login or a propagation login. The difference is whether the WSTokenHolderCallback callback contains propagation data. If the callback does not contain propagation data, initialize a new custom single sign-on token implementation and set it into the Subject. Also, look for the HTTP cookie from the HTTP request if the HTTP request object is available in the callback. You can get your custom single sign-on token both from a horizontal propagation login and from the HTTP request. However, it is recommended that you make the token available in both places because then the information arrives at any front-end application server, even if that server does not support propagation.

You can make your single sign-on token read-only in the commit phase of the login module. If you make the token read-only, additional attributes cannot be added within your applications.

Restriction:

- HTTP cookies have a size limitation. Size restrictions should be included in the documentation for your specific browser.
- The WebSphere Application Server runtime does not handle cookies that it does not generate, so this cookie is not used by the runtime.
- The SingleSignonToken object, when in the Subject, does affect the cache lookup of the Subject if you return something in the getUniqueID method.

3. Get the HTTP cookie from the HTTP request object during login or from an application. The sample code that is found in “Example: An HTTP cookie retrieval” on page 966 shows how you can retrieve the HTTP cookie from the HTTP request, decode the cookie so that it is back to your original bytes, and create your custom SingleSignonToken object from the bytes.
4. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule for receiving serialized versions of your custom propagation token. Because this login module relies on information in the sharedState state that is added by the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module, add this login module after the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module.

   For information on adding your custom login module into the existing login configurations, see Developing custom login modules for a system login configuration for JAAS.

Results

After completing these steps, you have implemented a custom single sign-on token.

Example: A com.ibm.wsspi.security.token.SingleSignonToken implementation:

Use this file to see an example of a single sign-on implementation. The following sample code does not extend an abstract class, but implements the com.ibm.wsspi.security.token.SingleSignonToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

For information on how to implement a custom single sign-on token, see “Implementing a custom single sign-on token for security attribute propagation” on page 960.

```

Example: A custom single sign-on token login module:

This file shows how to determine if the login is an initial login or a propagation login.

For information on initialization and on what to do during login and commit, see Developing custom login modules for a system login configuration for JAAS.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
     Map sharedState, Map options)
 {
  _sharedState = sharedState;
 }

 public boolean login() throws LoginException
 {
     // Handles the WSTokenHolderCallback to see if this is an initial or
     // propagation login.
  Callback callbacks[] = new Callback[1];
  callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

  try
  {
   callbackHandler.handle(callbacks);
  }
  catch (Exception e)
  {
   // handle exception
  }

  // Receives the ArrayList of TokenHolder objects (the serialized tokens)
  List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

  if (authzTokenList != null)
  {
   // iterate through the list looking for your custom token
   for (int i=0; i
   for (int i=0; i<authzTokenList.size(); i++)
   {
    TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

    // Looks for the name and version of your custom SingleSignonToken
          // implementation
    if (tokenHolder.getName().equals("myCookieName")
              && tokenHolder.getVersion() == 1)
    {
     // Passes the bytes into your custom SingleSignonToken constructor
            // to deserialize
```

```
    customSSOToken = new
     com.ibm.websphere.security.token.CustomSingleSignonTokenImpl
                 (tokenHolder.getBytes());

   }
  }
 }
 else
        // This is not a propagation login. Create a new instance of your
        // SingleSignonToken implementation
 {
     // Gets the principal from the default SingleSignonToken. This principal
     //  must match all tokens.
  defaultAuthToken = (com.ibm.wsspi.security.token.AuthenticationToken)
   sharedState.get(com.ibm.wsspi.security.auth.callback.Constants.WSAUTHTOKEN_KEY);
  String principal = defaultAuthToken.getPrincipal();

  // Adds a new custom single sign-on (SSO) token. This is an initial login.
      //  Pass the principal into the constructor
  customSSOToken = new com.ibm.websphere.security.token.
         CustomSingleSignonTokenImpl(principal);

  // add any initial attributes
  if (customSSOToken != null)
  {
   customSSOToken.addAttribute("key1", "value1");
   customSSOToken.addAttribute("key1", "value2");
   customSSOToken.addAttribute("key2", "value1");
   customSSOToken.addAttribute("key3", "something different");
  }
 }

    // Note: You can add the token to the Subject during commit in case something
    // happens during the login.
}

public boolean commit() throws LoginException
{
 if (customSSOToken != null)
 {
  // Sets the customSSOToken token into the Subject
  try
  {
   public final SingleSignonToken customSSOTokenPriv = customSSOToken;
         // Do this in a doPrivileged code block so that application code does not
         // need to add additional permissions
   java.security.AccessController.doPrivileged(new java.security.PrivilegedAction()
   {
    public Object run()
    {
     try
     {
      // Adds the custom SSO token if it is not null and
                //  not already in the Subject
                            if ((customSSOTokenPriv != null) &&
        (!subject.getPrivateCredentials().
                        contains(customSSOTokenPriv)))
      {
       subject.getPrivateCredentials().
                    add(customSSOTokenPriv);
      }
     }
     catch (Exception e)
     {
      throw new WSLoginFailedException (e.getMessage(), e);
     }

     return null;
    }
   });
  }
  catch (Exception e)
  {
   throw new WSLoginFailedException (e.getMessage(), e);
  }
 }
}

// Defines your login module variables
com.ibm.wsspi.security.token.SingleSignonToken customSSOToken = null;
com.ibm.wsspi.security.token.AuthenticationToken defaultAuthToken = null;
java.util.Map _sharedState = null;
}
```

Example: An HTTP cookie retrieval:

The following example shows you how to retrieve a cookie from an HTTP request, decode the cookie so that it is back to your original bytes, and create your custom SingleSignonToken object from the bytes. This example shows how to complete these steps from a login module. However, you also can complete these steps using a servlet.

For information on what to do during initialization, login and commit, see Developing custom login modules for a system login configuration for JAAS.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
     Map sharedState, Map options)
 {
  _sharedState = sharedState;
 }

 public boolean login() throws LoginException
 {
     // Handles the WSTokenHolderCallback to see if this is an
     // initial or propagation login.
  Callback callbacks[] = new Callback[2];
  callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");
  callbacks[1] = new WSServletRequestCallback("HttpServletRequest: ");

  try
  {
   callbackHandler.handle(callbacks);
  }
  catch (Exception e)
  {
   // Handles the exception
  }

  // receive the ArrayList of TokenHolder objects (the serialized tokens)
  List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();
  javax.servlet.http.HttpServletRequest request =
         ((WSServletRequestCallback) callbacks[1]).getHttpServletRequest();

  if (request != null)
  {

   // Checks if the cookie is present
   javax.servlet.http.Cookie[] cookies = request.getCookies();
   String[] cookieStrings = getCookieValues (cookies, "myCookeName1");

   if (cookieStrings != null)
   {
    String cookieVal = null;
    for (int n=0;n<cookieStrings.length;n++)
    {
     cookieVal = cookieStrings[n];
     if (cookieVal.length()>0)
     {
               // Removes the cookie encoding from the cookie to get
               // your custom bytes
      byte[] cookieBytes =
       com.ibm.websphere.security.WSSecurityHelper.
                     convertCookieStringToBytes(cookieVal);
      customSSOToken =
       new com.ibm.websphere.security.token.
                     CustomSingleSignonTokenImpl(cookieBytes);

               // Now that you have your cookie from the request,
               // you can do something with it here, or add it
               // to the Subject in the commit() method for use later.

```

Implementing a custom authentication token for security attribute propagation

This topic explains how you might create your own authentication token implementation, which is set in the login Subject and propagated downstream.

About this task

With this implementation you can specify an authentication token that can be used by a custom login module or application. Consider writing your own implementation if you want to accomplish one of the following tasks:

- Isolate your attributes within your own implementation.
- Serialize the information using custom serialization. You must deserialize the bytes at the target and add that information back on the thread. This task also might include encryption and decryption.
- Affect the overall uniqueness of the Subject using the getUniqueID application programming interface (API).

Important: Custom authentication token implementations are not used by the security runtime in WebSphere Application Server to enforce authentication. WebSphere Application Security runtime uses this token in the following situations only:

- Call the getBytes method for serialization
- Call the getForwardable method to determine whether to serialize the authentication token.
- Call the getUniqueId method for uniqueness
- Call the getName and the getVersion methods for adding serialized bytes to the token holder that is sent downstream

All of the other uses are custom implementations.

To implement a custom authentication token, you must complete the following steps:

Procedure

1. Write a custom implementation of the AuthenticationToken interface. Many different methods are available for implementing the AuthenticationToken interface. However, make sure the methods that are required by the AuthenticationToken interface and the token interface are fully implemented. After you implement this interface, you can place it in the *app_server_root*/classes directory. Alternatively, you can place the class in any private directory. However, make sure that the WebSphere Application Server class loader can locate the class and that it is granted the appropriate permissions. You can add the Java archive (JAR) file or directory that contains this class into the server.policy file so the class has the necessary permissions required by the server code.

   Tip: All of the token types that are defined by the propagation framework have similar interfaces. The token types are marker interfaces that implement the com.ibm.wsspi.security.token.Token interface. This interface defines most of the methods. If you plan to implement more than one token type, consider creating an abstract class that implements the com.ibm.wsspi.security.token.Token interface. All of your token implementations, including the authentication token, might extend the abstract class and then most of the work is complete.

   To see an implementation of the AuthenticationToken interface, see “Example: A com.ibm.wsspi.security.token.AuthenticationToken implementation” on page 970.
2. Add and receive the custom authentication token during WebSphere Application Server logins. This task is typically accomplished by adding a custom login module to the various application and system login configurations. However, to deserialize the information you must plug in a custom login module. After the object is instantiated in the login module, you can add the object to the Subject during the commit method.

   If you only want to add information to the Subject to get propagated, see “Propagating a custom Java serializable object for security attribute propagation” on page 975. If you want to ensure that the information is propagated, do your own custom serialization, or specify the uniqueness for Subject caching purposes, consider writing your own authentication token implementation.

   The code sample in “Example: A custom authentication token login module” on page 974, shows how to determine if the login is an initial login or a propagation login. The difference between these login types is whether the WSTokenHolderCallback callback contains propagation data. If the callback does not contain propagation data, initialize a new custom authentication token implementation and set it into the Subject. If the callback contains propagation data, look for your specific custom authentication token TokenHolder instance, convert the byte array back into your custom AuthenticationToken object, and set it back into the Subject. The code sample shows both instances.

   You can make your authentication token read-only in the commit phase of the login module. If you do not make the token read-only, attributes can be added within your applications.
3. Add your custom login module to WebSphere Application Server system login configurations that already contain the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module for receiving serialized versions of your custom authorization token.

Because this login module relies on information in the shared state that is added by the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module, add this login module after the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule login module. For information on how to add your custom login module to the existing login configurations, see Developing custom login modules for a system login configuration for JAAS.

Results

After completing these steps, you have implemented a custom authentication token.

Example: A com.ibm.wsspi.security.token.AuthenticationToken implementation:

The following example illustrates an authentication token implementation. The following sample code does not extend an abstract class, but rather implements the com.ibm.wsspi.security.token.AuthenticationToken interface directly. You can implement the interface directly, but it might cause you to write duplicate code. However, you might choose to implement the interface directly if considerable differences exist between how you handle the various token implementations.

```
package com.ibm.websphere.security.token;

import com.ibm.websphere.security.WSSecurityException;
import com.ibm.websphere.security.auth.WSLoginFailedException;
import com.ibm.wsspi.security.token.*;
import com.ibm.websphere.security.WebSphereRuntimePermission;
import java.io.ByteArrayOutputStream;
import java.io.ByteArrayInputStream;
import java.io.DataOutputStream;
import java.io.DataInputStream;
import java.io.ObjectOutputStream;
import java.io.ObjectInputStream;
import java.io.OutputStream;
import java.io.InputStream;
import java.util.ArrayList;

Example: A custom authentication token login module:

This examples shows how to determine if the login is an initial login or a propagation login.

For information on what to do during initialization, login and commit, see Developing custom login modules for a system login configuration for JAAS.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
    Map sharedState, Map options)
 {
  _sharedState = sharedState;
 }

 public boolean login() throws LoginException
 {
  // Handles the WSTokenHolderCallback to see if this is an initial or
     // propagation login.
  Callback callbacks[] = new Callback[1];
  callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

  try
  {
   callbackHandler.handle(callbacks);
  }
  catch (Exception e)
  {
   // Handles exception
  }

  // Receives the ArrayList of TokenHolder objects (the serialized tokens)
  List authzTokenList = ((WSTokenHolderCallback) callbacks[0]).getTokenHolderList();

  if (authzTokenList != null)
  {
   // Iterates through the list looking for your custom token
   for (int i=0; i<authzTokenList.size(); i++)
   {
    TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

          // Looks for the name and version of your custom AuthenticationToken
          // implementation
    if (tokenHolder.getName().equals("your_oid_name") && tokenHolder.getVersion() == 1)
    {
            // Passes the bytes into your custom AuthenticationToken constructor
            // to deserialize
     customAuthzToken = new
      com.ibm.websphere.security.token.
               CustomAuthenticationTokenImpl(tokenHolder.getBytes());

    }
   }
  }
  else
          // This is not a propagation login. Create a new instance of your
          // AuthenticationToken implementation
  {
        //  Gets the principal from the default AuthenticationToken. This principal
        //  should match all default tokens.
        //  Note: WebSphere Application Server runtime only enforces this for
        //  default tokens. Thus, you can choose
        //  to do this for custom tokens, but it is not required.
   defaultAuthToken = (com.ibm.wsspi.security.token.AuthenticationToken)
    sharedState.get(com.ibm.wsspi.security.auth.callback.Constants.WSAUTHTOKEN_KEY);
   String principal = defaultAuthToken.getPrincipal();

       // Adds a new custom authentication token. This is an initial login. Pass
       // the principal into the constructor
   customAuthToken = new com.ibm.websphere.security.token.
          CustomAuthenticationTokenImpl(principal);

   // Adds any initial attributes
   if (customAuthToken != null)
   {
    customAuthToken.addAttribute("key1", "value1");
    customAuthToken.addAttribute("key1", "value2");
    customAuthToken.addAttribute("key2", "value1");
    customAuthToken.addAttribute("key3", "something different");
   }
  }
```

```
    // Note: You can add the token to the Subject during commit in case
    // something happens during the login.
}

}
```

Propagating a custom Java serializable object for security attribute propagation

This document describes how to add an object into the Subject from a login module and describes other infrastructure considerations to make sure that the Java object gets propagated.

Before you begin

Prior to completing this task, verify that security propagation is enabled in the administrative console.

About this task

With security attribute propagation enabled, you can propagate data either horizontally with single sign-on (SSO) enabled or downstream using Common Secure Interoperability Version 2 (CSIv2). When a login occurs, either through an application login configuration or a system login configuration, a custom login module can be plugged in to add Java serialized objects into the Subject during login. This document describes how to add an object into the Subject from a login module and describes other infrastructure considerations to make sure that the Java object gets propagated.

Procedure

1. Add your custom Java object into the Subject from a custom login module. A two-phase process exists for each Java Authentication and Authorization Service (JAAS) login module. WebSphere Application Server completes the following processes for each login module present in the configuration:

login method

In this step, the login configuration callbacks are analyzed, if necessary, and the new objects or credentials are created.

commit method

In this step, the objects or credentials that are created during login are added into the Subject.

After a custom Java object is added into the Subject, WebSphere Application Server serializes the object on the sending server, deserializes the object on the receiving server, and adds the object back into the Subject downstream. However, some requirements exist for this process to occur successfully. For more information on the JAAS programming model, see the JAAS information provided in the Security: Resources for learning article.

Important: Whenever you plug a custom login module into the login infrastructure of WebSphere Application Server, make sure that the code is trusted. When you put the classes together in a Java archive (JAR) file and add the file to the *app_server_root*/lib/ext/ directory, the login module has Java 2 Security AllPermissions permissions . It is recommended that you add your login module and other infrastructure classes into any private directory. However, you must modify the *profile_root*/properties/server.policy file to make sure that your private directory, Java archive (JAR) file, or both have the permissions required to run the application programming interfaces (API) that are called from the login module. Because the login module might be run after the application code on the call stack, you might add doPrivileged code so that you do not need to add additional properties to your applications.

The following code sample shows how to add doPrivileged code. For information on what to do during initialization, login and commit, see Developing custom login modules for a system login configuration for JAAS.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
     Map sharedState, Map options)
 {

 }

 public boolean login() throws LoginException
 {
     // Construct callback for the WSTokenHolderCallback so that you
     // can determine if
     // your custom object has propagated
    Callback callbacks[] = new Callback[1];
    callbacks[0] = new WSTokenHolderCallback("Authz Token List: ");

    try
    {
         _callbackHandler.handle(callbacks);
    }
    catch (Exception e)
    {
    throw new LoginException (e.getLocalizedMessage());
    }

    // Checks to see if any information is propagated into this login
    List authzTokenList = ((WSTokenHolderCallback) callbacks[1]).
            getTokenHolderList();

    if (authzTokenList != null)
    {
        for (int i = 0; i< authzTokenList.size(); i++)
             {
            TokenHolder tokenHolder = (TokenHolder)authzTokenList.get(i);

                  //  Look for your custom object. Make sure you use
                  //  "startsWith"because there is some data appended
                  //  to the end of the name indicating in which Subject
                  //  Set it belongs. Example from getName():
                  //  "com.acme.CustomObject (1)". The class name is
                  //  generated at the sending side by calling the
                  //  object.getClass().getName() method. If this object
                  //  is deserialized by WebSphere Application Server,
                  //  then return it and you do not need to add it here.
                  //  Otherwise, you can add it below.
                  //  Note: If your class appears in this list and does
                  //  not use custom serialization (for example, an
                  //  implementation of the Token interface described in
```

```
                //  the Propagation Token Framework), then WebSphere
                //  Application  Server automatically deserializes the
                //  Java object for you. You might just return here if
                //  it is found in the list.

            if (tokenHolder.getName().startsWith("com.acme.CustomObject"))
           return true;
       }
    }
       //  If you get to this point, then your custom object has not propagated
        myCustomObject = new com.acme.CustomObject();
        myCustomObject.put("mykey", "mydata");
}

public boolean commit() throws LoginException
{
 try
 {
      // Assigns a reference to a final variable so it can be used in
      // the doPrivileged block
  final com.acme.CustomObject myCustomObjectFinal = myCustomObject;
  // Prevents your applications from needing a JAAS getPrivateCredential
      // permission.
  java.security.AccessController.doPrivileged(new java.security.
          PrivilegedExceptionAction()
  {
   public Object run() throws java.lang.Exception
   {
           // Try not to add a null object to the Subject or an object
           // that already exists.
    if (myCustomObjectFinal != null && !subject.getPrivateCredentials().
              contains(myCustomObjectFinal))
    {
             // This call requires a special Java 2 Security permission,
             // see the JAAS application programming interface (API)
             // documentation.
     subject.getPrivateCredentials().add(myCustomObjectFinal);
    }
    return null;
   }
  });
 }
 catch (java.security.PrivilegedActionException e)
 {
  // Wraps the exception in a WSLoginFailedException
  java.lang.Throwable myException = e.getException();
  throw new WSLoginFailedException (myException.getMessage(), myException);
 }
}

// Defines your login module variables
com.acme.CustomObject myCustomObject = null;
}
```

2. Verify that your custom Java class implements the java.io.Serializable interface. An object that is added to the Subject must be serialized if you want the object to propagate. For example, the object must implement the java.io.Serializable interface. If the object is not serialized, the request does not fail, but the object does not propagate. To make sure an object that is added to the Subject is propagated, implement one of the token interfaces that is defined in topics about security attribute propagation or add attributes to one of the following existing default token implementations:

   AuthorizationToken
   Add attributes if they are user-specific.

   PropagationToken
   Add attributes that are specific to an invocation.

   If you are careful adding custom objects and follow all the steps to make sure that WebSphere Application Server can serialize and deserialize the object at each hop, then it is sufficient to use custom Java objects only.

3. Verify that your custom Java class exists on all of the systems that might receive the request.

   When you add a custom object into the Subject and expect WebSphere Application Server to propagate the object, put the class definitions together in a Java archive (JAR) file and add the file to the *app_server_root*/lib/ext/ directory on all of the nodes where serialization or deserialization might occur. Also, verify that the Java class versions are the same.

4. Verify that your custom login module is configured in all of the login configurations used in your environment where you need to add your custom object during a login. Any login configuration that interacts with WebSphere Application Server generates a Subject that might be propagated outbound

for an Enterprise JavaBeans (EJB) request. If you want WebSphere Application Server to propagate a custom object in all cases, make sure that the custom login module is added to every login configuration that is used in your environment. For more information, see Developing custom login modules for a system login configuration for JAAS.

5. Verify that security attribute propagation is enabled on all of the downstream servers that receive the propagated information. When an EJB request is sent to a downstream server and security attribute propagation is disabled on that server, only the authentication token is sent for backwards compatibility. Therefore, you must review the configuration to verify that propagation is enabled in all of the cells that might receive requests. You must check several places in the administrative console to make sure propagation is fully enabled.
6. Add any custom objects to the propagation exclude list that you do not want to propagate. You can configure a property to exclude the propagation of objects that match specific class names, package names, or both. For example, you can have a custom object that is related to a specific process. If the object is propagated, it does not contain valid information. You must tell WebSphere Application Server not to propagate this object. Complete the following steps to specify the object in the propagation exclude list, using the administrative console:
   a. Click **Security > Global security > Custom properties > New**.
   b. Add `com.ibm.ws.security.propagationExcludeList` in the **Name** field.
   c. Add the name of the custom object in the **Value** field. You can add a list of custom objects to the propagation exclude list, separated by a colon (:). For example, you might enter `com.acme.CustomLocalObject:com.acme.private.*`. You can enter a class name such as `com.acme.CustomLocalObject` or a package name such as `com.acme.private.*`. In this example, WebSphere Application Server does not propagate any class that equals `com.acme.CustomLocalObject` or begins with `com.acme.private.`

      Although you can add custom objects to the propagation exclude list, you must be aware of a side effect. WebSphere Application Server stores the opaque token, or the serialized Subject contents, in a local cache for the life of the single sign-on (SSO) token. The life of the SSO token, which has a default of two hours, is configured in the SSO properties on the administrative console. The information that is added to the opaque token includes only the objects not in the exclude list.

      Ensure that your SSO token timeout value is greater that the authentication cache timeout value. To modify the authentication cache, see the documentation about the authentication cache settings.

Results

As a result of this task, custom Java serializable objects are propagated horizontally or downstream. For more information on the differences between horizontal and downstream propagation, see topics about security attribute propagation or add attributes to one of the following existing default token implementations:.

Developing a custom interceptor for trust associations

You can define the interceptor class method that you want to use. WebSphere Application Server supports two trust association interceptor interfaces: com.ibm.wsspi.security.TrustAssociationInterceptor and com.ibm.wsspi.security.tai.TrustAssociationInterceptor.

Before you begin

If you are using a third party reverse proxy server other than Tivoli® WebSEAL, you must provide an implementation class for the product interceptor interface for your proxy server. This article describes the com.ibm.wsspi.security.TrustAssociationInterceptor.java interface that you must implement.

Note: The Trust Association Interceptor (TAI) interface (com.ibm.wsspi.security.tai.TrustAssociationInterceptor) supports several new features and is different from the existing com.ibm.wsspi.security.TrustAssociationInterceptor interface.

Procedure

1. Define the interceptor class method. WebSphere Application Server provides the interceptor Java interface, com.ibm.wsspi.security.TrustAssociationInterceptor, which defines the following methods:
   - **public boolean isTargetInterceptor(HttpServletRequest req)** creates WebTrustAssociationException;.

     The isTargetInterceptor method determines whether the request originated with the proxy server associated with the interceptor. The implementation code must examine the incoming request object and determine if the proxy server forwarding the request is a valid proxy server for this interceptor. The result of this method determines whether the interceptor processes the request or not.
   - **public void validateEstablishedTrust (HttpServletRequest req)** creates WebTrustAssociationException;.

     The validateEstablishedTrust method determines if the proxy server from which the request originated is trusted or not. This method is called after the isTargetInterceptor method. The implementation code must authenticate the proxy server. The authentication mechanism is proxy-server specific. For example, in the product implementation for the WebSEAL server, this method retrieves the basic authentication information from the HTTP header and validates the information against the user registry used by WebSphere Application Server. If the credentials are invalid, the code creates the WebTrustAssociationException, indicating that the proxy server is not trusted and the request is to be denied.
   - **public String getAuthenticatedUsername(HttpServletRequest req)** creates WebTrustAssociationException;.

     The getAuthenticatedUsername method is called after trust is established between the proxy server and WebSphere Application Server. The product has accepted the proxy server authentication of the request and must now authorize the request. To authorize the request, the name of the original requestor must be subjected to an authorization policy to determine if the requestor has the necessary privilege. The implementation code for this method must extract the user name from the HTTP request header and determine if that user is entitled to the requested resource. For example, in the product implementation for the WebSEAL server, the method looks for an iv-user attribute in the HTTP request header and extracts the user ID associated with it for authorization.
2. Configuring the interceptor. To make an interceptor configurable, the interceptor must extend com.ibm.wsspi.security.WebSphereBaseTrustAssociationInterceptor. Implement the following methods:
   public int init (java.util.Properties props);

   The init(Properties) method accepts a java.util.Properties object, which contains the set of properties required to initialize the interceptor. All the properties set for an interceptor (by using the **Custom Properties** link for that interceptor or using scripting) is sent to this method. The interceptor then can use these properties to initialize itself. For example, in the product implementation for the WebSEAL server, this method reads the hosts and ports so that a request coming in can be verified to originate from trusted hosts and ports. A return value of **0** implies that the interceptor initialization is successful. Any other value implies that the initialization is not successful and the interceptor is ignored.

   Applicability of the following list

   If a previous implementation of the trust association interceptor returns a different error status you can either change your implementation to match the expectations or make one of the following changes:
   - Add the com.ibm.wsspi.security.trustassociation.initStatus property in the trust association interceptor custom properties. Set the property to the value that indicates that the interceptor is successfully initialized. All of the other possible values imply failure. In case of failure, the corresponding trust association interceptor is not used.
   - Add the com.ibm.wsspi.security.trustassociation.ignoreInitStatus property in the trust association interceptor custom properties. Set the value of this property to **true**, which tells WebSphere Application Server to ignore the status of this method. If you add this property to the custom properties, WebSphere Application Server does not check the return status, which is similar to previous versions of WebSphere Application Server.

public void cleanup ();
This method is called when the application server is stopped. It is used to prepare the interceptor for termination.

public void setVersion (String s);
This method is optional. The method is used to set the version and is for informational purpose only. The default value is `Unspecified`.

You must configure the following methods implemented by the custom interceptor implementation. **This listing only shows the methods and does not include any implementation.**

```
*********************************************************************
import java.util.*;
import javax.servlet.http.HttpServletRequest;
import com.ibm.websphere.security.*;

public class myTAIImpl extends WebSphereBaseTrustAssociationInterceptor
      implements TrustAssociationInterceptor
{

      public myTAIImpl ()
      {
      }

      public boolean isTargetInterceptor (HttpServletRequest req)
          throws WebTrustAssociationException
      {

           //return true if this is the target interceptor, else return false.
      }

      public TAIResult negotiateValidateandEstablishTrust (HttpServletRequest req, HttpServletResponse res)
           throws WebTrustAssociationFailedException
      {
           //validate the request and establish trust.
           //create and return the TAIResult
public int initialize (Properties props)
      {
           //initialize the implementation. If successful return 0, else return 1.
      }

     public String getVersion()
     {
        //Return version
     }

   public String getType()
     {
        //Return type
     }

      public void cleanup ()
      {
           //Cleanup code.

      }

}
```

Note: If the init(Properties) method is implemented as described previously in your custom interceptor, this note does not apply to your implementation, and you can move on to the next step. Previous versions of com.ibm.wsspi.security.WebSphereBaseTrustAssociationInterceptor include the public int init (String propsfile) method. This method is no longer required since the interceptor properties are not read from a file. The properties are now entered in the administrative console **Custom Properties** link of the interceptor using the administrative console or scripts. These properties then are made available to your implementation in the

init(Properties) method. However, for backward compatibility, the init(String) method still is supported. The init(String) method is called by the default implementation of init(Properties) as shown in the following example.

```
// Default implementation of init(Properties props) method. A Custom
   // implementation should override this.
   public int init (java.util.Properties props)
   {
      String type =
       props.getProperty("com.ibm.wsspi.security.trustassociation.types");
      String classfile=
       props.getProperty("com.ibm.wsspi.security.trustassociation."
       +type+".config");
      if (classfile != null && classfile.length() > 0 ) {
         return init(classfile);
      } else {
         return -1;
      }
   }
```

Change your implementation to implement the init(Properties) method instead of relying on init(String propsfile) method. As shown in the previous example, this default implementation reads the properties to load the property file. The com.ibm.wsspi.security.trustassociation.types property gets the file containing the properties by concatenating `.config` to its value.

Note: The init(String) method still works if you want to use it instead of implementing the init(Properties) method. The only requirement is that the file name containing the custom trust association properties should now be entered using the **Custom Properties** link of the interceptor in the administrative console or by using scripts. You can enter the property using *either* of the following methods. The first method is used for backward compatibility with previous versions of WebSphere Application Server.

Method 1:

The same property names used in the previous release are used to obtain the file name. The file name is obtained by concatenating the `.config` to the com.ibm.wsspi.security.trustassociation.types property value.

If the file name is called `myTAI.properties` and is located in the */properties* directory, set the following properties:

- com.ibm.wsspi.security.trustassociation.types = myTAItype
- com.ibm.wsspi.security.trustassociation.myTAItype.config = *app_server_root*/myTAI.properties

Method 2:

You can set the com.ibm.wsspi.security.trustassociation.initPropsFile property in the trust association custom properties to the location of the file. For example, set the following property:

```
com.ibm.wsspi.security.trustassociation.initPropsFile=
app_server_root/myTAI.properties
```

Type the previous code as one continuous line.

The location of the properties file is fully qualified (for example,*app_server_root*/`myTAI.properties`). Because the location can be different in a WebSphere Application Server, Network Deployment environment, use variables such as `${USER_INSTALL_ROOT}` to refer to the WebSphere Application Server installation directory. For example, if the file name is called `myTAI.properties`, and it is located in the `/properties` directory, then set the following properties:

- com.ibm.wsspi.security.trustassociation.types = myTAItype
- com.ibm.wsspi.security.trustassociation.myTAItype.config = *app_server_root*/myTAI.properties

3. Compile the implementation once you have implemented it. For example, *app_server_root*`/java/bin/javac -classpath` *install_root*`/plugins/com.ibm.ws.runtime.jar;<install_root>/dev/JavaEE/j2ee.jar myTAIImpl.java`
   a. Identify the trust association interceptor class file for use when the server is restarted. Place the file either at the*app_server_root/classes* directory OR use the Java Virtual Machine (JVM) system property, `-Dws.ext.dirs` to specify where the file resides.

b. Restart all the servers.

4. Delete the default WebSEAL interceptor in the administrative console and click **New** to add your custom interceptor. Verify that the class name is dot separated and appears in the class path.
5. Click the **Custom Properties** link to add additional properties that are required to initialize the custom interceptor. These properties are passed to the init(Properties) method of your implementation when it extends the com.ibm.wsspi.security.WebSphereBaseTrustAssociationInterceptor as described in the previous step.
6. Save and synchronize (if applicable) the configuration.
7. Restart the servers for the custom interceptor to take effect.

Example

Refer to the Security: Resources for Learning article for a reference to an example of a custom interceptor.

Trust association interceptor support for Subject creation

The trust association interceptor (TAI) com.ibm.wsspi.security.tai.TrustAssociationInterceptor interface supports several features that are different from the existing com.ibm.websphere.security.TrustAssociationInterceptor interface.

The TAI interface supports a multiphase, negotiated authentication process. For example, some systems require a challenge response protocol back to the client. The two key methods in this interface are:

Key method name

public boolean isTargetInterceptor (HttpServletRequest req)

The isTargetInterceptor method determines whether the request originated with the proxy server that is associated with the interceptor. The implementation code must examine the incoming request object and determine if the proxy server that forwards the request is a valid proxy server for this interceptor. The result of this method determines whether the interceptor processes the request.

Method result

A `true` value tells WebSphere Application Server to have the TAI handle the request.

A `false` value, tells WebSphere Application Server to ignore the TAI.

Key method name

public TAIResult negotiateValidateandEstablishTrust (HttpServletRequest req, HttpServletResponse res)

The negotiateValidateandEstablishTrust method determines whether to trust the proxy server from which the request originated. The implementation code must authenticate the proxy server. The authentication mechanism is proxy-server specific. For example, in the product implementation for the WebSEAL server, this method retrieves the basic authentication information from the HTTP header and validates the information against the user registry that WebSphere Application Serve uses. If the credentials are not valid, the code creates the WebTrustAssociationException exception, which indicates that the proxy server is not trusted and the request is denied. If the credentials are valid, the code returns a TAIResult result, which indicates the status of the request processing with the client identity (Subject and principal name) to use for authorizing the web resource.

Method result

Returns a TAIResult result, which indicates the status of the request processing. You can query the Request object and modify the Response object can be modified.

The TAIResult class has three static methods for creating a TAIResult result. The TAIResult create methods take an int type as the first parameter. WebSphere Application Server expects the result to be a valid HTTP request return code and is interpreted in one of the following ways:

- If the value is `HttpServletResponse.SC_OK`, this response tells WebSphere Application Server that the TAI completed its negotiation. The response also tells WebSphere Application Server to use the information in the TAIResult result to create a user identity.
- Other values tell WebSphere Application Server to return the TAI output, which is placed into the HttpServletResponse response, to the web client. Typically, the web client provides additional information and then places another call to the TAI.

Table 106. TAIResults definitions. The created TAIResults results have the following meanings:

TAIResult	Explanation
public static TAIResult create(int status);	Indicates a status to WebSphere Application Server. The status cannot be SC_OK because the identity information is provided.
public static TAIResult create(int status, String principal);	Indicates a status to WebSphere Application Server and provides the user ID or the unique ID for this user. WebSphere Application Server creates credentials by querying the user registry.
public static TAIResult create(int status, String principal, Subject subject);	Indicates a status to WebSphere Application Server, the user ID or the unique ID for the user, and a custom Subject. If the Subject contains a hashtable, the principal is ignored. The contents of the Subject become part of the eventual user Subject.

All of the following examples are within the negotiateValidateandEstablishTrust method of a TAI.

The following code sample indicates that additional negotiation is required:

```
// Modify the HttpServletResponse object
//  The response code is meaningful only on the client
 return TAIResult.create(HttpServletResponse.SC_CONTINUE);
```

The following code sample indicates that the TAI determined the user identity. WebSphere Application Server receives the user ID only and queries the user registry for additional information:

```
// modify the HttpServletResponse object
 return TAIResult.create(HttpServletResponse.SC_OK, userid);
```

The following code sample indicates that the TAI determined the user identity. WebSphere Application Server receives the complete user information that is contained in the hashtable. In this code sample, the hashtable is placed in the public credential portion of the Subject:

```
// create Subject and place Hashtable in it
 Subject subject = new Subject;
 subject.getPublicCredentials().add(hashtable);
// the response code is meaningful for only the client
 return TAIResult.create(HttpServletResponse.SC_OK, "ignored", subject);
```

The following code sample indicates that an authentication failure occured. WebSphere Application Server fails the authentication request:

```
//log error message
// ....
 throw new WebTrustAssociationFailedException("TAI failed for this reason");
```

The following methods are additional methods on the TrustAssociationInterceptor interface. These methods are used for initialization, for shutdown, and for identifying the TAI to WebSphere Application Server. For more information, see the Java documentation.

Method name

public int initialize(Properties props)

Method result

This method is called during TAI initialization and is called only if custom properties are configured for the interceptor.

Method name

public String getVersion()

Method result

This method returns the version of the TAI.

Method name
public String getType()

Method result
This method returns the type of the TAI.

Method name
public void cleanup()

Method result
This method is called when stopping the WebSphere Application Server process. Stopping the WebSphere Application Server process provides an opportunity for the TAI to perform any necessary cleanup. This method is not necessary if cleanup is not required.

Enabling a plugpoint for custom password encryption

Two properties govern the protection of passwords. By configuring these two properties, you can enable a plugpoint for custom password encryption.

Before you begin

To view an example code sample that illustrates the com.ibm.wsspi.security.crypto.CustomPasswordEncryption interface, see “Plug point for custom password encryption” on page 985.

About this task

The encryption method is called for password processing whenever the custom class is configured and custom encryption is enabled. The decryption method is called whenever the custom class is configured and the password contains the {`custom:alias`} tag. The `custom:alias` tag is stripped prior to decryption.

Procedure

1. To enable custom password encryption, you must configure two properties:
   - **com.ibm.wsspi.security.crypto.customPasswordEncryptionClass** - Defines the custom class that implements the com.ibm.wsspi.security.crypto.CustomPasswordEncryption password encryption interface.
   - **com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled** - Defines when the custom class is used for default password processing. When the passwordEncryptionEnabled option is not specified or set to `false`, and the passwordEncryptionClass class is specified, the decryption method is called whenever a {`custom:alias`} tag still exists in the configuration repository.
2. To configure custom password encryption, configure both of these properties in the `server.xml` file. How you perform this configuration is dependent on your existing directory structure. Choose one of the following ways to perform this configuration:
   - Place The custom encryption class (com.acme.myPasswordEncryptionClass) in a Java archive (JAR) file that resides in the `${WAS_INSTALL_ROOT}/classes` directory. In this case, you have created the `${WAS_INSTALL_ROOT}/classes` directory for this purpose.

     Note: WebSphere Application Server does not create the `${WAS_INSTALL_ROOT}/classes` directory.
   - Place the custom encryption class (com.acme.myPasswordEncryptionClass) in a Java archive (JAR) file that resides in the `${WAS_HOME}/lib/ext` directory or another valid existing directory.

   Every configuration document that contains a password (`security.xml` and any application bindings that contain RunAs passwords), must be saved before all of the passwords become encrypted with the custom encryption class.
3. If the custom implementation class defaults to the com.ibm.wsspi.security.crypto.CustomPasswordEncryptionImpl interface, and this class is present in the class path, then encryption is enabled by default. This simplifies the enablement process for all

nodes. It is not necessary to define any other properties except for those that the custom implementation requires. To disable encryption, but still use this class for decryption, specify the following class.

- com.ibm.wsspi.security.crypto.customPasswordEncryptionEnabled=false

What to do next

Whenever a custom encryption class encryption operation is called, and it creates a run-time exception or a defined PasswordEncryptException exception, the WebSphere Application Server runtime uses the {xor} algorithm to encode the password. This encoding prevents the storage of the password in plain text. After the problem with the custom class has been resolved, it automatically encrypts the password the next time the configuration document is saved.

When a RunAs role is assigned a user ID and password, it currently is encoded using the WebSphere Application Server encoding function. Therefore, after the custom plug point is configured to encrypt the passwords, it encrypts the passwords for the RunAs bindings as well. If the deployed application is moved to a cell that does not have the same encryption keys, or the custom encryption is not yet enabled, a login failure results because the password is not readable.

One of the responsibilities of the custom password encryption implementation is to manage the encryption keys. This class must decrypt any password that it encrypted. Any failure to decrypt a password renders that password to be unusable, and the password must be changed in the configuration. All encryption keys must be available for decryption there and no passwords are left using those keys. The master secret must be maintained by the custom password encryption class to protect the encryption keys.

You can manage the master secret by using a stash file for the keystore, or by using a password locator that enables the custom encryption class to locate the password so that it can be locked down.

Plug point for custom password encryption

A plug point for custom password encryption can be created to encrypt and decrypt all passwords in WebSphere Application Server that are currently encoded or decoded using Base64-encoding.

The implementation class of this plug point has the responsibility for managing keys, determining the encryption algorithm to use, and for protecting the master secret. The WebSphere Application Server runtime stores the encrypted passwords in their existing locations, preceded with {custom:alias} tags instead of {xor} tags. The custom part of the tag indicates that it is a custom algorithm. The alias part of the tag is specified by the custom implementation, which helps to indicate how the password is encrypted. The implementation can include the key alias, encryption algorithm, encryption mode, or encryption padding.

A custom provider of this plug point must implement an interface that is designed to encrypt and decrypt passwords. The interface is called by the WebSphere Application Server runtime whenever the custom plug point is enabled. The custom algorithm becomes one of the supported algorithms when the plug point is enabled. Other supported algorithms include {xor} (standard base64 encoding) and {os400} which is used on the iSeries platform.

The following example illustrates the com.ibm.wsspi.security.crypto.CustomPasswordEncryption interface:

```
package com.ibm.wsspi.security.crypto;
public interface CustomPasswordEncryption
{

    /**
     * The encrypt operation takes a UTF-8 encoded String in the form of a byte[].
     * The byte[] is generated from String.getBytes("UTF-8").
     * An encrypted byte[] is returned from the implementation in the EncryptedInfo
     * object.  Additionally, a logical key alias is returned in the EncryptedInfo
     * objectwhich is passed back into the decrypt method to determine which key was
     * used to encrypt this password. The WebSphere Application Server runtime has
     * no knowledge of the algorithm or the key used to encrypt the data.
     *
     * @param byte[]
```

```
     * @return com.ibm.wsspi.security.crypto.EncryptedInfo
     * @throws com.ibm.wsspi.security.crypto.PasswordEncryptException
     **/
    public EncryptedInfo encrypt (byte[] decrypted_bytes) throws PasswordEncryptException;

    /**
     * The decrypt operation takes the EncryptedInfo object containing a byte[]
     * and the logical key alias and converts it to the decrypted byte[].  The
     * WebSphere Application Server runtime converts the byte[] to a String
     * using new String (byte[], "UTF-8");
     *
     * @param com.ibm.wsspi.security.crypto.EncryptedInfo
     * @return byte[]
     * @throws com.ibm.wsspi.security.crypto.PasswordDecryptException
     **/
    public byte[] decrypt (EncryptedInfo info) throws PasswordDecryptException;

    /**
     * The following is reserved for future use and is currently not
     * called by the WebSphere Application Server runtime.
     *
     * @param java.util.HashMap
     **/
    public void initialize (java.util.HashMap initialization_data);
}
```

The com.ibm.wsspi.security.crypto.EncryptedInfo class contains the encrypted bytes with the user-defined alias that is associated with the encrypted bytes. This information is passed back into the encryption method to help determine how the password was originally encrypted.

```
package com.ibm.wsspi.security.crypto;
public class EncryptedInfo
{
    private byte[] bytes;
    private String alias;

/**
 * This constructor takes the encrypted bytes and a keyAlias as parameters.
 * This constructor is used to pass to or from the WebSphere Application Server
 * runtime to enable the runtime to associate the bytes with a specific key that
 * is used to encrypt the bytes.
 */

    public EncryptedInfo (byte[] encryptedBytes, String keyAlias)
    {
        bytes = encryptedBytes;
        alias = keyAlias;
    }

/**
 * This command returns the encrypted bytes.
 *
 * @return byte[]
 */
    public byte[] getEncryptedBytes()
    {
        return bytes;
    }

/**
 * This command returns the key alias.  The key alias is a logical string that is
 * associated with the encrypted password in the model. The format is
 * {custom:keyAlias}encrypted_password. Typically, just the key alias is placed
 * here, but algorithm information can also be returned.
 *
 * @return String
 */
    public String getKeyAlias()
    {
        return alias;
    }

}
```

The encryption method is called for password processing whenever the custom class is configured and custom encryption is enabled. The decryption method is called whenever the custom class is configured and the password contains the {`custom:alias`} tag . The `custom:alias` tag is stripped prior to decryption. For more information, see Enabling custom password encryption.

Implementing a custom authentication provider using JASPI

You can implement a custom authentication provider using Java Authentication SPI for Containers (JASPI, or sometimes called JASPIC) to handle the Java Platform, Enterprise Edition (Java EE) authentication of HTTP request and response messages destined for web applications.

Before you begin

For JASPI authentication processing to take place, application security must be enabled in the global or domain security configuration and the server must be restarted for the configuration changes to take effect. Read the Application security topic for more information.

About this task

This release of WebSphere Application Server supports the JSR 196: Java Authentication SPI for Containers (JASPI, or sometimes called JASPIC) specification, which enables third-party security providers to handle the Java Platform, Enterprise Edition (Java EE) authentication of HTTP request and response messages destined for web applications. The JASPI specification extends the pluggable authentication concepts of the Java Authentication and Authorization Service (JAAS) to the authentication of HTTP request and response messages. When application security is enabled, and a protected web resource is accessed, the web container and the security runtime collaborate to make an authentication decision for the caller. When using a third-party JASPI provider, the authentication decision is delegated to that provider.

The JASPI specification defines standard system programming interfaces that enable developers to write a pluggable custom authentication provider that can handle Java EE web authentication mechanisms as well as any extended authentication processing. The WebSphere Application Server runtime uses these standard system programming interfaces to invoke the JASPI authentication provider. Read the Servlet Container Profile section in the JSR 196: Java Authentication Service Provider Interface for Containers specification for the requirements that third-party authentication providers must satisfy for more information.

If application security is enabled with JASPI authentication, when the web resource (such as a servlet or a JavaServer Pages (JSP) file) is accessed, the security runtime checks if the web resource is mapped to a JASPI provider defined in the security configuration. If so, the runtime invokes the JASPI authentication provider to perform authentication for the HTTP request and response messages.

To implement a custom authentication provider using JASPI you must do the following:

Procedure

1. Develop a custom JASPI authentication provider.

   WebSphere Application Server provides support for the development of custom JASPI authentication providers to be used to perform authentication for the HTTP request and response messages destined for web applications. Read “Developing a custom JASPI authentication provider” on page 988 for more information.

2. Configure a new JASPI authentication provider.

   WebSphere Application Server allows an administrator to enable JASPI authentication and to define a third-party JASPI authentication provider as part of the global or domain security configuration. Read “Configuring a new JASPI authentication provider using the administrative console” on page 992 for more information.

3. Associate a JASPI authentication provider with an application or specific web modules.

   During application deployment, the administrator or deployer can use the Map JASPI Provider option to associate web applications and specific web modules with an existing JASPI authentication provider as defined in the security configuration. This association can also be made when editing the options for an existing installed application. By default, an application inherits the JASPI settings defined in the

WebSphere Application Server global or domain security configuration, and web modules inherit the application setting. The Map JASPI Provider option can be used to override these defaults. Read “Enabling JASPI authentication using the Map JASPI provider option during application deployment” on page 994 for more information.

Developing a custom JASPI authentication provider

You can develop a custom Java Authentication SPI for Containers (JASPI) authentication provider by creating classes that implement the required interfaces noted in the JSR 196: Java Authentication Service Provider Interface for Containers specification.

Before you begin

Review the specific interface implementation requirements for JASPI authentication providers and modules in the JSR 196: Java Authentication Service Provider Interface for Containers specification.

About this task

WebSphere Application Server supports the use of third-party authentication providers that are compliant with the servlet container profile specified in Java Authentication SPI for Containers (JASPI) Version 1.0.

The servlet container profile defines interfaces that are used by the security runtime environment in collaboration with the web container in WebSphere Application Server to invoke authentication modules before and after a web request is processed by an application. Authentication using JASPI modules is performed only when JASPI has been enabled in the security configuration and when a configured JASPI provider has been associated with the web module that processes the received web request.

To develop a custom authentication provider, create classes that implement the required interfaces noted in the JSR 196: Java Authentication Service Provider Interface for Containers specification. A provider can use one or more authentication modules for authentication. Modules can use callbacks to perform authentication, or they can manually add the necessary user identity information to the client subject. Depending on the scope of the provider, the implementation classes can be stored in various locations on the application server.

Procedure

1. Create a class that implements the javax.security.auth.message.config.AuthConfigProvider interface.

   The AuthConfigProvider implementation class must define a public two-argument constructor and the getServerAuthConfig public method:

   ```
   import java.util.Map;
   import javax.security.auth.callback.CallbackHandler;
   import javax.security.auth.message.AuthException;
   import javax.security.auth.message.config.AuthConfigFactory;
   import javax.security.auth.message.config.AuthConfigProvider;
   import javax.security.auth.message.config.ServerAuthConfig;

   public class SampleAuthConfigProvider implements AuthConfigProvider {

           public SampleAuthConfigProvider(Map<String, String> properties, AuthConfigFactory factory) {
                   ...
           }
           public ServerAuthConfig getServerAuthConfig(String layer, String appContext, CallbackHandler handler)
                   throws AuthException {
                   ...
           }
   }
   ```

   An instance of the AuthConfigProvider implementation class is used by WebSphere Application Server when a request arrives to be processed by the web module of the application. The getServerAuthConfig method is used to obtain a ServerAuthConfig instance. The CallbackHandler argument in the method call is used by the authentication module(s).
2. Create a class that implements the javax.security.auth.message.config.ServerAuthConfig interface.

The ServerAuthConfig implementation class must define the getAuthContextID and getAuthContext public methods:

```
import java.util.Map;
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.config.ServerAuthConfig;
import javax.security.auth.message.config.ServerAuthContext;

public class SampleServerAuthConfig implements ServerAuthConfig {

        public String getAuthContextID(MessageInfo messageInfo) throws IllegalArgumentException {
                ...
        }
        public ServerAuthContext getAuthContext(String authContextID, Subject serviceSubject, Map properties)
                throws AuthException {
                ...
        }
}
```

The getAuthContextID and getAuthContext methods in the ServerAuthConfig implementation class are used to obtain a ServerAuthContext instance.

3. Create a class that implements the javax.security.auth.message.config.ServerAuthContext interface.

   The ServerAuthContext implementation class must define the validateRequest and secureResponse public methods:

```
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.config.ServerAuthContext;

public class SampleServerAuthContext implements ServerAuthContext {

        public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
                throws AuthException {
                ...
        }
        public AuthStatus secureResponse(MessageInfo messageInfo, Subject serviceSubject)
                throws AuthException {
                ...
        }
}
```

   The validateRequest method in the ServerAuthContext implementation class is used to invoke the module that authenticates the received web request message. If the authentication result is successful, the web container dispatches the received web request message that the target web module processes in the application. If the authentication result is not successful, the request is rejected with the appropriate response status.

4. Create a class that implements the javax.security.auth.message.module.ServerAuthModule interface.

   The ServerAuthModule implementation class must define the initialize, validateRequest, and secureResponse public methods:

```
import javax.security.auth.Subject;
import javax.security.auth.callback.CallbackHandler;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.security.auth.message.MessagePolicy;
import javax.security.auth.message.module.ServerAuthModule;

public class SampleAuthModule implements ServerAuthModule {

        public void initialize(MessagePolicy requestPolicy, MessagePolicy responsePolicy, CallbackHandler handler, Map options)
                throws AuthException {
                ...
        }

        public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
                throws AuthException {
                ...
        }
```

```
        public AuthStatus secureResponse(MessageInfo messageInfo, Subject serviceSubject)
                throws AuthException {
                ...
        }
}
```

The initialize method in the ServerAuthModule implementation class is called by the ServerAuthContext implementation class to initialize the authentication module and to associate it with the ServerAuthContext instance.

The validateRequest and secureResponse methods in this class are used respectively to authenticate the javax.servlet.http.HttpServletRequest and javax.servlet.http.HttpServletResponse contained in the javax.security.auth.message.MessageInfo that is received. These methods can use the CallbackHandler instance received in the initialize method to interact with the WebSphere security runtime to validate a user password, and the active user registry to retrieve a unique-id and membership groups for a user. The retrieved data is placed in a Hashtable in the set of private credentials in the client subject. The WebSphere Application Server implementation of CallbackHandler supports three callbacks:

- CallerPrincipalCallback
- GroupPrincipalCallback
- PasswordValidationCallback

WebSphere Application Server expects the name values obtained with PasswordValidationCallback.getUsername() and CallerPrincipalCallback.getName() to be identical. If they are not, unpredictable results occur. The CallbackHandler's handle() method processes each callback given in the argument array of the method sequentially. Therefore, the name value set in the private credentials of the client subject is the one obtained from the last callback processed.

Note: Always use PasswordValidationCallback to validate a user password and to add the appropriate credentials to the client subject during authentication:

```
        import javax.security.auth.Subject;
        import javax.security.auth.callback.Callback;
        import javax.security.auth.message.AuthException;
        import javax.security.auth.message.AuthStatus;
        import javax.security.auth.message.MessageInfo;
        import javax.security.auth.message.callback.PasswordValidationCallback;

        public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
                throws AuthException {
                ...
                PasswordValidationCallback pvcb = new PasswordValidationCallback(clientSubject, username, password);
                handler.handle(new Callback[] {pvcb});
                ...
        }
```

If CallbackHandler is not used by the authentication module, and validateRequest returns a successful status, WebSphere Application Server requires that a Hashtable instance be included in the clientSubject with user identity information so that a custom login can be performed to obtain the credentials for the user. This Hashtable can be added to the client subject as in the following example:

```
import java.util.Hashtable;
import java.util.String;
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import com.ibm.wsspi.security.registry.RegistryHelper;
import com.ibm.wsspi.security.token.AttributeNameConstants.AttributeNameConstants;

public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
        throws AuthException {
        ...
        UserRegistry reg = RegistryHelper.getUserRegistry(null);
        String uniqueid = reg.getUniqueUserID(username);

        Hashtable hashtable = new Hashtable();
        hashtable.put(AttributeNameConstants.WSCREDENTIAL_UNIQUEID, uniqueid);
        hashtable.put(AttributeNameConstants.WSCREDENTIAL_SECURITYNAME, username);
        hashtable.put(AttributeNameConstants.WSCREDENTIAL_PASSWORD, password);
```

```
        hashtable.put(AttributeNameConstants.WSCREDENTIAL_GROUPS, groupList); //optional
        clientSubject.getPrivateCredentials().add(hashtable);
        ...
}
```

For more information about the Hashtable requirements and custom login, read about Developing custom login modules for a system login configuration for JAAS.

To support the login and authenticate methods of the Java Servlet 3.0 specification, the following logic must be added to the validateRequest method in the ServerAuthModule implementation class:

```
import java.util.Map;
import javax.security.auth.Subject;
import javax.security.auth.message.AuthException;
import javax.security.auth.message.AuthStatus;
import javax.security.auth.message.MessageInfo;
import javax.servlet.http.HttpServletRequest;

public AuthStatus validateRequest(MessageInfo messageInfo, Subject clientSubject, Subject serviceSubject)
        throws AuthException {
        ...
        Map msgMap = messageInfo.getMap();

        if ("login".equalsIgnoreCase(msgMap.get("com.ibm.websphere.jaspi.request"))) {
                // This request is for the login method
                String username = msgMap.get("com.ibm.websphere.jaspi.user");
                String password = msgMap.get("com.ibm.websphere.jaspi.password");
                // Authenticate using the user name and password set above.
        }
        else if ("authenticate".equalsIgnoreCase(msgMap.get("com.ibm.websphere.jaspi.request"))) {
                // this request is for the authenticate method
                String authHeader
                     = ((HttpServletRequest) messageInfo.getRequestMessage()).getHeader("Authorization");
                if (authHeader == null) {
                     // The user has not provided a username and password yet, return
                     // AuthStatus.SEND_CONTINUE to challenge
                }
                else {
                     // Authenticate using the user name and password in the authentication header.
                }
        }
        else {
                // This is not a Servlet 3.0 login or authenticate request; handle as usual.
        }
        ...
}
```

5. Compile all newly created classes.

   The following JAR files in your WebSphere Application Server installation must be specified in the class path to successfully compile the new classes:

   - *app_server_root*/dev/JavaEE/j2ee.jar
   - *app_server_root*/dev/was_public.jar (if any public WebSphere APIs were used)

6. Create a JAR file with the compiled classes.

   Depending on the requirements, the JAR file can be placed in one of three locations:

   - *app_server_root*/lib

     This location is always on the classpath for the WebSphere Application Server classloader. Using this location, the provider can be registered for a set of web modules or applications as the cell or domain default provider for all web modules and applications, and it can be registered manually as a persistent provider.

   - Shared library

     Place the provider JAR file anywhere on the WebSphere Application Server system. Configure a shared library that points to the JAR, and add that shared library to the application or server classpath. In a shared library, the provider can be registered for a set of web modules or applications, but the provider cannot be used as the cell or domain default provider. It also cannot

be registered as a persistent provider because the shared library is not in the classpath for provider registration during server startup. For more information about configuring a shared library, read about Creating shared libraries.

- Embedded in the application

  Include the provider JAR file in the application's EAR file as a utility JAR, or embed the compiled class files in the web module WAR. The embedded provider can be registered for the web modules in the application as long as the classes are included in the classpath for the web module. This provider cannot be used as a cell or domain default provider, nor can it be registered as a persistent provider. The classes in the application are not available for provider registration during server startup.

7. Configure the provider in the security configuration using the administrative console or an administration script.

   Read about “Configuring a new JASPI authentication provider using the administrative console” for more information.

Configuring a new JASPI authentication provider using the administrative console

You can configure a new Java Authentication SPI (JASPI) authentication provider in the cell or in the given security domain by using the administrative console.

About this task

This release of WebSphere Application Server supports integration of message authentication providers that are compliant with the JASPI for Containers Version 1.0 specification.

When JASPI authentication providers are configured, and WebSphere Application Server receives an HTTP request message, the security runtime environment determines if the target application is configured to use JASPI authentication. If so, the runtime environment invokes the selected authentication provider to validate the received message. Otherwise, authentication of the message request is done according to the authentication mechanism provided by WebSphere Application Server for the appropriate messaging layer.

If you want to use JASPI message authentication services, you must supply an implementation of the required interfaces as defined in the JASPI specification. Read “Developing a custom JASPI authentication provider” on page 988 for more information on these interfaces.

Authentication of HTTP request and response messages destined for JASPI-enabled deployed applications is performed according to the requirements of the Servlet Container Profile specified in the new specification.

Note: JASPI is supported in a mixed-cell environment, but can only be used in nodes that are version 8 or higher. Back-level nodes use existing authentication mechanisms.

To configure a new JASPI authentication provider using the administrative console, do the following:

Procedure

1. Click **Security > Global security**.
2. Select **Enable Java Authentication SPI (JASPI)** to enable support for JASPI authentication.
3. Click **Providers**.

   Note: It is not necessary to select **Enable Java Authentication SPI (JASPI)** until after you have configured a new JASPI authentication provider.

   Note: The Default provider option is used to specify a single JASPI authentication provider to perform authentication for all web modules when JASPI authentication is enabled, and you do not override the web module to JASPI provider mapping during application deployment. During

application deployment, you can override the default for every web module where it does not apply by choosing not to use JASPI or by naming a different provider to use for authentication. However, it is not recommended that you use this option unless you are certain that your default provider is capable of handling all types of web authentication (basic authentication, form authentication and client certificate authentication).

4. Click **New**.
5. Enter a name that uniquely identifies the JASPI authentication provider in the Provider name field.
6. Optional: Enter a textual description of the authentication provider in the Description field.
7. Enter the package-qualified name of the class that implements the authentication provider interface (javax.security.auth.message.config.AuthConfigProvider) in the Class name field.

   Note: In the Message layer field, WebSphere Application Server Version 8.5 supports only the HttpServlet message layer profile as defined in the JASPI specification. You cannot change this value.
8. Optional: Under Custom Properties, click **New** if you require more than one property. This parameter is a list of key/value pairs.
9. Click **OK** or **Apply**.

What to do next

You can also configure a new JASPI authentication provider by using **wsadmin** commands. Read JaspiManagement command group for the AdminTask object for more information.

Verify that your server has been restarted so that the changes to configure the JASPI provider will take effect.

Modifying an existing JASPI authentication provider using the administrative console

You can modify and configure an existing Java Authentication SPI (JASPI) authentication provider in the cell or in the given security domain by using the administrative console.

About this task

To modify and configure an existing JASPI authentication provider using the administrative console, do the following:

Procedure

1. Click **Security > Global security**.
2. Click **Providers**. You also have the option to change the Default provider from the drop-down list.

   Note: You can modify the value of the **Enable Java Authentication SPI (JASPI)** checkbox to indicate whether or not JASPI support is enabled at a later time.
3. Select an existing JASPI authentication provider to modify.
4. Optional: Enter a textual description of the authentication provider in the Description field.
5. Enter a new package-qualified name of the class that implements the authentication provider interface (javax.security.auth.message.config.AuthConfigProvider) in the Class name field if you wish to change it.

   Note: In the Message layer field, WebSphere Application Server Version 8.5 supports only the HttpServlet message layer profile as defined in the JASPI specification. You cannot change this value.

6. Optional: Under Custom Properties, select an existing custom configuration property. Click **Delete** to remove the property, **Edit** to modify the property, or click **New** to create a new property. If you select **Edit** to modify an existing property, you can enter new values for the Name field and Value field if you wish to change them.
7. Click **OK** or **Apply**.

What to do next

You can also modify an existing JASPI authentication provider by using **wsadmin** commands. For more information, read JaspiManagement command group for the AdminTask object.

Verify that your server has been restarted so that the changes to configure the JASPI provider will take effect.

Deleting a JASPI authentication provider using the administrative console

You can delete an existing Java Authentication SPI (JASPI) authentication provider in the cell or in the given security domain by using the administrative console.

About this task

To delete an existing JASPI authentication provider using the administrative console, do the following:

Procedure

1. Click **Security** > **Global security**.
2. Click **Providers**, You can optionally select or deselect the **Enable Java Authentication SPI (JASPI)** check box.

   Note: You can modify the value of the **Enable Java Authentication SPI (JASPI)** checkbox to indicate whether or not JASPI support is enabled at a later time.
3. Select an existing JASPI authentication provider to delete.
4. Click **Delete**.

What to do next

You can also delete a JASPI authentication provider by using wsadmin commands. For more information, read JaspiManagement command group for the AdminTask object.

Verify that your server has been restarted so that the changes to the JASPI provider configuration will take effect.

Enabling JASPI authentication using the Map JASPI provider option during application deployment

An administrator or deployer can use the Map JASPI Provider option during application deployment to associate web applications and specific web modules with an existing Java Authentication SPI (JASPI) authentication provider as defined in the security configuration. This association can also be made when editing the options for a previously installed application.

Before you begin

Before you perform this task, verify that a JASPI authentication provider is defined as part of the global or domain security configuration. Read about “Configuring a new JASPI authentication provider using the administrative console” on page 992 for more information.

About this task

By default, an application inherits the JASPI settings defined in the WebSphere Application Server global or domain security configuration, and web modules inherit the application setting. However, you can override these default values by using the Map JASPI Provider option during application deployment. Use this option to associate a specific JASPI provider from the global or domain security configuration with the entire application or with specific web modules. You can also use this option to specify that JASPI authentication not be used for an application or specific web module.

To associate a web application or specific web modules with an existing JASPI provider:

Procedure

1. From the administrative console, click **Applications > New Application > New Enterprise Application**. Complete the required steps until you see the step for Map JASPI Provider, or click the **Map JASPI Provider** step from the installation options. A list containing the application name and associated web modules is displayed. To update a JASPI provider association after an application has been deployed, click **Applications > Application Types > WebSphere enterprise applications**, and then select the application to be modified. Click **JASPI Provider** under the Detail properties.
2. Select the application or specific web module for which the JASPI provider setting is to be modified.
3. Click the **Select JASPI Provider** menu and select one of the following options:

   Do not use JASPI
   Select to disable JASPI authentication for the selected web module or for the application.

   Inherit JASPI provider
   Select to inherit the JASPI authentication settings from default values in the cell or domain security configuration, as appropriate.

   When **Inherit JASPI provider** is selected for a web module, JASPI authentication settings for the selected module are the settings that are specified for the application.

   When **Inherit JASPI provider** is selected for the application, JASPI authentication settings are the settings that are specified in the appropriate cell or domain security configuration.

   Provider name
   When a specific provider name is selected, that provider name is used to perform authentication of web requests for the selected application or web module.
4. Complete the remaining steps to finish installing and deploying the application.

What to do next

Verify that your server has been restarted to ensure that the configuration changes to define the JASPI provider take effect. Read about “Configuring a new JASPI authentication provider using the administrative console” on page 992 for more information.

JASPI authentication providers collection

The Java Authentication Service Provider Interface (JASPI) for Containers Version 1.0 specification defines standard system programming interfaces that enable developers to write a pluggable custom authentication provider that can handle Java EE web authentication mechanisms as well as any extended authentication processing. The WebSphere Application Server runtime uses these standard system programming interfaces to invoke the JASPI authentication provider.

Read the Servlet Container Profile section in the JSR 196: Java Authentication Service Provider Interface for Containers specification for the requirements that third-party authentication providers must satisfy for more information.

If application security is enabled, and JASPI authentication is enabled with providers configured, when a web resource (such as a servlet or a JavaServer Page (JSP) file) is accessed, the security runtime checks

if the web resource is mapped to a JASPI provider defined in the security configuration. If so, the runtime invokes the JASPI authentication provider to perform authentication for the HTTP request and response messages.

Note: WebSphere Application Server Version 8.5 supports only the HttpServlet message layer profile as defined in the JASPI specification.

To view this administrative console page, click **Security > Global security**. Under Authentication, click **Providers**.

To configure a new custom JASPI authentication provider in the cell or in the given security domain, click **New** and specify provider settings.

Provider name:

Specifies a name that uniquely identifies the authentication provider.

Select an existing custom JASPI authentication provider name to edit and configure it.

JASPI authentication provider details

Use this page to provide configuration details for your custom Java Authentication SPI (JASPI) authentication service provider.

To view this administrative console page, click **Security > Global security**. Under Authentication, click **Providers**. Select an existing authentication service provider name or click **New** to create a new one.

Provider name:

Specifies a name that uniquely identifies the authentication provider.

Description:

Specifies a textual description of the authentication provider.

Class name:

Specifies the package-qualified name of the class that implements the authentication provider interface (javax.security.auth.message.config.AuthConfigProvider).

Message layer:

WebSphere Application Server Version 8.5 supports only the HttpServlet message layer profile as defined in the JASPI specification.

Custom properties:

Specifies additional custom properties needed to initialize the authentication provider. This parameter is a list of key/value pairs.

Click **Delete** to remove a custom property or **Edit** to modify a custom property.

JASPI authentication enablement for applications

Use this page to enable or disable Java Authentication SPI (JASPI) authentication for an application or web module, and to specify the name of a JASPI authentication provider to be used for authenticating messages for the application or web module.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications**. Select an application, and under Detail Properties, select **JASPI provider**.

Select JASPI provider:

Select to indicate the web modules in the application that you wish to specify or to override the default JASPI authentication settings for.

Select one of the JASPI provider names to choose a provider to use to perform authentication of web requests for the selected Web module or the application.

To specify how JASPI authentication is performed for the selected web module or the application, choose one of the following:

Do not use JASPI
Select to disable JASPI authentication for the selected web module or for the application.

Inherit JASPI provider
Select to inherit the JASPI authentication settings from default values in the cell or domain security configuration, as appropriate.

When Inherit JASPI provider is selected for a web module, JASPI authentication settings for the selected module are the settings that are specified for the application.

When Inherit JASPI provider is selected for the application, JASPI authentication settings are the settings that are specified in the appropriate cell or domain security configuration.

Provider name
When a specific provider name is selected, that provider is used to perform authentication of web requests for the selected application or web module.

If JASPI authentication is enabled, and a specific provider name is not specified, then the default provider name is used. For more information, read about configuring a new JASPI authentication provider using the administrative console.

If JASPI authentication is disabled, or if no default provider is selected, JASPI authentication is not performed. Web authentication is then performed according to another authentication mechanism as selected in the cell or domain security configuration.

Chapter 22. Developing Startup beans

This page provides a starting point for finding information about startup beans.

Startup beans allow business logic to run when an application starts or stops.

Using startup beans

There are two types of startup beans: application startup beans and Module startup beans.

About this task

Note: The capabilities provided with startup singleton session beans (EJB 3.1 specification) causes the WebSphere Application Server proprietary startup beans function to be deprecated.

A module startup bean is a session bean that is loaded when an EJB Jar file starts. Module startup beans enable Java Platform Enterprise Edition (Java EE) applications to run business logic automatically, whenever an EJB module starts or stops normally. An application startup bean is a session bean that is loaded when an application starts. Application startup beans enable Java EE applications to run business logic automatically, whenever an application starts or stops normally.

Startup beans are especially useful when used with asynchronous bean features. For example, a startup bean might create an alarm object that uses the Java Message Service (JMS) to periodically publish heartbeat messages on a well-known topic. This enables clients or other server applications to determine whether the application is available. Refer to the Enabling an application to wait for a messaging engine to start article if you are using the default JMS provider.

Procedure

1. For Application startup beans, use the home interface, com.ibm.websphere.startupservice.AppStartUpHome, to designate a bean as an Application startup bean. For Module startup beans, use the home interface, com.ibm.websphere.startupservice.ModStartUpHome, to designate a bean as a Module startup bean.
2. For Application startup beans, use the remote interface, com.ibm.websphere.startupservice.AppStartUp, to define start() and stop() methods on the bean. For Module startup beans, use the remote interface, com.ibm.websphere.startupservice.ModStartUp, to define start() and stop() methods on the bean.

   The startup bean start() method is called when the module or application starts and contains business logic to be run at module or application start time.

   The start() method returns a boolean value. **True** indicates that the business logic within the start() method ran successfully. Conversely, **False** indicates that the business logic within the start() method failed to run completely. A return value of False also indicates to the Application server that application startup is aborted.

   The startup bean stop() methods are called when the module or application stops and contains business logic to be run at module or application stop time. Any exception thrown by a stop() method is logged only. No other action is taken.

   The start() and stop() methods must never use the TX_MANDATORY transaction attribute. A global transaction does not exist on the thread when the start() or stop() methods are invoked. Any other TX_* attribute can be used. If TX_MANDATORY is used, an exception is logged, and the application start is aborted.

   The start() and stop() methods on the remote interface use **Run-As** mode. **Run-As** mode specifies the credential information to be used by the security service to determine the permissions that a principal has on various resources. If security is on, the **Run-As** mode needs to be defined on all of the methods called. The identity of the bean without this setting is undefined.

There are no restrictions on what code the start() and stop() methods can run, since the full Application Server programming model is available to these methods.

3. Use an *optional* environment property integer, `wasStartupPriority`, to specify the start order of multiple startup beans in the same Java Archive (JAR) file. If the environment property is found and is the wrong type, application startup is aborted. If no priority value is specified, a default priority of `0` is used. It is recommended that you specify the priority property. Beans that have specified a priority are sorted using this property. Beans with numerically lower priorities are run first. Beans that have the same priority are run in an undefined order. All priorities must be positive integers. Beans are stopped in the opposite order to their start priority. The priority values for module startup beans and application startup beans are mutually exclusive. All modules will be started prior to the application being declared as "started" and therefore the start() methods for module startup beans within an application will be invoked prior to the start() methods for any application startup beans. Likewise, all application startup bean stop() methods for a specific Java Archive (JAR) file will be invoked prior to any module startup bean stop() methods for that JAR.

   Note: The `wasStartupPriority` environment property integer cannot be set through either a command or the administrative console. This environment property integer is an EJB environment entry that is to be set by an application developer not an administrator. You set the integer value in the `ejb-jar.xml` file as shown in the example below:

   ```
   <env-entry>
     <env-entry-name>wasStartupPriority</env-entry-name>
     <env-entry-type>java.lang.Integer</env-entry-type>
     <env-entry-value>3</env-entry-value>
   </env-entry>
   ```

   As with any other EJB environment entry, you set a separate `wasStartupPriority` value for each EJB.

4. For module startup beans, the order in which EJB modules are started can be adjusted via the "Starting weight" value associated with each module
5. To control who can invoke startup bean methods via WebSphere Security do the following:
   a. Define the method permissions for the Start() and Stop() methods as you would for any EJB module. (See "Defining method permissions for EJB modules".)
   b. Ensure that the user that is mapped to the Security Role defined for the startup bean methods is the same user that is defined as the Server user ID within the User Registry.

What to do next

View the startup beans service settings.

Enabling startup beans in the administrative console

Enabling startup beans in the administrative console enables Java 2 Platform Enterprise Edition (J2EE) applications to run business logic automatically, whenever an application starts or stops normally.

About this task

Use the following steps to enable startup beans in the administrative console.

Procedure

1. Start the administrative console.
2. Select **Servers** > **Application Servers** > *server_name* > **Container Services** > **Startup beans service**.
3. Select the **Enable service at server startup** check box.
4. Click **Apply** to save the configuration.

What to do next

View the startup beans service settings.

Startup beans service settings

Use this page to enable startup beans that control whether application-defined startup beans function on this server. Startup beans are session beans that run business logic through the invocation of start and stop methods when applications start and stop. If the startup beans service is disabled, then the automatic invocation of the start and stop methods does not occur for deployed startup beans when the parent application starts or stops. This service is disabled by default. Enable this service only when you want to use startup beans. Startup beans are especially useful when used with asynchronous beans.

Note: The capabilities provided with startup singleton session beans (EJB 3.1 specification) causes the WebSphere Application Server proprietary startup beans function to be deprecated.

To view this administrative console page, click **Servers > Server types > WebSphere application servers >** *server_name*. Under **Container Settings**, expand **Container Services** then click **Startup beans service**.

Enable service at server startup

Specifies whether the server attempts to initiate the startup beans service.

Information	**Value**
Default	Cleared
Range	**Selected** When the application server starts, it attempts to initiate the startup bean service automatically. **Cleared** The server does not try to initiate the startup beans service. All startup beans do not start or stop with the application. If you use startup beans on this server, then the system administrator must start the startup beans service manually or select this property, and then restart the server.

Chapter 23. Developing Service integration

This page provides a starting point for finding information about service integration.

Service integration provides asynchronous messaging services. In asynchronous messaging, producing applications do not send messages directly to consuming applications. Instead, they send messages to destinations. Consuming applications receive messages from these destinations. A producing application can send a message and then continue processing without waiting until a consuming application receives the message. If necessary, the destination stores the message until the consuming application is ready to receive it.

Programming mediations

Several distinct tasks are involved in programming a mediation. Typically, the mediation code is written by a programmer, and is then deployed and administered by an integrator.

Before you begin

Code examples for writing a mediation are provided in the following topic: “Adding mediation function to handler code” on page 1005.

The following application programming interfaces are provided for you to work with messages:

- You can use the SIMessage API to manipulate the contents of the message.
- You can use the SIMediationSession API to access the service integration bus so that your mediation can send and retrieve messages.

You can deploy mediations by using tooling such as the Rational Application Developer tools.

About this task

The tasks for programming a mediation are as follows:

Developing
Writing a mediation by adding functional code to a mediation handler.

Deploying
Adding a mediation to a mediation handler list, and deploying it.

Administering
Associating a mediation handler with a destination (optional), and configuring the parameters to be used by the mediation handler at run time.

Take the following steps to program a mediation:

Procedure

1. Create a mediation handler. For more information, see “Writing a mediation handler” on page 1004.
2. Add mediation function code to your mediation handler. For more information, see “Adding mediation function to handler code” on page 1005.
3. Optional: Working with the message payload, for example for logging messages within a mediation. For more information, see “Working with the message payload” on page 1012.
4. Use the Rational Application Developer tools to create a handler list, add your mediation handler to the list, and deploy the handler list as an Enterprise Archive (EAR file). See the Rational Application Developer information center for information about how to do this.

Serializing the content of SIMessage

Use this task to convert an SIMessage object to a byte array.

About this task

If you want to save an SIMessage object in your local file system or in a database, you must first convert the object to a byte array and format string. You can reconstruct the message from the byte array and format string. To do this, complete the following steps.

Procedure

1. In your application program, record the format string associated with the SIMessage instance. For example:

   ```
   String savedFormat=message.getFormat();
   ```

2. Call the `getDataGraphAsBytes`. For example:

   ```
   Bytes newDataGraph = message.getNewDataGraph(newFormat);
   ```

   This method returns a copy of the payload as a byte stream. You can store the bytes and the associated format string, as you require.

3. Optional: To reconstruct the message, call the method `createDataGraph` provided by the SIDataGraphFactory API. This method requires a byte array and a format string. For example:

```
DataGraph newDataGraph = SIDataGraphFactory.getInstance().createDataGraph(byteArray, newFormat);
```

   This method creates a new data graph by parsing the bytes according to the format passed to the method.

What to do next

You can use the newly created datagraph as the payload of an SIMessage instance by using the SIMessage setDataGraph() method. For example:

```
newMessage.setDataGraph(newDataGraph, savedFormat);
```

Writing a mediation handler

You can write a mediation handler, add mediation function to it, and prepare it for installation on an application server.

Before you begin

You should have access to a Java programming environment, and an assembly tool such as IBM Rational Application Developer.

About this task

A mediation handler can be deployed. Each mediation handler executes some specific message processing at run time, for example transforming a message format, or routing a message to a particular destination. A mediation handler is a Java program framework, to which you add the code that performs the mediation function.

You can define a mediation handler class either in a Java project or an EJB project (which is needed for the deployment artifact). Your programming and deployment artifacts can be separated in different projects. The steps below are for an EJB project, but the steps are very similar if you want to create a Java project, because you define a target server for either a Java project or an EJB project and the server runtime plug-in sets the class path correctly.

Procedure

1. Create a new EJB project:
   a. Switch to the Java EE perspective to work with Java EE projects. Click **Window > Open Perspective > Other > Java EE**.
   b. From the File menu, select **New > Project**.
   c. Expand the Java EE folder, and select Enterprise Application Project. Click **Next**.
   d. Optional: If you have created a Java project instead of an EJB project, right click on the Java project folder icon for the context menu and select Properties. When the Properties panel appears, select the Server properties and target the project to an appropriate server for your system, as in the next step.
   e. Enter a name for the project and target the project to an appropriate server for your system. (If this is the first time you target this server, click **New...**.) Click **Next** to take you to the EAR Module Projects window.
   f. Click **New Module...**.
   g. Create a new module project by selecting the check box against EJB project, and entering the name of your mediation handler.
   h. Click **Finish**. You are returned to the EAR Module Projects window.
   i. Click **Finish** to create the new project.
2. Create a mediation handler class by implementing the `com.ibm.websphere.sib.mediation.handler.MediationHandler` interface.
   a. From the File menu, select **New > Java Class**.
   b. Specify the source folder for your mediation EAR project.
   c. Specify a name for your mediation handler.
   d. Select Superclass `java.lang.Object`.
   e. Select Interface `com.ibm.websphere.sib.mediation.handler.MediationHandler`.
   f. Select the **Inherited abstract methods** check box.
   g. Click **Finish** to create the new mediation handler class.
3. Add functional code that transforms or routes messages to your mediation handler by using the IBM Rational Application Developer. For more information, see “Adding mediation function to handler code.” Beware that the default return value for the handle method created by the toolkit is `false`, which causes the message to be discarded. You must change the return value to `true` to preserve the message.
4. Generate an EAR file from your mediation handler class. Follow the instructions in the IBM Rational Application Developer documentation.

What to do next

Next, you are ready to install the EAR file containing your mediation handler into the application server.

Adding mediation function to handler code

A mediation handler is a wrapper for the mediation code that operates on the message. You can add mediation function to an existing mediation handler by working with the message context, the message properties, the message header or the message payload.

Before you begin

Create or open a mediation handler in an EJB project. For more information, see “Writing a mediation handler” on page 1004.

About this task

There are four main aspects of the message through which you can change the behavior of the mediation handler code, or influence the routing of a message. You can change the values in the message context and message properties, and you can work with the contents of the message (called the message payload), or with the message header:

- “Working with the message context”
- “Working with message properties” on page 1007
- “Working with the message header” on page 1008
- “Working with the message payload” on page 1012

Example: Using mediations to trace, monitor and log messages

The most straightforward use of a mediation is for tracing, monitoring or logging messages that pass through a destination or topics spaces. This type of mediation does not modify the message; it only extracts information from the message and saves or displays the information elsewhere.

For example, the following mediation handler displays the API message and correlation IDs for each message it is sent:

```
public boolean(MessageContext context)
{
  SIMessageContext   msgCtx  = (SIMessageContext)context;
  SIMediationSession session = msgCtx.getSession();
  SIMessage          msg     = msgCtx.getMessage();
  String             msgId   = msg.getApiMessageId();
  String             corrId  = msg.getCorrelationId();
  String             dest    = session.getDestinationName();

  System.out.println(msgId+" (correlation id="+corrid) is passing through "+dest+".");

  return true;
}
```

Working with the message context

You can work with the message properties to affect the way a message is mediated.

Before you begin

Before you start this task, you should read about how information is carried in the mediation context in Mediation context information

About this task

Interface SIMessageContext has a superinterface MessageContext. Methods in MessageContext allow you to manage a set of message properties, which enable handlers in a handler chain to share processing-related state. Most importantly, you can get the value of a specific property from the MessageContext by using the method getProperty, and you can set the name and value of a property associated with the MessageContext by using the method setProperty. You can also view the names of the properties in this MessageContext and remove a property (that is, a name-value pair) from the MessageContext.

At mediation runtime, all of the user-defined properties that have been set during configuration for the current mediation (see Configuring mediation context properties) are applied to the MediationContext property set.

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. As you are working with the MessageContext methods that give you access to message properties, you do not have to cast the interface to SIMessageContext **unless** you are also interested in the methods provided by SIMessageContext.
2. Get the SIMessage from the MessageContext object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`
3. Retrieve or set properties, by using the MessageContext methods. For instance, if a property has been defined during configuration with the name streetName, the type String, and the value "Main Street" your code to retrieve and print the street name might look like this:

Example

```
public boolean handle(MessageContext context) throws MessageContextException {

   ........
  {
    /* Retrieve the street name property */
    String myStreetName;
    myStreetName = (String) getProperty(streetName);

    /* Display property value */
    System.out.println(myStreetName);

  }
}
```

Working with message properties

You can work with the message properties to affect subsequent processing.

Before you begin

Before you start this task, you should read about the properties that are supported by the SIMessage interface in Message properties support for mediations.

About this task

There are two different types of message properties:

- System properties (including JMS headers, JMSX properties, and JMS_IBM_properties)
- User properties.

You can work with message properties to affect which messages a later mediation should process, or to affect processing by a downstream application or mediation. The rule set in the selector field during mediation configuration tests values in the message properties.

You can access, modify and clear properties by using the SIMessage interface (see “SIMessage” on page 1016.) There are three different sets of methods:

- These properties operate on system properties, plus user properties if the name is qualified with a prefix `user.`:
  - getMessageProperty
  - setMessageProperty
  - deleteMessageProperty
  - clearMessageProperties
- These properties operate on user properties only, without the need for the prefix `user.`:
  - getUserProperty

  - setUserProperty
  - deletUserProperty
  - clearUserProperties
- getUserPropertyNames returns a list of the names of the user properties in the message.

Typically, you can work with message properties in the following way, when programming a mediation:

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is MessageContext, and you should cast this to SIMessageContext **unless** you are only interested in the methods provided by MessageContext.
2. Get the SIMessage from the MessageContext object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`
3. Build your mediation header function in a similar way to these examples, by using the reference information in Message properties support for mediations to help:
   a. Get a user property of the message. For instance, `String task = (String)msg1.getUserProperty("task");`. In this case, the task string might refer to an operation that the mediation should perform.
   b. Set a user property, where message Properties are stored as name-value pairs. The setUserProperty method might only be used to set user properties, so the name passed into the method should not include the "user." prefix. For example, `msg1.setUserProperty("background","green");`
   c. Delete a user property from the message. For instance, `msg1.deleteUserProperty("task");`

Example

Mediation function code to work with message properties might look similar to the code snippet in this example:

```
String task = (String)msg1.getUserProperty("task");
if (task != null) {
  if (task.equals("addColor")) {
    msg1.setMessageProperty(SIProperties.JMS_IBM_Format, "colorful");
    msg1.setUserProperty("background","green");
    msg1.setUserProperty("foreground","purple");
    msg1.setUserProperty("depth",new Integer(3));
    msg1.deleteUserProperty("task");
  }
  else {
    msg1.clearUserProperties();
  }
}
```

Working with the message header

You can add function to a preexisting mediation handler to operate on the message header.

Before you begin

Create or open a basic mediation handler in an EJB project (see “Writing a mediation handler” on page 1004. It is useful to have understood the elements of the task “Working with the message payload” on page 1012, because some of those elements are used in this task

About this task

There are different types of field that you can set in message headers. Importantly, you can set the forward and return routing addresses for messages after they have been mediated at the current

destination. In addition there are other fields that you can set, such as priority and reliability for the message and its reply, and the remaining time before the message (or the reply) expires.

Procedure

1. To set routing addresses in the message header, see “Setting routing addresses in a message header.”
2. To set all other fields in the message header, see “Working with non-routing path fields in a message header” on page 1011.

Setting routing addresses in a message header:

You can add function to a pre-existing mediation handler to set routing addresses in the message header.

Before you begin

Before you start this task, you should have created the basic mediation handler in an EJB project (see “Writing a mediation handler” on page 1004.

About this task

To work with routing addresses, you will use the SIDestinationAddress and SIDestinationAddressFactory APIs. The SIDestinationAddress is the public interface that represents an service integration bus, and gives your mediation access to the name of the destination and the bus name. SIDestinationAddressFactory enables you to create a new SIDestinationAddress to represent an service integration bus destination. For reference information about these APIs, see “SIDestinationAddress” on page 1010 and “SIDestinationAddressFactory” on page 1011.

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is MessageContext, and you should cast this to SIMessageContext **unless** you are only interested in the methods provided by MessageContext.
2. Get the SIMessage from the MessageContext object. For example:
   ```
   SIMessage message = ((SIMessageContext)context).getSIMessage();
   ```
3. Build your mediation header function by using these basic steps:
   a. Get a handle to the runtime environment. For example:
      ```
      .... SIMediationSession mediationSession = mediationContext.getSession();
      ```
   b. Create a forward routing path to set on the cloned object. For example, use the Vector class to create a extendable array of objects.
   c. Get the SIDestinationAddressFactory that is to be used for creating SIDestinationAddress instances. For example:
      ```
      SIDestinationAddressFactory destFactory = SIDestinationAddressFactory.getInstance();
      ```
   d. Create a new SIDestinationAddress, representing a service integration bus destination. For example:
      ```
      SIDestinationAddress dest = destFactory.createSIDestinationAddress(remoteDestinationName(),false);
      ```
      In this case, the second parameter, the Boolean “false”, indicates that the destination should not be localized to the local messaging engine, but can be anywhere on the service integration bus.
   e. Use the add method of the Vector class to add another destination name to the array.
   f. Clone the message, and modify the forward routing path in the cloned message. For example:
      ```
      clonedMessage.setForwardRoutingPath(forwardRoutingPath);
      ```
   g. Send the cloned message by using the send method in the SIMediationSession interface to send the message to the service integration bus. For example, if named "clonedMessage":

```
mediationSession.send(clonedMessage, false);
```

4. Return *true* to ensure the message passed into the handle method of the MediationHandler interface continues along the handler chain.

Example

The complete mediation function code to change the forward routing path might look like this example:

```
/* A sample mediation that clones a message
 * and sends the clone off to another destination  */

public class RoutingMediationHandler implements MediationHandler {

 public String remoteDestinationName="newdest";

 public boolean handle(MessageContext context) throws MessageContextException {
  SIMessage clonedMessage = null;
  SIMessageContext mediationContext = (SIMessageContext) context;
  SIMessage message = mediationContext.getSIMessage();
  SIMediationSession mediationSession = mediationContext.getSession();

  // Create a forward routing path that will be set on the cloned message
  Vector forwardRoutingPath = new Vector();
  SIDestinationAddressFactory destFactory =
        SIDestinationAddressFactory.getInstance();
  SIDestinationAddress dest =
        destFactory.createSIDestinationAddress(remoteDestinationName,false);
  forwardRoutingPath.add(dest);

  try {
   // Clone the message
   clonedMessage = (SIMessage) message.clone();
   // Modify the forward routing path for the clone
   clonedMessage.setForwardRoutingPath(forwardRoutingPath);
   // Send the message to the next destination in the frp
   mediationSession.send(clonedMessage, false);
  } catch (SIMediationRoutingException e1) {
   e1.printStackTrace();
  } catch (SIDestinationNotFoundException e1) {
   e1.printStackTrace();
  } catch (SINotAuthorizedException e1) {
   e1.printStackTrace();
  } catch (CloneNotSupportedException e) {
   // SIMessage should clone OK so you shouldn't need to enter this block
   e.printStackTrace();
  }
  // allow original message to continue on its path
  return true;
 }
```

SIDestinationAddress:

The SIDestinationAddress public interface represents a service integration bus destination.

The API has three methods:

- isTemporary: This method determines whether the SIDestinationAddress represents a temporary or permanent Destination, returning a Boolean value.
- getDestinationName: Method to retrieve the name of the Destination represented by this SIDestinationAddress.

- getBusName: Method to retrieve the bus name of the Destination represented by this SIDestinationAddress.

For more information about the SIDestinationAddress interface, see the SIDestinationAddress generated API information.

SIDestinationAddressFactory:

The SIDestinationAddressFactory public interface extends java.lang.Object, and creates an SIDestinationAddressFactory at static initialization that is subsequently used for the creation of all instances of SIDestinationAddress.

The interface has three methods:
- getInstance: This method gets the singleton SIDestinationAddressFactory that is used for creating SIDestinationAddress instances.
- createSIDestinationAddress: These two methods are used to create a SIDestinationAddress to represent a service integration bus destination. The first will create a SIDestination that exists only on the local service integration bus (and maybe localized to the "local" messaging engine depending on the localOnly flag). The second method is used to create a SIDestination that exists on a remote service integration bus.
-

For more information about the SIDestinationAddressFactory interface, see the SIDestinationAddressFactory generated API information.

Working with non-routing path fields in a message header:

You can work with fields in a message header that identify and affect the behavior of messages.

About this task

In addition to the routing fields (see “Setting routing addresses in a message header” on page 1009), there are a number of fields in the message header that you can work with. These fields affect important qualities and characteristics of the message, such as priority and reliability, identity, and so on. See “Message header information” for information about the equivalence of the header fields to JMS message header fields, and the methods available to work with them.

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is MessageContext, and you should cast this to SIMessageContext **unless** you are only interested in the methods provided by MessageContext.
2. Get the SIMessage from the MessageContext object. For example, `SIMessage message = ((SIMessageContext)context).getSIMessage();`
3. Build your mediation header function in a similar way to these examples, and using the reference information in “Message header information” to help:
   a. Set the reliability of the message. For instance, `siMessage.setReliability(Reliability.ASSURED_PERSISTENT);`. In this case, the quality of service is set to the highest level.
   b. Set the time to live for a message - that is, the time, in milliseconds, that the message is allowed to remain on a queue before it is removed if it is not processed. For example, `siMessage.setRemainingTimeToLive(1000000);` will set the remaining time before the message should expire to 1000 seconds.

Message header information:

The non-routing SIMessage header fields, and the methods available to work with them, can be mapped to JMS message header fields.

Header fields

Table 107. Mapping of SIMessage header fields to JMS message header fields. The first column of the table lists the SIMessage header fields. The second column provides a brief description of the fields. The third column provides the corresponding JMS message header fields. The fourth column lists the SIMessage methods.

SIMessage header field	Field description	Corresponding JMS message header field	SIMessage methods
Priority (ReplyPriority)	Integer value 0-9, higher value is higher message priority	JMSPriority (integer)	• getPriority • setPriority • getReplyPriority • setReplyPriority
Reliability (ReplyReliability)	Specifies the reliability of message delivery. See Message reliability levels - JMS delivery mode and service integration quality of service for a description of the allowed values.	JMSDeliveryMode (string) supports two levels of reliability: PERSISTENT and NON_PERSISTENT	• getReliability • setReliability • getReplyReliebility • setReplyReliability
TimeToLive (ReplyTimeToLive, RemainingTimeToLive)	An integer that represents the time in milliseconds that a message can remain on the queue before it expires.	JMSExpiration (long) is the time of expiry, calculated as "current time" plus (+) "time-to-live".	• getTimeToLive • getReplyTimeToLive • getRemainingTimeToLive • setTimeToLive • setReplyTimeToLive • setRemainingTimeToLive
Discriminator (ReplyDiscriminator)	A string that contains a topic name that is tested by a selector rule to determine if the message should be mediated.	No corresponding JMS field	• getDiscriminator • setDiscriminator • getReplyDiscriminator • setReplyDiscriminator
RedeliveredCount	Read-only field (integer) that holds that counts each time a message is re-delivered.	JMSRedelivered (Boolean) indicates that it is likely, but not guaranteed, that the message was delivered but unacknowledged in the past.	getRedeliveredCount
ApiMessageId	A string that uniquely identifies each message sent.	JMSMessageId (string)	• getApiMessageId • setApiMessageId
CorrelationId	A string that links two messages, typically linking a request message with its response.	JMSCorrelationId (string)	• getCorrelationId • setCorrelationId
UserId	A string that represents the identity of the user sending the message.	JMSX Userid is a message property not used by WebSphere Application Server.	• getUserId • setUserId

Working with the message payload

You can work with the message payload in a pre-existing mediation handler, and transcode the message payload from one message format to another.

Before you begin

Create or open a mediation handler in an EJB project. For more information, see “Writing a mediation handler” on page 1004. You should also read the tips for successfully programming mediations in the topic Coding tips for mediations programming.

About this task

You can use this task to complete some or all of the following actions on the message payload:

- Locate the data objects within the message payload
- Convert the payload into another format
- Convert the payload into a byte array, for example if you want your mediation to log messages.

To work with the contents of a message, use the SIMessage and SIMessageContext APIs. Additionally, use SIMediationSession to provide your mediation with access to the service integration bus, to send and receive messages. For more information, see:

- Mediation programming
- “MediationHandler” on page 1015
- “SIMessageContext” on page 1015

To work with specific fields within a message, use Service Data Objects (SDO) Version 1 data graphs. For more information, see SDO data graphs. For more information about the format of supported message types, and examples of how to work with them, see “Mapping of SDO data graphs for web services messages” on page 1022.

To work with the message payload, take the following steps:

Procedure

1. Locate the point in your mediation handler where you insert the functional mediation code, in the method `handle (MessageContext context)`. The interface is MessageContext, and you should cast this to SIMessageContext unless you only want to work with the methods provided by MessageContext.
2. Retrieve the data graph of the message payload as follows:
   a. Get the SIMessage from the MessageContext object. For example:
      ```
      SIMessage message = ((SIMessageContext)context).getSIMessage();
      ```
   b. Get the message format string to determine its type. For example:
      ```
      String messageFormat = message.getFormat();
      ```
   c. Retrieve the DataGraph object from the message. For example:
      ```
      DataGraph dataGraph = message.getDataGraph();
      ```

      For more information, see SDO data graphs.
3. Optional: Locate data objects within the payload:
   a. Navigate within the graph to a named DataObject. For example, where DataObject has the name "data":
      ```
      DataObject dataObject = dataGraph.getRootObject().getDataObject("data");
      ```
   b. Retrieve information contained in the data object. For example, if the message is a text message:
      ```
      String textInfo = dataObject.getString("value");
      ```
4. Work with the fields within the message. For an example of how to do this, see “Example code for message fields” on page 1014.
5. Optional: Transcode the payload into another format:
   a. Review the topic “Transcoding between message formats” on page 1017 to understand the implications of transcoding the payload.
   b. Call the method getNewDataGraph, passing the new format as a parameter, which returns a copy of the payload in the new format. For example:
      ```
      DataGraph newDataGraph = message.getNewDataGraph(newFormat);
      ```
   c. Write the data graph in the new format back to the message using the setDataGraph method. For example:

```
message.setDataGraph(newDataGraph, newFormat);
```

6. Optional: Convert the payload into a stream of bytes:
   a. Review the topics “Transcoding a message payload into a byte array” on page 1019 and “Transcoding a byte array into a message payload” on page 1020 to understand the implications of converting between message format and byte stream, and back again.
   b. Call the method getDataGraphAsBytes, which returns a copy of the payload as a byte stream. For example:
      ```
      byte[] newByteArray = message.getDataGraphAsBytes();
      ```
   c. Call the method createDataGraph provided by the SIDataGraphFactory API, which creates a new data graph by parsing the bytes according to the format passed to the method. For example:
      ```
      DataGraph newDataGraph = SIDataGraphFactory.getInstance().createDataGraph( byteArray, format);
      ```
   d. Work with the message as a stream of bytes. For an example of how to do this, see “Example code for message fields”
7. Return *True* in your mediation code so that the MessageContext is passed to the next mediation handler in the handler list. If the return value is *False* the MessageContext will be discarded and will not be delivered to the destination.

   Note: If your mediation handler is the last handler in the handler list, and the forward routing path is empty, the message is made available to consuming applications on that destination. If the forward routing path not empty, the message is not made available to any consumers on that destination. Instead, the message is forwarded to the next destination in the routing path.

Example code for message fields

Below is an example of the code for a mediation for working with a field in a message:

```
public boolean handle(MessageContext context) throws MessageContextException {

 /* Get the SIMessage from the MessageContext object */
 SIMessage message = ((SIMessageContext)context).getSIMessage();

 /* Get the message format string */
 String messageFormat = message.getFormat();

 /* If you have a JMS TextMessage then extract the text contained in the message. */
 if(messageFormat.equals("JMS:text"))
 {
  /* Retrieve the DataGraph object from the message */
  DataGraph dataGraph = message.getDataGraph();

  /* Navigate down the DataGraph to the DataObject named 'data'. */
  DataObject dataObject = dataGraph.getRootObject().getDataObject("data");

  /* Retrieve the text information contained in the DataObject. */
  String textInfo = dataObject.get("value");

  /* Use the text information retrieved */
  System.out.println(textInfo);
 }

 /* Return true so the MessageContext is passed to any other mediation handlers
 * in the handler list */
 return true;

 }
```

The complete mediation function code for working with the message payload as a stream of bytes might look like this example:

```
  public boolean handle(MessageContext context)throws MessageContextException {

  /* Get the SIMessage from the MessageContext object */
  SIMessage message = ((SIMessageContext)context).getSIMessage();

    if (!SIApiConstants.JMS_FORMAT_MAP.equals(msg.getFormat()))
    {
      try
      {
        dumpBytes(msg.getDataGraphAsBytes());
      }
      catch(Exception e)
      {
        System.out.println("The message contents could not be retrieved due to a "+e);
      }
    }
    else
    {
      System.out.println("The bytes for a JMS:map format message cannot be shown.");
    }

    return true;
  }

  private static void dumpBytes(byte[] bytes)
  {
    // Subroutine to dump the bytes in a readable form to System.out
  }
}
```

MediationHandler:

The public interface MediationHandler has just one method: handle. This method is used by the runtime to invoke a mediation.

The method handle is called by the runtime when a message is to be mediated. The method returns Boolean *True* if the message passed into this method should continue along the handler list, otherwise *False*.

At the end of the handler list, the message is sent to the next destination on the routing path, unless the forward routing path is empty, when the message is made available to consuming applications on the current destination.

For more information about the MediationHandler interface, see the MediationHandler generated API information.

SIMessageContext:

Public interface SIMessageContext extends javax.xml.rpc.handler.MessageContext. This is the object that is required on the interface of a mediation handler. In addition to the context information that might be passed from one handler to another, it can return a reference to an SIMessage and an SIMediationSession.

The SIMessage is the service integration technologies representation of the message being processed by the MediationHandler. The SIMediationSession is a handle to the runtime resources.

The interface MessageContext abstracts the message context that is processed by a handler in the handle method. The MessageContext interface provides methods to manage a property set. MessageContext properties enable handlers in a handler chain to share processing related state.

As well as defining the method that is invoked by the mediation runtime environment, the interface might also specify properties following the Enterprise JavaBeans naming pattern, or by providing a BeanInfo class. Each property of the bean will be initialized from a single environment entry with the same name as the property. Bean properties of simple type are specified by using Java Platform, Enterprise Edition (Java EE) env-entry. If the handler has properties that are of non-simple type, then other environment definitions may be used.

The API has two methods:

- The getSIMessage method to get the service integration bus representation of the message being mediated. Read more about the SIMessage API in "SIMessage."
- The getSession method to get an SIMediationSession object that is a handle to the runtime environment. Read more about the SIMediationSession API in "SIMediationSession" on page 1017.

SIMessage:

The SIMessage interface is the public interface to a service integration bus message for use by mediations and other service integration bus components. This interface extends java.lang.Cloneable and java.lang.Serializable.

The version of Service Data Objects (SDO) supported by mediations is Version 1.

The SIMessage interface has many methods allowing you to work with message properties, header contents, routing path, metadata, and others:

- The method getDataGraph returns the SDO data graph. This contains the SIMessage payload content in a tree representation. Using the data graph, you can work directly with individual fields in the message payload. For more information about SDO data graphs, see SDO data graphs.
- You can transcode a message payload by calling the method getNewDataGraph(format). It returns a copy of the payload in the new format. You can write the new datagraph back to the message by using setDataGraph(DataGraph, format). For more information, see "Transcoding between message formats" on page 1017.
- If you want to log a message as a simple byte stream, you can retrieve the message payload as a byte array by using the method getDataGraphAsBytes. For more information about converting from data graph to bytes, and back again, see "Transcoding a message payload into a byte array" on page 1019 and "Transcoding a byte array into a message payload" on page 1020.
- There are methods to get, set, delete and clear user properties and message properties. You can also retrieve a list of user property names. For more information about working with properties, see "Working with message properties" on page 1007.
- Forward and reverse routing paths define a sequential list of intermediate bus destinations through which messages pass to reach a target bus destination. You use a routing path to apply the mediations configured on several destinations to the messages sent along the path. The following methods allow you to get and set the contents of the ForwardRoutingPath and ReverseRoutingPath for an SIMessage:
  - getForwardRoutingPath()
  - setForwardRoutingPath()
  - getReverseRoutingPath()
  - setReverseRoutingPath()

  For more information about routing paths, see Destination routing paths. For information about how to work with routing addresses, see "Setting routing addresses in a message header" on page 1009.
- If your mediation changes the content of the message, there is a risk that the message is no longer valid. If the data graph is not valid, the message cannot be sent through the service integration bus or

stored in the message store. In this case, the message is not **well formed**. A message is well formed when all the values of the message properties might be serialized, and the data graph of the message conforms to the format of the message. You can test your message by using the method isWellFormed. It returns *true* when the message contains a well formed data graph. This test has implications for performance. For more information, see Setting tuning properties for a mediation.

- You can work with the time for the message to live, measured in milliseconds from the time when the message was originally sent:
  - The methods getTimeToLive and setTimeToLive allow you to get and set the value of the TimeToLive field in the message header. A value of 0 indicates that the message will never expire.
  - The methods getRemainingTimeToLive and setRemainingTimeToLive allow you to get the remaining time in milliseconds before the message expires, and set the remaining time in milliseconds before the message should expire.

For more information about SIMessage, see the API documentation.

SIMediationSession:

The SIMediationSession public interface defines the methods for querying and interacting with the service integration bus. As well as defining the methods for working with the service integration bus, this interface also includes methods that provide information about where the mediation is invoked from, and the criteria that are applied before the message is mediated.

Both selector and discriminator control which messages are sent to the mediation, through a rule specified in a text string. The rule specified by the selector examines the header and properties of the message, whereas the discriminator examines the topic of the message. If a message contains both selector and discriminator, it must match both rules for the message to be mediated. If either the selector or the discriminator rule does not match, the message is not mediated.

The API has these methods:

- getBusName returns the name of the bus upon which the mediation is associated.
- getDestinationName returns the name of the destination with which the mediation is associated.
- getDiscriminator returns the discriminator that is defined in the mediation definition.
- getMediationName returns the name of the mediation that is being executed.
- getMessageSelector returns the message selector that is defined in the mediation definition.
- getMessagingEngineName returns the name of the messaging engine from which the mediation was invoked
- getSIDestinationConfiguration returns the SIDestinationConfiguration object associated with the destination, specified by destinationName or destinationAddress.
- receive receives an SIMessage from the service integration bus. There are four variants.
- resetIdentity changes the identity of the given message to the current run-as identity.
- send sends a copy of an SIMessage to the service integration bus, in addition to the message returned by the message interface.

See also the generated API information for SIMessageContext.

Transcoding between message formats:

A mediation can convert a message from one format to another without changing the semantic meaning of the message. This operation is referred to as transcoding a message.

The following code is an example mediation handler that transcodes a message into a new message format, providing that the message can be transcoded:

```
private static final String NEW_FORMAT = "JMS:text";

public boolean(MessageContext context) throws MessageContextException
{
  try
  {
    SIMessageContext msgCtx  = (SIMessageContext)context;
    SIMessage        msg     = msgCtx.getMessage();
    DataGraph        newDg   = msg.getNewDataGraph(NEW_FORMAT);

    msg.setDataGraph(newDg,NEW_FORMAT);
    return true;
  }
  catch(Exception e)
  {
    // Reroute the original message to the exception destination
    MessageContextException mce =
      new MessageContextException("Unable to transcode to "+NEW_FORMAT",e);
    throw mce;
  }
}
```

The table below describes which messages can be transcoded, and gives the outcome for each format pairing. Note that the abbreviation DG represents "data graph". The numbers within brackets in the table are explained as follows:

- (1) A message with format JMS: cannot have a payload. It does not carry any message data other than the message properties. If a mediation calls `getDataGraph()` on a message with format JMS:, `null` is always returned. All other message formats must have a message payload. This means that a message with format JMS: cannot be transcoded into another format. If a mediation needs to change a message with format JMS: into a message with any other format, the mediation needs to call the methods `SIDataGraphFactory.getInstance().createDataGraph(newFormat)` and `setDataGraph` on the SIMessage object to change the message contents.
- (2) `null` is always returned if a mediation calls `getDataGraph()` on a message with format JMS:
- (3) A mediation can call the method getNewDataGraph() on a message to return a copy datagraph with the same format as the message. The copy can be edited, leaving the original message unchanged. For SOAP and Beans, you can change the message model by editing the format string to change the value that follows the ":".

Table 108. Message transcoding. The table contains the different formats that can be used to convert the messages from one format to another. The table shows the transcoding options that is possible between the different formats, and it also provides the effect the conversion has on the messages.

	To JMS:	**To JMS:text**	**To JMS:bytes**	**To JMS:stream**	**To JMS:object**	**To SOAP:**	**To Bean:**
From JMS:	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)	DG=null (1)
From JMS:text	DG=null (2)	Yes (3)	Yes, bytes contain UTF-8	Yes, if text contains XML that conforms to the correct schema.	No	Yes, if message content is valid SOAP.	Yes, if message content is valid SOAP.
From JMS:bytes	DG=null (2)	Yes, but only when the bytes can correctly be interpreted as a UTF-8 string.	Yes (3)	Yes, if bytes contain XML that conforms to the correct schema.	Yes, assume that bytes are a serialized object.	Yes, if message content is valid SOAP.	Yes, if message content is valid SOAP.
From JMS:stream	DG=null (2)	Yes, text is XML transcoding.	Yes, bytes contain XML transcoding.	Yes (3)	No	No	No

Table 108. Message transcoding (continued). The table contains the different formats that can be used to convert the messages from one format to another. The table shows the transcoding options that is possible between the different formats, and it also provides the effect the conversion has on the messages.

	To JMS:	To JMS:text	To JMS:bytes	To JMS:stream	To JMS:object	To SOAP:	To Bean:
From JMS:object	DG=null (2)	No	Yes, bytes contain the object serialization.	No	Yes (3)	No	No
From SOAP:	DG=null (2)	Yes	Yes	No	No	Yes (3) - if message content matches the new WSDL.	Yes
From Bean:	DG=null (2)	Yes	Yes	No	No	Yes	Yes (3) - if message content matches the new WSDL.

XML schema definition for JMS stream messages:

This is the XML schema definition for transcoding JMS stream messages to message types.

The following XML schema definition uses the target namespace http://www.ibm.com/xmlns/prod/websphere/messaging/jms/ to express JMS stream messages in XML. Use this definition to transcode between a byte array and a message payload.

```
<xsd:schema elementFormDefault="qualified" xml:lang="EN"
  targetNamespace="http://www.ibm.com/xmlns/prod/websphere/messaging/jms"
  xmlns="http://www.ibm.com/xmlns/prod/websphere/messaging/jms"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">

  <xsd:element name="data" type="StreamBody"/>

  <xsd:complexType name="StreamBody">
    <xsd:sequence>
      <xsd:element name="value"
        type="streamTypes"
        minOccurs="0"
        maxOccurs="unbounded"
        nillable="true"/>
    </xsd:sequence>
  </xsd:complexType>

  <xsd:simpleType name="character">
    <xsd:restriction base="xsd:string">
      <xsd:minLength value="1"/>
      <xsd:maxLength value="1"/>
    </xsd:restriction>
  </xsd:simpleType>

  <xsd:simpleType name="streamTypes">
   <xsd:union memberTypes="xsd:long xsd:int xsd:short xsd:byte xsd:boolean
            xsd:float xsd:double xsd:string xsd:hexBinary character"/>
  </xsd:simpleType>
</xsd:schema>
```

Transcoding a message payload into a byte array:

You can transcode the message payload into a byte array.

For example, you might want to write a mediation handler that logs a message as a simple byte stream. You can retrieve the message payload as a byte array by using the method getDataGraphAsBytes. The table below describes the rules for transcoding an SIMessage data graph into a byte array.

Table 109. Rules for transcoding a message payload into a byte array. The first column of the table contains the datagraph formats used for transcoding a message into a byte array. The second column provides the preconditions for the datagraph format if available. The third column provides the result of the transcode. The fourth column contains the character set encodings if they are applicable for the messages.

Datagraph format	Pre-conditions	Outcome	Character set encoding
JMS:	None	Returns null.	Not applicable.
JMS:text	None	Returns the result of java.lang.String:getBytes(String charSetName) when applied to the `data/value` element of the graph, where charSetName = "UTF-8"	UTF-8
JMS:bytes	None	Returns a copy of the value of the `data/value` element of the data graph for the message.	Not applicable.
JMS:stream	None	Returns a byte buffer containing an XML serialization of the stream message according to the XML schema for stream messages.	UTF-8
JMS:object	None	Returns a copy of the value of the `data/value` element of the data graph for the message.	Not applicable.
SOAP:	If the byte array must be generated by this operation (instead of using an existing byte array available through lazy parsing) then the data graph must be valid with respect to the WSDL model.	Returns a byte buffer containing a SOAP serialization of the data graph. If the SOAP message contains an attachment, the buffer has the multipart MIME format.	Either UTF-8, or that of the source message for the graph, where logically equivalent to the graph state.
Bean:	The data graph must be valid with respect to the WSDL model. In the absence of a SOAP binding the serialization will be performed using RPC/literal encoding.	Returns a byte buffer containing a SOAP serialization of the data graph. If the Bean contains attachments then the buffer will be in multipart MIME format.	UTF-8

Transcoding a byte array into a message payload:

A mediation can transcode a byte array into a message payload without changing the meaning of the message.

A mediation can reconstruct the message payload from a byte array, for example after logging a message. To reconstruct the message, call the method `createDataGraph` provided by the SIDataGraphFactory API. This method requires a byte array and a format string and creates a new data graph by parsing the bytes according to the format passed to the method, as shown in the following example:

```
DataGraph newDataGraph = SIDataGraphFactory.getInstance().createDataGraph(byteArray, newFormat);
```

The table below describes the rules for transcoding a byte array into an SIMessage data graph.

Table 110. Rules for transcoding a byte array into an SIMessage data graph. The first column of the table contains the format arguments used for transcoding a byte array into an SIMessage data graph. The second column provides the preconditions if available for the format arguments. The third column provides the resultant SIMessage data graphs for the specified format arguments.

Format argument	Pre-conditions	Outcome
JMS:	None	Returns null
JMS:text	`java.lang.String(inputBytes, "UTF-8")` does not result in an exception.	Returns new data graph instance of format JMS:text. Value of graph at path `data/value` has value equal to `java.lang.String(inputBytes, "UTF-8")`.
JMS:bytes	`inputBytes` is not null.	Returns new data graph instance of format JMS:bytes. Value of graph at path `data/value` is a copy of the `inputBytes` byte array.
JMS:stream	Byte array is XML, and is valid with respect to the `JmsStreamBody` type of the XML schema definition.	Returns new data graph instance of format JMS:stream. Value of graph at path `data/value` has type List, containing a sequence of simple typed values according to the types and values of each of the elements in the XML document.
JMS:object	Not null **Note:** You must ensure that the byte array is a valid serialized object.	Returns new data graph instance of format JMS:object. Value of graph at path `data/value` is a copy of the `inputBytes` byte array.
SOAP:	The byte buffer contains valid SOAP with respect to the associated WSDL model.	Returns new data graph with type system defined by the WSDL referenced by the byte buffer, and values of the graph defined by the SOAP payload.
Bean:	The byte buffer contains valid Bean with respect to the associated WSDL model.	Returns new data graph with type system defined by the WSDL referenced by the byte buffer, and values of the graph defined by the Bean payload.

Web services messages overview:

To work with the data graph form of web services messages, you need to know the structure of the data graph, and how to develop code that can navigate the data graph.

The format of web services messages

WebSphere Application Server (base) supports two formats for web services messages: SOAP and enterprise beans. (These are similar to Java APIs for XML based RPC, or JAX-RPC.)

To work with web services messages, you need the following information:

- The structure of the Service Data Objects (SDO) Version 1 data graphs for web services messages. See “Mapping of SDO data graphs for web services messages” on page 1022 for more information about the data elements and the shape of the data graph.
- Reference information to help you develop code to navigate the data graphs of the messages that your program mediates. See “Mapping XML schema definitions to the SDO type system” on page 1026.
- For XML representations of the shape of each part of web services messages, sample code snippets and further information about the data graph format, see:“Web Services code example” on page 1029.

Format types

The web services message type is defined by a message format string within the message. The format string is prefixed with a domain identifier, which is either SOAP or Bean, followed by four comma-separated fields as follows:

```
SOAP:<wsdlLocation>,<serviceNameSpace>,<serviceName>,<portName>
Bean:<wsdlLocation>,<serviceNameSpace>,<serviceName>,<portName>
```

The fields are described in the following table:

Field name	Message format string	Field description
WSDL location	`<wsdlLocation>`	The URI where the WSDL for this message is located. The WSDL is deployed to the SDO repository, by using this location as the key.
Service namespace	`<serviceNamespace>`	Service namespace and Service name uniquely identify the Service definition within the WSDL.
Service name	`<serviceName>`	Service name and Service namespace uniquely identify the correct Service definition within the WSDL.
Port name	`<portName>`	Locates the Port definition within the Service, giving the PortType and Binding information that is required for message processing.

Mapping of SDO data graphs for web services messages:

The structure of web services messages is described by the Service Data Objects (SDO) Version 1 data graphs for web services messages.

Overall layout of a web services message

A web services message is described by a format string and three metadata fields: operationName, messageName, and messageType. The payload of the message is split across three other sections: headers, attachments and the body.

The Info node is the top-level of the SDO data graph for all web services messages. The following table describes the Info node properties and associated types.

Property name	Property type	Property description
operationName	`java.lang.String`	Identifies the WSDL operation that is associated with the message. If the data access service cannot identify the message, this field is null. See “Identifying web services messages” on page 1023.
messageName	`java.lang.String`	Identifies the WSDL message that is associated with the message. If the data access service cannot identify the message, this field is null. See “Identifying web services messages” on page 1023.

Property name	Property type	Property description
messageType	`java.lang.String`	Identifies WebService type of message instance. This field can have the values: *input*, *output*, *fault*, *ambiguous*. If the data access service cannot identify the message, this field is null. See “Identifying web services messages.”
headers	`java.util.List` of data objects.	Contains a list of header entry data objects. Each SOAP header in the message results in a header entry in this list. See “Message header layout ” on page 1024.
attachments	`java.util.List` of data objects.	Contains a list of attachment entry data objects. For SOAP messages with attachments, each MIME part in the message (except the MIME part containing the SOAP envelope) is mapped to an entry in this list. See “Message attachment layout” on page 1024.
body	`commonj.sdo.DataObject`	A nested data object, which represents the body of the SOAP envelope. See “Message body layout” on page 1025.

Identifying web services messages

Processing of messages depends on whether the messages have WSDL definitions. The minimum amount of information required for processing without WSDL is “SOAP:”. The minimum amount of information required for processing with WSDL is: “SOAP:location,namespace,service,port”. If the format string does not include all five of these fields, the SOAP data access service attempts to process the message without WSDL.

- Processing messages without WSDL definitions: If the format string does not include full WSDL information, the SOAP data access service processes the message without attempting to match the message against definitions in WSDL. As a result, operationName and messageName are set to null, and messageType is set only when processing a fault message.
- Processing messages with WSDL definitions: If the format string includes <WSDL location>,<Service namespace>,<Service name>, and <Port name>, the SOAP and Beans data access services process the message by using the WSDL definitions of the service.

  Note: In either of the following circumstances, SOAP message processing fails once it has supplied all the required WSDL information:
  - the SOAP data access service fails to locate the WSDL
  - the WSDL fails to corroborate the message

When the SOAP data access service processes a SOAP request or reply message, it tries to match it against the message definitions in the WSDL. Usually there is one matching definition, and the operationName, messageName, and messageType are filled in appropriately. If there is more than one matching definition, the data access service selects a message definition, fills in the operationName and messageName. and sets the messageType to *ambiguous*.

When processing fault messages, identification is slightly different. In all cases the messageType is set to *fault*. If the message matches a unique fault definition in the WSDL, the operationName and messageName properties are also set.

Message header layout

The list of headers has two types of entry, header entry or bound header entry, depending on whether the header is based on part of the message or not.

The header entry type is used to handle headers that meet either of the following criteria:

- the header is part of the message that is modeled in WSDL
- the header is part of the message that is not modeled in WSDL, but is based on a part of the message

For a model of this header, see “Header entry.”

The bound header entry type is used when the SOAP binding for the message has bound a part of the body into a MIME attachment. (This occurs when you use a <MIME:content> element to bind a part of the message to an attachment.) For consistent mediation programming, all of the body data is stored in the body node in the graph. Unlike the normal attachment entry, a bound attachment entry is placed into the attachments list. The bound attachment entry contains the MIME meta-data for the attachment and the name of the message part that contains the data taken from this attachment. This allows mediations designed to process attachments to locate the data in the body part of the data graph. For a model of this attachment see “Bound header entry.”

Header entry

Property name	Property type	Property description
mustUnderstand	`java.lang.Boolean`	Carries the value from the mustUnderstand attribute on the SOAP header, if present.
actor	`java.lang.String`	Carries the value from the actor attribute on the SOAP header, if present.
any	`commonj.sdo.Sequence`	Container for the contents of the SOAP header.

Bound header entry

Property name	Property type	Property description
mustUnderstand	`java.lang.Boolean`	Carries the value from the mustUnderstand attribute on the SOAP header, if present.
actor	`java.lang.String`	Carries the value from the actor attribute on the SOAP header, if present.
messagePart	`java.lang.String`	Contains the name of the message part that carries the data from this message header.

Message attachment layout

Message attachments are handled in a similar way to headers, and instances of them populate the attachments list in the Info node.

There are two types of attachment entry to handle MIME attachments: attachment entry and bound attachment entry.

Attachment entry is for general attachments: see “Attachment entry” on page 1025.

Bound attachment entry includes <MIME:content> elements that bind a part of the body into a MIME attachment. If you are programming a mediation, you must know how to locate the data within the graph. For consistent mediation programming, the attachment data is placed in the message body, referred to by the part name in the header entry, which includes the other MIME metadata. For a model of this attachment, see "Bound attachment entry."

Attachment entry

Property name	Property type	Property description
contentType	`java.lang.String`	Carries the contentType from the MIME part that is represented by the attachment entry.
contentTransferEncoding	`java.lang.String`	Carries the contentTransferEncoding from the MIME part that is represented by the attachment entry.
contentId	`java.lang.String`	Carries the contentId from the MIME part that is represented by the attachment entry.
data	`byte[]`	Carries the content of the MIME element as a byte array.

Bound attachment entry

Property name	Property type	Property description
contentType	`java.lang.String`	Carries the contentType from the MIME part that is represented by the attachment entry.
contentTransferEncoding	`java.lang.String`	Carries the contentTransferEncoding from the MIME part that is represented by the attachment entry.
contentId	`java.lang.String`	Carries the contentId from the MIME part that is represented by the attachment entry.
messagePart	`java.lang.String`	Contains the name of the message part that carries the data from this attachment.

Message body layout

The layout of the data object in the body is defined by the service WSDL. The type of the data object is derived from the message definition in the WSDL. The data object has one property for each part in the message definition. The layout of each message part follows the convention for mapping XML Schema into SDO. See "Web Services code example" on page 1029 for more information.

Web services fault message

If the message is a fault message, the messageType field in the Info node of the graph is set to "fault", and the message body has the following properties:

Property name	Property type	Property description
faultcode	`javax.xml.namespace.QName`	Carries the faultcode value from the SOAP Fault element
faultstring	`java.lang.String`	Carries the faultstring value from the SOAP Fault element
faultactor	`java.lang.String`	Carries the faultactor value from the SOAP Fault element

Property name	Property type	Property description
detail	`commonj.sdo.DataObject`	Carries the content within the detail child of the SOAP Fault element

Note: The detail element definition uses element and attribute wildcards, so the content of the detail data object contains a Sequence. See “Web Services code example” on page 1029 for more information.

Mapping XML schema definitions to the SDO type system:

Each XML schema type is mapped to an SDO type. Use this mapping to help you develop code to navigate the data graphs of the messages that your program mediates.

The version of Service Data Objects (SDO) supported by mediations is Version 1.

XML schemas can be embedded in the WSDL sections that describe the message parts and SOAP headers. However the SOAP header description is more likely to be available as a separate schema, in which case you should load it into the SDO repository where it can be used at run time to process any message with a matching header.

Schema to Java class mapping

Each XML schema complex type is mapped to an SDO type. This means that an element with a complex type is represented by an instance of an SDO data object. The type has a property for each element, attribute, or wildcard that is contained in the schema type definition.

The instance contains a value for each property that has been set. If the property is mapped from a schema complex type, the value is another SDO data object. If the property is mapped from a schema simple type, the value is an instance of a Java class, as shown in the following table.

Table 111. Schema types and corresponding Java classes. The first column of the table lists the schema types. The second column lists the corresponding Java classes. The third column refers you to one of the two notes that is given at the end of the table for your reference.

Schema type	Java class	Notes
anyURI	java.lang.String	
base64Binary	byte[]	See Note 2
boolean	java.lang.Boolean/ boolean	See Note 1
byte	java.lang.Byte / byte	See Note 1
date	java.lang.String	
dateTime	java.lang.String	
decimal	java.math.BigDecimal	
double	java.lang.Double / double	See Note 1
duration	java.lang.String	
ENTITIES	java.util.List	
ENTITY	java.lang.String	
float	ava.lang.Float / float	See Note 1
gDay	java.lang.String	
gMonth	java.lang.String	
gMonthDay	java.lang.String	
gYear	java.lang.String	
gYearMonth	java.lang.String	
hexBinary	byte[]	See Note 2

Table 111. Schema types and corresponding Java classes (continued). The first column of the table lists the schema types. The second column lists the corresponding Java classes. The third column refers you to one of the two notes that is given at the end of the table for your reference.

Schema type	Java class	Notes
ID	java.lang.String	
IDREF	java.lang.String	
IDREFS	java.util.List	
int	java.lang.Integer / int	See Note 1
integer	java.math.BigInteger	
language	java.lang.String	
long	java.lang.Long / long	See Note 1
Name	java.lang.String	
NCName	java.lang.String	
negativeInteger	java.math.BigInteger	
NKTOKENS	java.util.List	
NMTOKEN	java.lang.String	
nonNegativeInteger	java.math.BigInteger	
nonPositiveInteger	java.math.BigInteger	
normalisedString	java.lang.String	
NOTATION	javax.xml.namespace.QName	
positiveInteger	java.math.BigInteger	
QName	javax.xml.namespace.QName	
short	java.lang.Short / short	See Note 1
string	java.lang.String	
time	java.lang.String	
token	java.lang.String	
unsignedByte	java.lang.Short / short	See Note 1
unsignedInt	java.lang.Long / long	See Note 1
unsignedLong	java.math.BigInteger	
unsignedShort	java.lang.Integer / int	See Note 1

Notes:

1. SDO automatically converts primitives (int, long and so on) into objects, as needed. This means that you can use a mixture of the specialized methods (getInt, setInt, getLong, setLong) as well as the generic get and set methods.
2. As byte arrays are mutable, you can update the value without setting it back onto the data object. However, when this occurs, the data object may not be aware of implicit update. When working with byte array values, always use the setBytes() method to explicitly update the data object.

Working with global elements and attributes

When a schema is mapped to SDO, a special SDO type - typically called 'DocumentRoot' - is defined. This type is a container for all the global elements and attributes in the schema. Whenever you have to locate an SDO property for a global element or attribute, you should locate the ‘DocumentRoot' type and then locate the appropriate property within it.

The following schema defines the layout of web services messages. By comparing this schema with the information in “Mapping of SDO data graphs for web services messages” on page 1022 you can see the schema to SDO mapping in action.

```
<?xml version="1.0"?>

</xsd:schema>
```

Web Services code example:

This Web Services Description Language (WSDL) example and code snippets show how to access fields within a Web services message for programming a mediation.

Web services message definition

This topic contains an example of a web services message. The example is characterized in WSDL, an XML-based language that is used to describe the services a business offers and how those services might be accessed.

This topic shows how to program mediations to work with different parts of a web services message, which are described with the Service Data Objects (SDO) Version 1 representation in “Mapping of SDO data graphs for web services messages” on page 1022. For each part of the message, there is an XML description of the message, representing its SDO data graph. Each XML description is accompanied by code snippets that illustrate how to work with that part of the message.

Note: In the following example, the SOAP header schema is included in the WSDL. Alternatively, it can be included as a separate schema in the SDO repository.

This is a WSDL description of the message that is used as an example for subsequent code snippets:

companyInfo web service message description

```
<wsdl:definitions targetNamespace="http://example.companyInfo"
 xmlns:tns="http://example.companyInfo"
 xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
 xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:wsdlmime="http://schemas.xmlsoap.org/wsdl/mime/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema">

 <wsdl:types>
  <xsd:schema elementFormDefault="qualified"
   targetNamespace="http://example.header">

   <xsd:element name="sampleHeader">
    <xsd:complexType>
     <xsd:all>
      <xsd:element name="priority" type="xsd:int"/>
     </xsd:all>
    </xsd:complexType>
   </xsd:element>
  </xsd:schema>

  <xsd:schema elementFormDefault="qualified"
   targetNamespace="http://example.companyInfo">

   <xsd:element name="getCompanyInfo">
    <xsd:complexType>
     <xsd:all>
      <xsd:element name="tickerSymbol" type="xsd:string"/>
     </xsd:all>
    </xsd:complexType>
   </xsd:element>

   <xsd:element name="getCompanyInfoResult">
    <xsd:complexType>
     <xsd:all>
      <xsd:element name="result" type="xsd:float"/>
     </xsd:all>
    </xsd:complexType>
   </xsd:element>
  </xsd:schema>

 </wsdl:types>

 <wsdl:message name="getCompanyInfoRequest">
   <wsdl:part name="part1" element="tns:getCompanyInfo"/>
 </wsdl:message>

 <wsdl:message name="getCompanyInfoResponse">
  <wsdl:part name="part1" element="tns:getCompanyInfoResult"/>
  <wsdl:part name="part2" type="xsd:string"/>
  <wsdl:part name="part3" type="xsd:base64Binary"/>
 </wsdl:message>

 <wsdl:portType name="CompanyInfo">
  <wsdl:operation name="GetCompanyInfo">
   <wsdl:input message="tns:getCompanyInfoRequest"
               name="getCompanyInfoRequest"/>
   <wsdl:output message="tns:getCompanyInfoResponse"
```

```
                name="getCompanyInfoResponse"/>
  </wsdl:operation>
 </wsdl:portType>

 <wsdl:binding name="CompanyInfoBinding" type="tns:CompanyInfo">
  <wsdlsoap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>

  <wsdl:operation name="GetCompanyInfo">
   <wsdlsoap:operation soapAction=""/>
   <wsdl:input name="getCompanyInfoRequest">
    <wsdlsoap:body use="literal"/>
   </wsdl:input>
   <wsdl:output name="getCompanyInfoResponse">
    <wsdlsoap:body use="literal"/>
   </wsdl:output>
  </wsdl:operation>
 </wsdl:binding>

 <wsdl:service name="CompanyInfoService">
  <wsdl:port binding="tns:CompanyInfoBinding" name="SOAPPort">
   <wsdlsoap:address location="http://somewhere/services/CompanyInfoService"/>
  </wsdl:port>
 </wsdl:service>

</wsdl:definitions>
```

Working with the info node

This is an example of a simple SOAP request:

```
<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
    <env:Body>
        <ns1:getCompanyInfo>
            <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
        </ns1:getCompanyInfo>
    </env:Body>
</env:Envelope>
```

You can access the properties of the info node (see “Overall layout of a web services message” on page 1022) using code snippets such as this:

```
 // Get the info node (a child of the graph root object)
 DataObject rootNode = graph.getRootObject();
 DataObject infoNode = rootNode.getDataObject("Info");

  // Query the operationName, and messageType.
  String opName = infoNode.getString("operationName");
  String type   = infoNode.getString("messageType");
```

Working with a header

This is an example of a SOAP request including a header:

```
<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
    <env:Header>
        <example:sampleHeader
          env:mustUnderstand='1'
          xmlns:example='http://example.header'>
            <example:priority>4</example:priority>
        </example:sampleHeader>
    </env:Header>
```

```
    <env:Body>
        <ns1:getCompanyInfo>
            <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
        </ns1:getCompanyInfo>
    </env:Body>
</env:Envelope>
```

For a description of the properties of the header entry with a list of headers, see “Header entry” on page 1024. To work with a header entry and its properties, use code such as this:

```
   // Get the info node (a child of the graph root object)
    DataObject rootNode = graph.getRootObject();
    DataObject infoNode = rootNode.getDataObject("Info");

    // Access the list of headers
    List headerEntries = infoNode.getList("headers");

    // Get the first entry from the list
    DataObject headerEntry = (DataObject) headerEntries.get(0);

    // Query the mustUnderstand property of the header entry
    boolean mustUnderstand = headerEntry.getBoolean("mustUnderstand");

    // Get the Sequence that holds the content of the header entry
    Sequence headerContent = headerEntry.getSequence("any");

    // Get the first piece of content from the Sequence
    DataObject header = (DataObject) headerContent.getValue(0);

    // Read the priority from the header
    int priority = header.getInt("priority");

    // Shorthand for the above, using SDO path expressions that start
    // from the info node.
    mustUnderstand = infoNode.getBoolean("headers[1]/mustUnderstand");
    priority       = infoNode.getInt("headers[1]/any[1]/priority");
```

Working with an attachment

This is an example of a SOAP request including an XML attachment:

```
Content-Type: multipart/related; start="<start>"; boundary="boundary"

--boundary
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
Content-ID: <start>

<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
    <env:Body>
        <ns1:getCompanyInfo>
            <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
        </ns1:getCompanyInfo>
    </env:Body>
</env:Envelope>
--boundary
Content-Type: text/xml; charset=UTF-8
Content-Transfer-Encoding: binary
Content-ID: <myAttachment>

<info>Some attached information</info>
--boundary--
```

For a description of the properties of the attachment entry with byte array, see “Attachment entry” on page 1025. To work with a header entry and its properties, use code such as this:

```
// Get the info node (a child of the graph root object)
  DataObject rootNode = graph.getRootObject();
  DataObject infoNode = rootNode.getDataObject("Info");

  // Access the list of attachments
  List attachmentEntries = infoNode.getList("attachments");

  // Get the first entry from the list
  DataObject attachmentEntry = (DataObject) attachmentEntries.get(0);

  // Query the contentId property of the header entry
  String contentId = attachmentEntry.getString("contentId");

  // Get the data contained in the attachment
  byte[] data = attachmentEntry.getBytes("data");
```

Working with the message body

This is an example of a simple SOAP request:

```
<env:Envelope
  xmlns:env='http://schemas.xmlsoap.org/soap/envelope/'
  xmlns:ns1='http://example.companyInfo'>
    <env:Body>
        <ns1:getCompanyInfo>
            <ns1:tickerSymbol>IBM</ns1:tickerSymbol>
        </ns1:getCompanyInfo>
    </env:Body>
</env:Envelope>
```

To see the properties of the body, see “Message body layout” on page 1025. To work with the contents of the body, use code such as this:

```
  // Get the info node (a child of the graph root object)
  DataObject rootNode = graph.getRootObject();
  DataObject infoNode = rootNode.getDataObject("Info");

  // Get hold of the body node
  DataObject bodyNode = infoNode.getDataObject("body");

  // Get hold of the data object for the first part of the body
  DataObject part1Node = bodyNode.getDataObject("part1");

  // Query the tickerSymbol
  String ticker = part1Node.getString("tickerSymbol");

  // Shorthand for the above, using a SDO path expression that
  // starts from the info node.
  ticker = infoNode.getString("body/part1/tickerSymbol");
```

JMS formats:

To write code that can access the different JMS message types, you need to know how each message type is mapped to SDO, and how to retrieve the message format string from the message.

Format types

Each JMS message type is defined by a message format string within the message. You can retrieve the format string by using the code snippet in the following example . The table shows the mapping of message format strings to Service Data Objects (SDO):

JMS Message type	Message format string	Mapping to SDO[1]
JMS Bytes message	`JMS:bytes`	See “JMS Formats - bytes”
JMS Text message	`JMS:text`	See “JMS Formats - text”
JMS Stream message	`JMS:stream`	See “JMS formats - Stream” on page 1035
JMS Object message	`JMS:object`	See “JMS Formats - object” on page 1035
JMS Map message	`JMS:map`	The retrieval or construction of SDO data graphs for JMS map messages is not supported.

[1] The version of SDO supported by mediations is Version 1.

This code snippet is an example of how to retrieve the message format string from the message:

```
String format = siMsg.getFormat();
if (format.equals ....
```

JMS Formats - bytes:

Your program can retrieve the payload of a JMS bytes message by mapping the body of the message to an SDO data graph representing the message.

Bytes body

You can retrieve the payload of a JMS bytes message as a Java byte array (`byte[]`). First, you must retrieve a data graph representing the message from the SIMessage instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". In JMS bytes messages, the value property might be accessed as a Java byte array.

You can access the data within the data graph with code such as this:

```
SIMessage siMsg;
String format = siMsg.getFormat();
if (format.equals("JMS:bytes")) {
  DataGraph graph = siMsg.getDataGraph();
  byte[] payload = graph.getRootObject().getBytes("data/value");
}
```

JMS Formats - text:

Your program can retrieve the payload of a JMS text message by mapping the body of the message to an SDO data graph representing the message.

Text body

You can retrieve the payload of a JMS text message as a Java string value (java.lang.String). First, you must retrieve a data graph representing the message from the SIMessage instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". In JMS text messages the value property may be accessed as a Java string value.

You can access the data within the data graph with code such as this:

```
SIMessage siMsg;
String format = siMsg.getFormat();
if (format.equals("JMS:text")) {
  DataGraph graph = siMsg.getDataGraph();
  String payload = graph.getRootObject().getString("data/value");
}
```

JMS formats - Stream:

Your program can retrieve the payload of a JMS stream message by mapping the body of the message to an SDO data graph representing the message.

Stream body

You can retrieve the payload of a JMS Stream message as a Java list value (java.util.List). First, you must retrieve a data graph representing the message from the SIMessage instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". For a JMS Stream message the value property might be accessed as a List value. The member functions of the List interface can be used to access the individual objects within the JMS Stream message instance. (Note that the JMS standard places constraints on the kinds of objects that might be placed in a Stream message.)

You can access the data within the data graph with code such as this:

```
}SIMessage siMsg;
String format = siMessage.getFormat();
if (format.equals("JMS:stream")) {
  DataGraph graph = siMsg.getDataGraph();
  List payload = graph.getRootObject().getList("data/value");
  int streamLength = payload.size();
  if (streamLength > 0) {
    Object item1 = payload.get(0);
    // You can also access items directly, for example: (for the_same_ value)
    item1 = graph.getRootObject().get("data/value[1]");
  }
}
```

JMS Formats - object:

Your program can retrieve the payload of a JMS object message by mapping the body of the message to an SDO data graph representing the message.

Object body

You can retrieve the payload of a JMS object message as a Java byte array (`byte[]`). First, you must retrieve a data graph representing the message from the SIMessage instance. As is common to all data graphs representing JMS messages, the root data object of the graph contains a property named "data", and that data object in turn contains a property named "value". For a JMS object message the value property might be accessed as a Java byte array. The original Object instance that the payload represents might be reconstructed from the byte array.

You can access the data within the data graph with code such as this:

```
SIMessage siMsg;
String format = siMsg.getFormat();
if (format.equals("JMS:object")) {
  DataGraph graph = siMsg.getDataGraph();
  byte[] payload = graph.getRootObject().getBytes("data/value");
  if(payload != null) {
    // Need to deserialize to recover original object
```

```
    ObjectInputStream in =
      new ObjectInputStream(new ByteArrayInputStream(payload));
    Object obj = in.readObject();
  }
}
```

Writing a routing mediation

Use this topic to create a mediation that chooses a particular forward route for a message.

Before you begin

For an introduction to using mediations with the service integration bus, see Learning about mediations. For details of how to install a mediation into WebSphere Application Server and associate it with a bus destination, see Working with mediations.

This topic assumes that you are familiar with using a Java Platform, Enterprise Edition (Java EE) session bean development environment such as the assembly tools or IBM Rational Application Developer.

About this task

A routing mediation is a mediation application that contains a routing handler. You associate a routing mediation with a service integration bus destination, and use the mediation to choose a particular route from a range of available routes. For example when you create a new outbound service configuration or modify an existing outbound service configuration you can apply a port selection mediation to choose a particular outbound port from the range of ports that are available to the outbound service.

To create a routing mediation, use a Java Platform, Enterprise Edition (Java EE) session bean development environment to complete the following steps:

Procedure

1. Create an empty mediation handler project. This creates the project, and creates the handler class that implements the handler interface. For detailed instructions on how to do this, see Writing the mediation handler.
2. Use the mediation pane on the EJB descriptor to define the handler class as a mediation handler.

   Note: When you do this, you specify a name by which the mediation handler list is known. Make a note of this name, for later reference when you create the mediation in the bus.
3. Add the routing function to the handler. Before you begin, review Adding mediation function to handler code, in particular its subtopic Working with message context. Add import statements to your handler class, and modify the handle method by adding your routing code. Specify the routing destination by adding that destination to the front of the forward routing path list. The forward routing path list is available from the message context. For example:

```
import javax.xml.rpc.handler.MessageContext;
import com.ibm.websphere.sib.mediation.handler.MediationHandler;
import com.ibm.websphere.sib.mediation.handler.MessageContextException;
import com.ibm.websphere.sib.mediation.messagecontext.SIMessageContext;
import com.ibm.websphere.sib.SIMessage;
import com.ibm.websphere.sib.SIDestinationAddress;
import com.ibm.websphere.sib.SIDestinationAddressFactory;
import java.util.List;
public class RouteMediationHandler implements MediationHandler {

 public boolean handle(MessageContext ctx) throws MessageContextException {
  SIMessageContext siCtx = (SIMessageContext) ctx;
  SIMessage msg = siCtx.getSIMessage();
  List frp = msg.getForwardRoutingPath();
  try {
```

```
   SIDestinationAddress destination =
    SIDestinationAddressFactory
     .getInstance()
     .createSIDestinationAddress(
     "RoutingDestination", //this is the name of the target destination
     false);
   frp.add(0, destination);
  } catch (Exception e) {
   return false;
  }
  msg.setForwardRoutingPath(frp);
  return true;
 }

}
```

For more information about the service integration technologies classes, including the mediation handler and message context classes, see the Generated API documentation - Application programming interfaces .

4. Export the routing mediation enterprise application.

What to do next

You are now ready to install your mediation into WebSphere Application Server and associate it with a bus destination, as described in Working with mediations.

Writing a mediation that maps between attachment encoding styles

Use this topic to create a mediation that maps from SOAP Messages with Attachments encoding style to WS-I Attachments Profile Version 1.0 encoding style.

Before you begin

For an introduction to using mediations with the service integration bus, see Learning about mediations. For details of how to install a mediation into WebSphere Application Server and associate it with a bus destination, see Working with mediations.

This topic assumes that you are familiar with using a Java Platform, Enterprise Edition (Java EE) session bean development environment such as the assembly tools or IBM Rational Application Developer.

The example mediation given in this topic is based upon the WSDL examples that are given in Supporting bound attachments: WSDL examples

About this task

You can use a mediation to map from a SOAP Messages with Attachments encoding of a message to WS-I Attachments Profile Version 1.0 encoding. The WSDL definition is the same in both cases, so if you create a mediation that rewrites the Content ID values to match the Version 1.0 conventions then the message is encoded by service integration technologies according to Version 1.0 rules.

To create a mapping mediation, use a Java Platform, Enterprise Edition (Java EE) session bean development environment to complete the following steps:

Procedure

1. Create an empty mediation handler project. This creates the project, and creates the handler class that implements the handler interface. For detailed instructions on how to do this, see Writing the mediation handler.
2. Use the mediation pane on the EJB descriptor to define the handler class as a mediation handler.

Note: When you do this, you specify a name by which the mediation handler list is known. Make a note of this name, for later reference when you create the mediation in the bus.

3. Add the mapping function to the handler. Before you begin, review Adding mediation function to handler code. Here is an example of mediation handler code that rewrites the Content ID values to match the Version 1.0 conventions:

```
int uuidBase = 0;
DataObject root = SIMessage.getDataGraph().getRootObject();
List attachments = root.getList("info/attachments");
Iterator entries = attachments.iterator();
while(entries.hasNext()) {
  DataObject entry = (DataObject) entries.next();
  if(entry.getType().equals("BoundMIMEAttachmentEntryType")) {
    String newContentId = entry.getString("messagePart") + "=" +
                          Integer.toString(uuidBase++) +
                          "@some.domain";
  }
}
```

Note: For messages that use a SOAP with attachments reference (swaref) or some other URI mechanism to refer to the attachments, the URI values might also have to be updated to match the new Content ID values. However such mechanisms are usually used to refer to unbound attachments.

For more information about the service integration technologies classes, including the mediation handler classes, see the Generated API documentation - Application programming interfaces .

4. Export the mapping mediation enterprise application.

What to do next

You are now ready to install your mediation into WebSphere Application Server and associate it with a bus destination, as described in Working with mediations.

Choosing a target service and port through a routing mediation

Write a routing mediation and configure it to select a target service and port. If you have migrated a web services gateway that included a routing filter, use this task to recreate the equivalent functions by using a mediation.

About this task

One gateway service can map to one or more target services, and (for outbound target services) each target service can have one or more ports as defined in the outbound service WSDL. Without a routing mediation there is no point in mapping multiple targets because the gateway always picks the default destination. If you want to map multiple targets, you must write a routing mediation then configure it, for each gateway service, to select the target service and target port.

You associate routing mediations with service integration bus destinations. To pick a target service, you associate the mediation with the gateway service destination. To pick an outbound service port, you associate the mediation with the outbound service destination.

Use the steps described in Writing a routing mediation to help you write a mediation application that contains a routing handler, install it into WebSphere Application Server and associate it with a destination.

Using durable subscriptions

You use *durable subscriptions* for publish/subscribe messaging. A durable subscription can be used to preserve messages published on a topic while the subscriber is not active.

About this task

If there is no active subscriber for a durable subscription, JMS retains the subscription messages until they are received by the subscriber, or until they expire, or until the durable subscription is deleted. This enables subscriber applications to operate disconnected from the JMS provider for periods of time, and then reconnect to the provider and process messages that were published during their absence.

Each JMS durable subscription is identified by a subscription name (*subName*), which is defined when the durable subscription is created. A JMS connection also has an associated client identifier (*clientID*), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client. The subName assigned to a durable subscription must be unique within a given client ID.

If an application needs to receive messages published on a topic while the subscriber is inactive, it uses a *durable subscriber*.

In normal operation there can be at most one active (connected) subscriber for a durable subscription at a time. However, when running inside an application server it is possible to clone the application server for failover and load-balancing purposes. In this case, a cloned durable subscription can have multiple simultaneous consumers.

For information about durable subscriptions, see the JMS 1.1 Specification (for example, section 9.3.3 “Using Durable Subscriptions”).

The following operations for durable subscriptions are in addition to the usual JMS operations, such as to first look up a connection factory and a JMS destination, and to create a connection and session.

The following are the main operations for using durable subscriptions:

- Creating a new durable subscription
- Reconnecting to an existing durable subscription
- Unsubscribing (deleting) a durable subscription

Procedure

- Define the Durable Subscription Home This property must be set on the JMS connection factory if durable subscriptions are to be created using connections created from this connection factory. The value is the name of the messaging engine where all durable subscriptions accessed through this connection are managed.

  You can also set the Durable Subscription Home on the JMS topic destination, which enables a single connection to access durable subscriptions on more than one messaging engine.

  To be able to create durable subscriptions, the property on the connection factory must not be null (the default). Setting a value of null or empty string on the property of a destination indicates that the value specified on the connection factory should be inherited.
- Creating a new durable subscription A durable TopicSubscriber can be created by a Session or by a TopicSession.

  Having performed the normal setup, an application can create a durable subscriber to a destination. To do this, the client program creates a durable TopicSubscriber, by using session.createDurableSubscriber. The name *subName* is used as an identifier of the durable subscription.

```
session.createDurableSubscriber( Topic topic,
        java.lang.String subName,
        java.lang.String messageSelector,
        boolean noLocal);
```

Alternatively, you can use the two-argument form of this operation, which takes only a topic and name (*subName*) as parameters. This alternative form invokes the four-argument operation with null as the messageSelector and false as the noLocal parameters.

```
session.createDurableSubscriber( Topic topic, java.lang.String subName);
```

A JMS durable subscription is created with a unique identifier of the form *clientID*+"##"+*subName*. The characters ## should not be used in the clientID or subName if the JMS connection is to use a durable subscription.

Handling exceptions. The following JMS exceptions can be thrown for the reasons listed in the exception messages:

- InvalidDestination - The name of this durable subscription (*clientID*+"##"+*subName*) clashes with an existing destination.
- IllegalState - The method was invoked on a closed connection.
- IllegalState - This destination is not accepting consumers. This probably means that there is already an active subscriber for this durable subscription.
- InvalidDestination - The mediation named in the parameters cannot be found.
- InvalidDestination - The destination cannot be found.
- JMSSecurity - The user does not have authorization to perform this operation.
- JMSException - Errors occurred in the MsgStore, Comms or Core layers.

- Reconnecting to an existing durable subscription To reconnect to a topic that has an existing durable subscription, the subscriber application calls `session.CreateDurableSubscriber` again, using the same parameters that it used to originally create the durable subscription. However, consider the following important restrictions:
  - The subscriber must be attached to the same connection.
  - The destination and subscription name must be the same as in the original method call.
  - If a message selector was specified, it must be the same as in the original method call.

  By calling createDurableSubscriber again, the subscriber application reconnects to the topic, and receives any messages that arrived while the subscriber was disconnected.
- Unsubscribing (deleting) a durable subscription To unsubscribe (delete) a durable subscription to a topic, the subscriber application calls `session.unsubscribe(java.lang.String name)`.

  Do not call the unsubscribe method to delete a durable subscription if there is a TopicConsumer currently consuming messages from the topic.

Sending web service messages directly over the bus from a JAX-RPC client

Use this task to send web service messages over a bus by retargeting the JAX-RPC client.

About this task

Java API for XML-based remote procedure calls (JAX-RPC) client applications send and receive web service request and response messages. JAX-RPC client applications that use the IBM JAX-RPC run-time environment can do this in a number of different ways, depending on the bindings in the WSDL document that they are developed against, and the configuration data that is used at run time.

For an introduction to basic JAX-RPC programming concepts, including the JAX-RPC client and server programming models, see Getting Started with JAX-RPC.

If you want to use a JAX-RPC client to send messages over the service integration bus, you have two choices:

- Use a SOAP binding (SOAP over HTTP or SOAP over JMS), and pass messages indirectly through an endpoint listener to an inbound service. You would do this if you had SOAP-specific JAX-RPC handlers that must run in the client application context.
- Pass messages directly into the service integration bus at a destination by “retargeting” the JAX-RPC client application as described in this topic.

  Note: There are currently limitations regarding the Java types used by services that are retargeted through a JAX-RPC client application.

Retargeting involves setting the following two values into the client application deployment descriptor, or specifying them dynamically at run time from within the client application:

- The *binding namespace* is set to indicate that the client uses the messaging bus directly.
- The *endpoint address* is set to include the particular destination and (optionally) the format of messages that the client uses.

The destination also needs to be configured so that it knows the port type of messages that the JAX-RPC client is using. There are two ways to achieve this:

- Create an outbound service. An outbound service represents an externally-provided web service. In this case, requests from the JAX-RPC client pass through the service destination and are then sent on to the service provider defined by the outbound service configuration.
- Create an inbound service. An inbound service represents a service provided somewhere within or beyond the messaging bus. You can create an inbound service on any existing destination. The creation of an inbound service associates a WSDL port type with the destination. When retargeting to a destination with an inbound service, the client application needs to specify both the destination name and inbound service name, because it is possible to configure more than one inbound service against a single destination. In this case, requests from the JAX-RPC client pass through the destination and then onwards through the service integration bus depending on routing that is done at the initial destination.

To have web service messages sent directly to a destination using a JAX-RPC client, complete the following steps:

Procedure

1. Create the JAX-RPC client application.
2. Create the outbound service or inbound service with which you want the JAX-RPC client application to exchange messages.
3. Use the administrative console to access the port information for your JAX-RPC client application, as described in “Configuring web services client bindings” on page 2208 and Web services client port information.
4. Override the default SOAP binding for your JAX-RPC client application. Change the binding namespace to `http://www.ibm.com/ns/2004/02/wsdl/mp/sib`
5. Override the endpoint that your JAX-RPC client application uses to send web service requests. The new endpoint should use the sib: URL syntax and include either the outbound service destination name, or both the inbound service name and its corresponding destination name.

What to do next

After you change the *binding namespace*, any JAX-RPC handler lists that were configured for the retargeted port are ignored. For clients that are developed against WSDL with a SOAP binding, retargeting directly to the bus causes the handlers to be ignored. However if the client is developed against the non-bound WSDL for the service, retargeting to the bus is not considered to be changing the binding namespace, and so the handler information is retained. In this case the JAX-RPC handlers are called with the SDOMessageContext subclass.

Associated reference information:

- “sib: URL syntax”

sib: URL syntax

The `sib:` URL has the following syntax:

`sib:/[destination|path]?property_1=value_1&property_2=value_2&...`

where:

- Square brackets (“[ ]”) indicate that a parameter is optional.
- Transport type is `sib:`, followed by either `/destination` to specify destination type or `/path` to specify a forward routing path, followed by a “query string” that contains one or more properties. The permitted properties are described in the subsequent sections of this topic.

Required properties

The following properties are required. They are used to specify the destination for the request.

Note: All destination names must be fully-qualified. That is, they must include the name of the service integration bus as well as the destination name itself. Use the syntax *bus:destination*. If a bus or destination name contains a colon or comma, wrap the name in double quotation marks (“”). If it contains a double quotation mark, repeat the quotation mark.

destinationName
The destination name.

path The forward routing path, in the form of a sequence of destination names separated by commas.

replyDestinationName
The name of the destination to be used for the reply.

inboundService
The name of the inbound service that identifies the specific attachment that the requester application uses. You can omit this value if the destination is a service destination with an associated outbound service configuration, because in that case the requester is attaching to the outbound service through the service destination.

timeout
The time the requester waits for a response. The default value is 60 seconds. A zero value indicates an unlimited wait.

Service integration technologies-related properties

The following properties are optional. If you do not specify a value for a property, then the default value is used. For more information regarding the permitted values for these properties, see the generated API information for the SIMessage interface.

reliability
The reliability of the request message.

timeToLive
The amount of time (in milliseconds) before the request times out. A zero value indicates that the request never times out.

Note: The **timeout** property (see the required properties) is the time delay after which the requester application blocks the application thread that is waiting for a response to a request and response operation. The **time to live** and **replyTimeToLive** optional properties indicate how long the request and reply messages should be processed by the messaging

engines. This does not include the processing time at the service implementation. You would therefore usually set the timeout to be the sum of the request and response times to live, plus some amount for the service processing time.

priority
The priority of the request message.

user
The user ID required to access the request destination.

password
The password required to access the request destination.

replyReliability
The reliability of the reply message.

replyTimeToLive
The amount of time (in milliseconds) before the reply times out. A zero value indicates that the reply never times out.

replyPriority
The priority of the reply message.

Other properties

You can also include user-defined properties in the URL. These properties must be named with a `user.` prefix. For example:

```
sib:/destination?destinationName=myBus:myDestination & reliability=assured & user.customData=XYZ
```

After the request is sent, the URL itself is available within the message properties, named `inbound.url`.

Chapter 24. Developing Session Initiation Protocol (SIP) applications

This page provides a starting point for finding information about SIP applications, which are Java programs that use at least one Session Initiation Protocol (SIP) servlet written to the JSR 116 specification.

SIP is used to establish, modify, and terminate multimedia IP sessions including IP telephony, presence, and instant messaging.

Developing SIP applications

A SIP application is a set of SIP servlets packaged in a SIP application archive file (SAR).

About this task

A SIP servlet is an application component managed by the SIP container that performs SIP signaling. The programming and deployment models are analogous to web servlets and therefore will be mapped to the WebSphere administrative model accordingly. It is possible to include web servlets in a SAR file (along with the required web.xml deployment descriptor) to create what is known as a converged application. See JSR 116 for details on SIP applications, servlets, converged applications, and status codes.

Developing SIP applications that support PRACK

A SIP response to an INVITE request can be final or provisional. Final responses are always sent reliably, but provisional responses typically are not. For cases where you need to send a provisional response reliably, you can use the PRACK (Provisional response acknowledgement) method.

Before you begin

For you to be able to develop applications that support PRACK, the following criteria must be met:

- The client that sends the INVITE request must put a 100rel tag in the Supported or the Require header to indicate that the client supports PRACK.
- The SIP servlet must respond by invoking the sendReliably() method instead of the send() method to send the response.

About this task

PRACK is described in the following standards:

- RFC 3262 (“Reliability of Provisional Responses in the Session Initiation Protocol (SIP)”), which extends RFC 3261 (“SIP: Session Initiation Protocol”), adding PRACK and the option tag 100rel.
- Section 6.7.1 (“Reliable Provisional Responses”) of JSR 116 (“SIP Servlet API Version 1.0”).

Procedure

- For an application acting as a proxy, do this:
  - Make your application generate and send a reliable provisional response for any INVITE request that has no tag in the To field.
- For an application acting as a user agent client (UAC), do this:
  - Make your application add the 100rel tag to outgoing INVITE requests. The option tag must appear in either the Supported header or the Require header.
  - Within your application's doProvisionalResponse(...) method, prepare the application to create and send PRACK requests for incoming reliable provisional responses. The application must create the PRACK request on the response's dialog through a SipSession.createRequest(...) method, and it must set the RAck header according to RFC 3262 Section 7.2 (“RAck”).

  - The application that acts as an UAC will not receive doPrack( ) methods. The UAC sends INVITE and receives Reliable responses. When the UAC receives the Reliable response, it sends PRACK a request to the UAS and receives a 200 OK on the PRACK so it should next implement doResponse( ) in order to receive it.
- For an application acting as a user agent server (UAS), do this:
  - If an incoming INVITE request requires the 100rel tag, trying to send a 101-199 response unreliably by using the send() method causes an Exception.
  - Make the application declare a SipErrorListener to receive noPrackReceived() events when a reliable provisional response is not acknowledged within 64*T1 seconds, where T1 is a SIP timer. Within the noPrackReceived() event processing, the application should generate and send a 5*xx* error response for the associated INVITE request per JSR 116 Section 6.7.1.
  - Make the application have at most one outstanding, unacknowledged reliable provisional response. Trying to send another one before the first's acknowledgement results in an Exception.
  - Make sure that the application enforces the RFC 3262 offer/answer semantics surrounding PRACK requests containing session descriptions. Specifically, a servlet must not send a 2*xx* final response if any unacknowledged provisional responses contained a session description.

Setting up SIP application composition

The JSR 116 standard for SIP applications states in section 2.4 that multiple applications may be invoked for the same SIP request. The process of setting up applications to comply with this standard is called application composition.

About this task

Application composition requires that implementations use a cascaded services model. The cascaded services model requires that service applications triggered on the same host are triggered in sequence, as if the triggering occurred on different hosts. Therefore responses flow upstream and hit applications in the reverse order of the corresponding requests.

The JSR 116 standard does not specify how to implement application composition, thus there are many ways to comply with this standard. For WebSphere Application Server, composition of the application depends on the deployed application order, and on the order of mapping rules within the deployment descriptor of each application.

- For an initial incoming request, the SIP container tries each potential rule in order. When the container finds the n^{th} match, the container invokes the corresponding servlet.
- If the servlet must proxy the request, the container scans the rules again to search for additional matches. When the container finds the $(n+1)^{th}$ match, the container invokes the corresponding servlet.
- Any servlet in the same application as the previously invoked servlet is excluded from the matching process. No servlet can be invoked twice for the same SIP request.

You can specify load on start-up priority. The `<load-on-startup>` in the `sip.xml` defines the order in which servlets are initialized on startup. If this value is lower than zero, the servlets are initialized when the first request is matched to them according to matching rule and composition order. Zero is a legitimate weight for startup initialization order. If this tag does not exist or if it contains a negative value, the servlet does not initialize at startup.

You should also add `<load-on-startup>` to the same tag in the `web.xml` if you are changing it manually. It is the WebContainer that loads servlets (and siplets), and it looks only at the `web.xml`. When deploying a SAR, only the `sip.xml` needs to be changed. The `web.xml` is automatically constructed correctly after deployment.

The load-on-startup tag embedded in the SIP deployment descriptor tag for a servlet dictates the order that the application is loaded on start up of the server. It does not dictate the order that an application gets called when the application is a member of an application composition chain that matches rules to process a new message coming in.

The starting weight for applications and their modules is specified in the `deployment.xml` file. The order in which modules pickup requests on composition is evaluated by applications weight first and then modules weight. The following steps can be completed in any order to specify applications weight or modules weight from the administrative console.

Procedure

1. To specify the applications (EARs) weight, expand **Enterprise Applications** > ***applicationName*** > **Startup Behavior** and set the startup order.
2. To specify the modules (WARs) weight, expand **Enterprise Applications** > ***applicationName*** > **Manage Modules** and set the starting weight.
3. Restart the changed applications.

Example

Specifying load-on-startup priority example:

sip.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE sip-app
PUBLIC "-//Java Community Process//DTD SIP Application 1.0//EN"
"http://www.jcp.org/dtd/sip-app_1_0.dtd">
<sip-app>
 <display-name>SIPSampleProxy</display-name>

 <servlet>
  <servlet-name>SIPSampleProxy</servlet-name>
  <servlet-class>sipes.test.container.proxy.SIPSampleProxy</servlet-class>
  <load-on-startup>1</load-on-startup>
 </servlet>

 <servlet-mapping>
  <servlet-name>SIPSampleProxy</servlet-name>
  <pattern>
   <equal>
    <var>request.uri.user</var>
    <value>SIPSampleProxy</value>
   </equal>
  </pattern>
 </servlet-mapping>

 <proxy-config>
  <sequential-search-timeout>1000</sequential-search-timeout>
 </proxy-config>
 <session-config>
  <session-timeout>12</session-timeout>
 </session-config>
</sip-app>
```

web.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE web-app PUBLIC "-//Sun Microsystems, Inc.//DTD Web Application 2.3//EN" "http://java.sun.com/dtd/web-app_2_3.dtd">
<web-app id="WebApp">
 <display-name>SIPSampleProxy</display-name>
 <servlet>
  <servlet-name>SIPSampleProxy</servlet-name>
  <display-name>SIPSampleProxy</display-name>
  <servlet-class>sipes.test.container.proxy.SIPSampleProxy</servlet-class>
 </servlet>
 <servlet-mapping>
  <servlet-name>SIPSampleProxy</servlet-name>
  <url-pattern>/SIPSampleProxy</url-pattern>
 </servlet-mapping>
 <welcome-file-list>
  <welcome-file>index.html</welcome-file>
  <welcome-file>index.htm</welcome-file>
  <welcome-file>index.jsp</welcome-file>
  <welcome-file>default.html</welcome-file>
```

```
  <welcome-file>default.htm</welcome-file>
  <welcome-file>default.jsp</welcome-file>
 </welcome-file-list>
</web-app>
```

Specifying starting weight example:

The following example is for a stand-alone server.

deployment.xml

```
<?xml version="1.0" encoding="UTF-8" ?>
- <appdeployment:Deployment xmi:version="2.0" xmlns:xmi="http://www.omg.org/XMI"
xmlns:appdeployment="http://www.ibm.com/websphere/appserver/schemas/5.0/appdeployment.xmi"
xmi:id="Deployment_1137951186883">
- <deployedObject xmi:type="appdeployment:ApplicationDeployment" xmi:id="ApplicationDeployment_1137951186883"
deploymentId="0" startingWeight="1" binariesURL="$(APP_INSTALL_ROOT)/OrangeNode08Cell/SipContainerTestSuite.ear"
useMetadataFromBinaries="false" enableDistribution="true" createMBeansForResources="true" reloadEnabled="false"
appContextIDForSecurity="href:OrangeNode08Cell/SipContainerTestSuite"
filePermission=".*\.dll=755#.*\.so=755#.*\.a=755#.*\.sl=755" allowDispatchRemoteInclude="false"
allowServiceRemoteInclude="false">
  <targetMappings xmi:id="DeploymentTargetMapping_1137951186883" enable="true" target="ServerTarget_1137951186883" />
  <classloader xmi:id="Classloader_1137951186883" mode="PARENT_FIRST" />
- <modules xmi:type="appdeployment:WebModuleDeployment" xmi:id="WebModuleDeployment_1137951186883"
deploymentId="1" startingWeight="10000" uri="sipunit.war">
  <targetMappings xmi:id="DeploymentTargetMapping_1137951186884" target="ServerTarget_1137951186883" />
  <classloader xmi:id="Classloader_1137951186884" /> </modules>
  <properties xmi:id="Property_1137951186883" name="validateinstall" value="warn" /> </deployedObject>
  <deploymentTargets xmi:type="appdeployment:ServerTarget" xmi:id="ServerTarget_1137951186883"
name="server1" nodeName="OrangeNode10" /> </appdeployment:Deployment>
```

SIP servlets

This topic describes SIP servlets.

The SIP Servlet 1.0 specification (JSR 116) is standardized through Java Specification Request (JSR) 116. The idea behind the specification is to provide a Java application programming interface (API) similar to HTTP servlets, which provides an easy-to-use SIP programming model. Like the popular HTTP servlet programming model, some flexibility is limited to optimize ease-of-use and time-to-value.

However, the SIP Servlet API is different in many ways from HTTP servlets because the protocol is so different. While SIP is a request-response protocol, there is not necessarily only one response to every one request. This complexity and a need for a high performing solution meant that it was easier to make the SIP servlets natively asynchronous. Also, unlike HTTP servlets, the programming model for SIP servlets sought to make client requests easy to create alongside the other logic being written because many applications act as a client or proxy to other servers or proxies.

SipServlet requests

Like HTTP servlets, each SIP servlet extends a base javax.servlet.sip.SipServlet class. All messages come in through the service method, which you can extend. However, because there is not a one-to-one mapping of requests to responses in SIP, the suggested practice is to extend the doRequest or doResponse methods instead. When extending the doRequest or doResponse methods, it is important to call the extended method for the processing to complete.

Each request method, which the specification must support, has a doxxx method just like HTTP. In HTTP, methods such as doGet and doPost exist for GET and POST requests. In SIP, doInvite, doAck, doOptions, doBye, doCancel, doRegister, doSubscribe, doNotify, doMessage, doInfo, and doPrack methods exist for each SIP request method.

Unlike an HTTP servlet, SIP servlets have methods for each of the response types that are supported. So, SIP servlets include the doProvisionalResponse, doSuccessResponse, doRedirectResponse, and doErrorResponse responses. Specifically, the provisional responses (1xx responses) are used to indicate status, the success responses (2xx responses) are used to indicate a successful completion of the transaction, the redirect responses (3xx responses) are used to redirect the client to a moved resource or entity, and the error responses (4xx, 5xx, and 6xx responses) are used to indicate a failure or a specific

error condition. These types of response messages are similar to HTTP, but because the SIP Servlet programming model includes a client programming model, it is necessary to have responses handled programmatically as well.

Clarifications of JSR 116

JSR 289 has made some clarifications to JSR 116, as follows:

- JSR 289 Section 4.1.3: Contact Header Field
- JSR 289 Section 5.2: Implicit Transaction State
- JSR 289 Section 5.8: Accessibility of SIP Servlet Messages

SIP SipServletRequest and SipServletResponse classes

The SipServletRequest and SipServletResponse classes are similar to the HttpServletRequest and HttpServletResponse classes.

SipServletRequest and SipServletResponse classes

Each class gives you the capability to access the headers in the SIP message and manipulate them. Because of the asynchronous nature of the requests and responses, this class is also the place to create new responses for the requests. When you extend the doInvite method, only the SipServletRequest class is passed to the method. To send a response to the client, you must call the createResponse method on the Request object to create a response. For example:

```
protected void doInvite(SipServletRequest req) throws
 javax.servlet.ServletException, java.io.IOException {

 //send back a provisional Trying response
 SipServletResponse resp = req.createResponse(100);
resp.send();
```

Because of their asynchronous nature, SIP servlets can seem complicated. However, something as simple as the previous code sample sends a response to a client.

Here is a more complex example of a SIP servlet. With the following method included in a SIP servlet, the servlet blocks all of the calls that do not come from the example.com domain.

```
protected void doInvite(SipServletRequest req) throws
 javax.servlet.ServletException, java.io.IOException {

//check to make sure that the URI is a SIP URI
      if (req.getFrom().getURI().isSipURI()){
                  SipURI uri = (SipURI)req.getFrom.getURI();
                  if (!uri.getHost().equals("example.com")) {
                     //send forbidden response for calls outside domain
                     req.createResponse(SipServletResponse.SC_FORBIDDEN).send();
                     return;
                  }
               }
               //proxy all other requests on to their original destination
               req.getProxy().proxyTo(req.getRequestURI);
        }
```

SIP SipSession and SipApplicationSession classes

Possibly the most complex portions of the SIP Servlet 1.0 specification are the SipSession and SipApplicationSession classes.

SIP SipSession and SipApplicationSession classes

Both of these classes have some useful purposes and can act as the primary place to store data in applications that are designed for distributed or highly available environments.

The SipSession class is the best representative of a specific point-to-point communication between two entities and is the closest to the HttpSession object. Because historically no proxying or forking existed for the HTTP request in HTTP servlets, the need for something higher than a single point-to-point session did not exist. However, even HTTP users can see the growing need for this type of function since portlets began essentially forking HTTP requests. The SIP users expect the proxying and forking activities that require multiple layers of SIP session management. The SipSession class is the lowest point-to-point layer.

The SipApplicationSession class represents the higher layer of SIP session management. One SipApplicationSession class can own one or more SipSession objects. However, each SipSession class can be related to one SipSession object only. The SipApplicationSession class also supports the attachment of any number of other protocol sessions. Currently, only HTTP sessions are supported by any implementations. The SipApplicationSession class has a getSessions method, which takes the requested protocol type as an argument.

You might find it useful for many applications to combine HTTP and SIP. For example, you might use this approach to tie together HTTP and SIP sessions to monitor a phone call or to start a phone call through a rich HTTP graphical user interface.

Example: SIP servlet simple proxy

This is a servlet example of a simple proxy.

Simple proxy

```
import java.io.IOException;

import javax.servlet.Servlet;
import javax.servlet.ServletException;
import javax.servlet.sip.Proxy;
import javax.servlet.sip.SipFactory;
import javax.servlet.sip.SipServlet;
import javax.servlet.sip.SipServletRequest;
import javax.servlet.sip.SipServletResponse;
import javax.servlet.sip.SipSession;
import javax.servlet.sip.SipURI;
import javax.servlet.sip.URI;

public class SimpleProxy extends SipServlet implements Servlet {

 final static  private String  SHUTDOWN_KEY = new String("shutdown");
 final static  private String  STATE_KEY = new String("state");
 final static  private int   INVITE_RECEIVED = 1;

 /* (non-Java-doc)
  * @see javax.servlet.sip.SipServlet#SipServlet()
  */
 public SimpleProxy() {
  super();
 }

 /* (non-Javadoc)
  * @see javax.servlet.sip.SipServlet#doInvite(javax.servlet.sip.SipServletRequest)
  */
 protected void doInvite(SipServletRequest request) throws ServletException,
   IOException {

  //log("SimpleProxy: doInvite: TOP");

  try {
   if (request.isInitial() == true)
   {
    // This should cause the sip session to be created. This sample only uses the session on receiving
    // a BYE but the Tivoli performance viewer can be used to track the creation of calls by viewing the
```

```
   // active session count.
   Integer state = new Integer(INVITE_RECEIVED);
   SipSession session = request.getSession();
   session.setAttribute(STATE_KEY, state);
            log("SimpleProxy: doInvite: setting attribute");

   Proxy proxy = request.getProxy();

   SipFactory sipFactory = (SipFactory) getServletContext().getAttribute(SIP_FACTORY);
         if (sipFactory == null) {
             throw new ServletException("No SipFactory in context");
         }

         String callingNumber = request.getTo().toString();
         if (callingNumber != null)
         {
             String destStr = format_lookup(callingNumber);
             URI dest = sipFactory.createURI(destStr);

             //log("SimpleProxy: doInvite: Proxying to dest URI ="  + dest.toString());

          if (((SipURI)request.getRequestURI()).getTransportParam() != null)
           ((SipURI)dest).setTransportParam(((SipURI)request.getRequestURI()).getTransportParam());

          proxy.setRecordRoute(true);
    proxy.proxyTo(dest);
         }
   else
   {
             //log("SimpleProxy: doInvite: Request is invalid. Did not contain a To: field.");
    SipServletResponse sipresponse = request.createResponse(400);
    sipresponse.send();
   }
  }
  else
  {
         //log("SimpleProxy: doInvite: target refresh, let container handle invite");
   super.doInvite(request);
  }
 }
 catch (Exception e){
  e.printStackTrace();
 }
}

/* (non-Javadoc)
 * @see javax.servlet.sip.SipServlet#doResponse(javax.servlet.sip.SipServletResponse)
 */
protected void doResponse(SipServletResponse response) throws ServletException,
  IOException {
  super.doResponse(response);

  // Example of using the session object to store session state.
 SipSession session = response.getSession();
 if (session.getAttribute(SHUTDOWN_KEY) != null)
 {
  //log("SimpleProxy: doResponse: invalidating session");
  session.invalidate();
 }
}

/* (non-Javadoc)
 * @see javax.servlet.sip.SipServlet#doBye(javax.servlet.sip.SipServletRequest)
 */
protected void doBye(SipServletRequest request) throws ServletException,
  IOException {
```

```
  SipSession session = request.getSession();
  session.setAttribute(SHUTDOWN_KEY, new Boolean(true));

        //log("SimpleProxy: doBye: invalidate session when responses is received.");
  super.doBye(request);
 }

 protected String format_lookup(String toFormat){
  int start_index = toFormat.indexOf('<') + 1;
  int end_index = toFormat.indexOf('>');

  if(start_index == 0){
   //don't worry about it
  }
  if(end_index == -1){
   end_index = toFormat.length();
  }

  return toFormat.substring(start_index, end_index);
 }
}
```

Example: SIP servlet SendOnServlet class

The SendOnServlet class is a simple SIP servlet that would perform the basic function of being called on each INVITE and sending the request on from there.

SendOnServlet class

Function could easily be inserted to log this invite request or reject the INVITE based on some specific criteria.

```
package com.example;
import java.io.IOException;
import javax.servlet.sip.*;
import java.servlet.ServletException;
public class SendOnServlet extends SipServlet {
  public void doInvite(SipServletRequest req)
       throws ServletException, java.io.IOException {
     //send on the request
     req.getProxy().proxyTo(req.getRequestURI);
  }
}
```

The doInvite method could be altered to do something such as reject the invite for some specific criteria simply. In the following example, all requests from domains outside of example.com will be rejected with a Forbidden response.

```
   public void doInvite(SipServletRequest req)
throws ServletException, java.io.IOException {
if (req.getFrom().getURI().isSipURI()){
    SipURI uri = (SipURI)req.getFrom.getURI();
    if (!uri.getHost().equals("example.com")) {
  //send forbidden response for calls outside domain
req.createResponse(SipServletResponse.SC_FORBIDDEN, "Calls outside example.com not accepted").send();
return;
    }
 }
 //proxy all other requests on to their original destination
 req.getProxy().proxyTo(req.getRequestURI());
   }

SendOnServlet deployment descriptor:
<sip-app>
    <display-name>Send-on Servlet</display-name>
    <servlet>
```

```
        <servlet-name>SendOnServlet</servlet-name>
        <servlet-class>com.example.SendOnServlet</servlet-class>
    </servlet>

    <servlet-mapping>
        <servlet-name>SendOnServlet</servlet-name>
        <pattern>
              <equal>
                <var>request.method</var>
                <value>INVITE</value>
              </equal>
        </pattern>
    </servlet-mapping>
</sip-app>
```

Example: SIP servlet Proxy servlet class

Proxy servlet class

After the initial INVITE, this application will be called on every subsequent SIP message. For each Request and Response, this class will simply print out the action and who it is to or from.

```
package com.example;
import java.io.IOException;
import javax.servlet.sip.*;
import java.servlet.ServletException;
public class ProxyServlet extends SipServlet {
  public void doInvite(SipServletRequest req)
       throws ServletException, java.io.IOException {
     //get the Proxy
     Proxy p=req.getProxy();
     //turn on supervised mode so that all events come through us
     //The default on this is true but it is set to emphasize the function.
     p.setSupervised(true);
     //set record route so we see the ACK, BYE, and OK
     p.setRecordRoute(true);
     //proxy on the request
     p.proxyTo(req.getRequestURI());
  }
public void doRequest(SipServletRequest req)
     throws ServletException, java.io.IOException {
   System.out.println(req.getMethod()+" Request from "+req.getFrom().getDisplayName());
   super.doRequest(req);
}
public void doResponse(SipServletResponse resp)
     throws ServletException, java.io.IOException {
   System.out.println(resp.getReasonPhrase()+" Response from "+resp.getTo().getDisplayName());
   super.doResponse(resp);
}
}

Proxy deployment descriptor
<sip-app>
    <display-name>ProxyServlet</display-name>
    <servlet>
        <servlet-name>ProxyServlet</servlet-name>
        <servlet-class>com.example.ProxyServlet</servlet-class>
    </servlet>

    <servlet-mapping>
        <servlet-name>ProxyServlet</servlet-name>
        <pattern>
              <equal>
                <var>request.method</var>
                <value>INVITE</value>
```

```
            </equal>
        </pattern>
    </servlet-mapping>
</sip-app>
```

JSR 289 overview

Version 8.5 includes support for SIP Servlet Specification 1.1, also referred to as Java Specification Request (JSR) 289.

The SIP Servlet Specification provides the Java API standards for Session Initiation Protocol (SIP). JSR 289 is an update to the existing SIP Servlet specification that addresses new requirements determined by industry users.

SIP is a signaling protocol used for creating, modifying, and terminating IP communication sessions such as telephony and presence applications. SIP is not limited to voice communication and can mediate any type of communication session, such as multimedia.

The following is a brief description of new features available in the JSR 289 specification.

- Application router for application selection

  Application routing enables developers to build complex services out of smaller applications. On initial requests the container calls the application router to determine which application to invoke based on the type of request. The application router is the central hub for selecting application order. See the topic on configuring a SIP application router for more information.

- Annotation-based programming

  Annotations provide a fast way to develop applications by embedding metadata directly in applications. For example, you can use the `@SipServlet` annotation to indicate that a class is a SIP servlet. The `@SipApplication` is a package level annotation. All servlets in the package belong to the same application unless the servlet uses `@SipServlet(applicationName)`. For more information on annotations, see section 18 of the JSR 289.

- Converged applications

  JSR 289 provides a new, standardized mechanism for building converged applications. A converged application contains SIP servlet components and other Java EE components, like HTTP servlets and enterprise beans. The specification includes two new classes to support convergence.

  – `ConvergedHttpSession` is an extension to HttpSession for converged applications.

  – `SipSessionUtil` handles session management for converged applications.

  For more information on converged applications, see section 13 of the JSR 289.

- Back-to-back user agent (B2BUA) APIs

  JSR 289 simplifies the B2BUA pattern in applications with the use of the B2BUA helper class. The B2BUA is a frequently used application pattern. The B2BUA acts as an endpoint for two or more dialogs and forwards requests and responses between those dialogs. The B2BUA helper has the ability to create a copy of an incoming request. It also automatically maintains links between sessions on both sides of the B2BUA. For more information on B2BUAs, see section 12 of the JSR 289.

Note: Support for the Session Initiation Protocol (SIP) session key-based targeting mechanism that is described in JSR 289 section 15.11.2 is only supported in stand-alone environments. The session key-based targeting mechanism is not supported in clustered environments. Alternatively, you can use one of the other targeting mechanisms that are described in JSR 289 within a clustered environment:

- Encode the URI mechanism that is described in section 15.11.3.
- Join and replace the targeting mechanism that is described in section 15.11.4.

SIP application router:

The SIP application router is used by the SIP container to select the order in which applications are run within the container.

The SIP container can invoke multiple applications in order to deploy a complete service or function. This modular and compositional approach makes it easier for application developers to develop new applications. The modular applications can be more easily combined and managed, while individual application implementations remain independent.

The application router is responsible for selecting the correct applications in the correct order to service an incoming message. An application router is required for a container to function, but it is a separate logical entity from the container. The application router is based on the JSR 289 specification. See the specification for more details about the application router function.

The default application router (DAR) can be configured with a standard configuration file, which is supplied to the container through a SIP container custom property, as defined in JSR 289. The DAR configuration file can also be uploaded in the administrative console for each target of the DAR.

Application routing, also referred to as application composition, can be handled in a number of ways:

- Specify the order in which the applications should run using the administrative console.
- Upload a custom application router implementation class either by specifying the path of the Java archive (JAR) file containing the application router implementation and provider through the console or adding it to the class path. A specific provider can be defined with a SIP container custom property.
- Configure the DAR by uploading its properties file and providing its location through a system property.
- Use an interactive wizard to generate a DAR configuration file.

Restriction: WebSphere Application Server has a default way of sorting the order of SIP applications invocation using the Startup behavior settings. The sorting order is based on the application weight. This weighting policy only applies if you do not specify a DAR property file and no custom application router has been associated with the server or cluster.

Note: If CEA features are used, the CEA system application requires special consideration when enabled on the same server or cluster as a custom application router. To deploy an application router and still maintain the capabilities of the CEA system application, use one of the following two options:

- Only enable CEA on an isolated server or cluster that includes no custom application router.
- Make sure the custom application router routes all CEA specific messages to the CEA system application. To do this, the developer of the application router must check the mappings that are defined in the sip.xml file associated with the CEA system application. The sip.xml file associated with the CEA system application can be found in the directory path at *app_server_root/systemApps*.

  The following information explains how to configure a custom application router to route to the commsvc system application. The examples show a custom application router configuration with and without the commsvc application.

  First, here is an example configuration without commsvc:

```
INVITE: ("TestB2bua", "DAR:To", "NEUTRAL", "", "NO_ROUTE", "0")
```

  The first element after the INVITE is the display name of the test application, and this one-line application router routes b2bua calls to the application successfully. With the preceding application router configured on the SIP container, however, CEA Web collaboration attempts fail.

  To enable routing to the CEA system application, just clone the routing element and change the application name in the second element instance:

```
INVITE: ("TestB2bua", "DAR:To", "NEUTRAL", "", "NO_ROUTE", "0"),("commsvc", "DAR:To", "NEUTRAL", "", "NO_ROUTE", "0")
```

  This action ensures that CEA messages are routed correctly.

Tuning considerations using the JSR 289 Application Router with multiple applications:

This topic describes performance adjustments and considerations using the JSR 289 Application Router™ with multiple applications.

Note: This topic references one or more of the application server log files. As a recommended alternative, you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files on distributed and IBM i systems. You can also use HPEL in conjunction with your native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

When you deploy more than one application, you might see the following errors in the log files when heavy SIP protocol traffic exists for a single application server or cluster of servers:

- Unexpected and excessive SIP application 503 Server Unavailable error messages
- Proxy and Server overload errors

Note: These error messages do not occur when you deploy one application.
The proxy server and Session Initiation Protocol (SIP) containers are not synchronized when they are tracking the amount of messages that are flowing through the system. Using the application router, multiple messages might be routed between applications. These messages cause container message counters to increment even though the messages do not flow through the proxy server.

You can diagnose this problem when you have the following conditions:

- Heavy SIP protocol traffic exists.
- Multiple applications are deployed on a single node or cluster.

Check the proxy server, the application server SystemOut.log log files, or both for an unexpected overload condition that is detected at the proxy server, the application server, or both. Also, look for 503 Server unavailable messages that are logged from the SIP application.

Resolving the problem

Messages are shared between applications at the SIP container before they are sent to the proxy server. To avoid these error messages and a decrease in SIP performance, tune the SIP containers to consider the additional SIP messages that are generated when using the application router with multiple applications. Complete the following steps in the administrative console to tune the SIP containers:

1. Expand **Servers** > **Server Types** and click **WebSphere application servers** > ***server_name***
2. Under **Container Settings**, expand **SIP Container Settings** and click **SIP container**.
3. Increase the **Maximum messages per averaging period** value to compensate for the anticipated increase in messages that are generated by the SIP application router.
4. Increase the **Maximum application sessions** value to compensate for the increased **Maximum messages per averaging period** value.

The proxy server cannot detect the amount of messages that are generated at the server. However, modifications to the following settings might increase the messaging capacity at the containers for the number of applications that are deployed per container.

Table 112. DAR and CAR SIP container tuning values.

This table lists the DAR and CAR SIP container tuning values for the number of applications that are deployed per container.

SIP Container	Single Deployed SIP Application	Three Deployed SIP Applications
Maximum messages per averaging period	value = 26640	value = 79920
Maximum application sessions	value = 36000	value = 96000

Note: The values for the **Maximum messages per averaging period** and **Maximum application sessions** fields depend on the processing power, memory, and the deployed application. Use the values for these fields as listed in the SIP container settings topic and adjust them to meet the needs of your environment.

Developing applications that use the Asynchronous Invocation API

You can use the Asynchronous Invocation API to transfer events that require processing in the context of a Session Initiation Protocol (SIP) application session to any server in a cluster based on the related application session ID. The Asynchronous Invocation API transfers the event task to the correct server.

Before you begin

Read the API documentation for information on the following asynchronous work classes:

- com.ibm.websphere.sip.AsynchronousWork
- com.ibm.websphere.sip.AsynchronousWorkListener

For more information about the API classes, see the Reference section in the information center and click APIs - Application Programming Interfaces to view a list of the product API specifications.

About this task

When running code outside of a SIP thread, application developers can use the Asynchronous Invocation API to create an object, and configure the server to run that object either on a different thread in the same container, or on a different server, if that is where the session exists.

The following example shows the class structure for the AsynchronousWork class, which is the abstract base class that is extended when using the API.

```
public abstract class AsynchronousWork implements Serializable
{
private String sessionId;
public AsynchronousWork(String sessionId)
{
this.sessionId = sessionId;
....
}
public void dispatch (AsynchronousWorkListener listener)
{
....
}
public abstract Serializable doAsyncTask();
}
```

Procedure

1. Extend the abstract class AsynchronousWork with the SIP related code. The extended implementation of the doAsyncTask() method is invoked on the target server that contains the SipApplicationSession, and whose ID was set in the constructor that implements the AsynchronousWork class. The implementation class must pass the session ID to the base class by calling super in the constructor.

```
public class MyClass extends AsynchronousWork
{
String _sessionId;

public MyClass(String sessionId) {
super(sessionId);
_sessionId = sessionId;
}

// This code is invoked on the target machine or thread
public Serializable doAsyncTask() {
// Application code goes here; for instance:
appSession = sessionUtils.getApplicationSession(_sessionId);
appSession.createRequest().....

Serializable myResponse = new MyResponse();
myResponse.setStatus(200);
return (myResponse);
}
}
```

2. To receive information about the task completion, implement the AsynchronousWorkListener class, as in the following example. The code in these methods are invoked on the source server.

```
public class MyListener implements AsynchronousWorkListener
{
public void workCompleted(Serializeable myResponse)
{
....
}
public void workFailed(int reasonCode, String reason)
{
}
}
```

3. To invoke the asynchronous call; for example, when you receive the proprietary message, use this sample code as an example.

```
public void onMyMessage()
{
// Obtain the session ID from the message or
// somewhere else
String sessionId = obtainIdFromMessage();

// Create the runnable
MyClass myClass = new MyClass(sessionId);

// Create the listener
MyListener myListener = new MyListener();

// Dispatch it
myClass.dispatch(myListener);
}
```

Results

The SIP container ensures the task is invoked in the correct server and on the correct thread, so that the application can avoid synchronization on the session level.

Asynchronous Invocation API

Use the Asynchronous Invocation API to transfer events that require processing in a Session Initiation Protocol (SIP) application session to any server in a cluster based on an application session ID.

The Asynchronous Invocation API, also referred to as the asynchronous work dispatcher, can transfer events that require processing in the context of a SIP application session to any server in a cluster, using

the related application session ID. These transfers are usually triggered by events that cause a state change to SIP sessions that reside on another server. The asynchronous work dispatcher transfers the event task to the correct server to be run.

In Websphere Application Server, all related SIP messages are delivered to the same server in the cluster, and sessions always reside in the same SIP container. To prevent synchronicity issues and locking, tasks in the same application session cannot be processed simultaneously (that is, on different threads or processes), which limits handling of certain types of events.

For more in-depth information about SIP sessions and SIP application sessions and their relationship, see Section 6 of Java Specification Request (JSR) 289.

The following two scenarios are resolved by implementing the Asynchronous Invocation API.

1. Two requests related to the same SIP application session are simultaneously run on two different threads. For example, a Java EE (J2EE) applications working with a message-driven bean (MDB) can retrieve an event to send a SIP message on a certain SIP application session. At the same time, the SIP container receives an incoming SIP message on another session that is connected to the same application session and handles that on a different thread. It would be necessary to synchronize the session access to avoid race conditions and to ensure that all session attributes are synchronized. To employ the locking mechanism in this case would not be effective, because the SIP application session might contain multiple SIP sessions.
2. A server that does not own a certain SIP application session receives a request, through non-SIP protocol, to send a message in the context of that session. For example, a Web service that is initiating SIP dialogs can reside in a server different from the server that owns the SIP application session it must use.

The Asynchronous Invocation API ensures that the specific application code is run on the correct server and correct thread according to the SIP application session ID.

The Asynchronous Invocation API provides the following benefits:

1. No more than two servers are involved in the asynchronous invocation process: one is the server that retrieves the work task, and the other is the target server that handles the SIP application session for that task and to which the task will be transferred.
2. The asynchronous invocation allows working in a thread-safe manner. This approach ensures that only one thread processes the messages related to the SIP application session. Thus, there is no need to synchronize access to the session.
3. The asynchronous invocation provides a scalable solution. There is no performance impact when more servers are added to the cluster.
4. Cross-server invocation is used only when required, which results in better performance.

Chapter 25. Developing Spring applications

This page provides a starting point for finding information about how to develop Spring applications that can run successfully in a WebSphere Application Server environment.

The Spring Framework is an open source project that provides a framework for simple Java objects that enables them to use the Java EE container through wrapper classes and XML configuration.

Configuring access to a Spring application data source

You can use WebSphere Application Server to manage access to a data source for a Spring application.

About this task

For a Spring application to access a data source, such as a Java Database Connectivity (JDBC) data source, the application must use a resource provider that is managed by the WebSphere Application Server. For more information about Spring applications and the Spring Framework see the following topics:

- Spring Framework
- Data access and the Spring Framework

Procedure

1. During development, configure the WAR module with a resource reference. For example:

```
<resource-ref>
    <res-ref-name>jdbc/springdbres-ref-name>jdbc/springdb>
    <res-type>javax.sql.DataSourceres-type>javax.sql.DataSource>
    <res-auth>Containerres-auth>Container>
    <res-sharing-scope>Shareableres-sharing-scope>Shareable>
</resource-ref>
```

2. For Enterprise JavaBeans (EJB) Java archive (JAR) files, declare the same resource reference in each EJB that needs to access the data source. Use one of the following steps:
   - Declare a data source proxy bean. In the Spring application configuration, declare a proxy bean that references a resource provider that the application server manages. Set the value of the jndiName property to java:comp/env/ followed by the value of res-ref-name property that you declared in the resource reference. For example:

```
<bean id="wasDataSource" class="org.springframework.jndi.JndiObjectFactoryBean">
    <property name="jndiName" value="java:comp/env/jdbc/springdb"/>
    <property name="lookupOnStartup" value="false"/>
    <property name="cache" value="true"/>
    <property name="proxyInterface" value="javax.sql.DataSource"/>
</bean>
```

   - Alternatively, for Spring Framework Version 2.5 or later, use the <j2ee:jndi-lookup/> approach. Set the value of the jndi-name property to the value of the res-ref-name property that you declared in the resource reference, and the value of the resource-ref property to `true`. For example:

```
<jee:jndi-lookup id=" wasDataSource "
    jndi-name="jdbc/springdb"
    cache="true"
    resource-ref="true"
    lookup-on-startup="false"
    proxy-interface="javax.sql.DataSource"/>
```

   The Spring application can then use the data source proxy bean as appropriate.
3. When the application is deployed to an application server, configure a resource provider and resource data source that the Spring application resource reference can use.

Results

The resource reference that is declared in the deployment descriptor of the module will be bound to the configured data source of the application server during deployment.

Chapter 26. Developing Transactions

This page provides a starting point for finding information about Java Transaction API (JTA) support. Applications running on the server can use transactions to coordinate multiple updates to resources as one unit of work, such that all or none of the updates are made permanent.

The product provides advanced transactional capabilities to help application developers avoid custom coding. It provides support for the many challenges related to integrating existing software assets with a Java EE environment.

More introduction...

Developing components to use transactions

These topics provide information about developing WebSphere application components to use transactions

About this task

The way that applications use transactions depends on the type of application component, as follows:
- A session bean can either use container-managed transactions (where the bean delegates management of transactions to the container) or bean-managed transactions (component-managed transactions where the bean manages transactions itself).
- Entity beans use container-managed transactions.
- Web components (servlets) and application client components use component-managed transactions.

Use the following tasks to develop WebSphere application components that use transactions:

Procedure

- Configure transactional deployment attributes. This task determines whether EJB components use container- or bean-managed transactions by setting an appropriate value on the Transaction type deployment attribute. You can also configure other transactional deployment descriptor attributes.
- Use component-managed transactions. If you want a session bean, web component, or application client component to manage its own transactions, you must write the code that explicitly demarcates the boundaries of a transaction. There are some limitations to the transaction support available to application client components, as described in the topic about client support for transactions.

Configuring transactional deployment attributes

You can configure the transactional deployment descriptor attributes associated with an EJB or web module, to enable an enterprise application to use transactions.

Before you begin

You must have an enterprise archive (EAR) file for an application component that can be deployed in the application server.

About this task

You can configure the deployment attributes of an application by using an assembly tool.

You can use Rational Application Developer, or an equivalent tool, to configure the deployment attributes of an application.

To use Rational Application Developer to set transactional attributes in the deployment descriptor for an application component (enterprise bean or servlet), complete the following steps.

Procedure

1. Start the assembly tool. For more information, refer to the Rational Application Developer information.
2. Create or edit the application EAR file. For example, to change attributes of an existing application, use the Import wizard to import the EAR file into the assembly tool. To start the Import wizard:
   a. Click **File** > **Import** > **EAR file**.
   b. Click **Next**, then select the EAR file.
   c. Click **Finish**.
3. In the Project Explorer view of the Java EE perspective, right-click the component instance, then click **Open With** > **Deployment Descriptor Editor**. To locate the component instance, use the appropriate step:
   - For a session bean, expand **EJB Modules** > ***ejb_module_instance*** > **Deployment Descriptor** > **Session Beans**, then select the bean instance.
   - For a servlet, expand **Web Modules** > ***web_application*** > **Deployment Descriptor** > ***web component***, then select the servlet instance.

   A property dialog notebook for the deployment descriptor of the component is displayed in the property pane.
4. Optional: For session beans only, set the “Transaction type” attribute, which defines the transactional manner in which the container invokes a method. You can set this attribute to Container or Bean, as follows:
   - To use container-managed transactions, set the attribute to Container.
   - To use bean-managed transactions, set the attribute to Bean.
5. In the deployment descriptor notebook, select the **Bean** tab. Optionally, in the WebSphere Extensions section, configure the Local Transaction attributes. To enable management of local transaction containments, configure the following component extensions attributes. These attributes configure, for the component, the behavior of the local transaction containment (LTC) environment that the container establishes whenever a global transaction is not present.

   Boundary

   This setting specifies the containment boundary at which all contained resource manager local transactions (RMLTs) must be completed. Possible values are BeanMethod or ActivitySession.
   - BeanMethod: This is the default value. If you select this option, RMLTs must be resolved within the same bean method in which they were started.
   - [For EJB components only] ActivitySession: RMLTs must be resolved within the scope of any ActivitySession in which they were started or, if no ActivitySession context is present, within the same bean method in which they were started.

     Note: The ActivitySession option is not supported in the web container.

   Resolver

   This setting specifies the component responsible for initiating and ending RMLTs. Possible values are Application or ContainerAtBoundary.
   - Application: This is the default value. The application is responsible for starting RMLTs and for completing them within the local transaction containment (LTC) boundary. Any RMLTs that are not completed by the end of the LTC boundary are cleaned up by the container according to the value of the Unresolved action attribute.
   - ContainerAtBoundary: The container is responsible for starting RMLTs and for completing them within the LTC boundary. The container begins an RMLT when a connection is first used within the LTC scope, and completes it automatically at the end of the LTC scope. If Boundary is set to ActivitySession, the RMLTs are enlisted as ActivitySession resources and directed to complete by the ActivitySession. If Boundary is set to BeanMethod, the RMLTs are committed at the end of the method by the container.

   Unresolved action

Specifies the direction that the container requests RMLTs to take, if those transactions are unresolved at the end of the LTC boundary scope and the Resolver is set to Application. Possible values are Rollback or Commit.

- Rollback: This is the default value. At end of the LTC boundary scope, the container instructs all unresolved RMLTs to roll back.
- Commit: At the end of the LTC boundary scope, the container instructs all unresolved RMLTs to commit. The container instructs the RMLTs to commit only in the absence of an un-handled exception. If the application method that is running in the local transaction context ends with an exception, any unresolved RMLTs are rolled back by the container. This is the same behavior as for global transactions.

Shareable

Specifies whether the component can share an LTC. A new LTC is started only if a shareable LTC does not already exist. Applications that use shareable LTCs cannot explicitly commit or roll back resource manager connections that are used in a shareable LTC (although they can use connections that have an autoCommit capability).

If an application starts any non-autocommit work in an LTC for which the Resolver attribute is set to `Application`, and the Shareable attribute is set to `true`, an exception is thrown at run time. For example, on a JDBC Connection, non-autocommit work is work that the application performs after using the setAutoCommit(false) method to switch off the autocommit option on the connection. Enterprise beans that use bean managed transactions (BMT) cannot be assembled with the Shareable attribute set on the LTC configuration.

You must specify the **`Shareable`** attribute for all components that share the LTC. The component that creates the shareable LTC determines the other properties of the shared LTC, for example the value of the Resolver attribute.

6. In the WebSphere Extensions section, configure the Global Transaction attributes. These attributes configure, for the component, behavior in the presence of a global transaction.

Component Transaction Timeout

For enterprise beans that use container-managed transactions only, specifies the transaction timeout, in seconds, for any new global transaction that the container starts on behalf of the enterprise bean. For transactions started on behalf of the component, the Component Transaction Timeout setting overrides the default total transaction lifetime timeout that is configured in the transaction service settings for the application server.

The following attributes enable WS-AtomicTransaction and WS-BusinessActivity support for JAX-RPC applications only:

Use Web Services Atomic Transaction

For enterprise beans only, when this attribute is selected, if the application component makes any web service requests, any transaction context is propagated with the web service requests in accordance with the WebSphere WS-AtomicTransaction support described in Web Services Atomic Transaction support in the application server. When this attribute is not selected, web service requests do not carry transaction context.

Send Web Services Atomic Transaction on requests

For web components only, when this attribute is selected, if the application component makes any web service requests, any transaction context is propagated with the web service requests in accordance with the WebSphere WS-AtomicTransaction support described in Web Services Atomic Transaction support in the application server. When this attribute is not selected, web service requests do not carry transaction context.

Execute using Web Services Atomic Transaction on incoming requests

For web components only, when this attribute is selected, Web application components are prepared to run under a received WS-AtomicTransaction context. A web application component can run under a received WS-AtomicTransaction context in a similar way to an enterprise bean deployed with a container transaction type of Supports. When this attribute is not selected, the container of the web application component suspends any received

transaction context, in a similar way to the behavior of an EJB container for an enterprise bean deployed with a container transaction type of NotSupported.

If your application uses JAX-WS, enable support for WS-AtomicTransaction or WS-BusinessActivity by creating a policy set, adding the WS-Transaction policy type to the policy set, and attaching the policy set to the service or client.

If a policy set that is attached to a client includes the WS-Transaction policy type, any active global transaction context is propagated with a Web service request, in a similar way to the deployment descriptors Use Web Services Atomic Transaction and Send Web Services Atomic Transaction on requests, described earlier in this topic. Also, when the WS-Transaction policy type is included, the service runs under any received WS-AtomicTransaction context, in a similar way to the deployment descriptor Execute using Web Services Atomic Transaction on incoming requests, described earlier in this topic.

7. For EJB components only, for container-managed transactions, configure how the container manages the transaction boundaries when delegating a method invocation to the business method of an enterprise bean:
   a. In the deployment descriptor notebook, select the **Assembly** tab. The Container Transactions section displays a table of the methods for enterprise beans.
   b. For each method of the enterprise bean, set the container transaction type to an appropriate value. The default value for the container transaction type is Required, meaning that the method invocation occurs in the context of a transaction. This transaction is either the (local or remote) client component transaction or, if the client component does not run in a transaction, a new transaction started by the component container.

   If the application uses ActivitySessions, how the container manages transaction boundaries when delegating a method invocation depends on both the container transaction type that you set in this task, and the ActivitySession kind attribute, which is described in “Setting EJB module ActivitySession deployment attributes” on page 4. For more detail about the relationship between these two properties, see ActivitySession and transaction container policies in combination.
8. For web services applications that use a SOAP/JMS binding and participates in WS-AtomicTransactions, set the container transaction type of the message-driven bean named “JMS router MDB” to a value of NotSupported, as described in the previous step. Web service applications that use a SOAP/JMS binding include a router message-driven bean named “JMS router MDB” in the assembled EAR. If a web service uses a SOAP/JMS binding and participates in WS-AtomicTransactions, as described in Web Services Atomic Transaction support in the application server, set the container transaction type of the “JMS router MDB” to a value of NotSupported.

   For web services applications that use a SOAP/HTTP binding and participate in WS-AtomicTransactions, you do not have to do this.
9. For client application components only, if required, enable support for transaction demarcation by the client. In the deployment descriptor notebook, select the **Allow JTA demarcation** check box. This option directs the client container to bind the Java Transaction API (JTA) UserTransaction interface into JNDI at java:comp/UserTransaction for the client component. There are constraints on transaction support in the client container, which are described in Client support for transactions.
10. Save your changes to the deployment descriptor.
    a. Close the deployment descriptor editor.
    b. When prompted, click **Yes** to save changes to the deployment descriptor.
11. Verify the archive files. For more information about verifying files by using Rational Application Developer, refer to the Rational Application Developer information.
12. From the menu of the project, click **Deploy** to generate EJB deployment code.
13. Optional: Test your completed module on an application server installation. Right-click a module, click **Run on Server**, and follow the instructions in the resulting wizard.

Important: Use the **Run On Server** option for unit testing only. The assembly tool controls the application server installation, and when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use the **Run On Server** option on production servers.

What to do next

After assembling your application, use a systems management tool, for example the administrative console, to deploy the EAR file onto the application server that is to run the application.

Using component-managed transactions

You can enable a session bean, servlet, or application client component to use component-managed transactions, to manage its own transactions directly instead of letting the container manage the transactions.

About this task

Note: Entity beans cannot manage transactions (so cannot use bean-managed transactions).

To enable a session bean, servlet, or application client component to use component-managed transactions, complete the following steps:

Procedure

1. For session beans, set the **`Transaction type`** attribute in the component deployment descriptor to `Bean`, as described in “Configuring transactional deployment attributes” on page 1063.
2. For application client components, enable support for transaction demarcation by setting the **`Allow JTA Demarcation`** attribute in the component deployment descriptor, as described in “Configuring transactional deployment attributes” on page 1063.
3. Write the component code to actively manage transactions.

   For stateful session beans, a transaction started in a given method does not have to be completed (that is, committed or rolled back) before completing that method. The transaction can be completed at a later time, for example on a subsequent call to the same method, or even within a different method. However, it is usually preferable to construct the application so that a transaction is begun and completed within the same method call, because it simplifies application debugging and maintenance.

   The following code extract shows the standard code required to obtain an object encapsulating the transaction context, and involves the following steps:
   - Create a javax.transaction.UserTransaction object by calling a lookup on java:comp/UserTransaction.
   - Use the UserTransaction object to demarcate the boundary of a transaction by using transaction methods such as begin and commit, as needed. If an application component begins a transaction, it must also complete that transaction by invoking either the commit method or the rollback method.

```
...
import javax.transaction.*;
import javax.naming.InitialContext;
import javax.naming.NamingException;
...
    public float doSomething(long arg1)throws NamingException {
        InitialContext initCtx = new InitialContext();
        UserTransaction userTran = (UserTransaction)initCtx.lookup(
           "java:comp/UserTransaction");
        ...
        //Use userTran object to call transaction methods
        userTran.begin ();
        //Do transactional work
        ...
        userTran.commit ();
```

```
        ...
    }
    ...
}
```

Using one-phase and two-phase commit resources in the same transaction

Use these topics to help you coordinate the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction.

About this task

You can coordinate the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction. You can have multiple interactions that involve the one-phase commit resource in the same transaction, but only one such resource can be involved. This coordination is enabled by the *last participant support*.

At transaction commit, the two-phase commit resources are prepared first using the two-phase commit protocol, and if this is successful the one-phase commit-resource is then called to commit. The two-phase commit resources are then committed or rolled back depending on the response of the one-phase commit resource.

For more information about using one-phase and two-phase commit resources within the same transaction, see the following topics:

Procedure

- “Coordination of access to one-phase commit and two-phase commit capable resources in the same transaction” on page 1070
- “Assembling an application to use one-phase and two-phase commit resources in the same transaction”
- Configuring an application server to log heuristic reporting

Assembling an application to use one-phase and two-phase commit resources in the same transaction

Use this task to assemble an application to use one-phase and two-phase commit resources in the same transaction.

Before you begin

This task description assumes that you have an EAR file for an application component that can be deployed in WebSphere Application Server. For more details about assembling applications, see the topic about assembling applications.

About this task

To enable an application to use one-phase and two-phase commit capable resources in the same transaction, you must configure the deployment attributes of the application to accept the heuristic hazard, that is, the increased risk of an heuristic outcome. You can configure the deployment attributes of an application by using an assembly tool.

You can also configure an application to accept the heuristic hazard after deployment, by using the administrative console and the Last participant support extension settings. Alternatively, you can configure the transaction service for an application server to accept the heuristic hazard.

This topic describes the use of Rational Application Developer to configure the deployment attributes of an application.

To configure an application to indicate that you accept the increased risk of an heuristic outcome, complete the following steps:

Procedure

1. Start the assembly tool. For more information, refer to the Rational Application Developer information.
2. Create or edit the application EAR file.

   Note: Ensure that you set the target server as WebSphere Application Server Version 7.0.

   For example, to change attributes of an existing application, use the Import wizard to import the EAR file into the assembly tool. To start the Import wizard:

   a. Click **File** > **Import** > **EAR file**.
   b. Click **Next**, then select the EAR file.
   c. In the Target server field, select `WebSphere Application Server v7.0`.
   d. Click **Finish**.
3. In the Project Explorer view of the Java EE perspective, complete the following steps:
   a. Expand the Enterprise Application instance.
   b. Right click on the Deployment Descriptor.
   c. Click **Open With** > **Deployment Descriptor Editor**.

   A property dialog notebook for the component is displayed in the property pane.
4. Complete the following steps to display the Extended Services tab.
   a. Close the Enterprise Application Deployment Descriptor editor.
   b. In the toolbar, select **Windows** > **Preferences**.
   c. In the left pane, select **Capabilities**.
   d. In the right pane, expand **Advanced Java EE** and select the **WebSphere PME Development** option.
   e. Click **Apply**.
   f. Open the Enterprise Application Deployment Descriptor editor.
5. On the Extended Services tab, in the Last Participant Support section, select the **Last participant support** check box.
6. Save your changes to the deployment descriptor.
   a. Close the Deployment Descriptor Editor.
   b. When prompted, click **Yes** to save changes to the deployment descriptor.
7. Verify the archive files. For more information about verifying files using Rational Application Developer, refer to the Rational Application Developer information.
8. From the popup menu of the project, click **Deploy** to generate EJB deployment code.
9. Optional: Test your completed module on a WebSphere Application Server installation. Right-click a module, click **Run on Server**, and follow the instructions in the displayed wizard.

   Important: Use **Run On Server** only for unit testing. The assembly tool controls the WebSphere Application Server installation and, when an application is published remotely, the assembly tool overwrites the server configuration file for that server. Do not use the **Run On Server** option on production servers.

What to do next

After assembling your application, use a systems management tool to deploy the EAR file onto the application server that is to run the application; for example, using the administrative console, as described in the topic about deploying and administering enterprise applications.

Last participant support extension settings:

Use this page to configure settings for last participant support. Last participant support is an extension to the transaction service that enables a single one-phase resource to participate in a two-phase transaction with one or more two-phase resources. Values on this panel are ignored if you select **Use configuration information in binary** on the Application binaries panel.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications >** *application_name*. Under **Detailed Properties**, click **Last participant support extension**.

Accept heuristic hazard:

Specifies whether an application accepts the possibility of a heuristic hazard occurring in a two-phase transaction that contains a one-phase resource.

Information	**Value**
Default	Cleared
Range	**Selected** The application accepts the increased risk of an heuristic outcome. **Cleared** The application does not accept the increased risk of an heuristic outcome.

Coordination of access to one-phase commit and two-phase commit capable resources in the same transaction

Last participant support enables the use of a single one-phase commit capable resource with any number of two-phase commit capable resources in the same global transaction. You can have multiple interactions that involve the one-phase commit resource in the same transaction, but only one such resource can be involved.

At transaction commit, the two-phase commit resources are prepared first using the two-phase commit protocol, and if this is successful, the one-phase commit-resource is then called to commit. The two-phase commit resources are then committed or rolled back, depending on the response of the one-phase commit resource.

Note: If the global transaction is distributed across multiple application servers *that are all running at WebSphere Application Server version 6.1 or later*, you can exploit last participant support to coordinate a one-phase commit capable resource and any number of two-phase commit capable resources in the same transaction, in a limited number of scenarios.

- The main scenario is where the one-phase commit resource provider is accessed in the application server process (the “transaction root” server) in which the transaction is started.

  In this scenario, last participant support can coordinate a one-phase commit capable resource and any number of two-phase commit capable resources in the same transaction.
- If the one-phase commit resource provider is accessed in a different application server (a “transaction subordinate” server) from the one in which the transaction was started; for example, as a result of a transactional invocation on a remote EJB interface where the EJB implementation accesses a one-phase commit resource provider.

  In this scenario, the transaction typically cannot be committed. To be able to commit (as part of a global transaction) a one-phase commit resource enlisted on a transaction subordinate server, the transaction service must delegate coordination responsibility from the transaction root to the subordinate server. This occurs only if no other resources were registered with the transaction root server.

Last participant support introduces an increased risk of an heuristic outcome to the transaction. That is, the transaction manager cannot be sure that all resources were completed in the same direction (either committed or rolled back). For this reason, to enable an application to coordinate access to one-phase and two-phase commit capable resources in the same transaction, you configure the application to accept the heuristic hazard, that is, accept the increased risk of an heuristic outcome.

An heuristic outcome occurs if the transaction service (JTS) receives no response from the commit one-phase flow on the one-phase commit resource. In this situation, the transaction service cannot determine whether changes for the one-phase commit resource were committed or rolled back, so cannot drive reliably the correct outcome of the global transaction on the other two-phase commit resources.

You can configure the transaction service for an application server to accept the heuristic hazard, or you can configure applications individually to accept the heuristic hazard. You can configure applications individually either when they are assembled, or after they are deployed.

You can configure the transaction service for an application server to indicate whether or not to log that it is about to commit the one-phase commit resource. This does not reduce the heuristic hazard, but ensures that any failure, and subsequent recovery, of the application server during the one-phase commit phase occurs with knowledge of whether or not the one-phase commit resource was asked to commit:
- If the one-phase commit resource was asked to commit, a heuristic outcome is reported to the activity log.
- If the one-phase commit resource was not asked to commit, then the transaction is rolled back consistently.

Transaction exceptions that involve both one-phase and two-phase commit resources

The exceptions that can be thrown by transactions that involve one-phase and two-phase commit resources are the same as those that can be thrown by transactions involving only two-phase commit resources.

The exceptions that can occur are listed in the application programming interface (API) reference information in the WebSphere Application Server information center.

Last Participant Support: Resources for learning:

Use the links in this topic to find relevant supplemental information about Last Participant Support. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

- WebSphere technical library, including links to white papers

Chapter 27. Developing web applications

This page provides a starting point for finding information about web applications, which are comprised of one or more related files that you can manage as a unit, including:

- HTML files
- Servlets can support dynamic web page content, provide database access, serve multiple clients at one time, and filter data.
- Java ServerPages (JSP) files enable the separation of the HTML code from the business logic in web pages.

IBM extensions to the JSP specification make it easy for HTML authors to add the power of Java technology to web pages, without being experts in Java programming. More introduction...

Developing web applications

Learn about selecting tools for developing web applications.

Before you begin

Design a web application and the required components.

About this task

There are two basic approaches to selecting tools for developing web applications:

- You can use one of the available integrated development environments (IDEs). IDE tools automatically generate significant parts of the servlet and JavaServer Pages (JSP) code, and Hypertext Markup Language (HTML) files. They also contain integrated tools for packaging and testing the web application components.
- If you decide to develop web components without an IDE, you need at least an ASCII text editor. You can also use tools available in the Java SE Development Kit 6 and in this product to assemble, test, and deploy the Web application components.

The following steps support the second approach, development without an IDE.

Procedure

1. If necessary, migrate any pre-existing code to the required version of the servlet and JSP specification.
2. Write and compile the components of the web application. To access classes that were extended, compile your code using the `-classpath` option on the `javac` compiler. This option allows you to reference the `j2ee.jar` file in the product directory:
   - *<install_root>*`\dev\JavaEE`

   To compile that same servlet on the Windows NT version of WebSphere Network Deployment, specify:

   ```
   javac -classpath D:\Program Files\WebSphere\DeploymentManager\dev\JavaEE\j2ee.jar MyServlet.java
   ```
3. Optionally disable JavaServer Pages (JSP) runtime compilation, if necessary.

What to do next

Assemble the application components in one or more web modules.

Developing servlets

Developing servlets with WebSphere Application Server extensions

Use this task to provide a summary of the WebSphere Application Server extensions that you can use to develop servlets.

About this task

Several WebSphere Application Server extensions are provided for enhancing your servlets. This task provides a summary of the extensions that you can utilize.

Procedure

1. Review the supported specifications.

   Create Java components, referring to the Servlet specifications.

   The application server includes its own packages that extend and add to the Java Servlet Application Programming Interface (API). These extensions and additions make it easier to manage session states, create personalized Web pages, generate better servlet error reports, and access databases. Locate the API documentation for the application server APIs in the `install_root\web\apidocs` directory for the default installation. All of the public Application Server APIs are located in the `com.ibm.websphere` packages, however, com.ibm.websphere.servlet package is specific to the product servlet APIs.
2. Use your favorite integrated development environment (IDE), or a text editor, to develop or migrate code artifacts that meet the specifications.
3. Test the code artifacts.

What to do next

Assemble your code artifacts into a web module using assembly tools as a prerequisite to deploying the code to the application server.

Configuring page list servlet client configurations:

You can define PageListServlet configuration information in the IBM Web Extensions file. The IBM Web Extensions file is created and stored in the web applications archive (WAR) file by an assembly tool.

About this task

Attention: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 8.5 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes. Starting from the Servlet 2.3 specification, javax.servlet.filter classes you can intercept requests and examine responses. You can also use javax.servlet.filter classes to achieve chaining functionality, as well as embellishing or truncating responses.

To configure and implement page lists:

Procedure

1. To configure page list information, use the Add Markup Language entry dialog of an assembly tool. On the Servlets tab of a web deployment descriptor editor, select a servlet and click **Add** under WebSphere Extensions.
2. Add the `callPage()` method to your servlet to invoke a JavaServer Page (JSP) file in response to a client request.

   The PageListServlet has a `callPage()` method that invokes a JSP file in response to the HTTP request for a page in a page list. The `callPage()` method can be invoked in one of the following ways:

- `callPage(String pageName, HttpServletRequest request, HttpServletResponse response)`

  where the method arguments are:

  pageName
  A page name defined in the PageListServlet configuration

  request
  The HttpServletRequest object

  response
  The HttpServletResponse object
- `callPage(String mlName, String pageName, HttpServletRequest request, HttpServletResponse response)`

  where the method arguments are:

  mlName A markup language type

  pageName
  A page name defined in the PageListServlet configuration

  request
  The HttpServletRequest object

  response
  The HttpServletResponse object

3. Use the PageList Servlet client type detection support to determine the markup language type a calling client requires for the response.

Extending PageListServlet

The following example shows how a servlet extends the PageListServlet class and determines the markup-language type required by the client. The servlet then uses the callPage method to call an appropriate JavaServer Pages (JSP) file. In this example, the JSP file that provides the correct markup-language for the response is *Hello.page*.

```
public class HelloPervasiveServlet extends PageListServlet implements Serializable
{
     /*
     * doGet -- Process incoming HTTP GET requests
     */
    public  void doGet(HttpServletRequest request, HttpServletResponse response)
    throws IOException, ServletException
    {
       // This is the name of the page to be called:
       String pageName = "Hello.page";

       // First check if the servlet was invoked with a queryString that contains
    // a markup-language value.
       // For example, if this is how the  servlet is invoked:
       //  http://localhost/servlets/HeloPervasive?mlname=VXML
       //  then use the following method:
       String mlname= getMLNameFromRequest(request);

        // If no markup language type is provided in the queryString,
        // then try to determine the client
        // Type from the request, and use the markup-language name configured in
        // the client_types.xml file.
        if (mlName == null)
        {
          mlName = getMLTypeFromRequest(request);
         }
         try
         {
           // Serve the request page.
           callPage(mlName, pageName, request, response);
          }
          catch (Exception e)
          {
```

```
            handleError(mlName, request, response, e);
           }
       }
}
```

Page lists:

Page lists allow you to avoid hard-coding Uniform Resource Locators (URLs) in servlets and JSP files. A page list specifies the location where a request is to be forwarded, but automatically customizes that location depending on the MIME type of the servlet. Use these properties to specify a markup language and an associated MIME type. For the given MIME type, you also specify a set of pages to invoke.

Note: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 8.5 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes. Starting from the Servlet 2.3 specification, javax.servlet.filter classes you can intercept requests and examine responses. You can also use javax.servlet.filter classes to achieve chaining functionality, as well as embellishing or truncating responses.

The following list of classes are deprecated:

- com.ibm.servlet.ClientList
- com.ibm.servlet.ClientListElement
- com.ibm.servlet.MLNotFoundException
- com.ibm.servlet.PageListServlet
- com.ibm.servlet.PageNotFoundException

WebSphere Application Server supplies the PageListServlet servlet, which you can use to call a JavaServer Pages (JSP) file by name based on the configuration data in the `client_types.xml` file. This file maps a JSP file to a Uniform Resource Identifier (URI). When the URI is invoked, it specifies another JSP file in a web module. This support allows you to access multiple URLs without hard-coding them in your servlets.

You can also logically group page lists according to the markup language type, such as, Hypertext Markup Language (HTML) or Wireless Markup Language (WML). This allows applications that use servlets to extend the PageListServlet servlet, to call JSP files which return the proper markup-language type for the client request. For example, a request that originates from a PDA device requires WML data. The application server sends the request to a servlet that extends the PageListServlet servlet, and the servlet calls a JSP file that returns a WML response.

Client type detection support:

In addition to providing the page list mapping capability, the PageListServlet also provides Client Type Detection support. A servlet determines the markup language type that a calling client needs in the response, using the configuration information in the `client_types.xml` file.

Client type detection support allows a servlet, extending the PageListServlet, to call an appropriate JavaServer Pages (JSP) file. The servlet invokes the **`callPage`** method, which calls a JSP file based on the markup-language type of the request.

The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 8.5 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes.

The client_types.xml file:

The client_types.xml file provides client type detection support for servlets extending PageListServlet. Using the configuration data in the client_types.xml file, servlets can determine the language type that calling clients require for the response.

Attention: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 8.5 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes.

The client type detection support allows servlets to call appropriate JavaServer Pages (JSP) files with the callPage method. Servlets select JSP files based on the markup-language type of the request.

Servlets must use the following version of the callPage method to determine the markup language type required by the client:

```
callPage(String mlName, String pageName, HttpServletRequest request,
                  HttpServletResponse response)
```

where the arguments are:
- mlName - a markup language type
- pageName - a page name defined in the PageListServlet configuration
- request - the HttpServletRequest object
- response - the HttpServletResponse object

Review the Extending the PageListServlet code example in the Extending the PageListServlet topic, to see how the callPage method is invoked by a servlet.

In the example, the client type detection method, getMLTypeFromRequest(HttpServletRequestrequest), provided by the PageListServlet, inspects the HttpServletRequest object request headers, and searches for a match in the client_types.xml file.

The client type detection method does the following:
- Uses the input HttpServletRequest and the client_types.xml file, to check for a matching HTTP request name and value.
- Returns the markup-language value configured for the <client-type> element, if a match is found.
- If multiple matches are found, this method returns the markup-language for the first <client-type> element for which a match is found.
- If no match is found, returns the value of the markup-language for the default page defined in the PageListServlet configuration.

Location

The client_types.xml file is located in the *install_root*/properties directory.

Usage notes

Review the answers to the following usage questions:
- Is this file read-only?

  No
- Is this file updated by a product component?

  No
- If so, what triggers its update?

  This file is created and updated manually by users.
- How and when are the contents of this file used?

  Servlets that extending the PageListServlet servlet use this file to determine the language type that calling clients require for the response.

Sample file entry

```
<?xml version="1.0" >
<!DOCTYPE clients [
<!ELEMENT client-type (description, markup-language,request-header+)>
<!ELEMENT description (#PCDATA)>
<!ELEMENT markup-language (#PCDATA)>
<!ELEMENT request-header (name, value)>
<!ELEMENT clients (client-type+)>
<!ELEMENT name (#PCDATA)>
<!ELEMENT value (#PCDATA)>]>
<clients>
      <client-type>
      <description>IBM Speech Client</description>
      <markup-language>VXML</markup-language>
      <request-header>
           <name>user-agent</name>
           <value>IBM VoiceXML pre-release version 000303</value>
      </request-header>
      <request-header>
           <name>accept</name>
           <value>text/vxml</value>
      </request-header>
      </client-type>
      <client-type>
           <description>WML Browser</description>
           <markup-language>WML</markup-language>
      <request-header>
           <name>accept</name>
           <value>text/x-wap.wml</value>
      </request-header>
      <request-header>
           <name>accept</name>
           <value>text/vnd.wap.xml</value>
      </request-header>
    </client-type>
</clients>
```

The client_types.xml file:

The `client_types.xml` file provides client type detection support for servlets extending PageListServlet. Using the configuration data in the `client_types.xml` file, servlets can determine the language type that calling clients require for the response.

Attention: The PageList Servlet custom extension is deprecated in WebSphere Application Server Version 8.5 and will be removed in a future release. Re-architect your legacy applications to use javax.servlet.filter classes instead of com.ibm.servlet classes.

The client type detection support allows servlets to call appropriate JavaServer Pages (JSP) files with the `callPage` method. Servlets select JSP files based on the markup-language type of the request.

Servlets must use the following version of the `callPage` method to determine the markup language type required by the client:

```
callPage(String mlName, String pageName, HttpServletRequest request,
                  HttpServletResponse response)
```

where the arguments are:
- mlName - a markup language type
- pageName - a page name defined in the PageListServlet configuration
- request - the HttpServletRequest object

- response - the HttpServletResponse object

Review the Extending the PageListServlet code example in the Extending the PageListServlet topic, to see how the `callPage` method is invoked by a servlet.

In the example, the client type detection method, `getMLTypeFromRequest(HttpServletRequestrequest)`, provided by the PageListServlet, inspects the HttpServletRequest object request headers, and searches for a match in the `client_types.xml` file.

The client type detection method does the following:
- Uses the input HttpServletRequest and the `client_types.xml` file, to check for a matching HTTP request name and value.
- Returns the markup-language value configured for the `<client-type>` element, if a match is found.
- If multiple matches are found, this method returns the markup-language for the first `<client-type>` element for which a match is found.
- If no match is found, returns the value of the markup-language for the default page defined in the PageListServlet configuration.

Location

The `client_types.xml` file is located in the *`install_root`*`/properties` directory.

Usage notes

Review the answers to the following usage questions:
- Is this file read-only?

  No
- Is this file updated by a product component?

  No
- If so, what triggers its update?

  This file is created and updated manually by users.
- How and when are the contents of this file used?

  Servlets that extending the PageListServlet servlet use this file to determine the language type that calling clients require for the response.

Sample file entry

```
<?xml version="1.0" >
<!DOCTYPE clients [
<!ELEMENT client-type (description, markup-language,request-header+)>
<!ELEMENT description (#PCDATA)>
<!ELEMENT markup-language (#PCDATA)>
<!ELEMENT request-header (name, value)>
<!ELEMENT clients (client-type+)>
<!ELEMENT name (#PCDATA)>
<!ELEMENT value (#PCDATA)>]>
<clients>
      <client-type>
      <description>IBM Speech Client</description>
      <markup-language>VXML</markup-language>
      <request-header>
           <name>user-agent</name>
           <value>IBM VoiceXML pre-release version 000303</value>
      </request-header>
      <request-header>
           <name>accept</name>
           <value>text/vxml</value>
      </request-header>
```

```
      </client-type>
      <client-type>
           <description>WML Browser</description>
           <markup-language>WML</markup-language>
      <request-header>
           <name>accept</name>
           <value>text/x-wap.wml</value>
      </request-header>
      <request-header>
           <name>accept</name>
           <value>text/vnd.wap.xml</value>
      </request-header>
    </client-type>
</clients>
```

Java Servlet 3.0 considerations:

When using Servlet 3.0 web modules, keep in mind the following features.

Java Servlet 3.0 has many, new powerful features. Some of these features are not fully documented in the Servlet 3.0 specification or they entail trade-offs. Consider the following topics to make best use of the new features.

Annotations

Java Servlet 3.0 annotations are picked up in Servlet 2.5 web modules, which can include exposing a servlet on the web. Use caution when upgrading prerequisites of an older application, because the new annotations are processed and the prerequisites JAR file might include annotations that you do not want applied.

File upload

When using the file upload (multipart forms) support that is new to Servlet 3.0, the default location for writing files is the same as the value of the javax.servlet.context.tempdir servlet context attribute. For example, `C:\opt\WAS\profiles\node1\temp\node1\server1\fragmentTest\fragmentTest24.war` is produced for a configuration with the following attributes:

- profile home=C:\opt\WAS\profiles\node1
- server name=server1
- enterprise application name=fragmentTest
- web module name=fragmentTest24.war

Relative paths are also relative to this default location.

You can change the value of the javax.servlet.context.tempdir servlet context attribute to be relative to a different directory by setting the com.ibm.websphere.servlet.temp.dir system property. This system property affects all applications on a server-wide basis. For example, if you set com.ibm.websphere.servlet.temp.dir to `/foo`, the application temp directory is `/foo/node1/server1/fragmentTest/fragmentTest24.war`. If you want to change the value at an application level, use the scratchdir JavaServer Pages (JSP) attribute. View the JSP engine configuration parameters topic for more information about the scratchdir attribute.

Programmatic or dynamic HTTP session configuration

Programmatic HTTP session configuration enables an application to modify the session configuration in use, either through `web.xml` file configuration or through API method calls. After the application starts, a dynamically modified cookie name cannot be changed. For security purposes, administrators can disable programmatic session configuration for particular cookies that can be shared between applications.

Generally, it is safe to modify the cookie configuration, if the application uses a unique cookie name or path. You can change the default cookie path for each application to use the context root through the session management.

Important: Changing the path can affect certain IBM extensions, such as session sharing or the IBMSessionExt.invalidateAll method that rely on using one cookie for multiple applications.

Dynamic cookies have the following impact on intermediary services:

- An enterprise proxy automatically retrieves a dynamic cookie when an application starts and uses the cookie for session affinity.
- A DMZ proxy in low or medium secure mode also automatically retrieves a dynamic cookie when an application starts. For a DMZ proxy in high secure mode, the retrieval is not automatic; the application must be running before the target routing information is exported.
- A web server plug-in cannot obtain the dynamic cookie automatically because it does not communicate with application servers for configuration information. You must start the application, generate the plug-in configuration, propagate the configuration to the plug-in, and then reload the configuration for the plug-in to obtain the cookie.
- In the cluster environment, the generated dynamic cookie name on each server must be the same, otherwise the front-end intermediary services might not be able to route requests.

Servlet 3.0 programmatic configuration:

The configuration methods, addListener, addFilter, and addServlet are introduced in the Servlet 3.0 specification.

The methods for Servlet 3.0 are part of the ServletContext interface. You can call these methods from either a ServletContainerInitializer or a ServletContextListener.

addListener

The addGlobalListener method is deprecated in WebSphere Application Server Version 8.5. It is replaced with the addListener method.

- Use the following method to add the listener with the given class name to this servlet context:
  ```
  void addListener(java.lang.String className)
  ```
- Use the following method to add the given listener to this servlet context:
  ```
  <T extends java.util.EventListener> void addListener(T t)
  ```
- Use the following method to add a listener of the given class type to this servlet context:
  ```
  void addListener(java.lang.Class<? extends java.util.EventListener> listenerClass)
  ```

The given listener class must implement one or more of the following interfaces:

- ServletContextAttributeListener
- ServletRequestListener
- ServletRequestAttributeListener
- HttpSessionListener
- HttpSessionAttributeListener

addFilter

The addMappingFilter method is deprecated in WebSphere Application Server Version 8.5. It is replaced with the addFilter method. This method adds the filter with the given name, description, and class name to the Web application context. The registered filter might be further configured using the returned FilterRegistration object.

- Use the following method to add the filter with the given name and class type to this servlet context:
  `addFilter(java.lang.String filterName, java.lang.Class<? extends Filter> filterClass)`
- Use the following method to register the given filter instance with this servlet context under the given filterName:
  `addFilter(java.lang.String filterName, Filter filter)`
- Use the following method to add the filter with the given name and class name to this servlet context:
  `addFilter(java.lang.String filterName, java.lang.String className)`

addServlet

The addServlet methods dynamically adds servlets to a servletContext. These methods will add the servlet with the given parameters to the web application context. The registered servlet might be further configured using the returned ServletRegistration object.

- Use the following method to add the filter with the given name and class type to this servlet context:
  `addFilter(java.lang.String filterName, java.lang.Class<? extends Filter> filterClass)`
- Use the following method to register the given filter instance with this servlet context under the given filterName:
  `addFilter(java.lang.String filterName, Filter filter)`
- Use the following method to add the filter with the given name and class name to this servlet context:
  `addFilter(java.lang.String filterName, java.lang.String className)`

ServletContainerInitializer

When you configure a JAR file for a shared library and a ServletContainerInitializer is discovered within the JAR, the ServletContainerInitializer is invoked for every application that the shared library associates with.

Deprecated classes in Servlet 3.0

The following classes are deprecated from com.ibm.websphere.servlet.context.IBMServletContext:

- public void addDynamicServlet(String servletName, String servletClass, String mappingURI, Properties initParameters) throws ServletException, java.lang.SecurityException;
- public void removeDynamicServlet(String servletName) throws java.lang.SecurityException

There is no replacement for the removeDynamicServlet method because removing a servlet can lead to timing issues if a request was servicing that servlet at the same time. The addServlet and createServlet methods replace the addDynamicServlet method.

Initial parameters for servlets settings:

Use this page to specify initial parameters that are passed to the init method of web module servlet filters. You can specify initial parameter values for servlets in web modules during or after installation of an application onto a WebSphere Application Server deployment target. The `<param-value>` values specified in `<init-param>` statements in the `web.xml` file of web modules are used by default.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Init parameters for servlets**. This page is the same as the Init parameters for servlets in each web module panel on the application installation and update wizards.

Module:

Specifies the name of a module in the application that you are installing or that you are viewing after installation.

URI:

Specifies the location of the module relative to the root of the application (EAR file).

Servlet:

Specifies a unique name for the servlet within the application.

A *servlet* is a Java program that uses the Java Servlet Application Programming Interface (API). You must package servlets in a Web archive (WAR) file or web module for deployment to an application server. Servlets run on a Java-enabled web server and extend the capabilities of a web server, similar to the way applets run on a browser and extend the capabilities of a browser.

Name:

Specifies the name of the initial parameter passed to the init method of the web module servlet filter.

The following example servlet filter statement in a `web.xml` file specifies an initial parameter name of `attribute`:

```
<init-param>
   <param-name>attribute</param-name>
   <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
</init-param>
```

Value:

Specifies the value assigned to an initial parameter passed to the init method of the web module servlet filter.

The following example servlet filter statement in a `web.xml` file specifies an initial parameter value of `tests.Filter.DoFilter_Filter.SERVLET_MAPPED` for the init parameter `attribute`:

```
<init-param>
   <param-name>attribute</param-name>
   <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
</init-param>
```

Description:

Specifies information on the initial parameter.

Servlet filtering:

Servlet filtering provides a new type of object called a filter that can transform a request or modify a response.

You can chain filters together so that a group of filters can act on the input and output of a specified resource or group of resources.

Filters typically include logging filters, image conversion filters, encryption filters, and Multipurpose Internet Mail Extensions (MIME) type filters (functionally equivalent to the servlet chaining). Although filters are not servlets, their life cycle is very similar.

Filters are handled in the following manner:

1. The web container determines whether it needs to construct a `FilterChain` containing the `LoggingFilter` for the requested resource.

   The `FilterChain` begins with the invocation of the `LoggingFilter` and ends with the invocation of the requested resource.

2. If other filters need to go in the chain, the web container places them after `theLoggingFilter` and before the requested resource.
3. The web container then instantiates and initializes the `LoggingFilter` (if it was not done previously) and invokes its `doFilter(FilterConfig)` method to start the chain.
4. The `LoggingFilter` preprocesses the request and response objects and then invokes the filter chain `doFilter(ServletRequest, ServletResponse)` method.

   This method passes the processing to the next resource in the chain, the requested resource.
5. Upon return from the filter chain `doFilter(ServletRequest, ServletResponse)` method, the `LoggingFilter` performs post-processing on the request and response object before sending the response back to the client.

Java Servlet Specification 2.4 enables you to define a new `<dispatcher>` element in the deployment descriptor with possible values such as REQUEST, FORWARD, INCLUDE, ERROR, instead of invoking filters with RequestDispatcher.

Java Servlet Specification 3.0 enables you to define a new `<dispatcher>` element in the deployment descriptor with possible values such as ASYNC, REQUEST, FORWARD, INCLUDE, ERROR, instead of invoking filters with RequestDispatcher.

For example:

```
<filter-mapping>
<filter-name>Logging Filter</filter-name>
<url-pattern>/products/*</url-pattern>
<dispatcher>FORWARD</dispatcher>
<dispatcher>REQUEST</dispatcher>
</filter-mapping>
```

This indicates that the filter should be applied to requests directly from the client as well as forward requests. Adding the INCLUDE and ERROR values also indicates that the filter should additionally be applied for included requests and `<error-page>` requests. If you do not specify any <dispatcher> elements, then the default is REQUEST.

Filter, FilterChain, FilterConfig classes for servlet filtering

The following interfaces are defined as part of the javax.servlet package:
- Filter interface - methods: doFilter, getFilterConfig, setFilterConfig
- FilterChain interface - methods: doFilter
- FilterConfig interface - methods: getFilterName, getInitParameter, getInitParameterNames, getServletContext

The following classes are defined as part of the javax.servlet.http package:
- HttpServletRequestWrapper - methods: See the Servlet 2.4 Specification
- HttpServletResponseWrapper - methods: See the Servlet 2.4 Specification

autoRequestEncoding and autoResponseEncoding:

Starting with WebSphere Application Server Version 5, the web container no longer automatically sets request and response encodings, and response content types. Programmers are expected to set these values using available methods in the Servlet 2.3 specification or later. If programmers choose not to use the character encoding methods, they can specify the **autoRequestEncoding** and **autoResponseEncoding** extensions, which enable the application server to set the encoding values and content type.

The values of the **autoRequestEncoding** and **autoResponseEncoding** extensions are either `true` or `false`. The default value for both extensions is `false`. If the value is `false` for both **autoRequestEncoding** and **autoResponseEncoding**, then the request and response character encoding is set to the Servlet Specification default, which is ISO-8859-1. Also, if the value is set to `false` for a response, the web

container cannot set a response content type. Different character encodings are possible if the client defines character encoding in the request header, or if the code includes the **setCharacterEncoding(String encoding)** method.

If the **autoRequestEncoding** value is set to `true`, and the client did not specify character encoding in the request header, and the code does not include the **setCharacterEncoding(String encoding)** method, the web container tries to determine the correct character encoding for the request parameters and data.

Use an assembly tool to change the default values for the **autoRequestEncoding** and **autoResponseEncoding** extensions.

The web container performs each step in the following list until a match is found:
- Looks at the character set (charset) in the **Content-Type** header.
- Attempts to map the servers locale to a character set using defined properties.
- Attempts to use the **DEFAULT_CLIENT_ENCODING** system property, if one is set.
- Uses the ISO-8859-1 character encoding as the default.

If the **autoResponseEncoding** value is set to `true`, and the client did not specify character encoding in the request header, and the code does not include the **setCharacterEncoding(String encoding)** method, the web container does the following:
- Attempts to determine the response content type and character encoding from information in the request header.
- Uses the ISO-8859-1 character encoding as the default.

Application life cycle listeners and events:

With application life cycle listeners and events, which are now part of the Servlet API, you can notify interested listeners when servlet contexts and sessions change. For example, you can notify users when attributes change and if sessions or servlet contexts are created or destroyed.

The life cycle listeners give the application developer greater control over interactions with ServletContext and HttpSession objects. Servlet context listeners manage resources at an application level. Session listeners manage resources that are associated with a series of requests from a single client. Listeners are available for life cycle events and for attribute modification events. The listener developer creates a class that implements the javax listener interface, corresponding to the listener functionality that you want.

At application startup time, the container uses introspection to create an instance of your listener class and registers it with the appropriate event generator.

When a servlet context is created, the contextInitialized method of your listener class is invoked, which creates the database connection for the servlets in your application to use if this context is for your application. All servlet context listeners are notified of context initialization before any servlet in the web application is initialized.

When the servlet context is destroyed, your contextDestroyed method is invoked, which releases the database connection, if this context is for your application. You must destroy all servlets before any servlet context listeners are notified of context destruction.

Notifications to session listeners precede notifications to context listeners.

Listener classes for servlet context and session changes

The following methods are defined as part of the javax.servlet.ServletContextListener interface:
- void contextInitialized(ServletContextEvent)

Notification that the web application is ready to process requests. Place code in this method to see if the created context is for your web application and if it is, allocate a database connection and store the connection in the servlet context.

- void contextDestroyed(ServletContextEvent)

  Notification that the servlet context is about to shut down. Place code in this method to see if the created context is for your web application and if it is, close the database connection stored in the servlet context.

The following methods are defined as part of the `javax.servlet.ServletRequestListener` interface:

- public void requestInitialized(ServletRequestEvent re)
  - Notification that the request is about to come into scope

    A request is defined as coming into scope when it is about to enter the first filter in the filter chain that processes the request.
- public void requestDestroyed(ServletRequestEvent re)
  - Notification that the request is about to go out of scope

    A request is defined as going out of scope when it exits the last filter in its filter chain.

The following listener interfaces are defined as part of the javax.servlet package:

- ServletContextListener
- ServletContextAttributeListener

The following filter interface is defined as part of the javax.servlet package:

- FilterChain interface - methods: doFilter()

The following event classes are defined as part of the javax.servlet package:

- ServletContextEvent
- ServletContextAttributeEvent

The following interfaces are defined as part of the javax.servlet.http package:

- HttpSessionListener
- HttpSessionAttributeListener
- HttpSessionActivationListener

The following event class is defined as part of the javax.servlet.http package:

- HttpSessionEvent

Example: Creating a servlet context listener with com.ibm.websphere.DBConnectionListener.java

The following example shows how to create a servlet context listener:

```
package com.ibm.websphere;

import java.io.*;
import javax.servlet.*;

public class DBConnectionListener implements ServletContextListener
{
     // implement the required context init method
    void contextInitialized(ServletContextEvent sce)
    {
    }

     // implement the required context destroy method
    void contextDestroyed(ServletContextEvent sce)
    {
    }
}
```

Developing JSP files

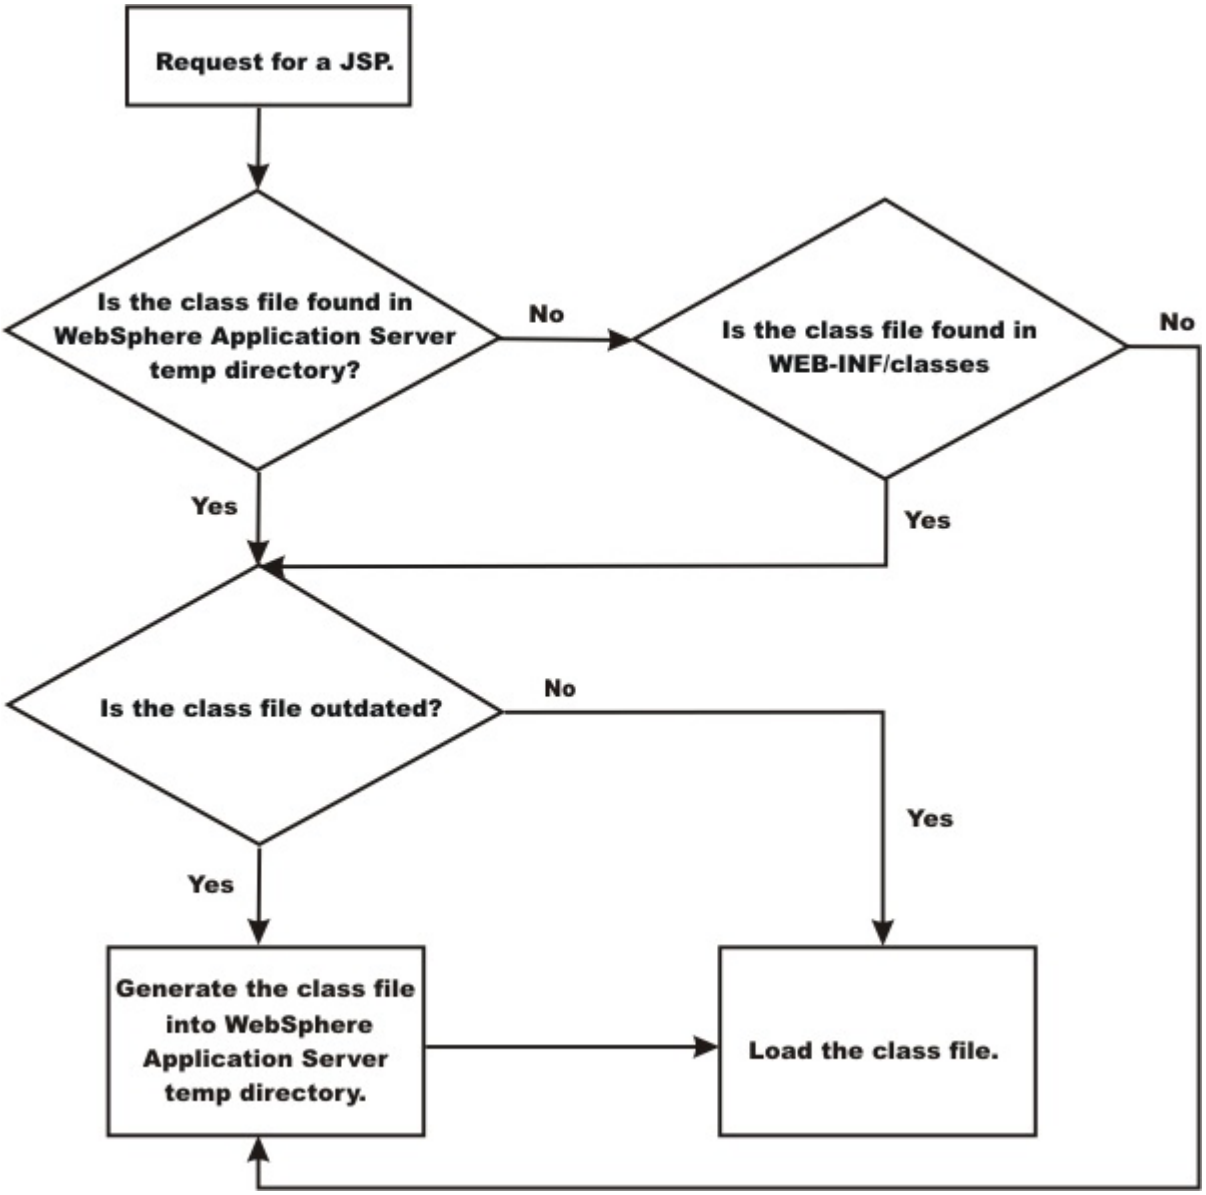
Learn about JSP files.

JSP class file generation

At runtime, the WebSphere Application Server JavaServer Pages (JSP) engine loads JSP class files from either the WebSphere Application Server `temp` directory or a web module's `WEB-INF/classes` directory. The JSP engine first searches for a class file in the `temp` directory and then it searches in the web module's `WEB-INF/classes` directory.

In a default installation, the WebSphere Application Server `temp` directory is typically *profile_root*/`temp`. Figure 1 shows the processing logic of the JSP engine at runtime.

You should not use the **CANCEL appserver_proc_name** command to stop a server. Every time a server is cleanly stopped, these `temp` directories are removed. However, if the server is frequently not stopped cleanly, which happens if you cancel rather than stop the server, these directories are not removed and the HFS used for the temp directory eventually becomes full. You can also prevent this storage problem from occurring if you precompile your JSP files when you install an application or if you use the JspBatchCompiler function to precompile them before they are invoked.



The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables the generation of class files into any directory on the filesystem, outside of the target application. Generating class files into a web module's `WEB-INF/classes` directory enables you to deploy the web module as a self-contained web application archive (WAR) file, or a WAR file inside an enterprise archive (EAR) file. The following table shows the batch compiler's behavior when compiling class files.

Table 113. Batch compiler behavior. Batch compiler behavior when compiling class files

	ear.path or war.path supplied	**enterpriseApp.name supplied**
compileToDir not supplied; *compileToWebInf* not supplied, or is true	The class files are compiled into the web module's `WEB-INF/classes` directory.	The class files are compiled into the web module's `WEB-INF/classes` directory.
compileToDir not supplied; *compileToWebInf* is false	The class files are compiled into the web module's `WEB-INF/classes` directory.	The class files are compiled into the WebSphere Application Server temp directory, usually *profile_root*/`temp`.

Table 113. Batch compiler behavior (continued). Batch compiler behavior when compiling class files

	ear.path or war.path supplied	enterpriseApp.name supplied
compileToDir is supplied; *compileToWebInf* not supplied, or is either true or false	The class files are compiled into the directory indicated by *compileToDir*.	The class files are compiled into the directory indicated by *compileToDir*.

Web container configuration for JavaServer Pages static file access

The web container searches for static files and JavaServer Pages (JSP) files in up to four different locations, depending on application configuration. This search is relevant to finding the appropriate resource to serve an inbound request and for results returned from the following APIs:

```
URL ServletContext.getResource(String path)
Set ServletContext.getResourcePaths(String path)
```

Attention: Static files are only searched when the **fileServing** property is enabled and the application does not include a `/*` servlet mapping. Also, JSP files include files with the following extensions, in addition to any other patterns that are defined in the web.xml file

- .jsp
- .jspx
- .jsw
- .jsv

The four locations, in priority order, are as follows:

Application WAR directory

The web container first searches the application WAR directory for a requested resource. However, you cannot serve resources under the WEB-INF or META-INF directories for inbound requests, although they are accessible using the getResource() and getResourcePaths() methods.

Pre-fragment document roots

The web container searches any application defined pre-fragment document roots second. Define a pre-fragment document root in the `ibm-web-ext.xmi` file, located in the WEB-INF directory for the application. Define a pre-fragment document root for static files or JSP files, as follows:

```
Static files:
<fileServingAttributes xmi:id="<user-provided name>"
 name="preFragmentExtendedDocumentRoot"
 value="<user provided value>"/>
```

```
JSP files:
<jspAttributes xmi:id="<user provided name>" name="preFragmentExtendedDocumentRoot"
 value=<user provided value>"/>
```

The *<user provided name>* is a comma-separated list of directories that can include JAR or ZIP files from which static files or JSP files can be accessed. The list can be fully qualified or relative to the application ear directory. The attributes can be specified with identical values. Further, you can specify the same values by different applications.

Attention: Pre-fragment document roots is a new function in WebSphere Application Server Version 8.5.

META-INF/resources directories of fragments under the WEB-INF/Lib directory in the application WAR file

After searching pre-fragment document roots, the web container searches web fragments. A web

fragment comprises a JAR file in an application WEB-INF/lib directory. The JAR might include static resources in a META-INF/resources directory that are defined within the JAR file. To prevent the web container from searching META-INF/resources directories, set the com.ibm.ws.webcontainer.SkipMetaInfResourcesProcessing web container custom property to `true`. The default value for the custom property is false.

```
com.ibm.ws.webcontainer.SkipMetaInfResourcesProcessing = true
```

Attention: META-INF/resources directories of fragments under the WEB-INF/Lib directory in the application WAR file is a new function in WebSphere Application Server Version 8.5.

Extended document roots

Finally, the web container searches any application defined as extended document roots. Extended document roots were available in previous releases and are defined in the `ibm-web-ext.xmi` file, which is located in the application WEB-INF directory. Define extended document root for static files or JSP files, as follows:

```
Static files:
<fileServingAttributes xmi:id="<user provided name>" name="extendedDocumentRoot"
 value="<user provided value>"/>
```

```
JSP files:
<jspAttributes xmi:id="<user provided name>" name="extendedDocumentRoot"
 value=<user provide value>"/>
```

```
com.ibm.ws.webcontainer.SkipMetaInfResourcesProcessing = true
```

The *<user provided name>* is a comma-separated list of directories that can include JAR or ZIP files from which static files or JSP files can be accessed. The list can be fully qualified, or relative to the application EAR directory. You can specify both attributes with identical values. Also, different applications can specify the same values.

Attention: You might set the com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot custom property to **true** to enable serving static welcome pages from a static file extended document root. The default value for the custom property is **false**.

```
com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot = true
```

When the com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot property is set to **true**, the web container searches in a static file extended document root for a static welcome file to serve for a request comprising a valid partial URL. For example, if a request specifies only the application context, and a welcome file is specified as index.html, the property must be set if index.html is to be served from a static file extended document.

```
com.ibm.ws.webcontainer.enablepartialurltoextendeddocumentroot = true
```

The default value is **false**.

If this property is set to **true**, the web container includes the contents of a static file extended document root when determining whether an inbound request is for a valid partial URL. For example, if a request specifies a URL that ends with `/<application context>/<text>` and `<text>` does not map to a servlet or static file, the web container considers this URL a valid partial URL

only if <text> is a valid directory of the application. As a result if directory <text> exists only in a static file extended document root, this property must be set for the URI to be considered a valid partial URI.

Important: These properties are not required for static file pre-fragment document roots. Also, when determining a valid partial URL, the web container does not consider JSP pre-fragment and extended document roots.

Packages and directories for generated .java and .class files

By default, the `.java` files for all JavaServer Pages (JSP) files are generated with the package statement, `package com.ibm._jsp;`. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The `.java` files are located in the filesystem within a directory structure mirroring the JSP source directory structure.

If the JSP engine configuration parameter **useFullPackageNames** is set to true, the `.java` files are generated with the package statement

```
Package _ibmjsp.<directory structure in which the jsp is located>;
```

The usage of full package names enables the configuration of a JSP as a servlet in the `web.xml` file. Refer to the JSP class loading settings topic for more information. The table later in this section gives examples of packages and directory structures for generated `.java` and `.class` files.

Table 114. Packages and directory structures for generated .java and .class files. Examples of packages and directory structures for generated .java and .class files.

Directory		File name		Location of .java or .class files in file system
JSP file	default	useFullPackageNames=true	default	useFullPackageNames=true
/myJsp.jsp	com.ibm._jsp	_ibmjsp	/	/_ibmjsp
/jspFiles/ jspOne.jsp	com.ibm._jsp	_ibmjsp.jspFiles	/jspFiles	/_ibmjsp/jspFiles
/dir with spaces/jspTwo.jsp	com.ibm._jsp	_ibmjsp.dir_20_with_20_spaces	/dir with spaces	/_ibmjsp/ dir_20_with_20_spaces

Generated .java files:

When the JSP engine's **keepgenerated** configuration parameter is set to true, the `.java` file that is generated for JavaServer Pages (JSP) is retained. The `.java` file contains information that is useful in debugging.

Dependency information

In the `.java` file, immediately following the class declaration, an array of dependent files is defined, if the source JSP has any dependencies. There are three types of files that are tracked as dependencies:

1. Files that are statically included in the JSP
2. Tag files that are used by the JSP, but only tag files that are not in Java Archive (JAR) files
3. TLD files that are used by the JSP, but only TLDs that are not in JAR files

This array is always generated, but the JSP engine uses it, in determining whether a JSP needs to be recompiled, only when the trackDependencies parameter is set to true.

In the example below, three JSP fragments, one TLD and one tag file are dependencies of the JSP jsp1.jsp. There are three parts to each array entry:

1. The path to the dependency, relative to the web module's context root. For example: `/dir1/frag1.jspf`

2. The long value representing the time the file was last modified. For example: 1082407108000
3. The String representation of the long value. For example: Mon Apr 19 16:38:28 EDT 2004

```
public final class _jsp1 extends com.ibm.ws.jsp.runtime.HttpJspBase
  implements com.ibm.ws.jsp.runtime.JspClassInformation {

  private static String[] _jspx_dependants;
  static {
  _jspx_dependants = new String[5];
  _jspx_dependants[0] = "/Banner.jspf^1082407108000^Mon Apr 19 16:38:28 EDT 2004";
  _jspx_dependants[1] = "/Footer.jspf^1077657462000^Tue Feb 24 16:17:42 EST 2004";
  _jspx_dependants[2] = "/dir1/frag1.jspf^1035396680000^Wed Oct 23 14:11:20 EDT 2002";
  _jspx_dependants[3] = "/utility.tld^1080069938000^Tue Mar 23 14:25:38 EST 2004";
  _jspx_dependants[4] = "/WEB-INF/tags/top.tag^1065440490000^Mon Oct 06 07:41:30 EDT 2003";
  }
```

Version, JSP engine options, and WEB.XML information

The generated .java source contains a comment that lists information about the file which is located at the bottom of the generated file. This information includes:

- The date and time the `.java` file was generated
- The version, build number and build date of the WebSphere Application Server on which the `.java` file was generated
- The values of the JSP engine configuration parameters that were in effect when the file was generated
- The values of any `<jsp-config>` elements in the `web.xml` file that pertained to the source JSP file.

```

```

JSP batch compilation

As an IBM enhancement to JavaServer Pages (JSP) support, IBM WebSphere Application Server provides a batch JSP compiler that allows JSP page compilation before application deployment. The batch compiler validates the syntax of JSP pages, translates the JSP pages into Java source files, and compiles the Java source files into Java servlet class files. The batch compiler also validates tag files and generates their Java implementation classes.

Batch compilation of JSP pages in a predeployed application simplifies the deployment process and improves the runtime performance of JSP page by eliminating first-request compilations. The batch compiler also operates on enterprise applications that have been deployed into WebSphere Application Server.

The JSP batch compiler works on web modules that support Servlet 2.2 and later. The batch compiler works on JSP pages written to the JSP 2.1 specification or previous specifications back to JSP 1.0. It recognizes a Servlet 2.5 or later deployment descriptor, `web.xml`, and can use any jsp-config elements that it may contain. In a Servlet 2.3 (JSP 1.2) or Servlet 2.2 (JSP 1.1) deployment descriptor the batch compiler recognizes and uses any taglib elements that the descriptor may contain.

Batch compiling makes the first request for a JSP page much faster because the JSP page is already translated and compiled into a servlet. Batch compiling is also useful as a fast way to resynchronize all of the JSP pages for an application.

The batch compiler supports the generation of class files in both the WebSphere Application Server `temp` directory and a web module's `WEB-INF/classes` directory, depending on the type of batch compiler target. In addition, the batch compiler enables generation of class files into any directory on the filesystem, outside the target application. Generating class files into a web module's `WEB-INF/classes` directory enables the web module to be deployed as a self-contained WAR file, or a WAR inside an EAR.

Also, you can use shared libraries with the JSP batch complier. When you use the JSP batch compiler, you must either add the JAR to the WAR in the `<WEB-INF>/lib` directory, or add the JAR to the JVM class path to use shared libraries.

JSPBatchCompiler command:

The batch compiler validates the syntax of JavaServer Pages, translates the JSP pages into Java source files, and compiles the Java source files into Java Servlet class files. The batch compiler also validates tag files and generates their Java implementation classes. Use this function to batch compile your JSP files and thereby enable faster responses to the initial client requests for the JSP files on your production web server.

The batch compiler can be executed against compressed or expanded enterprise archive (EAR) files and web application archive (WAR) files, as well as enterprise applications and web modules that have been deployed into WebSphere Application Server. When the target is a deployed enterprise application, the server does not need to be running to execute the batch compiler. If the batch compiler is executed while the target sever is running, the server is not aware of an updated class file and does not load that class file unless the enterprise application is restarted. When the target is a compressed EAR file or WAR file, the batch compiler must expand it before executing.

Processing of web modules

The batch compiler operates on one web module at a time. If the target is either an EAR file or an installed enterprise application that contains more than one web module, the batch compiler operates on each web module individually. This is done because JSP pages are configured on a web module basis, through the web module's web.xml deployment descriptor file. Within a web module, the batch compiler processes one directory at a time. It validates and translates each JSP page individually, and then invokes the Java compiler for the entire group of generated Java sources files in that directory. If one JSP page fails during the Java compilation phase, the Java compiler might not create class files for most or all of the JSP pages that successfully compiled in that directory.

JSP file extensions

The batch compiler uses four things to determine what file extensions it should process:

1. Standard JSP file extensions
   - *.jsp
   - *.jspx
   - *.jsw
   - *.jsv
2. The url-pattern property of the jsp-property-group elements in the deployment descriptor file in Servlet 2.4 web modules
3. The `jsp.file.extensions` JSP engine configuration parameter (for pre-Servlet 2.4 web modules)
4. The batch compiler configuration parameter `jsp.file.extensions`

The standard extensions are always used by the batch compiler. If the web module contains a Servlet 2.4 deployment descriptor, the batch compiler also processes any url-patterns found within the jsp-config element. If the batch compiler target contains the JSP engine configuration parameter `jsp.file.extensions`, then those extensions are also processed. If the batch compiler configuration parameter `jsp.file.extensions` is present, the extensions given are also processed and will override the JSP engine configuration parameter `jsp.file.extensions`.

It is a good idea to give JSP 'fragments' an extension that is not processed by the batch compiler. Statically-included fragments that do not stand alone generate translation or compilation errors if processed. The JSP 2.0 Specification suggests that you use the extension `.jspf` for such files.

Batch compiler command

Both a Windows batch file, `JspBatchCompiler.bat` and UNIX shell script `JspBatchCompiler.sh` for running the batch compiler from the command line are found in the `{WAS_ROOT}/bin` directory. An Ant task is also available for executing the batch compiler using Ant. See the topic, Batch Compiler Ant Task for additional information.

The batch compiler target is the only required parameter. The target is one of -ear.path, -war.path or -enterpriseapp.name.

```
JspBatchCompiler -ear.path | -war.path | -enterpriseapp.name <name>
   [-response.file <filename>]
   [-webmodule.name <name>]
   [-filename <jsp name | directory name>
   [-recurse <true | false>]
   [-config.root <path>]
   [-cell.name <name>]
   [-cluster.name <name>]   [-node.name <name>]
   [-server.name <name>]
   [-profileName <name>]
   [-extractToDir <path>]
   [-compileToDir <path>]
```

```
[-compileToWebInf <true | false>]
   [-compileToWebInf <true | false>]
   [-compileAfterFailure <true | false>]
[-translate <true | false>]
[-compile <true | false>]
[-removeTempDir <true | false>]
[-forceCompilation <true | false>]
[-useFullPackageNames <true | false>]
[-trackDependencies <true | false>]
[-createDebugClassfiles <true | false>]
[-keepgenerated <true | false>]
[-keepGeneratedclassfiles <true | false>]
[-usePageTagPool <true | false>]
[-useThreadTagPool <true | false>]
[-classloader.parentFirst <true | false>]
[-classloader.singleWarClassloader <true | false>]
[-additional.classpath <classpath to additional JAR files and classes>]

[-verbose <true | false>]
[-deprecation <true | false>]
[-javaEncoding <encoding>
[-jdkSourceLevel <13 | 14 | 15 | 16 | 17>]
[-compilerOptions <space-separated list of java compiler options>]
[-useJikes <true | false>]
[-jsp.file.extensions <file extensions to process>]
[-log.level <SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF>]
*** See batchcompiler.properties.default in WAS_ROOT/bin for more information. ***
*** See JspCBuild.xml in WAS_ROOT/bin for information about the public WebSphere Ant task JspC. ***
```

The batch compiler is aware of three groups of configuration parameters:

1. JSP engine configuration parameters for a web module.

   Refer to the JSP engine configuration parameters topic.
2. Batch compiler response file configuration parameters.

   These are the parameters that are found in a batch compiler response file. See -response.file, below.
3. Batch compiler command line configuration parameters.

   These are the parameters entered on the command line when running the batch compiler.

The batch compiler looks at all three groups of configuration parameters in order to determine which value for a parameter is used when compiling JSP pages. When resolving the value for a given parameter, the precedence is:

1. If the parameter is found on the command line, its value is used.
2. If the parameter is not found on the command line, the batch compiler looks for the parameter in a response file named on the command line.
3. If no response file is named, or if the parameter is not found therein, the batch compiler looks for the parameter in the web module's JSP engine configuration parameters.

If a configuration parameter is not found among these three groups, then a default value is used. The default values for the configuration parameters are given below along with the description of the parameters.

With one exception, these parameters are not case sensitive; -profileName is case sensitive. If the values specified for these arguments are comprised of two or more words separated by spaces, you must add quotation marks around the values.

The batch compiler does not create, or set the values of, equivalent JSP engine parameters. This means that if a JSP page in a deployed Web module is modified and is recompiled by the JSP engine at run time, the JSP engine's configuration parameters will determine the engine's behavior. For example, if you use the batch compiler to compile a web module and you use the -useFullPackageNames true option, the JSP

files will be compiled to support that option. But the JSP engine parameter useFullPackageNames must also be set to true in order for the JSP runtime to be able to load the compiled JSP pages. If JSP pages are modified in a deployed web module, then the engine's parameters should be set to the same values used in batch compilation.

To use the JSP batch compiler, enter one of the following commands on a single line at an operating system command prompt.:

- *ear.path* | *war.path* | *enterpriseapp.name*

  Represents the full path to a single compressed or expanded enterprise application archive (EAR) file or web application archive (WAR) file, or the name of the deployed enterprise application that you want to compile. For example:
  - JspBatchCompiler -ear.path /myhfs/myprojects/sampleApp.ear
  - JspBatchCompiler -war.path c:\myWars\examples.war
  - JspBatchCompiler -enterpriseapp.name myEnterpriseApp -webmodule.name my.war -filename aDir/main.jsp
- `response.file`

  Specifies the path to a file that contains configuration parameters used by the batch compiler. The `response.file` is used only if it is given on the command line; it is ignored if it is present in a response file.

  In a default installation, the template response file, batchcompiler.properties.default, is found in the `{WAS_ROOT}/bin` directory. Copy this template to create your own response files containing defaults for the parameters in which you are interested. All the required and optional parameters (except response.file) can be configured in a response file. For example: JspBatchCompiler -response.file c:\myproject\batchc.props

  Default : null
- *webmodule.name*

  Represents the name of the specific web module that you want to batch compile. If this argument is not set, all web modules in the enterprise application are compiled. This parameter is used only when *ear.path* or *enterpriseapp.name* is given. This parameter is useful when JSP pages in a specific web module within a deployed enterprise application need to be regenerated, because all shared library dependencies are picked up.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -webmodule.name myWebModule.war

  Default: All web modules in an EAR file or enterprise application are compiled if this parameter is not given.
- *filename*

  Represents the name of a single JSP file that you want to compile. If this argument is not set, all files in the web module are compiled. Alternatively, if *filename* is set to the name of a directory, only the JSP files in that directory and that directory's child directories are complied. The name is relative to the context root of the web module.

  Example 1: If you want to compile the file, *myTest.jsp*, and it is found in */subdir/myJSPs*, you would enter *-filename /subdir/myJSPs/myTest.jsp*.

  Example 2: If you want to compile all JSP files in */subdir/myJSPs* and its child directories, you would enter *-filename subdir/myJSPs*.

  Default: All JSP files in the web module are compiled. Entering *-filename /* is equivalent to the default.
- recurse

  Determines whether subdirectories beneath the target directory are processed. This parameter is used only when the *filename* parameter is given. Set value to `false` to process only the directory named *filename* parameter; and not its subdirectories.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -filename /subdir1 -recurse false.

  Default: true; All directories beneath the target directory are processed.
- *config.root*

Specifies the location of the WebSpehere Application Server configuration directory. This parameter is used only when *enterpriseapp.name* is given.

Default: *{WAS_ROOT}/profiles/profilename/config*

- *cell.name*

  Specifies the name of the cell in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_CELL.

- *cluster.name*

  Specifies the name of the cluster in which the application is deployed. This parameter provides the batch compiler with access to cluster scoped shared libraries, and is used only when *enterpriseapp.name* is given.

  Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_CLUSTER.

- *node.name*

  Specifies the name of the node in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: The default is obtained from the profile script that is used. The symbolic name of this variable is WAS_NODE.

- *server.name*

  Represents the name of the server in which the application is deployed. This parameter is used only when *enterpriseapp.name* is given.

  Default: server1

- *profileName*

  Specifies the name of the profile you want to use. This parameter is used only when the *enterpriseapp.name* or *-ear*. path is given.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -profileName AppServer-3

  Default: The default profile is used. This is obtained from the file `setupCmdLine` script in the `install_root/bin` directory. The symbolic name is DEFAULT_PROFILE_SCRIPT.

- *extractToDir*

  Specifies the directory into which predeployed enterprise archive (EAR) files and web application archive (WAR) files will be extracted before the batch compiler operates on them. This parameter is ignored when *enterpriseapp.name* is given. The extractToDir parameter is used as described in the table below.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -extractToDir c:\myTempDir.

  Use-case: You must extract a compressed archive before it is batch compiled. You can also extract an expanded archive to a new directory as well. In both cases, extraction leaves the original archive untouched, which may be useful while development is underway.

Table 115. extractToDir. Default values

	Expanded archive	**Compressed archive**
extractToDir supplied	The batch compiler extracts the archive to extractToDir before operating on it. If a file or directory of the same name as the archive already exists in the extractToDir, the batch compiler removes the archive completely before extracting that archive. If the batch compiler exits with no errors, it compresses the archive in place in the extractToDir, even if the original EAR file or WAR file was expanded. If errors are encountered during compilation, the EAR file or WAR file is left in the expanded state even if the original EAR file or WAR file was compressed.	

Table 115. extractToDir (continued). Default values

	Expanded archive	**Compressed archive**
extractToDir not supplied	The batch compiler operates on the EAR file or WAR file in place (does not extract it to another directory) and the archive remains expanded after the batch compiler finishes.	The batch compiler extracts the archive to the directory returned by the JVM property “java.io.tmpdir”. The rest of the behavior described above, when extractToDir is supplied, is the same in this case.

The default is *server1*.

- *compileToDir*

  Specifies the directory into which JSP pages are translated into Java source files and compiled into class files. This directory can be anywhere on the filesystem, but the batch compiler's default behavior is usually adequate. The batch compiler's behavior when compiling class files is described in the table below

  Example:: JspBatchCompiler -enterpriseApp.name sampleApp -compileToDir c:\myTargetDir

  Use-case: This parameter enables you to generate the Java and class files into a directory outside of the target, which may be useful if you want to compare the newly generated files with their previous versions which remain untouched within the target.

Table 116. compileToDir. Default values

	ear.path or war.path supplied	**enterpriseApp.name supplied**
compileToDir not supplied; compileToWebInf not supplied, or is true	The class files are compiled into the web module's `WEB-INF/classes` directory	The class files are compiled into the web module's `WEB-INF/classes` directory.
compileToDir not supplied; compileToWebInf is false	The class files are compiled into the web module's `WEB-INF/classes` directory.	The class files are compiled into the WebSphere Application Server temp directory (usually *{WAS_ROOT}/temp*).
compileToDir is supplied; compileToWebInf not supplied, or is either true or false	The class files are compiled into the directory indicated by compileToDir.	The class files are compiled into the directory indicated by compileToDir.

- *compileToWebInf*

  Specifies whether the target directory for the compiled JSP class files should be the web module's `WEB-INF/classes` directory. This parameter is used only when *enterpriseApp.name* is given, and it is overridden by *compileToDir* if *compileToDir* is given.

  The batch compiler's default behavior is to compile to the web module's `WEB-INF/classes` directory. The batch compiler's behavior when compiling class files is described in the table above.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -compileToWebInf false.

  Use-case: Set this parameter to false when enterpriseApp.name is supplied and you want the class files to be compiled to the WebSphere Application Server temp directory instead of the web module's `WEB-INF/classes` directory. Recommendation: if this parameter is set to false, set forceCompilation to true if there are any JSP class files in the `WEB-INF/classes` directory.

  Default: true; see the table above.

- *compileAfterFailure*

  Specifies whether the JDK JSP batch compiler continues to compile the other JavaServer Pages (JSP) files in the current directory if one or more of the JavaServer Pages (JSP) files in that directory cannot be complied. Typically when one of the files cannot be compiled, the JSP batch complier skips all of the remaining JSPs in that directory, and starts to compile the files in the next directory.

  If you set this parameter to true, you must also specify the useJDKCompiler parameter and set that parameter to true.

Example: JspBatchCompiler -enterpriseApp.name sampleApp -useJDKCompiler true –compileAfterFailure false.

Use-case: Set this parameter to true if you want the JSP batch compiler compile the other JavaServer Pages (JSP) files in the current directory even if one or more of the JSP files in that directory cannot be complied.

Default: false

- *forceCompilation*

  Specifies whether the batch compiler is forced to recompile all JSP resources regardless or whether the JSP page is outdated.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -forceCompilation true.

  Use-case: Especially useful when creating an archive for deployment, to make sure all JSP classes are up to date.

  Default: false

- *useFullPackageNames*

  Specifies whether the batch compiler generates full package names for JSP classes. The default is to generate all JSP classes in the same package. The JSP engine's class loader knows how to load JSP classes when they are all in the same package. The default has the benefit of generating smaller file-system paths. Full package names have the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without use of the `jsp-file` attribute, resulting in a single class loader (the web application's class loader) being used to load all such JSP classes. Similarly, when the JSP engine's configuration attributes `useFullPackageNames` and `disableJspRuntimeCompilation` are both true, a single class loader is used to load all JSP classes, even if the JSP pages are not configured as servlets in the `web.xml` file.

  When `useFullPackageNames` is set to true, the batch compiler generates a file called `generated_web.xml` in the web module's `WEB-INF` directory. This file contains servlet configuration information for each JSP page that is successfully translated and compiled. The information can optionally be copied into the web module's `web.xml` file so that the JSP pages are loaded as servlets by the web container. Note that if a JSP page is configured as a servlet in this way, no reloading of the JSP page is done at run time if the JSP page is modified. This is because the JSP page is treated as a regular servlet and requests for it do not pass through the JSP engine.

  Example: JspBatchCompiler –enterpriseApp.name sampleApp –useFullPackageNames true

  Use-case: Enables JSP classes to be loaded by a single class loader.

  Default: false

- *removeTempDir*

  Specifies whether the web module's temp directory is removed. The batch compiler by default generates JSP class files into a web module's `WEB-INF/classes` directory. JSP class files are generated into the `temp` directory at run time if a JSP page is modified and JSP reloading is enabled. By batch compiling all the JSP pages in a web module and also removing the `temp` directory, disk resources are preserved. You can only use the removeTempDir parameter when -enterpriseApp.name is given.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -removeTempDir true.

  Use-case: Free up disk space by clearing out a web application's `temp` directory.

  Default: false

- *translate*

  Specifies whether JSP pages are translated and compiled. Set translate to false if you do not want JSP pages to be translated and compiled. You must use this option in conjunction with `-removeTempDir` to tell the batch compiler to remove only the `temp` directory and to do no further processing.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -translate false -removeTempDir true.

  Use-case: Free up disk space by clearing out a web application's `temp` directory, without invoking JSP processing.

  Default: true

- *compile*

Specifies whether JSP pages go through the Java compilation phase. Set compile to `false` if you do not want JSP pages to go through the Java compilation phase.

Example: JspBatchCompiler -enterpriseApp.name sampleApp -compile false

Use-case: If you only want JSP pages to be syntax-checked, set -compile to false. You can set -keepgenerated to true if you want to see the `.java` files that are generated during the translation phase.

Default: true

- *trackDependencies*

  Specifies whether the batch compiler recompiles a JSP page when any of its dependencies have changed, even if the JSP page itself has not changed. Tracking dependencies incurs a significant runtime performance penalty because the JSP Engine checks the filesystem on every request to a JSP page to see if any of its dependencies have changed. The dependencies tracked by WebSphere Application Server are :
  1. Files statically included in the JSP page
  2. Tag files used by the JSP page (excluding tag files that are in JAR files)
  3. TLD files used by the JSP page (excluding TLD files that are in JAR files)

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -trackDependencies true.

  Use-case: Useful in a development environment.

  Default: false
- *createDebugClassfiles*

  Specifies whether the batch compiler generates class files that contain SMAP information, as per JSR 45, Debugging support for Other Languages.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -createDebugClassfiles true

  Use-case: Use this parameter when you want to be able to debug JSP pages in your JSR 45-compliant IDE.

  Default: false
- *keepgenerated*

  Specifies whether the batch compiler saves or erases the generated Java source files created during the translation phase.

  If set to `true`, WebSphere Application Server saves the generated `.java` files used for compilation on your server. By default, this argument is set to `false` and the `.java` files are erased after the class files have compiled.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -keepgenerated true

  Use-case: Use this parameter when you want to review the Java code generated by the batch compiler.

  Default: false
- *keepGeneratedclassfiles*

  Specifies whether the batch compiler saves or erases the class files generated during the compilation of Java source files.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -keepGeneratedclassfiles false -keepgenerated false

  Use-case: Set this parameter to false if you only want to see if there are any translation or compilation errors in your JSP pages. If paired with -keepgenerated false, this parameter results in all generated files being removed before the batch compiler completes.

  Default: true
- *usePageTagPool*

  Enables or disables the reuse of custom tag handlers on an individual JSP page basis.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -usePageTagPool true

  Use-case: Use this parameter to enable JSP-page-based reuse of tag handlers.

  Default: false
- *useThreadTagPool*

Enables or disables the reuse of custom tag handlers on a per request thread basis per web module.

Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -useThreadTagPool true

Use-case: Use this parameter to enable web module-based reuse of tag handlers.

Default: false

- *classloader.parentFirst*

  Specifies the search order for loading classes by instructing the batch compiler to search the parent class loader prior to application class loader. This parameter is only used when *ear.path* or *enterpriseApp.name* is given.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -classloader.parentFirst false

  Use-case: Set this parameter to false when your web module contains a JAR file that is also found in the server lib directory, and you want your web module's JAR file to be picked up first.

  Default: true

- *classloader.singleWarClassloader*

  Specifies whether to use one class loader per enterprise archive (EAR) file or one class loader per web application archive (WAR) file. Used only when *ear.path* or *enterpriseApp.name* is given.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -classloader.singleWarClassloader true

  Use-case: Set this parameter to true when a Web module depends on JAR files and classes in another web module in the same enterprise application.

  Default: false; One class loader is created per WAR file with no visibility of classes in other web modules.

- *additional.classpath*

  Specifies additional class path entries to be used when parsing and compiling JSP pages. This parameter is used only when *war.path* is given. When *war.path* is the target, WebSphere Shared Libraries are not picked up by the batch compiler. Therefore, if your WAR file relies on, for example, a JAR file that is configured in WebSphere Application Server as a shared library, then use this option to point to that JAR file. In addition, if you give *war.path* and also use the *-extractToDir* parameter, then any JAR files that are in the WAR file's manifest class-path is not added to the class path (since the WAR file has now been extracted by itself outside the EAR file in which it resides). Use *-additional.classpath* in this case to point to the necessary JAR files. Add the full path to needed resources, separated by your system-dependent path separator.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -additional.classpath c:\myJars\someJar.jar;c:\myClasses

  Use-case: Use this parameter to add to the class path JAR files and classes outside of your WAR file. At run time, these same JAR files and classes have to be made available through the standard WebSphere Application Server configuration mechanisms.

  Default: null

- *verbose*

  Specifies whether the batch compiler should generate verbose output while compiling the generated sources.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -verbose true

  Use-case: Set this parameter to true when you want to see Java compiler class loading and other messages.

  Default: false

- *deprecation*

  Indicates the compiler should generate deprecation warnings while compiling the generated sources.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -deprecation true

  Use-case: Set this parameter to true when you want to see Java compiler deprecation messages.

  Default: false

- *javaEncoding*

  Specifies the encoding that will be used when the .java file is generated, and when it is compiled by the Java compiler. When -javaEncoding is set, that encoding is passed to the java compiler via the -encoding argument. Note that encoding is not supported by Jikes.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -javaEncoding Shift-JIS

  Use-case: Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible.

  Default value: UTF-8.

- *jdkSourceLevel*

  This JSP engine parameter was introduced in WebSphere Application Server version 6.1 to support JDK 5. Use this parameter instead of the compileWithAssert parameter, although compile WithAssert still works in version 6.1.

  The default value for this parameter is 16. This parameter requires regeneration of Java source. The following are jdkSourceLevel paramater values:

  – 13 - This value will disable all new language features of JDK 1.4, JDK 5.0, JDK 6.0, and JDK 7.0.
  – 14 - This value will enable the use of the assertion facility and will disable all new language features of JDK 5.0, JDK 6.0, and JDK 7.0.
  – 15 - This value will enable the use of the assertion facility and will disable all new language features of JDK 6.0 and JDK 7.0.
  – 16 - This value will enable the use of the assertion facility and will disable all new language features of JDK 7.0.
  – 17 - This value will enable the use of the new features of JDK 7.0.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -jdkSourceLevel 14

  Use-case: Set this parameter when you want to enable or disable the language features of JDK 1.4 , JDK 5.0, JDK 6.0, and JDK 7.0

  Default value: 16

- *compilerOptions*

  Specifies a list of strings to be passed on the Java compiler command. This is a space-separated list of the form “arg1 arg2 argn”.

  Example: JspBatchCompiler -war.path c:\myproject\examples.war -compilerOptions “-bootclasspath <path>”

  Use-case: Use this parameter if you need Java compiler arguments other than verbose, deprecation and Assert facility support.

  Default: null

- *useJikes*

  Specifies whether Jikes should be used for compiling Java sources. NOTE: Jikes is not shipped with WebSphere Application Server.

  Example: JspBatchCompiler -ear.path c:\myproject\sampleApp.ear -useJikes true

  Use-case: Set this parameter to true in order for the batch compiler to use Jikes as the Java compiler.

  Default value: false

- *jsp.file.extensions*

  Specifies the file extensions to be processed by the batch compiler. This is a semicolon- or colon-separated list of the form “*.ext1;*.ext2:*.extn”. Note that this parameter is not necessary for Servlet 2.4 web applications because the url-pattern property of the jsp-property-group elements in the deployment descriptor can be used to identify extensions that should be treated as JSP pages.

  Example: JspBatchCompiler -enterpriseApp.name sampleApp -jsp.file.extensions *jspz;*.jspt

  Use-case: Use this parameter to add additional extensions to the be processed by the batch compiler.

  Default: null. See section, “JSP file extensions”, in this topic for additional information.

- *log.level*

Specifies the level of logging that is directed to the console during batch compilation. Values are SEVERE | WARNING | INFO | CONFIG | FINE | FINER | FINEST | OFF

Example: JspBatchCompiler -enterpriseApp.name sampleApp -log.level FINEST

Use-case: Set this parameter higher or lower to control logging output. FINEST generates the most output useful for debugging.

Default: CONFIG

Batch compiler ant task:

The ant task **JspC** exposes all the batch compiler configuration options. It runs the batch compiler under the covers. It is backward compatible with the WebSphere Application Server 5.x version of the **JspC** ant task. The following table lists all of the ant task attributes and their batch compiler equivalents.

Table 117. Ant task attributes and their batch compiler equivalents. JspC attributes and the equivalent batch compiler parameters.

JspC attribute	Equivalent batch compiler parameter
earPath	-ear.path
warPath	-war.path
src Same as warPath, for backward compatiblity	-war.path
enterpriseAppName	-enterpriseapp.name
responseFile	-response.file
webmoduleName	-webmodule.name
fileName	-filename -config.root
configRoot	-config.root
cellName	-cell.name
nodeName	-node.name
serverName	-server.name
profileName	-profileName
extractToDir	-extractToDir
compileToDir same as compileToDir, for backward compatibility	-compileToDir -compileToDir
compileToWebInf	-compileToWebInf
compilerOptions	-compilerOptions
recurse	-recurse
removeTempDir	-removeTempDir
translate	-translate
compile	-compile
forceCompilation	-forceCompilation
useFullPackageNames	-useFullPackageNames
trackDependencies	-trackDependencies
createDebugClassfiles	-createDebugClassfiles
keepgenerated	-keepgenerated
keepGeneratedclassfiles	-keepGeneratedclassfiles
usePageTagPool	-usePageTagPool
useThreadTagPool	-useThreadTagPool
classloaderParentFirst	-classloader.parentFirst
classloaderSingleWarClassloader	-classloader.singleWarClassloader
additionalClasspath	-additional.classpath
classpath same as additionalClasspath, for backward compatibility	-additional.classpath
verbose	-verbose

Table 117. Ant task attributes and their batch compiler equivalents (continued). JspC attributes and the equivalent batch compiler parameters.

JspC attribute	Equivalent batch compiler parameter
deprecation	-deprecation
javaEncoding	-javaEncoding
compileWithAssert	-compileWithAssert
useJikes	-useJikes
jspFileExtensions	-jsp.file.extensions
logLevel	-log.level
wasHome	none
Classpathref	none
jdkSourceLevel	-jdkSourceLevel

Below is an example of a build script with multiple targets, each with different attributes. The following commands are used to launch the script:

On Windows:

```
ws_ant -Dwas.home=%WAS_HOME% -Dear.path=%EAR_PATH% -Dextract.dir=%EXTRACT_DIR%
ws_ant jspc2 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME%
ws_ant jspc3 -Dwas.home=%WAS_HOME% -Dapp.name=%APP_NAME% -Dwebmodule.name=%MOD_NAME% -Ddir.name=%DIR_NAME%
```

On UNIX or i5/OS:

```
ws_ant -Dwas.home=$WAS_HOME -Dear.path=$EAR_PATH -Dextract.dir=$EXTRACT_DIR
ws_ant jspc2 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME
ws_ant jspc3 -Dwas.home=$WAS_HOME -Dapp.name=$APP_NAME -Dwebmodule.name=$MOD_NAME -Ddir.name=$DIR_NAME
```

Example build.xml file using the JspC task

```
<project name="JSP Precompile" default="jspc1" basedir=".">
 <taskdef name="wsjspc" classname="com.ibm.websphere.ant.tasks.JspC"/>
 <target name="jspc1" description="example using  a path to an EAR, and extracting the EAR to a directory">
  <wsjspc wasHome="${was.home}"
            earpath="${ear.path}"
            forcecompilation="true"
            extractToDir="${extract.dir}"
            useThreadTagPool="true"
            keepgenerated="true"

  />
 </target>
 <target name="jspc2" description="example using an enterprise app and webmodule">
  <wsjspc wasHome="${was.home}"
            enterpriseAppName="${app.name}"
            webmoduleName="${webmodule.name}"
            removeTempDir="true"
            forcecompilation="true"
            keepgenerated="true"

  />
 </target>
 <target name="jspc3" description="example using an enterprise app, webmodule and specific directory">
  <wsjspc wasHome="${was.home}"
            enterpriseAppName="${app.name}"
            webmoduleName="${webmodule.name}"
            fileName="${dir.name}"
            recurse="false"
            forcecompilation="true"
            keepgenerated="true"

  />
 </target>
</project>
```

Pre-touch tool for compiling and loading JSP files:

When enabled, the pre-touch mechanism causes all JavaServer Pages (JSP) files to be compiled within the web module for which they are configured. You can also configure some or all JSP files to be class loaded and JIT-compiled.

To enable the pre-touch mechanism, use Rational Application Developer to specify the following JSP attributes, which are Assembly Property Extensions for your web module:

- **prepareJSPs (Required)**

  When this attribute is present, all JSP files are compiled at application server startup. This activity runs in a separate thread, allowing the application server to finish other startup actions in parallel. The numeric attribute value represents the minimum size in kilobytes that a JSP file must be in order to also be class loaded and JIT-compiled. The default is 0, which causes all JSP files to be class loaded and JIT-compiled.

  Note: JSP file compilation is different from JIT compilation. JSP compilation generates bytecodes, whereas JIT translates the bytecodes into machine code at run time.

- **prepareJSPAttribute (Optional)**

  The pre-touch mechanism compiles and JIT-compiles JSP files by directly invoking the JSP service method, thus making the JSP file susceptible to incurring exceptions because it is called out of context. Such exceptions are avoided by immediately checking the value of this attribute, causing a quick exit from the service method when the JSP was prepared by this tool. This attribute value is added as a request parameter and is composed of alphanumeric characters that your JSP files do not expect to use during normal initiation.

- **prepareJSPThreadCount (Optional)**

  Set this numeric attribute to the number of threads that you would like this mechanism to start up to compile your JSP files. Since a thread makes use of just one processor, multi-processor systems may better utilize this pre-touch mechanism by specifying a value greater than 1. The default setting for this attribute is 1, representing the number of threads that are created to perform pre-touch processing for this web module.

- **prepareJSPClassload (Optional)**

  Set this attribute to either a whole number or the word *changed*. By entering *changed*, only those JSP filess that have been updated or not previously touched, for example, those JSP files that need to be converted from a `.jsp` file to a `.java` file, are class loaded. By entering a numerical value, for example, 1000, the pre-touch tool starts class loading at the 1000th JSP that it processes and all subsequent JSP files. This is convenient in the event that the application server is stopped when starting the pre-touch tool. You can then check the server logs to see how many JSP files have been processed and update the prepareJSPClassload value accordingly to avoid duplicating work. If a JSP file is not class loaded, it cannot be JIT compiled. As a result, if a JSP file does not satisfy the requirements of the prepareJSPClassload attribute, but satisfies the requirements of the prepareJSPs attribute, the JSP file is compiled if it has been updated, but is not class loaded or JIT compiled.

Batch compiler class path:

The batch compiler builds its class path as shown in the table later in this topic. When the batch compiler target is a web application archive (WAR) file and `war.path` is supplied, the configuration `additional.classpath` parameter is used to give extra class path information.

Table 118. Batch compiler. Batch compiler target.

Location added to class path	enterpriseapp.name	ear.path	war.path
WebSphere Application Server JAR files and classes	yes	yes	yes

Table 118. Batch compiler (continued). Batch compiler target.

Location added to class path	enterpriseapp.name	ear.path	war.path
JAR files listed in manifest class path for a web module	yes	yes	yes, when the target WAR is inside an EAR and –extractToDir is not used; otherwise, no.
Shared libraries	yes	no	no
Web module JAR files and classes	yes	yes	yes
additional.classpath parameter to batch compiler	no	no	yes

Global tag libraries (deprecated)

JavaServer Pages (JSP) tag libraries contain classes for common tasks such as processing forms and accessing databases from JSP files.

Tag libraries encapsulate, as simple tags, core functionality common to many web applications. The Java Standard Tag Library (JSTL) supports common programming tasks such as iteration and conditional processing, and provides tags for:

- manipulating XML documents
- supporting internationalization
- using Structured Query Language (SQL)

Tag libraries also introduce the concept of an expression language to simplify page development, and include a version of the JSP expression language.

A tag library has two parts - a Tag Library Descriptor (TLD) file and a Java archive (JAR) file.

tsx:dbconnect tag JavaServer Pages syntax (deprecated):

Use the <tsx:dbconnect> tag to specify information needed to make a connection to a database through Java DataBase Connectivity (JDBC) or Open Database Connectivity (ODBC) technology.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The <tsx:dbconnect> syntax does not establish the connection. Use the <tsx:dbquery> and <tsx:dbmodify> syntax instead to reference a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file to establish the connection.

When the JSP file compiles into a servlet, the Java processor adds the Java coding for the <tsx:dbconnect> syntax to the servlet service() method, which means a new database connection is created for each request for the JSP file.

This section describes the syntax of the <tsx:dbconnect> tag.

```
<tsx:dbconnect id="connection_id"
    userid="db_user" passwd="user_password"
    url="jdbc:subprotocol:database"
    driver="database_driver_name"
    jndiname="JNDI_context/logical_name">
</tsx:dbconnect>
```

where:

- **id**

Represents a required identifier. The scope is the JSP file. This identifier is referenced by the connection attribute of a <tsx:dbquery> tag.

- **userid**

  Represents an optional attribute that specifies a valid user ID for the database that you want to access. Specify this attribute to add the attribute and its value to the request object.

  Although the userid attribute is optional, you must provide the user ID. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this information in the JSP file.

- **passwd**

  Represents an optional attribute that specifies the user password for the userid attribute. (This attribute is not optional if the userid attribute is specified.) If you specify this attribute, the attribute and its value are added to the request object.

  Although the passwd attribute is optional, you must provide the password. See <tsx:userid> and <tsx:passwd> for an alternative to hard coding this attribute in the JSP file.

- **url** and **driver**

  Respresents a required attribute if you want to establish a database connection. You must provide the URL and driver.

  The application server supports connection to JDBC databases and ODBC databases.

  – For a JDBC database, the URL consists of the following colon-separated elements: jdbc, the subprotocol name, and the name of the database to access. An example for a connection to the Sample database included with IBM DB2 is:

    ```
    url="jdbc:db2:sample"
    driver="com.ibm.db2.jdbc.app.DB2Driver"
    ```

  – For an ODBC database, use the Sun JDBC-to-ODBC bridge driver included in their Java2 Software Developers Kit (SDK) or another vendor's ODBC driver.

    The url attribute specifies the location of the database. The driver attribute specifies the name of the driver to use in establishing the database connection.

    If the database is an ODBC database, you can use an ODBC driver or the Sun JDBC-to-ODBC bridge. If you want to use an ODBC driver, refer to the driver documentation for instructions on specifying the database location with the url attribute and the driver name.

    If you use the bridge, the url syntax is `jdbc:odbc:`*`database`*. An example follows:

    ```
    url="jdbc:odbc:autos"
    driver="sun.jdbc.odbc.JdbcOdbcDriver"
    ```

    Note: To enable the application server to access the ODBC database, use the ODBC Data Source Administrator to add the ODBC data source to the System DSN configuration. To access the ODBC Administrator, click the ODBC icon on the Windows NT Control Panel.

- **jndiname**

  Represents an optional attribute that identifies a valid context in the application server Java Naming and Directory Interface (JNDI) naming context and the logical name of the data source in that context. The web administrator configures the context using an administrative client such as the WebSphere Administrative Console.

  If you specify the jndiname attribute, the JSP processor ignores the driver and url attributes on the <tsx:dbconnect> tag.

An empty element (such as <url></url>) is valid.

dbquery tag JavaServer Pages syntax (deprecated):

Use the <tsx:dbquery> tag to establish a connection to a database, submit database queries, and return the results set.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The <tsx:dbquery> tag does the following:
1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information the tag provides to determine the database URL and driver. You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are provided in the <tsx:dbconnect> tag.
2. Establishes a new connection
3. Retrieves and caches data in the results object.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbquery> tag.

```
<%-- SELECT commands and (optional) JSP syntax can be placed within the tsx:dbquery. --%>
<%-- Any other syntax, including HTML comments, are not valid. --%>
<tsx:dbquery id="query_id" connection="connection_id" limit="value" >
</tsx:dbquery>
```

where:
- **id**

  Represents the identifier of this query. The scope is the JSP file. Use `id` to reference the query. For example, from the <tsx:getProperty> tag, use `id` to display the query results.

  The `id` is a tsx reference to the bean and can be used to retrieve the bean from the page contect. For example, if id is named mySingleDBBean, instead of using:
  – if (mySingleDBBean.getValue("UISEAM",0).startsWith("N"))

  use:
  – com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults bean = (com.ibm.ws.webcontainer.jsp.tsx.db.QueryResults)pageContext. findAttribute("mySingleDBBean"); if (bean.getValue("UISEAM",0).startsWith("N")). . .

  The bean properties are dynamic and the property names are the names of the columns in the results set. If you want different column names, use the SQL keyword for specifying an alias on the SELECT command. In the following example, the database table contains columns named FNAME and LNAME, but the SELECT statement uses the `AS` keyword to map those column names to FirstName and LastName in the results set:

  ```
  Select FNAME, LNAME AS FirstName, LastName from Employee where FNAME='Jim'
  ```
- **connection**

  Represents the identifier of a <tsx:dbconnect> tag in this JSP file. The <tsx:dbconnect> tag provides the database URL, driver name, and optionally, the user ID and password for the connection.
- **limit**

  Represents an optional attribute that constrains the maximum number of records returned by a query. If this attribute is not specified, no limit is used. In such a case, the effective limit is determined by the number of records and the system caching capability.
- SELECT command and JSP syntax

  Represents the only valid SQL command, SELECT. The <tsx:dbquery> tag must return a results set. Refer to your database documentation for information about the SELECT command. See other articles in this section for a description of JSP syntax for variable data and inline Java code.

dbmodify tag JavaServer Pages syntax (deprecated):

The <tsx:dbmodify> tag establishes a connection to a database and then adds records to a database table.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The <tsx:dbmodify> tag does the following:

1. References a <tsx:dbconnect> tag in the same JavaServer Pages (JSP) file and uses the information provided by that tag to determine the database URL and driver.

   Note: You can also obtain the user ID and password from the <tsx:dbconnect> tag if those values are provided in the <tsx:dbconnect> tag.
2. Establishes a new connection.
3. Updates a table in the database.
4. Closes the connection and releases the connection resource.

This section describes the syntax of the <tsx:dbmodify> tag.

```
<%-- Any valid database update commands can be placed within the DBMODIFY tag. -->
<%-- Any other syntax, including HTML comments, are not valid. -->
<tsx:dbmodify connection="connection_id">
</tsx:dbmodify>
```

where:

- connection

  Represents the identifier of a <tsx:dbconnect> tag in this JSP file. The <tsx:dbconnect> tag provides the database URL, driver name, and (optionally) the user ID and password for the connection.
- Database commands

  Represents valid database commands. Refer to your database documentation for details

In the following example, a new employee record is added to a database. The values of the fields are based on user input from this JavaServer Pages (JSP) file and referenced in the database commands using the <tsx:getProperty> tag.

```
<tsx:dbmodify connection="conn" >
insert into EMPLOYEE
    (EMPNO,FIRSTNME,MIDINIT,LASTNAME,WORKDEPT,EDLEVEL)
values
('<tsx:getProperty name="request" property=request.getParameter("EMPNO") />',
'<tsx:getProperty name="request" property=request.getParameter("FIRSTNME") />',
'<tsx:getProperty name="request" property=request.getParameter("MIDINIT") />',
'<tsx:getProperty name="request" property=request.getParameter("LASTNAME") />',
'<tsx:getProperty name="request" property=request.getParameter("WORKDEPT") />',
<tsx:getProperty name="request" property=request.getParameter("EDLEVEL") />)
</tsx:dbmodify>
```

tsx:getProperty tag JavaServer Pages syntax and examples (deprecated):

The <tsx:getProperty> tag gets the value of a bean to display in a JavaServer Pages (JSP) file.

Note: Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

This IBM extension of the Sun JSP <jsp:getProperty> tag implements all of the <jsp:getProperty> function and adds the ability to introspect a database bean created using the IBM extension <tsx:dbquery> or <tsx:dbmodify>.

Note: You cannot assign the value from this tag to a variable. The value, generated as output from this tag, displays in the browser window.

This section describes the syntax of the <tsx:getProperty> tag:

```
<tsx:getProperty name="bean_name"
  property="property_name" />
```

where:

- **name**

Represents the name of the bean declared by the `id` attribute of a <tsx:dbquery> syntax within the JSP file. Refer to the <tsx:dbquery> article for an explanation. The value of this attribute is case-sensitive.

- **property**

  Represents the property of the bean to access for substitution. The value of the attribute is case-sensitive and is the locale-independent name of the property.

Tag example:

```
<tsx:getProperty name="userProfile" property="username" />
```

tsx:userid and tsx:passwd tag JavaServer Pages syntax (deprecated):

With the <tsx:userid> and <tsx:passwd> tags, you do not have to hard code a user ID and password in the <tsx:dbconnect> tag.

Note: Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

Use the <tsx:userid> and <tsx:passwd> tags to accept user input for the values and then add that data to the request object. You can access the request object with a JavaServer Pages (JSP) file, such as the `JSPEmployee.jsp` example that requests the database connection.

You must use <tsx:userid> and <tsx:passwd> tags within a <tsx:dbconnect> tag.

This section describes the syntax of the <tsx:userid> and <tsx:passwd> tags.

```
<tsx:dbconnect id="connection_id"
    <font color="red"><userid></font>
    <tsx:getProperty name="request" property=request.getParameter("userid") />
    <font color="red"></userid></font>
    <font color="red"><passwd></font>
    <tsx:getProperty name="request" property=request.getParameter("passwd") />
    <font color="red"></passwd></font>
    url="protocol:database_name:database_table"
    driver="JDBC_driver_name">
</tsx:dbconnect>
```

where:

- <tsx:getProperty>

  Represents the syntax as a mechanism for embedding variable data.

- userid

  Represents a reference to the request parameter that contains the user ID. You must add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string to pass the user-specified request parameters.

- passwd

  Represents a reference to the request parameter that contains the password. Add the parameter to the request object that passes to this JSP file. You can set the attribute and its value in the request object, using an HTML form or a URL query string, to pass user-specified values.

tsx:repeat tag JavaServer Pages syntax (deprecated):

The <tsx:repeat> tag repeats a block of HTML tagging.

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

Use the <tsx:repeat> syntax to iterate over a database query results set. The <tsx:repeat> syntax iterates from the start value to the end value until one of the following conditions is met:
- The end value is reached.
- An exception is thrown.

If an exception of the types **ArrayIndexOutOfBoundsException** or **NoSuchElementException** is created before a block completes, output is written only for the iterations up to and not including the iteration during which the exception was created. All other exceptions results in no output being written for that tag instance.

This section describes the syntax of the <tsx:repeat> tag:

```
<tsx:repeat index="name" start="starting_index" end="ending_index">
</tsx:repeat>
```

where:
- **index**

  Represents an optional name used to identify the index of this repeat block. The scope of the index is NESTED. Its type must be integer.
- **start**

  Represents an optional starting index value for this repeat block. The default is 0.
- **end**

  Represents an optional ending index value for this repeat block. The maximum value is 2,147,483,647.

  If the value of the end attribute is less than the value of the start attribute, the end attribute is ignored.

Combining tsx:repeat and tsx:getProperty JavaServer Pages tags (deprecated)

Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The following code snippet shows you how to code these tags:

```
<tsx:repeat>
<tr>
    <td><tsx:getProperty name="empqs" property="EMPNO" />
    <tsx:getProperty name="empqs" property="FIRSTNME" />
    <tsx:getProperty name="empqs" property="WORKDEPT" />
    <tsx:getProperty name="empqs" property="EDLEVEL" />
    </td>
</tr>
</tsx:repeat>
```

Example: Using tsx:repeat JavaServer Pages tag to iterate over a results set (deprecated):

The <tsx:repeat> tag iterates over a results set. The results set is contained within a bean. The bean can be a static bean, for example, a bean created by using the IBM WebSphere Studio database wizard, or a dynamically generated bean, for example, a bean generated by the <tsx:dbquery> syntax.

Note: Support for tsx tags in the JavaServer Pages (JSP) engine are deprecated in WebSphere Application Server Version 6.0. Instead of using the tsx tags, you should use equivalent tags from the JavaServer Pages Standard Tag Library (JSTL).

The following table is a graphic representation of the contents of a bean called, *myBean*:

Table 119. Graphic representation of myBean.. myBean contents.

Column	col1	col2	col3
row0	friends	Romans	countrymen

Table 119. Graphic representation of myBean. (continued). myBean contents.

Column	col1	col2	col3
row1	bacon	lettuce	tomato
row2	May	June	July

Some observations about the bean:
- The column names in the database table become the property names of the bean. The <tsx:dbquery> section describes a technique for mapping the column names to different property names.
- The bean properties are indexed. For example, `myBean.get(Col1(row2))` returns `May`.
- The query results are in the rows. The <tsx:repeat> tag iterates over the rows, beginning at the start row.

The following table compares using the <tsx:repeat> tag to iterate over a static bean, versus a dynamically generated bean:

Table 120. Static Bean and <tsc:repeat> Bean example. Use this table to compare the two beans.

Static Bean Example	<tsx:repeat> Bean Example

myBean.class
`// Code to get a connection`
 	
`// Code to get the data`
`Select * from myTable;`
 	
`// Code to close the connection`
 	
JSP file
`<tsx:repeat index=abc>`
`<tsx:getProperty name="myBean"`
`property="col1(abc)" />`
`</tsx:repeat>`
 	
Note:
• The bean (myBean.class) is a static bean.
• The method to access the bean properties is myBean.get(*property*(*index*)).
• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.
• The <tsx:repeat> tag iterates over the bean properties row by row, beginning with the start row.
	JSP file
	`<tsx:dbconnect id="conn"`
	`userid="alice"passwd="test"`
	`url="jdbc:db2:sample"`
	`driver="COM.ibm.db2.jdbc.app.DB2Driver">`
	`</tsx:dbconnect >`
	
	`<tsx:dbquery id="dynamic"`
	`connection="conn" >`
	`Select * from myTable;`
	`</tsx:dbquery>`
	
	`<tsx:repeat index=abc>`
	`<tsx:getProperty name="dynamic"`
	`property="col1(abc)" />`
	`</tsx:repeat>`
	
	Note:
	• The bean (dynamic) is generated by the <tsx:dbquery> tag and does not exist until the syntax executes.
	• The method to access the bean properties is dynamic.getValue("*property*", *index*).
	• You can omit the property index, in which case the index of the enclosing <tsx:repeat> tag is used. You can also omit the index on the <tsx:repeat> tag.
	• The <tsx:repeat> tag syntax iterates over the bean properties row by row, beginning with the start row.

Implicit and explicit indexing

Examples 1, 2, and 3 show how to use the <tsx:repeat> tag. The examples produce the same output if all indexed properties have 300 or fewer elements. If there are more than 300 elements, Examples 1 and 2 display all elements, while Example 3 shows only the first 300 elements.

Example 1 shows *implicit indexing* with the default start and default end index. The bean with the smallest number of indexed properties restricts the number of times the loop repeats.

```
<table>
<tsx:repeat>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" />
```

```
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone" />
  </tr></td>
</tsx:repeat>
</table>
```

Example 2 shows indexing, starting index, and ending index:

```
<table>
<tsx:repeat index=myIndex start=0 end=2147483647>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=city(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=address(myIndex) />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property=telephone(myIndex) />
</tr></td>
</tsx:repeat>
</table>
```

Example 3 shows *explicit indexing* and ending index with implicit starting index. Although the index attribute is specified, you can still implicitly index the indexed property city because the (`myIndex`) tag is not required.

```
<table>
<tsx:repeat index=myIndex end=299>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="city" /t>
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="address(myIndex)" />
  </tr></td>
  <tr><td><tsx:getProperty name="serviceLocationsQuery" property="telephone(myIndex)" />
  </tr></td>
</tsx:repeat>
</table>
```

Nesting <tsx:repeat> blocks

You can nest <tsx:repeat> blocks. Each block is separately indexed. This capability is useful for interleaving properties on two beans, or properties that have subproperties. In the example, two <tsx:repeat> blocks are nested to display the list of songs on each compact disc in the user's shopping cart.

```
<tsx:repeat index=cdindex>
  <h1><tsx:getProperty name="shoppingCart" property=cds.title /></h1>
  <table>
  <tsx:repeat>
    <tr><td><tsx:getProperty name="shoppingCart" property=cds(cdindex).playlist />
    </td></tr>
  </tsx:repeat>
  </table>
 </tsx:repeat>
```

Developing JSF files

Learn about JSF files.

JavaServer Faces

JavaServer Faces (JSF) is a user interface framework or application programming interface (API) that eases the development of Java-based web applications.

WebSphere Application Server supports JavaServer Faces 2.0 at a runtime level. The JSF runtime also:

- Makes it easy to construct a user interface from a set of reusable user interface components
- Simplifies migration of application data to and from the user interface

- Helps manage user interface state across server requests
- Provides a simple model for wiring client-generated events to server-side application code
- Supports custom user interface components to be easily build and reused

Both the Sun Reference Implementation and Apache MyFaces implementation are shipped with the product.

The Apache MyFaces JSF Implementation provides the foundation of the code used for the JSF support in WebSphere Application Server. The version of the JSF runtime provided by the Application Server resides in the normal runtime library location and is available to all web applications that use JSF APIs. Loading the JSF servlet works in the same manner as if the run time was packaged with the web application. The bundled version includes enhancements for better integration with the built-in annotation scanning and other runtime components of WebSphere Application Server.

The specification-related classes (javax.faces.*) for JSF and the IBM modified version of the Apache MyFaces JSF Implementation and the JSF Sun reference implementation are packaged in the Application Server run time.

Typically, web applications that use this API/Framework embed the JSF API and implementation Java archive (JAR) files within their web application archive (WAR) file. This practice is not required when these web applications are deployed and run within WebSphere Application Server. Only the removal of these JAR files along with any JSTL JAR files from the WAR file is required. However, because JavaServer Faces 2.0 is a part of the Java Platform, Enterprise Edition (Java EE) platform, a web application does not need to bundle a JavaServer Faces implementation when it runs on a web container that is Java EE technology compliant. If a JavaServer Faces implementation is bundled with a web application, it is ignored as the JavaServer Faces implementation provided by the platform always takes precedence.

The JSF run time for WebSphere Application Server does not support the use of a single class loader for the entire application. This support is not available when the application contains multiple web modules and one of those modules is a JSF module. A single class loader for the entire application is not supported because the FacesConfig initialization requires a single class loader for each JSF module to perform the initialization. Therefore, you must use multiple class loaders when the application contains multiple web modules and at least one JSF module.

For using different implementations of JSF, the WebSphere Application Server JSF engine determines if the SUN RI or Apache MyFaces is used from the application server run time. After the JSF engine determines the implementation that is used, the correct listener class is registered with the web container. You do not need to add the com.sun.faces.ConfigureListener or the org.apache.myfaces.StartupConfigureListener to the `web.xml` file.

If you want to use a third party JSF implementation that is not shipped with the product, leave the configuration set to MyFaces, add the third party listener to the `web.xml` file that is required and add the third party implementation JAR files to the web module as an isolated shared library. Using an isolated shared library, the web application version of the JSF or JSTL classes load before the Application Server.

JavaServer Faces widget library (JWL)

JavaServer Faces widget library (JWL) is an IBM JSF-based web widget library that integrates widgets from a number of sources. The IBM JSF-based web widget library is deprecated, however, you can obtain the latest version from Rational Application Developer version 6 to work with JSF 1.2.

JWL includes the JSF components from Rational Application Developer except for the base JSF components, which are included in the Application Server run time. This includes the IBM extended JSF components and the extended FacesClient Component. JWL also extends JSF with client-side features for rich browser-based experiences in the form of the FacesClient Component.

Important: JWL is not supported in pages using the JSF 2.0 Facelets format.

Note: You must update the JavaServer Faces widget library (JWL) libraries in JavaServer Faces Web projects that are developed using Rational® Application Developer, Version 7.x with the latest updates from Rational Application Developer before deploying WebSphere® Application Server. Update Rational Application Developer with the latest updates, and update the JWL libraries in the WEB_PROJECT/WEB-INF/lib folder.

JWL Java archive files

JWL is packaged into two Java archive (JAR) files, `odc-jsf.jar` and `jsf-ibm.jar`, which are located in the `${WAS_HOME}\optionalLibraries\IBM\jwl\2.0` directory.

To include JWL in your application, you can use the JWL shared library named JWLLib, which is created at installation time. To assign the library to an application, see the topic, Using installed optional packages.

Configuring Portlet Bridge for JavaServer Faces

Use this task to configure IBM Portlet Bridge for JavaServer Faces (JSF) 2.0.

About this task

Portlet Bridge for JavaServer Faces is available as Version 8.0.0.2.

Procedure

1. Open the portlet.xml file and modify the portlet class for JSF 2.0 portlet bridge, as follows:

```
<portlet-class>com.ibm.faces20.portlet.FacesPortlet</portlet-class>
  <init-param>
    <name>com.ibm.faces.portlet.page.view</name>
    <value>/TestProjectView.xhtml</value>
  <init-param>
```

2. Open the faces-config.xml file and add the JSF 2.0 portlet bridge variable resolver, view handler, and resource handler entry

```
<application>
  <variable-resolver>com.ibm.faces20.portlet.PortletVariableResolver</variable-resolver>
  <view-handler>com.ibm.faces20.portlet.FaceletPortletViewHandler</view-handler>
  <resource-handler>com.ibm.faces20.portlet.httpbridge.PortletResourceHandler</resource-handler>
</application>
```

What to do next

If the portlet project has a custom portlet class, these changes are also necessary:

- Point the portlet-class entry in the portlet.xml file to the particular custom portlet class used.
- Modify the portlet class to extend the com.ibm.faces20.portlet.FacesPortlet class from the IBM Portlet Bridge for JSF 2.0.

Configuring JavaServer Faces implementation

Use this task to specify which JavaServer Faces implementation to use. You can use Apache MyFaces 2.0 or the SUN Reference Implementation 1.2 of JSF, or your own implementation.

Before you begin

Ensure that your application is configured for JavaServer Faces (JSF) using the specific `web.xml` context parameters for the implementation that you have chosen.

Attention: The JSF implementation is a server-wide configuration setting. Thus, if you have multiple applications which require different JSF implementations, you must separate the applications into different application servers or clusters, and specify the implementation by following the steps in this topic for each application server or cluster. Alternatively, you can use an isolated shared library, as described for third-party JSF implementations, as follows.

About this task

Note: The Application Server JSF engine determines if the SUN Reference Implementation (RI) 1.2 or Apache MyFaces 2.0 is used from the Application Server run time. If either is used, the correct listener class is registered with the web container. You do not need to add the com.sun.faces.ConfigureListener or the org.apache.myfaces.StartupConfigureListener to your `web.xml` file.

Be Aware: If you want to use a third-party JSF implementation that is not shipped with the product, then:

- Keep the configuration set to MyFaces.
- Add the third-party listener to the `web.xml` file that is required.
- Add the third-party implementation Java archive (JAR) files to the application as an isolated shared library and associate it with your application.

You can also configure the JSF implementation on the Provide JSP reloading options for web modules panel for application installation and update wizards.

Procedure

Configure the server or cluster to use the JSF implementation that you want. You can do this task using the administrative console or the wsadmin tool.

- In the administrative console panel, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **JSP and JSF options**

  Select one of the following implementations:
  - Sun Reference Implementation 1.2 - Select this option to use the Sun Reference Implementation 1.2 JSF implementation.
  - MyFaces 2.0 - Select this option to use the MyFaces 2.0 JSF implementation. This option is the default JSF implementation.
- Using the wsadmin tool:
  - An example of setting a single server to use the Sun RI 1.2 JSF implementation:

```
wsadmin>set server [$AdminConfig list ApplicationServer *server1*]
server1(cells/myNode01Cell/nodes/myNode01/servers/server1|server.xml#ApplicationServer_1183122130078)
wsadmin>$AdminConfig modify $server {{jsfProvider SunRi1.2}}

wsadmin>$AdminConfig save
```

  - An example of setting a cluster to use the MyFaces 2.0 JSF implementation:

```
wsadmin>set cluster [$AdminConfig list ServerCluster]
cluster1(cells/myNode01Cell/nodes/myNode01/clusters/cluster1|cluster.xml#ServerCluster_1173916133721)
wsadmin>$AdminConfig modify $cluster {{jsfProvider MyFaces}}

wsadmin>$AdminConfig save
```

Results

What to do next

Configure JSF engine parameters as necessary.

Configuring JSF engine parameters:
About this task

WebSphere Application Server does not support the modification of deployment descriptor extension parameters through the administrative console or through administrative scripting.

To add, change or delete JSF engine configuration parameters, complete the following steps:

Procedure

1. Open the WEB-INF/web.xml file.

   JSP engine configuration parameters are stored in a web module's configuration directory or in a web modules's binaries directory in the WEB-INF/web.xml file. Open the WEB-INF/web.xml file from:

   - The configuration directory, as in the following example: {WAS_ROOT}/profiles/*profilename*/config/cells/*cellname*/applications/*enterpriseappname*/ deployments/*deployedname*/*webmodulename*
   - The binaries directory if an application was deployed into WebSphere Application Server with the flag "Use Binary Configuration" set to true. An example of a binaries directory is: {WAS_ROOT}/profiles/*profilename*/installedApps/*nodename*/*EnterpriseAppName*/*WebModuleName*/

2. Edit the WEB-INF/web.xml file.

   - To add configuration parameters, use the following format:

     ```
     <context-param>
       <description>descriptive text</description>
       <param-name>parameter name</param-name>
       <param-value>parameter value</param-value>
     </context-param>
     ```

   - To delete configuration parameters, either delete the line from the file, or enclose the statement with <!-- --> tags.

3. Save the file.

4. Restart the Enterprise Application. It is not necessary to restart the server for parameter changes to take effect. However, some JSP engine configuration parameters affect the Java source code that is generated for a JSP. If such a parameter is changed, then you must retranslate the JSP files in the web module to regenerate Java source. You can use the batch compiler to retranslate all JSP files in a web module. The batch compiler uses the JSP engine configuration parameters that you have set in the web.xml file, unless you specifically override them. The JSP engine configuration topic identifies the parameters that affect the generated Java source.

Example

The following is a sample of the WEB-INF/web.xml file.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns="http://java.sun.com/xml/ns/javaee" xmlns:web="http://java.sun.com/xml/ns/javaee/web-app_2_5.xsd"
 xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/web-app_2_5.xsd"
 id="WebApp_ID" version="2.5">
 <display-name>Servlet 2.5 example</display-name>
 <welcome-file-list>
  <welcome-file>index.html</welcome-file>
  <welcome-file>index.htm</welcome-file>
  <welcome-file>index.jsp</welcome-file>
  <welcome-file>default.html</welcome-file>
  <welcome-file>default.htm</welcome-file>
  <welcome-file>default.jsp</welcome-file>
 </welcome-file-list>
 <context-param>
       <param-name>javax.faces.CONFIG_FILES</param-name>
       <param-value>/WEB-INF/faces-config.xml</param-value>
    </context-param>
    <context-param>
        <param-name>javax.faces.STATE_SAVING_METHOD</param-name>
        <param-value>server</param-value>
    </context-param>
    <context-param>
        <param-name>com.ibm.ws.jsf.LOAD_FACES_CONFIG_AT_STARTUP</param-name>
        <param-value>true</param-value>
    </context-param>
    <servlet>
        <servlet-name>Faces Servlet</servlet-name>
        <servlet-class>javax.faces.webapp.FacesServlet</servlet-class>
```

```
    </servlet>
    <servlet-mapping>
        <servlet-name>Faces Servlet</servlet-name>
        <url-pattern>/faces/*</url-pattern>
    </servlet-mapping>
    <servlet-mapping>
        <servlet-name>Faces Servlet</servlet-name>
        <url-pattern>*.faces</url-pattern>
    </servlet-mapping>
</web-app>
```

JSF engine configuration parameters:

In WebSphere Application Server, you can configure the JavaServer Faces (JSF) engine configuration parameters for optimal performance in a production server environment and for the needs of developers in a development environment.

The JSF engine parameters are case-sensitive. If the value specified for a parameter is composed of two or more words separated by spaces, you must add quotation marks around the value.

JSF options using SUN RI

Table 121. JSF options using SUN RI. The table shows SUN RI parameter names, descriptions and default values.

SUN RI parameter name	Description	Default value
com.sun.faces.numberOfViewsInSession	Specifies the number of views that are stored in the session when Server-Side State Saving is used. If set to true while client-side state saving is being used, reduces the number of bytes sent to the client by compressing the state before it is encoded and written as a hidden field.	15
com.sun.faces.numberOfLogicalViews	Specifies the number of logical views that are stored in the session when Server-Side State Saving is used.	15
com.sun.faces.enableHighAvailability	If set to true while server-side state saving is used, a serialized representation of the view is stored on the server. This provides failover and server clustering support.	false
com.sun.faces.injectionProvider	Defines an injection provider that is used for JSF annotations.	
com.sun.faces.serializationProvider	Defines a serialization provider that is used for serializing JSF objects into session.	
com.sun.faces.responseBufferSize	Define the size of the response buffer for a JSF response.	1048
com.sun.faces.clientStateWriteBufferSize		8192
com.sun.faces.expressionFactory	Specifies the default EL Expression Factory to use.	org.apache.el.ExpressionFactoryImpl
com.sun.faces.clientStateTimeout	The timeout value used for client side state saving. When the value set has been reached then the state is lost.	infinite
com.sun.faces.displayConfiguration		false
com.sun.faces.validateXml	When set to true, tag library XML files and faces configuration XML files using schema are validated during application start.	false
com.sun.faces.verifyObjects		false
com.sun.faces.forceLoadConfiguration		false
com.sun.faces.disableVersionTracking		false
com.sun.faces.enableHtmTagLibValidator		false
com.sun.faces.prerefXHTML		false
com.sun.faces.compressViewState		true
com.sun.faces.compressJavaScript		true
com.sun.faces.sendPoweredByHeader		true
com.sun.faces.enableJSStyleHiding		false
com.sun.faces.writeStateAtFormEnd		true
com.sun.faces.enableLazyBeanValidation		true
com.sun.faces.enableLoadBundle11Compatibility		false
com.sun.faces.enableRestoreView11Compatibilty		false
com.sun.face.serializeServerState		false
com.ibm.ws.jsf.JSP_UPDATE_CHECK	This parameter monitors Faces JavaServer Pages (JSP) files for modifications and synchronizes a running server with the changes without restarting the server. If this parameter is set to false or removed from the deployment descriptor, any changes made to Faces JSP files might not be seen by the server until it is restarted. Set this parameter to true while developing and debugging the Faces JSP files to improve the performance of the development environment.	

Table 121. JSF options using SUN RI (continued). The table shows SUN RI parameter names, descriptions and default values.

SUN RI parameter name	Description	Default value
com.ibm.ws.jsf.JSF_IMPL_CHECK	Set the com.ibm.ws.jsf.JSF_IMPL_CHECK parameter to true to check at application restart if the SUN RI and MyFaces implementations were switched. If the implementation has switched, then the runtime removes any generated JSP files from the temp directory and the JSP file is retranslated the next time it is requested.	

com.ibm.ws.jsf.associateLabelWithId	The com.ibm.ws.jsf.associateLabelWithId custom property changes the rendering behavior for both the <h:selectOneRadio> and <h:selectManyCheckbox> components. The label no longer wraps the input element. Instead, each input element has a unique ID and the label is associated with that ID used for that attribute. Define and set the com.ibm.ws.jsf.associateLabelWithId context parameter to `true` in the `web.xml` file.
	
	Use the following code as an example.
	`<context-param>`
	`<description>`
	`Set to true to explicitly associate labels`
	`with their input elements for select one`
	`radio buttons and select many check box lists.`
	`</description>`
	`<param-name>com.ibm.ws.jsf.associateLabelWithId`
	`</param-name>`
	`<param-value>true</param-value>`
	`</context-param>`	

com.ibm.ws.jsf.disableEnqueuedMessagesWarning	The com.ibm.ws.jsf.disableEnqueuedMessagesWarning custom property disables the `FacesMessage(s) have been enqueued, but may not have been displayed` warning message. When this property is set to `true` in the `web.xml` file, this warning message is not included in the `SystemOut.log` file .
	gotcha: This context parameter only applies to JSF applications that use the Sun Reference Implementation (RI) for JSF implementation.
	Note: This topic references one or more of the application server log files. As a recommended alternative, you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files on distributed and IBM i systems. You can also use HPEL in conjunction with your native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.
	
	Use the following code as an example of how to define and set the com.ibm.ws.jsf.disableEnqueuedMessagesWarning context parameter to `true` in the web.xml file.
	`<context-param>`
	`<description>`
	`Set to true to disable the following warning`
	`message:`
	`FacesMessage(s) have been enqueued, but might`
	`not have been displayed`
	`</description>`
	`<param-name>`
	` com.ibm.ws.jsf.disableEnqueuedMessagesWarning`
	`</param-name>`
	`<param-value>true</param-value>`
	`</context-param>`	

com.ibm.ws.jsf.disableStylePassthroughForCheckboxList	This custom property prevents passing the style information into the items in the check box list. This property defaults to false to maintain the current behavior. Define and set the com.ibm.ws.jsf.disableStylePassthroughForCheckboxList context parameter to `true` in the web.xml file prevent passing style information into items in the check box list. Use the following code as an example.
	`<context-param>`
	`<description>`
	`Set to true if style information should not`
	`be passed into items of check box list`
	`</description>`
	`<param-name>`
	`com.ibm.ws.jsf.disableStylePassthroughForCheckboxList`
	`</param-name>`
	`<param-value>true</param-value>`
	`</context-param>`	

Table 121. JSF options using SUN RI (continued). The table shows SUN RI parameter names, descriptions and default values.

SUN RI parameter name	Description	Default value

com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK	The com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK custom property determines whether unique IDs are generated for UIData components that are nested inside iterator components that are not UIData components. When this property is set to `true` in the web.xml file, unique IDs are generated for UIData components even if they are nested inside iterator components that are not UIData components.
	
	When this property is set to `false`, if a JSF dataTable component is nested within a component that does not extend UIData, such as the Java Widget Library (JWL) dataIterator component, the IDs that are generated for the rows do not increment properly. This situation can result in duplicate IDs being assigned to multiple JSF components.
	
	Use the following code as an example of how to define and set the com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK context parameter to `true` in the `web.xml`file.
	`<context-param>`
	`<description>`
	`Set to true to enable unique IDs to be`
	`generated for UIData components evenif they`
	`are nested inside iterator components that are`
	`not UIData components.`
	`</description>`
	`<param-name>`
	`com.ibm.ws.jsf.DISABLE_UIDATA_NESTED_CHECK`
	`</param-name>`
	`<param-value>true</param-value>`
	`</context-param>`	

com.ibm.ws.jsf.loadExternalDtd	When parsing the faces-config.xml file from included libraries, the Faces configuration parser attempts to load the DTD even when validation is disabled. The Faces configuration parser uses a SAXParser to read the faces-config.xml. The default behavior of the SAXParser parser is to always load the DTD even if validation is disabled. This behavior can lead to errors initializing the Faces Servlet on systems isolated from the internet.
	
	In your `web.xml` file, set the com.ibm.ws.jsf.loadExternalDtd context paramater to `false` to have the Faces configuration parser set the "http://apache.org/xml/features/nonvalidating/load-external-dtd" feature to false.
	`<context-param>`
	`<description>`
	`When set to false, this property sets a`
	`feature on the SAX parser to prevent loading`
	`the external DTD.`
	`</description>`
	`<param-name>com.ibm.ws.jsf.loadExternalDtd</param-name>`
	`<param-value>false</param-value>`
	`</context-param>`	

enableRestoreView11Compatibility	A JSF 1.2 application might create the ViewExpiredException exception under load when using the Sun Reference Implementation. If your view is not found in session, you can use a compatibility mode in JSF to create a new view. This can have adverse behaviors because it is a new view and items that are usually in the view, such as state, will no longer be available. Use the following code as an example to set the com.sun.faces.enableRestoreView11Compatibility context parameter to `true` in the web.xml file. This is only applicable when the Sun Reference Implementation is in use.
	`<context-param>`
	`<param-name>`
	`com.sun.faces.enableRestoreView11Compatibility`
	`</param-name>`
	`<param-value>true</param-value>`
	`</context-param>`	

enableViewStateIdRendering	The com.sun.faces.enableViewStateIdRendering custom property controls the rendering of the id attribute of the javax.faces.ViewState hidden field. Use the following code as an example to set the com.sun.faces.enableViewStateIdRendering context parameter to `true` in the web.xml file.
	`<context-param>`
	`<param-name>com.sun.faces.enableViewStateIdRendering`
	`</param-name>`
	`<param-value>true</param-value>`
	`</context-param>`	

JSF options for MyFaces

Table 122. JSF options for MyFaces. The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
org.apache.myfaces.RESOURCE_VIRTUAL_PATH		/faces/myFacesExtensionResource

Table 122. JSF options for MyFaces (continued). The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
org.apache.myfaces.PRETTY_HTML	If this value is true, rendered HTML code is formatted so that it is human-readable. Additional line separators and white space are written that do not influence the HTML code.	true
org.apache.myfaces.ALLOW_JAVASCRIPT	This parameter tells MyFaces if javascript code is allowed in the rendered HTML output. If javascript is allowed, command_link anchors have javascript code that submits the corresponding form. If javascript is not allowed, the state saving information and nested parameters are added as URL parameters.	true
org.apache.myfaces.DETECT_JAVASCRIPT		false
org.apache.myfaces.AUTO_SCROLL	If true, a javascript function is rendered that can restore the former vertical scroll on every request. This feature is convenient if you have pages with long lists and you do not want the browser page to jump to the top of the page if you trigger a link or button action that stays on the same page.	false
org.apache.myfaces.ADD_RESOURCE_CLASS		org.apache.myfaces.renderkit.html.util.DefaultAddResource
org.apache.myfaces.CHECK_EXTENSIONS_FILTER	This parameter checks for a properly-configured Extensions-Filter if it is needed by the web application.	true
org.apache.myfaces.COMPRESS_STATE_IN_SESSION	Set this option to `true` to compress the serialized state before it is written to the session. If this option is set to `false`, the state is not compressed. This option is only applicable if the state saving method is set to server and if org.apache.myfaces.SERIALIZE_STATE_IN _SESSION is set to `true`.	true
org.apache.myfaces.NUMBER_OF_VIEWS_IN_SESSION	Defines the number of the latest views that are stored in session. This option is only applicable if the state saving method is set to server.	20
org.apache.myfaces.READONLY_AS_DISABLED_FOR _SELECTS		true
org.apache.myfaces.SERIALIZE_STATE_IN_SESSION	Set this option to `true` to serialize the state to a byte stream before it is written to the session. If this option is set to `false`, the state is not serialized to a byte stream. This option is only applicable if the state saving method is set to server.	true
org.apache.myfaces.STRICT_JSF_2_CC_EL_RESOLVER	Ensures that, when a getType() is called over the source EL expression, components working with chained EL expressions can use the metadata information that composite:attribute added. Setting this property to `true` disables this function.	false
com.ibm.ws.jsf.disablealternatefacesconfigsearch	Disables MyFaces searching for META-INF/*.faces-config.xml for only the web application that this context parameter is set on. If the context parameter and the web container custom property are set, the context parameter takes precedence.	false

Table 122. JSF options for MyFaces (continued). The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value

org.apache.el.parser.COERCE_TO_ZERO	Allows for the expression language (EL) that WebSphere Application Server uses to coerce null and empty string integer values to a 0 value or for NOT allowing a coerce to a 0 value and retaining the null or empty string integer. The default is `true` and permits a null or empty string integer value to be coerced to a 0 value.
	Important: In order to keep a null value from being coerced to a 0 value in a MyFaces application, the following context parameter in the `web.xml` of the application: should be set to ensure that all possible instances of an empty or null value are inhibited from being coerced to zero.
	`<context-param>`
	` <param-name>javax.faces.`
	`  INTERPRET_EMPTY_STRING_SUBMITTED_VALUES_AS_NULL`
	` </param-name>`
	` <param-value>true</param-value>`
	`</context-param>`
	
	You set the `org.apache.el.parser.COERCE_TO_ZERO` property using the administrative console.
	1. Expand Servers > Select WebSphere Application Servers > Click on the appropriate server from the list.
	2. Under Server Infrastructure, expand Java and Process Management > Click on Process definition.
	3. Under Additional Properties, click Java virtual Machine.
	4. Under Additional Properties, click Custom properties.
	5. Click `New` and add the `org.apache.el.parser.COERCE_TO_ZERO` property with the value of `false` if you do NOT want a null value coerced to zero.
	6. Click `Save` to save the change and restart the WebSphere Application Server to ensure the change takes place.
		true

org.apache.myfaces.DEBUG_PHASE_LISTENER	Enables the `DebugPhaseListener` in the Development Project Stage.	true

JSF options using SUN RI or MyFaces

The following options are valid for both the SUN RI and the MyFaces implementations.

Table 123. JSF options using SUN RI or MyFaces. The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
javax.faces.STATE_SAVING_METHOD	Specifies the location where state information is saved. Valid values are 'server', which is saved in HttpSession, and 'client', which is saved as a hidden field in the form.	server
javax.faces.CONFIG_FILES	Use this parameter to specify a comma-delimited list of context-relative resource paths under which the JSF implementation looks for application configuration resources before loading a configuration resource named `/WEB-INF/facesconfig.xml`, if a resource exists.	n/a
javax.faces.DEFAULT_SUFFIX	Specifies the default suffix for extension-mapped resources that contain JSF components.	.jsp
javax.faces.LIFECYCLE_ID	Use this parameter to configure an alternate life cycle ID.	n/a

Table 123. JSF options using SUN RI or MyFaces (continued). The table shows JSF parameter names, descriptions and default values.

JSF parameter name	Description	Default value
com.ibm.ws.jsf.JSF_IMPL_CHECK	Specifies that the JSP files in a web module must be recompiled when the application is restarted because the implementation of JSF that is used has changed. After the application is restarted, the next time a JSP file is accessed for this module the JSP file is recompiled against the selected implementation of JSF specified in the administration console. Subsequent calls to the JSP file do not recompile. The default setting for this option is false. Use this option for development and not in a production environment.	n/a

Sun RI context parameters that have an equivalent behavior in MyFaces

Table 124. Sun RI context parameters and equivalent MyFaces behavior. The table shows SUN RI parameters names and MyFaces equivalent.

SUN RI parameter name	Description	RI default	MyFaces equivalent	MyFaces default
com.sun.faces.numberOfViewsInSession	Defines the maximum number of serialized views stored in the session. Works with server state saving.	15	org.apache.myfaces.NUMBER_OF_VIEWS_IN_SESSION	20
com.sun.faces.compressViewState	When true the view is compressed after it is serialized and before base64 encoded. Works with client state saving. As of 1.2_09, this option also affects server-side state saving when com.sun.faces.serializeServerState is set to true (this has a large impact of the size of the state in the session when using this option, at the expense of more CPU.)	true	org.apache.myfaces.COMPRESS_STATE_IN_CLIENT for client-side state saving or org.apache.myfaces.COMPRESS_STATE_IN_SESSION for server-side state saving	false for client-side state saving, true for server-side state saving
com.sun.faces.validateXml	When true JSF validates the configuration files.	false	org.apache.myfaces.VALIDATE	false
com.sun.faces.injectionProvider	This parameter specifies a class that implements the InjectionProvider.	n/a	injection provider is provided by the WebSphere Application Server run time	n/a
com.sun.faces.serializationProvider	This parameter specifies a class that implements the SerializationProvider SPI. This implementation represents a hook the JSF implementation uses to enable using alternate Serialization implementations.	n/a	org.apache.myfaces.SERIAL_FACTORY - class must implement org.apache.myfaces.shared_impl.util.serial.SerialFactory SPI instead of com.sun.faces.spi.SerializationProvider	n/a
com.sun.faces.enabledJSStyleHiding	If true, inline JavaScript rendered by the HTML ResponseWriter implementation is rendered so that the script is hidden from older browser implementations.	false	org.apache.myfaces.WRAP_SCRIPT_CONTENT_WITH_XML _COMMENT_TAG	true
com.sun.faces.serializeServerState	If enabled the component state (not the tree) is serialized before being stored in the session. This might be desirable for applications that have issues with view state being sensitive to model changes.	false	org.apache.myfaces.SERIALIZE_STATE_IN_SESSION	true

Defining an extension for the registry filter

The registry filter specifies if an extensions is applicable to all registry instances or to specified instances.

Before you begin

You must have an extensible application to define an extension for the registry filter.

About this task

Complete the following steps to filter out extensions for an application.

Procedure

1. Define an extension for the registry filter extension point for a named registry instance in the `plugin.xml` file.

```
<extension point="org.eclipse.extensionregistry.RegistryFilter">
 <filter name="AdminConsole*"
   class="com.ibm.ws.admin.AdminConsoleExtensionFilter"/>
 </extension>
```

2. Add the filter implementation to the application by creating a class to implement the com.ibm.workplace.extension.IExtensionRegistryFilter interface.

```
package com.ibm.ws.admin;
import com.ibm.workplace.extension.IExtensionRegistryFilter;
public class AdminConsoleExtensionFilter implements IExtensionRegistryFilter {
        :
}
```

3. The extensible application declares the registry name by defining an extension for the RegistryInstance extension point. This way, the registry can prepare an IExtensionRegistry instance and put it in JNDI in advance.

```
<extension point="org.eclipse.extensionregistry.RegistryInstance">
  <registry name="AdminConsole"/>

</extension>
```

4. The extensible application obtains a named instance of the registry to activate any associated filters:

```
InitialContext ic = new InitialContext();
String lookupName = "services/extensionregistry/AdminConsole";
IExtensionRegistry reg = (IExtensionRegistry)ic.lookup( lookupName );
```

Application extension registry

WebSphere Application Server has enabled the Eclipse extension framework for applications to use. Applications are extensible when they contain a defined extension point and provide the extension processing code for the extensible area of the application.

An application can be plugged in to another extensible application by defining an extension that adheres to what the target extension point requires. The extension point can find the newly added extension dynamically and the new function is seamlessly integrated in the existing application. It works on a cross Java Platform, Enterprise Edition (Java EE) module basis. The application extension registry uses the Eclipse plug-in descriptor format and application programming interfaces (APIs) as the standard extensibility mechanism for WebSphere applications. Developers that build WebSphere application modules can use WebSphere Application Server extensions to implement their functionality to an extensible application, which defines an extension point. This is done through the application extension registry mechanism.

The architecture of extensible Java EE applications follow a modular design to add new functional modules or to replace an existing module, particularly by those outside of its core development team. Each module is a pluggable unit, or plug-in that is either deployed into the portal or removed from the Java EE application using a deployment tool that is based upon standard Java EE and portal web module deployment tooling. A plug-in module describes where it is extensible and what capability it provides to other plug-ins in the `plugin.xml` file. The `plugin.xml` manifest file can be created with a simple text editor or in Eclipse's Plug-in Development Environment (PDE), which provides a simplified view of the same underlying XML data.

WebSphere Application Server implementations to the Eclipse model

Some minor differences exist in the WebSphere Application Server implementation of this architecture because of platforms, specifically, Eclipse Workbench or Java 2 Platform, Enterprise Edition (Java EE). The highlights of the WebSphere Application Server implementation include:

- Implementing all of the extension registry-related interfaces from Eclipse 3.6 and later.
- The identical `plugin.xml` syntax, however, some attributes are not used, for example, <runtime>.
- The discovery and addition of plug-ins to the registry, when the containing Java EE module starts, and plug-ins are dismissed and removed from the registry when the containing Java EE module stops.
- Access to an IExtensionRegistry object is through the Java Naming and Directory Interface (JNDI), instead of by using the Platform.getExtensionRegistry method in the Eclipse Workbench.
- Filtering capability is available by providing a filter implementation and using a named registry instance that finds and invokes the filter as necessary. See the developer API documentation for the IExtensionRegistryFilter interface for more details.

Available Eclipse 3.6 interfaces

The following Eclipse 3.6 and later interfaces are available on WebSphere Application Server:

- Extension registry API
- Extension point API
- Extension API
- Configuration element API
- Registry change listener API
- Registry change event API
- Extension delta API
- Status API

The following interfaces are recognized and processed the same as in Eclipse:

- Executable extension API
- Executable extension factory API

Application extension registry filtering

The extension registry exposes the registry filter extension point. The registry filter removes elements within the extension registry for client applications. Extensions that are attached to the registry filter extension point and that also implement this interface are called as necessary when a client operates on a named registry instance that matches the target specification.

You can create a filter extension for all registry instances or for named instances that are specified by the extension. In the first case, the filter is applied to all instances of the extension registry, and all client applications use the filter without requesting the filter. In the latter case, a client application must predefine the registry name by defining an extension, called *RegistryInstance*, which is another extension point that is exposed by the extension registry. After the registry name is defined, the client can obtain the named registry instance and use that registry instance. The filter extension is invoked by the named registry instance as necessary.

Registry filter API

Supported arguments include:

`org.eclipse.core.runtime.IExtension[]`
doFilter(org.eclipse.core.runtime.IExtension[] extensions)

This code returns an array of IExtension objects that are included in the valid extension list.

Registry instance extension point

The extension registry exposes the *RegistryInstance* . The instance name is declared in the application's `plugin.xml` file, and the application requests an registry instance for that name at runtime.

plugin.xml file

A plug-in is described in an XML manifest file, called `plugin.xml`, which is part of the plug-in deployment files. The manifest file tells the portal application's runtime what it needs to know to register and activate the plug-in. The manifest file essentially serves as the contract between the pluggable component and the portal application's runtime. Although the WebSphere Application Server `plugin.xml` closely follows the one provided for the Eclipse workbench, it does diverge from the Eclipse workbench in several places as outlined below.

Location

The `plugin.xml` file must reside in the `WEB-INF` directory under the context of the hierarchy of directories that exist for a web application or when included in the Web application archive file.. The `plugin.xml` file must reside in the root directory when the`plugin.xml` file is placed in an Enterprise JavaBeans Java archive (JAR) file or shared library JAR file. The extension registry service includes the `plugin.xml` file as the participating components are loaded and started on the application server.

Usage notes

- Is this file read-only?

  No
- Is this file updated by a product component?

  ???
- If so, what triggers its update?

  Rational Application Developer updates the `web.xml` file when you assemble web components into a web module, or when you modify the properties of the web components or the web module.
- How and when are the contents of this file used?

  WebSphere Application Server functions use information in this file during the configuration and deployment phases of web application development.
- The manifest markup definitions below make use of various naming tokens and identifiers. To eliminate ambiguity, the following are productions rules for these naming conventions. In general, all identifiers are case-sensitive.

```
SimpleToken := sequence of characters from ('a-z','A-Z','0-9')
ComposedToken := SimpleToken | (SimpleToken '.' ComposedToken)
PlugInId := ComposedToken
PlugInPrereq := PlugInId
ExtensionId := SimpleToken
ExtensionPointId := SimpleToken
ExtensionPointReference := ExtensionPointId | (PlugInId '.' ExtensionPointId)
```

Sample file entry

The entire plug-in manifest DTD is as follows. XML Schema is not used to define the manifest since the current Eclipse tooling for plug-in's requires a DTD. The XML DTD construction rule element* means zero or more occurrences of the element; element? means zero or one occurrence of the element; and element+ means one or more occurrences of the element.

```
<?xml encoding="US-ASCII"?>

<!ELEMENT plugin (requires?, extension-point*, extension*)>
<!ATTLIST plugin
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  version CDATA #REQUIRED
  provider-name CDATA #IMPLIED
```

```
>
<!ELEMENT requires (import+)>

<!ATTLIST import
  plugin CDATA #REQUIRED
  version CDATA #IMPLIED
  match (exact | compatible | greaterOrEqual) #IMPLIED
>
<!ELEMENT extension-point EMPTY>
<!ATTLIST extension-point
  name CDATA #IMPLIED
  id CDATA #REQUIRED
  schema CDATA #IMPLIED
>
<!ELEMENT extension ANY>
<!ATTLIST extension
  point CDATA #REQUIRED
  id CDATA #IMPLIED
  name CDATA #IMPLIED
>
```

WebSphere Application Server differences

The `plugin.xml` file closely follows the `plugin.xml` file provided for the Eclipse workbench. However it diverges within the following elements.

The `plugin` element

The plugin element provided in this manifest does not contain class attributes. The class attribute is unnecessary since the plug-in mechanism does not require the plug-in developer to extend or use any specific classes as is required by the Eclipse workbench. Also, the plugin element does not contain a runtime element since standards such as J2EE that already define the location of runtime libraries for the applications.

The `import` element

The requires element does not contain export attribute since J2EE modules are encouraged to be self-contained to improve manageability. In addition to eliminating the export attribute, the match attribute has an option for a greater than or equal to match for versions (greaterOrEqual).

The `extension-point` element

The extension-point element has the name attribute as optional since it has no real use in this J2EE implementation.

you can find details regarding the plug-in manifest in the Eclipse documentation, under Platform Plug-In Developer Guide>Other reference information>Plug-in manifest.

The following is an example of how adding a link to an existing page can be accomplished by an extension point. The plug-in manifest of this plug-in declares an extension point (linkExtensionPoint) and an extension to this extension point (linkExtension). The plug-in declaring the extension point does not need to be the plug-in that implements the extension point. Another plug-in can also define an extension to the link extension point in its plug-in manifest by including the contents of the <extension> and </extension> tags in its manifest.

```
<?xml version="1.0"?>
<!--the plugin id is derived from the vendor domain name -->
<plugin
   id="com.ibm.ws.console.core"
   version="1.0.0"
   provider-name="IBM WebSphere">

  <!--declaration of prerequisite plugins-->
 <requires>
    <import plugin="com.ibm.data" version="2.0.1" match="compatible"/>
    <import plugin="com.ibm.resources" version="3.0" match="exact"/>
```

```
 </requires>

 <!--declaration of link extension point -->
 <extension-point
    id="linkExtensionPoint"
    schema="/schemas/linkSchema.xsd"/>

 <!--declaration of an extension to the link extension point -->
 <extension
    point="com.ibm.ws.console.core.linkExtensionPoint"
    id="linkExtension">

   <link
     label="Example.displayName"
     actionView="com.ibm.ws.console.servermanagement.forwardCmd.do?
        forwardName=example.config.view&
        lastPage=ApplicationServer.config.view">
   </link>
 </extension>
</plugin>
```

Contexts and Dependency Injection (CDI)

Learn about Contexts and Dependency Injection (CDI).

Developing applications that use Contexts and Dependency Injection (CDI)

Use this task to provide a summary of the WebSphere Application Server extensions that you can use to develop servlets.

About this task

Several WebSphere Application Server extensions are provided for enhancing your servlets. This task provides a summary of the extensions that you can use.

Procedure

1. Review the supported specifications.

   Create Java™ components, referring to the CDI specifications. Place a beans.xml file in the WEB-INF directory of the WAR module, or META-INF directory of a JAR file, so the container identifies it as a bean deployment archive.
2. Use your favorite integrated development environment (IDE), or a text editor, to develop or migrate code artifacts that meet the specifications.
3. Test the code artifacts.

What to do next

Assemble your code artifacts into a web module using assembly tools as a prerequisite to deploying the code to the application server.

Contexts and Dependency Injection (CDI)

Contexts and Dependency Injection for the Java EE platform (CDI) is a JSR 299 implementation that is based on Apache OpenWebBeans.

CDI is activated in an application by the presence of a beans.xml file inside that module, as defined by the JSR 299 specification. You can find the beans.xml file in the WEB-INF directory of a web archive (WAR) or META-INF directory of other types of archives. When activated, the container provides services such as:

- Context management
- Type-safe dependency injection: A CDI-managed bean is instantiated and injected as needed.

- Decorators, which implement one or more bean interfaces and can contain business logic. Decorators are disabled by default. You can have multiple decorators per bean and order is defined by the beans.xml file.
- Interceptor bindings. Interceptors, which are enabled manually in the beans.xml file, are bound using an interceptor binding type.
- Event model
- Integration into JavaServer Faces (JSF) and JavaServer Pages (JSP) files using the Expression Language (EL)

The specification-related API classes for JSR 299 and JSR 330 and IBM modified implementation classes that are based on Apache OpenWebBeans are packaged with the application server runtime environment.

Although the WebSphere Application Server CDI implementation is based on Apache OpenWebBeans, there are some changes and additions on top of OpenWebBeans to support integration with the server run time:

- Integration with other Java Platform, Enterprise Edition (Java EE) containers in WebSphere Application Server that support injectable components.
- ScannerService implementation that uses the WebSphere Application Server byte code scanner.
- Direct use of WebSphere Application Server Enterprise JavaBeans (EJB) metadata for determining EJB types.
- Automatic registration of Servlet Listeners, Filters, Interceptors for CDI applications so these no longer must be added by each application.
- WebSphere Application Server-specific implementations of many OpenWebBeans Service Programming Interfaces (SPI), such as ResourceInjectionService, TransactionService, failover service, and so on.

Important: Container-managed transactions and security are not provided by CDI.

Contexts and Dependency Injection custom properties:

WebSphere Application Server Contexts and Dependency Injection (CDI) implementation is based on OpenWebBeans, which is configurable through the openwebbeans.properties file.

To specify CDI custom properties, place the openwebbeans.properties file inside the META-INF/openwebbeans directory of your application. Properties that are not listed below, such as those that control the lifecycle and services, should remain at the default value for the application server. See the following list of some of the available CDI custom properties:

org.apache.webbeans.conversation.Conversation.periodicDelay:

Specifies a delay in milliseconds. Use the conversation periodic delay custom property to search for and delete unused conversations.

Value	Default
integer	15000

org.apache.webbeans.application.jsp:

Specifies that an application is a full JavaServer Pages (JSP) application. Specify true if you want to add the JSP ELResolver class to the application.

Value	Default
true	true

org.apache.webbeans.useOwbSpecificXmlConfig:

Specify true if you want to use OpenWebBeans-specific beans.xml files for the application. The default value is false, which is the portable specification beans.xml format.

Value	Default
true	false

org.apache.webbeans.fieldInjection.useOwbSpecificInjection:

Specify true if you want to use OpenWebBeans-specific injection for the application. The default value is false, which is the portable specification behavior.

Value	Default
true	false

org.apache.webbeans.application.useJSF2Extensions:

Specify true to enable JavaServerFaces (JSF) 2.0-based CDI extensions.

Value	Default
true	false

org.apache.webbeans.application.supportsConversation:

Specify true to support conversation scopes in the application.

Value	Default
true	true

CDI integration with JavaServer Faces:

Contexts and Dependency Injection (CDI) primarily integrates with JavaServer Faces (JSF) through the Expression Language (EL). It enables CDI beans to be exposed through the unified EL-to-JSF components. It also provides a built-in context for conversation scope that is active during standard JSF life cycle phases.

As part of the WebSphere Application Server integration with CDI containers, several JSF components are automatically registered for CDI applications, including:

- EL Resolver
- Phase Listener
- View Handler
- Application Factory

Only the default JSF implementation (based on MyFaces) is supported for use with CDI.

Contexts and Dependency Injection (CDI) integration with EJB container:

The CDI specification enhances the EJB component model with contextual life cycle management.

Relationship of the CDI to the EJB specification

The EJB specification defines a programming model for application components that access transactional resources in a multi-user environment. Concerns, such as role-based security, transaction demarcation, concurrency, and scalability are specified declaratively using annotations and XML deployment descriptors that are enforced by the EJB container at run time. EJB components might be stateful, but are not by nature, contextual.

The following session bean instances are obtained using dependency injection:

- Contextual
- Bound to a life cycle context
- Available to other instances that launch in that context
- Container creates an instance when needed
- Container destroys an instance when context ends

The WebSphere Application Server CDI container performs dependency injection on all session and message-driven bean instances, even instances that are not contextual instances. WebSphere Application Server CDI supports injection of CDI beans inside enterprise beans and vice versa.

Usage

Note: Use the following best practices when injecting enterprise beans:

- Use the @Inject method for contextual injection of local session beans.
- Use the @EJB method for remote session beans

See the following examples of using the @EJB method in CDI:

Define producers making the EJB available for non-contextual injection:

```
@Produces @EJB PaymentService paymentService;
```

Consume the injected types in other CDI beans:

```
@Inject PaymentService myPaymentService
```

Practical considerations

You can define CDI-style interceptors with interceptor bindings and decorators enterprise beans. Interceptors are declared using @Interceptors methods or in ejb-jar.xml files, which are called before interceptors and are declared using interceptor bindings. Interceptors are called before decorators.

WebSphere Application Server supports failover (activation and passivation) of CDI beans and enterprise beans, along with their interceptors and decorators. EJB failover support with CDI only works for stateful session beans and requires the same configuration as stateful session bean failover. See the stateful session bean failover for the EJB container topic for more information. Configure EJB failover with web HTTP session failover. See the “Configuring for database session persistence” and the “Configuring memory-to-memory replication for the peer-to-peer mode (default memory-to-memory replication)” topics for more information. Except for abstract decorators, failover services are based on currentWebSphere Application Server failover providers. Web session failover and EJB stateful session bean failover and configured separately.

When a contextual (@Injected) instance of an EJB container is destroyed as a result of going out of scope, and if the underlying EJB container was not already removed by direct invocation of a remove method by the application, the WebSphere Application Server CDI container removes the stateful session bean.

The WebSphere Application Server CDI container removes the stateful session bean when:

- You use the @Inject method to create a contextual injection instance and that instance in an EJB container is destroyed as a result of going out of scope.
- The underlying EJB container was not already removed by direct invocation of a remove method by the application.

You must also consider the scope and state propagation of CDI beans. The request and application scope CDI beans maintain state in their respective contexts across the web and EJB containers. For instance, a request-scoped CDI bean injected in a servlet holds its state when a business method on stateful session enterprise bean accesses the same request-scoped bean.

Developing RRD extensions

Servlet extension interfaces

You can use extension generators and handlers to add content to the remote message for servlet and portlets calls. The servlet extension can also modify existing behavior by leveraging the filter concept. The Remote Request Dispatcher (RRD) extension framework relies on extension generators, which attach arbitrary data to an outbound RRD request, and extension handlers, which consume the data and perform actions based on the data received. For more information on the `com.ibm.wsspi.rrd.extension` package, refer to the Additional Application Programming Interfaces (APIs) article for administrators.

Extension generators

Extension generators, which are part of an extension generator chain, are invoked prior to initiating an RRD request. This extension generator chain is defined in the com.ibm.wsspi.rrd.generators extension point of the `plugin.xml` file, which can reside in one of the following locations:

- Another OSGI Bundle.
- Any shared library. For example, a shared library bound to a server class loader.
- In the `WEB-INF` directory of an RRD-enabled local web application.

Each extension generator is defined by a generator element, which contains an id attribute, which is used to assign a unique identifier to the extension generator such that any extension generator can be targeted by extensions added to RRD response data. The class attribute is used to specify the class name of the extension generator, which must implement the `com.ibm.wsspi.rrd.extension.generator.ExtensionGenerator` interface. Each extension generator can also have an execution order associated with it via the order attribute, which is useful for enforcing extension generator execution order in an environment where multiple extension generator descriptor files are present. Additionally, a generator has a mandatory attribute called type that defines the type of the generator. For servlet RRD, the value is “servlet” and the class must implement the `com.ibm.wsspi.rrd.extension.generator.ExtensionGenerator` interface.

Additionally, each extension generator may be provided with an arbitrary number of initialization parameters, which are specified by including zero or more `init-param` elements as children of the generator element. An example extension generator declaration follows:

```
<extension point="com.ibm.wsspi.rrd.generators">
  <generator id="int1"
        class="com.ibm.ws.rrd.example.extension.IntExtensionGenerator"
        order="1"
        type="servlet">
    <init-param>
              <param-name>intValue</param-name>
              <param-value>100</param-value>
    </init-param>
   </generator>
   <generator id="string1"
        class="com.ibm.ws.rrd.example.extension.StringExtensionGenerator"
```

```
        order="2"
        type="servlet">
      <init-param>
              <param-name>stringValue</param-name>
              <param-value>This is an example string</param-value>
      </init-param>
   </generator>
   <generator id="int2"
        class="com.ibm.ws.rrd.example.extension.IntExtensionGenerator"
        order="3"
        type="servlet">
      <init-param>
              <param-name>intValue</param-name>
              <param-value>200</param-value>
      </init-param>
   </generator>
</extension>
```

For more information on the `com.ibm.wsspi.rrd.extension.generator` package, refer to the Additional Application Programming Interfaces (APIs) article for administrators.

Extension handlers

Extension handlers, which are part of an extension handler chain, are invoked after an RRD request has been received. This extension handler chain is defined in the `com.ibm.wsspi.rrd.handlers` extension point of the `plugin.xml` file, which can reside in one of the following locations:

- Another OSGI Bundle.
- Any shared library. For example, a shared library bound to a server class loader.
- In the `WEB-INF` directory of an RRD-enabled local web application.

Each extension handler is defined by a handler element, which contains namespaceURI and localName attributes, the combination of which defines the qualified name of the extension data that the extension handler can process. Each extension handler additionally requires a unique identifier, specified by the id attribute. The value specified by this attribute must correspond to an extension generator, which generates extension data of a matching qualified name and identifier. The class attribute is used to specify the class name of the extension handler, which must implement the com.ibm.wsspi.extension.handler.ExtensionHandler interface. Additionally a handler has a mandatory attribute called type that defines the type of the handler. The value is “servlet” and the class must implement the com.ibm.wsspi.rrd.extension.handler.ExtensionHandler interface.

Additionally, each extension handler may be provided with an arbitrary number of initialization parameters, which are specified by including zero or more `init-param` elements as children of the handler element. An example extension handler declaration follows:

```
  <extension point="com.ibm.wsspi.rrd.handlers">
      <handler id="int1"
               class="com.ibm.ws.rrd.example.extension.IntExtensionHandler"
               namespaceURI="http://www.ibm.com/ws/rrd/ext/types"
               localName="SimpleType" order="1"
               type="servlet"/>
      <handler id="string1"
               class="com.ibm.ws.rrd.example.extension.StringExtensionHandler"
               namespaceURI="http://www.ibm.com/ws/rrd/ext/types"
               localName="SimpleType" order="2"
               type="servlet"/>
      <handler id="int2"
               class="com.ibm.ws.rrd.example.extension.IntExtensionHandler"
               namespaceURI="http://www.ibm.com/ws/rrd/ext/types"
               localName="SimpleType" order="3"
               type="servlet"/>
</extension>
```

For more information on the com.ibm.wsspi.rrd.extension.handler package, refer to the Additional Application Programming Interfaces (APIs) article for administrators.

Extension delegators

An extension delegator enables RRD to handle arbitrary servlet containers by allowing users to specify the specific extension generator and handler chain instances that are to be used during an RRD call. RRD maintains a user-extendable list of extension delegators and selects an appropriate delegator at runtime based on the type of servlet request being issued.

Custom extension delegators may be defined in the com.ibm.wsspi.rrd.rrd-extension-delegator extension point of the plugin.xml file, which can reside in one of the following locations:

- Another OSGI Bundle.
- Any shared library. For example, a shared library bound to a server class loader.
- In the WEB-INF directory of an RRD-enabled local web application.

Each extension delegator is defined by an ExtensionDelegator element, which contains a priority attribute for defining the relative order in which an extension delegator is initiated, and a classname attribute that defines the implementing class for a particular extension delegator, which must implement the com.ibm.wsspi.rrd.extension.factory.ExtensionDelegator interface. Note that the execution order of two or more extension delegators with the same priority is not predictable. An example extension delegator declaration follows:

```
<extension point="com.ibm.wsspi.rrd.rrd-extension-delegator">
  <ExtensionDelegatorRegistration>
    <ExtensionDelegator priority="1" classname="com.ibm.ws.rrd.extension.PortletExtensionDelegator"/>
    <ExtensionDelegator priority="2" classname="com.ibm.ws.rrd.extension.ServletExtensionDelegator"/>
  </ExtensionDelegatorRegistration>
</extension>
```

Custom EMF packages

Extension data produced by an extension generator and consumed by an extension handler is serialized using the Eclipse Modeling Framework (EMF). Users intending to use custom extension data should utilize the com.ibm.wsspi.rrd.rrd-emf-packages extension point in order to ensure that the proper EMF packages are initialized prior to use by RRD. This extension point is part of the plugin.xml file, which can reside in one of the following locations:

- Another OSGI Bundle.
- Any shared library. For example, a shared library bound to a server class loader.
- In the WEB-INF directory of an RRD-enabled local web application.

Each EMF package is defined by an emfPackage element, which contains a className element that must point to the generated EMF factory implementation class for a particular EMF package (the generated model class which implements org.eclipse.emf.ecore.impl.EFactoryImpl). An example EMF package declaration follows:

```
<extension point="com.ibm.wsspi.rrd.rrd-emf-packages">
  <emfPackages>
    <emfPackage className="com.ibm.ws.rrd.webservices.types.emf.impl.TypesFactoryImpl" />
  </emfPackages>
</extension>
```

Note: If the same generated EMF model code is shared among multiple web applications that the EMF model code must be part of a shared server library, but only in the case that all web applications are running in the same application server. In production, this is usually not the case, and common EMF model code may exist at the web application level.

Developing servlet applications using asyncrhonous request dispatcher

Developing servlet applications using asynchronous request dispatcher

Web modules can dispatch requests concurrently on separate threads. Requests can be dispatched by the server or client.

Before you begin

For additional information about the AsyncRequestDispatcherConfig and the AsyncRequestDispatcher interfaces, review the com.ibm.websphere.webcontainer.async package in the application programming interfaces (API) documentation. The generated API documentation is available in the information center table of contents from the path Reference > APIs - Application Programming Interfaces.

Review the asynchronous request dispatcher application (ARD) design considerations topic before completing the following steps.

About this task

Concurrent dispatching can improve servlet response time. If operations are dependant on each other, do not enable asynchronous request dispatching, therefore, select Disabled. Concurrent dispatching might result in errors when operations are dependant. Select Server side to enable the server to aggregate requests dispatched concurrently. Select Client side to enable the client to aggregate requests dispatched concurrently.

Procedure

1. Logically separate resource intensive operations.
2. Develop servlets that use an asynchronous request dispatcher to include these operations.
3. Enable asynchronous request dispatching on an application server.
4. Deploy the application in an application server that has asynchronous request dispatching enabled.
5. Select an aggregation type for the application that needs ARD.
6. Optional: Configure the AsyncRequestDispatcherWorkManager work manager that is used for the request dispatch threads.
7. Restart the application server.

What to do next

Restart the modified applications if already installed or start newly installed applications to enable ARD on each application.

Assembling web applications

Assembling web applications

Assemble a web module to contain servlets, JavaServer Pages (JSP) files, and related code artifacts. (Group enterprise beans, client code, and resource adapter code in separate modules). After assembling a web module, you can install it as a stand-alone application or combine it with other modules into an enterprise application.

Before you begin

This topic assumes that you have created and unit tested Servlets and JavaServer Pages (JSP) files and other web components that you want to assemble in an enterprise application and deploy onto an application server.

About this task

Use an assembly tool to assemble a web module in any of the following ways:
- Import an existing web module (WAR file).
- Create a new web module.
- Copy code artifacts (such as servlets) from one web module into a new web module.

Although you can input various properties for web archives, available properties are specific to the Servlet, JSP, and Java Platform, Enterprise Edition (Java EE) specification level.

Procedure

1. Start an assembly tool.
2. If you have not done so already, configure the assembly tool for work on Java EE modules. Ensure that **J2EE** and **Web** capabilities are enabled.
3. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to an assembly tool. To migrate files, import your WAR files to the assembly tool.
4. Create a new web module.
5. Copy code artifacts (such as servlets) from one web module into a new web module.

Results

A web project is migrated or created. Files for the Web project are shown in the Project Explorer view under **Enterprise Applications** and **Web Projects**.

What to do next

You can now deploy your web project to an application server.

web.xml file

The `web.xml` file provides configuration and deployment information for the web components that comprise a web application.

The Java Servlet specification defines the `web.xml` deployment descriptor file in terms of an XML schema document. For backwards compatibility, any `web.xml` file that is written to Servlet 2.2 or above that worked in previous versions of WebSphere Application Server are supported by the web container.

If you use Rational Application Developer Version 6 to create your portlets, you must remove the following reference to the `std-portlet.tld` from the `web.xml` file:

```
<taglib id="PortletTLD">
  <taglib-uri>http://java.sun.com/portlet</taglib-uri>
  <taglib-location>/WEB-INF/tld/std-portlet.tld</taglib-location>
</taglib>
```

Location

The `web.xml` file must reside in the `WEB-INF` directory under the context of the hierarchy of directories that exist for a web application.

For example, if the application is `client.war`, then the `web.xml` file is placed in the *install_root*/*client war*/`WEB-INF` directory.

Usage notes

- Is this file read-only?

  No
- Is this file updated by a product component?

  This file is updated by the assembly tool.
- If so, what triggers its update?

  The assembly tool updates the `web.xml` file when you assemble web components into a web module, or when you modify the properties of the web components or the web module.
- How and when are the contents of this file used?

  WebSphere Application Server functions use information in this file during the configuration and deployment phases of web application development.

Sample file entry

Note: The web.xml file does not represent the entire configuration that is available for the web application. There are other servlets filters, and listeners that can be defined using programmatic configurations, annotations, and web fragments.

Note: Marking the web application metadata complete will prevent annotations and web fragments from being able to configure components.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_9" version="3.0" xmlns="http://java.sun.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
  http://java.sun.com/xml/ns/javaee/web-app_3_0.xsd">
 <display-name>Servlet 3.0 application</display-name>
 <filter>
    <filter-name>ServletMappedDoFilter_Filter</filter-name>
    <filter-class>tests.Filter.DoFilter_Filter</filter-class>
    <init-param>
      <param-name>attribute</param-name>
      <param-value>tests.Filter.DoFilter_Filter.SERVLET_MAPPED</param-value>
    </init-param>
  </filter>

  <servlet-class>tests.Filter.IncludedServlet</servlet-class>
 </servlet>
 <servlet>
  <servlet-name>ForwardedServlet</servlet-name>
  <servlet-class>tests.Filter.ForwardedServlet</servlet-class>
 </servlet>
 <servlet-mapping>
  <servlet-name>welcome</servlet-name>
  <url-pattern>/hello.welcome</url-pattern>
 </servlet-mapping>
 <servlet-mapping>
  <servlet-name>ServletErrorPage</servlet-name>
  <url-pattern>/ServletErrorPage</url-pattern>
 </servlet-mapping>
 <servlet-mapping>
  <servlet-name>IncludedServlet</servlet-name>
  <url-pattern>/IncludedServlet</url-pattern>
 </servlet-mapping>
 <servlet-mapping>
  <servlet-name>ForwardedServlet</servlet-name>
  <url-pattern>/ForwardedServlet</url-pattern>
 </servlet-mapping>
 <welcome-file-list>
  <welcome-file>hello.welcome</welcome-file>
 </welcome-file-list>
 <error-page>
  <exception-type>java.lang.ArrayIndexOutOfBoundsException</exception-type>
  <location>/ServletErrorPage</location>
 </error-page>
  <error-page>
   <error-code>404</error-code>
   <location>/error404.html</location>
  </error-page>
</web-app>
```

Note: For each <error-page> declaration, select either <exception-type> or <error-code>, but not both. The <location> tag is required.

File serving

In file serving, web applications can serve static file types, such as HTML. File-serving attributes are used by the servlet that implements file-serving behavior.

The file-serving behavior is implemented by setting the fileservingenabled property to true when configuring the web module.

Example attributes:

bufferSize

Sets buffer size that is used for serving static files.

extendedDocumentRoot

Enables you to configure an application with one or more directory paths from which you can serve static files and Java ServerPages (JSP) files. You can use this attribute when an application requires access to files that exist outside of the application web application archive (WAR) directory. For example, if several applications require access to a set of common files, you can place the common files in a directory to which you can link each application as an extended document root directory.

Use this attribute in addition to the contextRoot attribute.

You can also use this attribute to define a WebSphere variable on multiple nodes to the appropriate directory.

Example:

```
<fileServingEnabled="true">
<fileServingAttributes xmi:id="FileServingAttribute_1" name="extendedDocumentRoot"
   value="${MY_CUSTOM_VARIABLE}"/>
```

where *MY_CUSTOM_VARIABLE* is the WebSphere variable that you want to define on multiple nodes.

For more information, see JSP engine configuration parameters.

file.serving.patterns.allow
Specifies that only files matching the specified pattern are served.

file.serving.patterns.deny
Specifies that files that match the specified file pattern are denied

Configuring JavaServer Faces implementation

Configuring JavaServer Faces implementation

Use this task to specify which JavaServer Faces implementation to use. You can use Apache MyFaces 2.0 or the SUN Reference Implementation 1.2 of JSF, or your own implementation.

Before you begin

Ensure that your application is configured for JavaServer Faces (JSF) using the specific `web.xml` context parameters for the implementation that you have chosen.

Attention: The JSF implementation is a server-wide configuration setting. Thus, if you have multiple applications which require different JSF implementations, you must separate the applications into different application servers or clusters, and specify the implementation by following the steps in this topic for each application server or cluster. Alternatively, you can use an isolated shared library, as described for third-party JSF implementations, as follows.

About this task

Note: The Application Server JSF engine determines if the SUN Reference Implementation (RI) 1.2 or Apache MyFaces 2.0 is used from the Application Server run time. If either is used, the correct listener class is registered with the web container. You do not need to add the com.sun.faces.ConfigureListener or the org.apache.myfaces.StartupConfigureListener to your `web.xml` file.

Be Aware: If you want to use a third-party JSF implementation that is not shipped with the product, then:

- Keep the configuration set to MyFaces.
- Add the third-party listener to the `web.xml` file that is required.
- Add the third-party implementation Java archive (JAR) files to the application as an isolated shared library and associate it with your application.

You can also configure the JSF implementation on the Provide JSP reloading options for web modules panel for application installation and update wizards.

Procedure

Configure the server or cluster to use the JSF implementation that you want. You can do this task using the administrative console or the wsadmin tool.

- In the administrative console panel, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **JSP and JSF options**

Select one of the following implementations:

- Sun Reference Implementation 1.2 - Select this option to use the Sun Reference Implementation 1.2 JSF implementation.
- MyFaces 2.0 - Select this option to use the MyFaces 2.0 JSF implementation. This option is the default JSF implementation.

- Using the wsadmin tool:
  - An example of setting a single server to use the Sun RI 1.2 JSF implementation:

```
wsadmin>set server [$AdminConfig list ApplicationServer *server1*]
server1(cells/myNode01Cell/nodes/myNode01/servers/server1|server.xml#ApplicationServer_1183122130078)
wsadmin>$AdminConfig modify $server {{jsfProvider SunRi1.2}}

wsadmin>$AdminConfig save
```

  - An example of setting a cluster to use the MyFaces 2.0 JSF implementation:

```
wsadmin>set cluster [$AdminConfig list ServerCluster]
cluster1(cells/myNode01Cell/nodes/myNode01/clusters/cluster1|cluster.xml#ServerCluster_1173916133721)
wsadmin>$AdminConfig modify $cluster {{jsfProvider MyFaces}}

wsadmin>$AdminConfig save
```

Results

What to do next

Configure JSF engine parameters as necessary.

Developing session management in servlets

About this task

This information, combined with the coding example SessionSample.java, provides a programming model for implementing sessions in your own servlets.

Procedure

1. Get the HttpSession object.

   To obtain a session, use the getSession method of the javax.servlet.http.HttpServletRequest object in the Java Servlet 3.0 API.

   When you first obtain the HttpSession object, the Session Management facility uses one of three ways to establish tracking of the session: cookies, URL rewriting, or Secure Sockets Layer (SSL) information.

   Note: Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or modify the application to use URL rewriting

   Assume the Session Management facility uses cookies. In such a case, the Session Management facility creates a unique session ID and typically sends it back to the browser as a *cookie*. Each subsequent request from this user (at the same browser) passes the cookie containing the session ID, and the Session Management facility uses this ID to find the user's existing HttpSession object.

   In Step 1 of the code sample, the Boolean(create) is set to `true` so that the HttpSession object is created if it does not already exist. (With the Servlet 2.3 API and later, the javax.servlet.http.HttpServletRequest.getSession() method with no boolean defaults to `true` and creates a session if one does not already exist for this user.)

2. Store and retrieve user-defined data in the session.

   After a session is established, you can add and retrieve user-defined data to the session. The HttpSession object has methods similar to those in java.util.Dictionary for adding, retrieving, and removing arbitrary Java objects.

In Step 2 of the code sample, the servlet reads an integer object from the HttpSession, increments it, and writes it back. You can use any name to identify values in the HttpSession object. The code sample uses the name sessiontest.counter.

Because the HttpSession object is shared among servlets that the user might access, consider adopting a site-wide naming convention to avoid conflicts.

3. (Optional) Output an HTML response page containing data from the HttpSession object.
4. Provide feedback to the user that an action has taken place during the session. You may want to pass HTML code to the client browser indicating that an action has occurred. For example, in step 3 of the code sample, the servlet generates a web page that is returned to the user and displays the value of the sessiontest.counter each time the user visits that web page during the session.
5. (Optional) Notify Listeners. Objects stored in a session that implement the javax.servlet.http.HttpSessionBindingListener interface are notified when the session is preparing to end and become invalidated. This notice enables you to perform post-session processing, including permanently saving the data changes made during the session to a database.
6. End the session. You can end a session:
   - Automatically with the Session Management facility if a session is inactive for a specified time. The administrators provide a way to specify the amount of time after which to invalidate a session.
   - By coding the servlet to call the invalidate() method on the session object.

Example

```
import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class SessionSample  extends HttpServlet {
  public void doGet (HttpServletRequest request, HttpServletResponse response)
       throws ServletException, IOException {

   // Step 1: Get the Session object

      boolean create = true;
      HttpSession session = request.getSession(create);

   // Step 2: Get the session data value

      Integer ival = (Integer)
      session.getAttribute ("sessiontest.counter");
      if (ival == null) ival = new Integer (1);
      else ival = new Integer (ival.intValue () + 1);
      session.setAttribute ("sessiontest.counter", ival);

   // Step 3: Output the page

      response.setContentType("text/html");
      PrintWriter out = response.getWriter();
      out.println("<html>");
      out.println("<head><title>Session Tracking Test</title></head>");
      out.println("<body>");
      out.println("<h1>Session Tracking Test</h1>");
      out.println ("You have hit this page " + ival + " times" + "<br>");
      out.println ("Your " + request.getHeader("Cookie"));
      out.println("</body></html>");
   }
}
```

Assembling so that session data can be shared

By default, the session management facility supports session scoping by web module in accordance with the Servlet 2.3 and later API specification. Only servlets in the same web module can access the data associated with a particular session. However, you can use the IBMApplicationSession object or the IBM extension, shared session context, to share data outside of the web module scope.

About this task

The IBMApplicationSession object is a parent session object that can be retrieved by a web module's session and can share session attributes across all of the web modules in a business-level application. The default scope of the business-level application is the enterprise application. The shared session context option extends the scope of the session attributes as well. Using the shared session context extension, there is only one session object for the entire business-level application or for the default enterprise application.

If you are using a shared session for a business-level application, then the class files for all objects placed in the session must exist in an isolated shared library and be common among all applications.

The benefit to using the IBMApplicationSession method is that each web module can maintain its own session as well as have a reference to the shared session.

If you're migrating an application from a previous version of the product, the IBMApplicationSession method requires a change to the application logic of the application.

Restriction: To use a shared session, you must install all applications within a business-level application on a given server. You cannot split up the enterprise application by servers. For example, you cannot use this option when one enterprise application in "BLA1" is installed on one server and a second enterprise application also in "BLA1" is installed on a different server. In such split installations, applications might share session attributes across web modules using distributed sessions, but session data integrity is lost when concurrent access to a session is made in different web modules. It also severely restricts use of some session management features, like TIME_BASED_WRITES.

For enterprise applications on which this shared session context extension is enabled, the session management configuration on the web module inside the enterprise application is ignored. Then session management configuration defined on enterprise application is used if session management is overwritten at the enterprise application level. Otherwise, the session management configuration on the web container is used. If using multiple enterprise applications within a business-level application, the session management configuration must be common among all applications and web modules within this business-level application.

HttpSession listeners that are defined in all the web modules inside the business-level application or enterprise application are invoked for session events. The order of listener invocation is not guaranteed.

Complete the following to share session data across the business-level application.

Procedure

1. Complete the following to share session data using the IBMApplicationSession object within the application code.
   a. Retrieve the session object
      ```
      HttpSession session = request.getSession();
      ```
   b. Cast this object to an IBMSession object and call the getIBMApplicationSession method.
      ```
      IBMApplicationSession appSession = ((IBMSession)session).getIBMApplicationSession();
      ```
   c. Use the appSession like a normal session object.

2. Do the following to share session data using the Shared session context extension.
   a. Start an assembly tool.
   b. In the assembly tool, right-click the application (EAR file) that you want to share and click **Open With > Deployment Descriptor Editor**.
   c. In the application deployment descriptor editor of the assembly tool, select **Shared session context** under WebSphere Extensions. Make sure the class definition of attributes put into session are available to all web modules in the enterprise application. The shared session context does not fully meet the requirements of the specifications.
   d. Save the application (EAR) file. In the assembly tool, after you close the application deployment descriptor editor, confirm that you want to save changes made to the application.

Chapter 28. Developing web services

This page provides a starting point for finding information about web services.

Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a very flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

Using JAXB for XML data binding

Java Architecture for XML Binding (JAXB) is a Java technology that provides an easy and convenient way to map Java classes and XML schema for simplified web services development. JAXB provides the xjc schema compiler, the schemagen schema generator and a runtime framework to support marshalling and unmarshalling of XML documents to and from Java objects.

About this task

JAXB is an XML-to-Java binding technology that enables transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB technology consists of a runtime API and accompanying tools that simplify access to XML documents. You can use JAXB APIs and tools to establish mappings between Java classes and XML schema. An XML schema defines the data elements and structure of an XML document. JAXB technology provides tooling to enable you to convert your XML documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the XML data structure.

JAXB is the default data binding technology used by the Java API for XML Web Services (JAX-WS) tooling and implementation within this product. You can develop JAXB objects to use within your JAX-WS applications. You can also use JAXB independently of the JAX-WS programming model as a convenient way to leverage the XML data binding technology to manipulate XML within your Java applications.

JAXB is also the default data binding technology used by Service Component Architecture (SCA) applications. JAXB enables the SCA service implementation side and the SCA client reference side to interact with Java objects without worrying about how the data is transformed into and from XML.

Note: This version of the application server supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding. JAXB 2.2 provides minor enhancements to its annotations for improved schema generation and better integration with JAX-WS.

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

JAXB provides the **xjc** schema compiler tool, the **schemagen** schema generator tool, and a runtime framework. The **xjc** schema compiler tool enables you to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. You can also start with a set of JavaBeans and use the **schemagen** schema generator tool to create the XML schema. After using either the schema compiler or the schema generator command-line tools, you can convert your XML documents both to and from Java objects and use the resulting Java classes to assemble a web services application.

In addition to using the tools from the command-line, you can invoke these JAXB tools from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the **xjc** schema compiler tool. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the

Ant build environment to invoke the **schemagen** schema generator tool. These Ant tasks require that the com.ibm.jaxb.tools.jar and the com.ibm.jaxws.tools.jar files be in the classpath.

JAXB annotated classes and artifacts contain all the information that the JAXB runtime API needs to process XML instance documents. The JAXB runtime API enables marshaling of JAXB objects to XML files and unmarshaling the XML document back to JAXB class instances. The JAXB binding package, `javax.xml.bind`, defines the abstract classes and interfaces that are used directly with content classes. In addition the package defines the marshal and unmarshal APIs.

You can optionally use JAXB binding customizations to override the default generated type mappings. You can customize JAXB bindings using inline annotations in the source schema, or by using an external bindings customization file to pass your customizations to the JAXB binding compiler, xjc, to control the Java type mappings. Alternatively, you can add Java annotations to existing Java classes to pass to the schema generator, schemagen, to control the schema or XML type mappings. See the JAXB specification for information regarding binding customization options and Java annotations.

Using JAXB, you can manipulate data objects in the following ways:

Procedure

- Generate an XML schema from a Java class. Use the schema generator **schemagen** command to generate an XML schema from Java classes.
- Generate Java classes from an XML schema. Use the schema compiler **xjc** command to create a set of JAXB-annotated Java classes from an XML schema.
- Marshal and unmarshal XML documents. After the mapping between XML schema and Java classes exists, use the JAXB binding runtime to convert XML instance documents to and from Java objects.

Results

You now have JAXB objects that your Java application can use to manipulate XML data.

Using JAXB schemagen tooling to generate an XML schema file from a Java class

Use Java Architecture for XML Binding (JAXB) schemagen tooling to generate an XML schema file from Java classes.

Before you begin

Identify the Java classes or a set of Java objects to map to an XML schema file.

About this task

Use JAXB APIs and tools to establish mappings between Java classes and XML schema. XML schema documents describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

To develop web services using a bottom-up development approach starting from existing JavaBeans or enterprise beans, use the **wsgen** tool to generate the artifacts for Java API for XML-Based Web Services (JAX-WS) applications. After the Java artifacts for your application are generated, you can create an XML schema document from an existing Java application that represents the data elements of a Java application by using the JAXB schema generator, **schemagen** command-line tool. The JAXB schema generator processes either Java source files or class files. Java class annotations provide the capability to customize the default mappings from existing Java classes to the generated schema components. The

XML schema file along with the annotated Java class files contain all the necessary information that the JAXB runtime requires to parse the XML documents for marshaling and unmarshaling.

You can create an XML schema document from an existing Java application that represents the data elements of a Java application by using the JAXB schema generator, **schemagen** command-line tool. The JAXB schema generator processes either Java source files or class files. Java class annotations provide the capability to customize the default mappings from existing Java classes to the generated schema components. The XML schema file along with the annotated Java class files contain all the necessary information that the JAXB runtime requires to parse the XML documents for marshaling and unmarshaling.

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

Note: This product supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding.

JAXB provides compilation support to enable you to configure the **schemagen** schema generator so that it does not automatically generate a new schema. This is helpful if you are using a common schema such as the World Wide Web Consortium (W3C), XML Schema, Web Services Description Language (WSDL), or WS-Addressing and you do not want a new schema generated for a particular package that is referenced. The `location` attribute on the @XmlSchema annotation causes the schemagen generator to refer to the URI of the existing schema instead of generating a new one.

In addition to using the **schemagen** tool from the command-line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the Ant build environment to invoke the **schemagen** schema generator tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

Note: When running the **schemagen** tool, the schema generator does not correctly read the @XmlSchema annotations from the package-info class file to derive targetNamespaces. Instead of using the @XMLSchema annotation, use one of the following methods:

- Provide a package-info.java file with the @XmlSchema; for example:

```
schemagen sample.Address sample\package-info.java
```

- Use the @XmlType annotation namespace attribute to specify a namespace; for example:

```
@XmlType(namespace="http://myNameSpace")
```

Procedure

1. Locate the Java source files or Java class files to use in generating an XML schema file. Ensure that all classes referenced by your Java class files are contained in the classpath or are provided to the tool using the`-classpath/-cp` options.
2. Use the JAXB schema generator, **schemagen** command to generate an XML schema. The schema generator is located in the *app_server_root*\bin\ directory.

The parameters, `myObj1.java` and `myObj2.java`, are the names of the Java files containing the data objects. If `myObj1.java` or `myObj2.java` refer to Java classes that are not passed into the **schemagen** command, you must use the `-cp` option to provide the classpath location for these Java classes.Read about the **schemagen** command to learn more about this command and additional options that you can specify.

3. (Optional) Use JAXB program annotations defined in the `javax.xml.bind.annotations` package to customize the JAXB XML schema mappings.
4. (Optional) Configure the `location` property on the @XmlSchema annotation to indicate to the schema compiler to use an existing schema rather than generating a new one. For example,

```
@XmlSchema(namespace="foo")
package foo;
@XmlType
class Foo {
@XmlElement Bar zot;
}
@XmlSchema(namespace="bar",
location="http://example.org/test.xsd")
package bar;
@XmlType
class Bar {
...
}
<xs:schema targetNamespace="foo">
<xs:import namespace="bar"
schemaLocation="http://example.org/test.xsd"/>
<xs:complexType name="foo">
<xs:sequence>
<xs:element name="zot" type="bar:Bar" xmlns:bar="bar"/>
</xs:sequence>
</xs:complex
```

the `location="http://example.org/test.xsd"` indicates the location on the existing schema to the **schemagen** tool and a new schema is not generated.

Results

Now that you have generated an XML schema file from Java classes, you are ready to marshal and unmarshal the Java objects as XML instance documents.

Note: The schemagen command does not differentiate the XML namespace between multiple @XMLType annotations that have the same @XMLType name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates you have class names or @XMLType.name values that have the same name, but exist within different Java packages. To prevent this error, add the @XML.Type.namespace class to the existing @XMLType annotation to differentiate between the XML types.

Example

The following example illustrates how JAXB tooling can generate an XML schema file from an existing Java class, Bookdata.java.

1. Copy the following `Bookdata.java` file to a temporary directory.

```
package generated;

import javax.xml.bind.annotation.XmlAccessType;
import javax.xml.bind.annotation.XmlAccessorType;
import javax.xml.bind.annotation.XmlAttribute;
import javax.xml.bind.annotation.XmlElement;
import javax.xml.bind.annotation.XmlType;
import javax.xml.datatype.XMLGregorianCalendar;

@XmlAccessorType(XmlAccessType.FIELD)
@XmlType(name = "bookdata", propOrder = {
    "author",
```

```
    "title",
    "genre",
    "price",
    "publishDate",
    "description"
})
public class Bookdata {

    @XmlElement(required = true)
    protected String author;
    @XmlElement(required = true)
    protected String title;
    @XmlElement(required = true)
    protected String genre;
    protected float price;
    @XmlElement(name = "publish_date", required = true)
    protected XMLGregorianCalendar publishDate;
    @XmlElement(required = true)
    protected String description;
    @XmlAttribute
    protected String id;

     public String getAuthor() {
        return author;
    }
    public void setAuthor(String value) {
        this.author = value;
    }
    public String getTitle() {
        return title;
    }

     public void setTitle(String value) {
        this.title = value;
    }

    public String getGenre() {
        return genre;
    }

    public void setGenre(String value) {
        this.genre = value;
    }

    public float getPrice() {
        return price;
    }

    public void setPrice(float value) {
        this.price = value;
    }

    public XMLGregorianCalendar getPublishDate() {
        return publishDate;
    }

    public void setPublishDate(XMLGregorianCalendar value) {
        this.publishDate = value;
    }

    public String getDescription() {
        return description;
    }

    public void setDescription(String value) {
        this.description = value;
    }

    public String getId() {
        return id;
    }

    public void setId(String value) {
        this.id = value;
    }

}
```

2. Open a command prompt.

3. Run the schemagen schema generator tool from the directory where you copied the `Bookdata.java` file.
4. The XML schema file, `schema1.xsd` is generated:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<xs:schema version="1.0" xmlns:xs="http://www.w3.org/2001/XMLSchema">

  <xs:complexType name="bookdata">
    <xs:sequence>
      <xs:element name="author" type="xs:string"/>
      <xs:element name="title" type="xs:string"/>
      <xs:element name="genre" type="xs:string"/>
      <xs:element name="price" type="xs:float"/>
      <xs:element name="publish_date" type="xs:anySimpleType"/>
      <xs:element name="description" type="xs:string"/>
    </xs:sequence>
    <xs:attribute name="id" type="xs:string"/>
  </xs:complexType>
</xs:schema>
```

Refer to the JAXB Reference implementation documentation for additional information about the **schemagen** command.

Using JAXB xjc tooling to generate JAXB classes from an XML schema file

Use Java Architecture for XML Binding (JAXB) xjc tooling to compile an XML schema file into fully annotated Java classes.

Before you begin

Develop or obtain an XML schema file.

About this task

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. XML schemas describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

To develop web services using a top-down development approach starting with an existing Web Services Description Language (WSDL) file, use the **wsimport** tool to generate the artifacts for your Java API for XML-Based Web Services (JAX-WS) applications when starting with a WSDL file. After the Java artifacts for your application are generated, you can generate fully annotated Java classes from an XML schema file by using the JAXB schema compiler, **xjc** command-line tool. The resulting annotated Java classes contain all the necessary information that the JAXB runtime requires to parse the XML for marshaling and unmarshaling. You can use the resulting JAXB classes within Java API for XML Web Services (JAX-WS) applications or other Java applications for processing XML data.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

Note: This product supports the JAXB 2.2 specification. JAX-WS 2.2 requires JAXB 2.2 for data binding.

In addition to using the **xjc** tool from the command-line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the **xjc** schema compiler tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

Note: If you are using the **xjc** Ant task, you must use the `destdir` parameter to specify the destination directory instead of the `target` option. Specifying the `target` option when using the **xjc** Ant task causes an error.

Procedure

1. Use the JAXB schema compiler, **xjc** command to generate JAXB-annotated Java classes. The schema compiler is located in the *app_server_root*\bin\ directory. The schema compiler produces a set of packages containing Java source files and JAXB property files depending on the binding options used for compilation.
2. (Optional) Use custom binding declarations to change the default JAXB mappings. Define binding declarations either in the XML schema file or in a separate bindings file. You can pass custom binding files by using the **-b** option with the **xjc** command.
3. Compile the generated JAXB objects. To compile generated artifacts, add the Thin Client for JAX-WS with WebSphere Application Server to the classpath.

Results

Now that you have generated JAXB objects, you can write Java applications using the generated JAXB objects and manipulate the XML content through the generated JAXB classes.

Example

The following example illustrates how JAXB tooling can generate Java classes when starting with an existing XML schema file.

1. Copy the following `bookSchema.xsd` schema file to a temporary directory.

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
   <xsd:element name="CatalogData">
     <xsd:complexType >
       <xsd:sequence>
         <xsd:element name="books" type="bookdata" minOccurs="0"
    maxOccurs="unbounded"/>
       </xsd:sequence>
     </xsd:complexType>
   </xsd:element>
   <xsd:complexType name="bookdata">
     <xsd:sequence>
       <xsd:element name="author" type="xsd:string"/>
       <xsd:element name="title" type="xsd:string"/>
       <xsd:element name="genre" type="xsd:string"/>
       <xsd:element name="price" type="xsd:float"/>
       <xsd:element name="publish_date" type="xsd:dateTime"/>
       <xsd:element name="description" type="xsd:string"/>
     </xsd:sequence>
     <xsd:attribute name="id" type="xsd:string"/>
   </xsd:complexType>
 </xsd:schema>
```

2. Open a command prompt.
3. Run the JAXB schema compiler, **xjc** command from the directory where the schema file is located. The **xjc** schema compiler tool is located in the *app_server_root*\bin\ directory.

   Running the **xjc** command generates the following JAXB Java files:

```
generated\Bookdata.java
generated\CatalogdData.java
generated\ObjectFactory.java
```

4. Use the generated JAXB objects within a Java application to manipulate XML content through the generated JAXB classes.

Refer to the JAXB Reference implementation documentation for additional information about the **xjc** command.

Using the JAXB runtime to marshal and unmarshal XML documents

Use the Java Architecture for XML Binding (JAXB) run time to manipulate XML instance documents.

Before you begin

Use JAXB to generate Java classes from an XML schema with the schema compiler, **xjc** command or to generate an XML schema from a Java class with the schema generator, **schemagen** command.

About this task

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. After data bindings exist, use the JAXB binding runtime API to convert XML instance documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the data structure. JAXB annotated classes and artifacts contains all the information that the JAXB runtime API needs to process XML instance documents. The JAXB runtime API enables marshaling of JAXB objects to XML and unmarshaling the XML document back to JAXB class instances.

Procedure

- Marshal JAXB objects to XML instance documents.

  Use the JAXB runtime API to marshal or convert JAXB object instances into an XML instance document.

  1. Instantiate your JAXB classes.
  2. Invoke the JAXB marshaller.

  This example demonstrates how to instantiate the generated JAXB objects within an application and use the JAXBContext class and the JAXB runtime marshaller APIs to marshal the JAXB objects into XML instances.

```
JAXBContext jc = JAXBContext.newInstance("myPackageName");
//Create marshaller
Marshaller m = jc.createMarshaller();
//Marshal object into file.
m.marshal(myJAXBObject, myOutputStream);
```

  The JAXB Reference Implementation introduces additional vendor specific marshaller properties such as namespace prefix mapping, indentation, and character escaping control that are not defined by the JAXB specification. Use these properties to specify additional controls of the marshaling process. These properties operate with the JAXB Reference Implementation only and might not with other JAXB providers. Additional information regarding the vendor specific properties is located in the Java Architecture for XML Binding JAXB RI Vendor Extensions Runtime Properties specification.

- Unmarshal XML files to JAXB objects.

  Use the JAXB runtime API to unmarshal or convert an XML instance document to JAXB object instances.

  1. Obtain an existing XML instance document.
  2. Invoke the JAXB unmarshaller.

  This example demonstrates a program that reads an XML document and unmarshals or converts the XML document into JAXB object instances. Use the JAXBContext class and JAXB runtime Unmarshaller APIs to unmarshal the XML document.

```
JAXBContext jc = JAXBContext.newInstance("myPackageName");
//Create unmarshaller
Unmarshaller um = jc.createUnmarshaller();
//Unmarshal XML contents of the file myDoc.xml into your Java
  object instance.
MyJAXBObject myJAXBObject = (MyJAXBObject)
um.unmarshal(new java.io.FileInputStream( "myDoc.xml" ));
```

Results

You can now marshal JAXB Java classes, and unmarshal XML data using the JAXB binding framework. Refer to the JAXB Reference implementation documentation for additional information about the marshal and unmarshal runtime APIs

Note: If Java 2 Security is enabled, wrap your JAXBContext.newInstance(), Unmarshaller.unmarshal() and, Marshaller.marshal() method calls within a AccessController.doPrivileged method to avoid a security exception.

.

xjc command for JAXB applications

Use the Java Architecture for XML Binding (JAXB) tools to generate Java classes from an XML schema with the xjc schema compiler tool.

JAXB is an XML-to-Java binding technology that enables transformation between schema and Java objects and between XML instance documents and Java object instances. JAXB technology consists of a runtime API and accompanying tools that simplify access to XML documents. You can use JAXB APIs and tools to establish mappings between Java classes and XML schema. An XML schema defines the data elements and structure of an XML document. JAXB technology provides a runtime environment to enable you to convert your XML documents to and from Java objects. Data stored in an XML document is accessible without the need to understand the XML data structure.

You can generate fully annotated Java classes from an XML schema file by using the JAXB schema compiler, **xjc** command-line tool. Use the **xjc** schema compiler tool to start with an XML schema definition (XSD) to create a set of JavaBeans that map to the elements and types defined in the XSD schema. Once the mapping between XML schema and Java classes exists, XML instance documents can be converted to and from Java objects through the use of the JAXB binding runtime API. The resulting annotated Java classes contains all the necessary information that the JAXB runtime requires to parse the XML for marshaling and unmarshaling. You can use the resulting JAXB classes within Java API for XML Web Services (JAX-WS) applications or in your non-JAX-WS Java applications for processing XML data.

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

In addition to using the **xjc** tool from the command line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.xjc.XJCTask` Ant task from within the Ant build environment to invoke the **xjc** schema compiler tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

Note: If you are using the **xjc** Ant task, you must use the `destdir` parameter to specify the destination directory instead of the `target` option. Specifying the `target` option when using the **xjc** Ant task causes an error.

Syntax

The command-line syntax is:

If a directory is specified, all schema files in the directory are compiled.

Parameters

The `schema file/URL` JAR file name or location of the directory is the only parameter that is required. The following parameters are optional for the **xjc** command:

-b <file_name or directory>
Specifies the external JAX-WS or JAXB binding files. You can specify multiple JAX-WS and JAXB binding files by using the `-b` option; however, each file must be specified with its own `-b` option. If a directory is specified, `**/*.xjb` is searched.

-catalog <file_name>
Specifies the catalog file to resolve external entity references. It supports the TR9401, XCatalog, and the OASIS XML Catalog formats.

-classpath <path>
Specifies the location of the class files.

-d <directory>
Specifies where to place the generated output files.

-dtd
Specifies to treat the input as XML Document Type Definition (DTD). This option is unsupported and experimental.

-extension
Specifies whether to enable custom extensions for functionality not specified by the JAXB specification. Use of the extensions can result in applications that are not portable or do not interoperate with other implementations.

-help
Displays the help menu.

-httpproxy <[user[:password]@]<proxyhost>:<proxyport>>
Specifies an HTTP or HTTPs proxy.

-httpproxyfile <file_name>
This parameter is similar to the `-httpproxy` parameter, but takes the argument in a file to protect the password.

-no-header
Specifies to suppress the generation of a file header with a timestamp.

-npa
Specifies to suppress the generation of the `**/package-info.java` package level annotation.

-nv
Specifies to not perform a strict validation of the input schemas.

-p <package_name>
Specifies a target package.

-quiet
Specifies to suppress the output from the **xjc** tool.

-relaxng
Specifies to treat the input as REgular LAnguage for XML Next Generation (RELAX NG). This option is unsupported and experimental.

-readOnly
Specifies that the generated files are in read-only mode.

-relaxng-compact
Specifies to treat the input as REgular LAnguage for XML Next Generation (RELAX NG) compact syntax. This option is unsupported and experimental.

-target <version>
Specifies to generate output to conform to the specified level of the JAX-WS specification. Specify `2.0` or `2.1` for the tool to generate compliant code for the JAXB 2.0 or JAX-WS 2.1 specification respectively. Specify `2.1` for the tool to generate compliant code for the JAXB 2.1 specification. The default target version is `2.2` and generates compliant code for the JAXB 2.2 specification.

-verbose
Specifies to output messages about what the compiler is doing.

-version
Prints the version information. If you specify this option, only the version information is output and typical command processing does not occur.

-wsdl
Specifies to treat the input as a Web Services Description Language (WSDL) file and compile schemas inside the WSDL. This option is unsupported and experimental.

-xmlschema
Specifies to treat the input as a World Wide Web Consortium (W3C) XML schema. This value is the default.

schemagen command for JAXB applications

Use the schema generator tool, schemagen, to generate an XML schema using Java Architecture for XML Binding (JAXB).

Use JAXB APIs and tools to establish mappings between an XML schema and Java classes. XML schemas describe the data elements and relationships in an XML document. After a data mapping or binding exists, you can convert XML documents to and from Java objects. You can now access data stored in an XML document without the need to understand the data structure.

You can generate a schema file from Java classes using the **schemagen** schema generator tool to create the XML schema. After the mapping between XML schema and Java classes exists, XML instance documents can be converted to and from Java objects through the use of the JAXB binding runtime API. The resulting Java classes contain all the necessary information that the JAXB run time requires to parse the XML for marshaling and unmarshaling. You can use the JAXB classes within Java API for XML Web Services (JAX-WS) applications or in your non-JAX-WS Java applications for processing XML data.

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other

compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

Note: When running the **schemagen** tool to process JavaBeans, the schema generator will not automatically process the @XmlSchema annotations from existing package-info.class files to derive targetNamespaces. To assure that the **schemagen** tool processes namespace values correctly, use one of the following methods:

- Explicitly specify the package-info.java source file in the **schemagen** invocation; for example:

```
schemagen sample.Address sample\package-info.java
```

- Use the @XmlType annotation namespace attribute within your JavaBeans to specify a namespace; for example:

```
@XmlType(namespace="http://myNameSpace")
public class Address {...}
```

In addition to using the **schemagen** tool from the command line, you can invoke this JAXB tool from within the Ant build environments. Use the `com.sun.tools.jxc.SchemaGenTask` Ant task from within the Ant build environment to invoke the **schemagen** schema generator tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

Syntax

The command-line syntax is:

Parameters

The following parameters are optional for the **schemagen** command:

-classpath <path>
Specifies the location of the Java source or class files.

-cp <path>
Specifies the location of the Java source or class files.

-d <path>
Specifies where to place the processor and the generated Java class files.

-episode<file_name>
Specifies to generate an episode file for separate compilation.

-encoding <encoding>
Specifies to use encoding when invoking the -apt or -javac tool. This property is applicable for JAXB 2.2 and later.

-help
Displays the help menu.

-version
Prints the version information. If you specify this option, only the version information is output and typical command processing does not occur.

Developing JAX-WS web services (bottom-up)

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

1. Set up the environment.
   Run the **setupCmdLine** script from the */profile_root/<application_server>/bin* directory.
2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:

```
set PATH=%WAS_PATH%;%PATH%
```

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Developing JAX-WS web services with annotations

Java API for XML-Based Web Services (JAX-WS) supports two different service endpoint implementations types, the standard web service endpoint interface and a new Provider interface to enable services to work at the XML message level. By using annotations on the service endpoint implementation or client, you can define the service endpoint as a web service.

Before you begin

Set up a development environment for web services.

About this task

This task is a required step to develop JAX-WS web services.

JAX-WS technology supports the implementation of web services based on both the standard service endpoint interface and a new Provider interface. JAX-WS endpoints are like the endpoint implementations in the Java API for XML-based RPC (JAX-RPC) specification. Unlike JAX-RPC, the requirement for a service endpoint interface (SEI) is optional for JAX-WS web services. JAX-WS services that do not have an associated SEI are regarded as having an implicit SEI; whereas services that have an associated SEI are regarded as having an explicit SEI. The service endpoint interfaces required by JAX-WS are also more

generic than the service endpoint interfaces required by JAX-RPC. With JAX-WS, the SEI is not required to extend the `java.rmi.Remote` interface as required by the JAX-RPC specification.

The JAX-WS programming model also uses support for annotating Java classes with metadata to define a service endpoint implementation as a web service and define how a client can access the web service. JAX-WS supports annotations based on the Metadata Facility for the Java Programming Language (JSR 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 (JSR 224) specification, which includes Java Architecture for XML Binding (JAXB) annotations. Using annotations, the service endpoint implementation can independently describe the web service without requiring a WSDL file. Annotations can provide all the WSDL information necessary to configure your service endpoint implementation or web services client. You can specify annotations on the service endpoint interface used by the client and the server, or on the server-side service implementation class.

For details regarding the supported standards and specifications, see the web services specifications and API documentation.

When developing a JAX-WS web service starting from existing Java classes, known as the bottom-up approach, you must annotate the class with either the `@WebService` (`javax.jws.WebService`) annotation or `@WebServiceProvider` (`javax.xml.ws.Provider`) annotation to initially define the class as a web service. The `@WebService` annotation defines the service as an SEI-based endpoint, while the `@WebServiceProvider` annotation defines the service as a Provider-based endpoint.

Develop SEI-based JAX-WS web services

For an SEI-based endpoint, the service endpoint interface (SEI), whether it is a Java class or a Java interface, declares the business methods provided by a particular web service. The only methods that a web services client can invoke on a JAX-WS endpoint are the business methods that are defined in the explicit or implicit SEI.

All SEI-based endpoints are required to have the `@WebService` annotation included on the implementation class. If the service implementation uses an explicit SEI, then that interface must be referenced by the `endpointInterface` attribute on the `@WebService` annotation. If the service implementation does not use an explicit SEI, then the service is described implicitly by the implementation class and is an implicit SEI.

Develop JAX-WS web services using the Provider interface

The JAX-WS programming model introduces the Provider interface for Provider endpoints, `javax.xml.ws.Provider`, as the dynamic alternative to SEI-based endpoints. The Provider interface supports a more messaging-oriented approach to web services. With the Provider interface, you can create a Java class that implements a simple interface to produce a generic service implementation class. The Provider interface defines one method, the `invoke` method, which uses generics to control both the input and output types when working with various messages or message payloads. All Provider endpoints must be annotated with the `@WebServiceProvider` (`javax.xml.ws.WebServiceProvider`) annotation. A service implementation cannot specify the `@WebService` annotation if it implements the `javax.xml.ws.Provider` interface.

Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations. In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre-Java EE 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatability with the feature pack from previous releases, you must configure

either the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a web application archive (WAR) file or EJB module or define the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations information.

Procedure

1. Determine if you want to define your web services using SEI endpoints or the Provider interface. If you prefer a high-level Java-centric abstraction that hide the details of converting between Java objects and their XML representation, consider using SEI-based endpoints to develop your web services. However, if you prefer that your web service operate more at the XML message level, consider using Provider-based endpoints.
2. Annotate the service endpoints.
   a. Annotate the SEI-based endpoint with the `javax.jws.WebService` annotation.
      - For an SEI-based endpoint, annotate the implementation class with the `javax.jws.WebService` annotation. You can choose to explicitly reference a service endpoint interface by defining the `@WebService.endpointInterface` attribute, which specifies this endpoint is an explicit SEI. In this case, the Java interface that is referenced must also contain the `javax.jws.WebService` annotation. If the `endpointInterface` attribute is not defined or is empty, the implementation bean is considered an implicit SEI. You can add the `@WebMethod` annotation to methods of a service endpoint interface to customize the Java-to-WSDL mappings. All public methods are considered exposed methods regardless of whether the `@WebMethod` annotation is specified. It is incorrect to have an `@WebMethod` annotation on a service endpoint interface that contains the `exclude` attribute.
      - If you use an implicit SEI, you can apply more granular control on how the methods are exposed through selective use of the `@WebMethod` annotation. For a more detailed explanation, see the exposing methods in SEI-based JAX-WS web services information.
   b. Annotate the Provider-based endpoint with the `javax.xml.ws.WebServiceProvider` annotation.
      - For a Provider-based endpoint, annotate the implementation class with the `javax.xml.ws.WebServiceProvider` annotation. This annotation must be specified only on a class that implements a strongly typed `javax.xml.ws.Provider.interface` class such as `Provider<Source>` or `Provider<SOAPMessage>`, in contrast to a class that is unbounded, such as `Provider<T>`. A strongly typed class is one that is associated with a specific input and output Java type, such as `Source` or `SOAPMessage`, for example.

```
@WebServiceProvider(
        serviceName="StringProviderService",
        wsdlLocation="META-INF/echostring.wsdl",
        targetNamespace="http://stringprovider.sample.test.org")
```

      - (optional) According the JAX-WS 2.2 specification, if you are defining a Provider-based endpoint so that the Provider implementation returns a null value, no response is needed. If the `javax.xml.ws.WebServiceProvider` annotation does not specify a WSDL, and the Provider `invoke()` method returns a null value, the default behavior of the JAX-WS runtime environment is to return a response that consists of a `SOAPEnvelope` that contains an empty `SOAPBody`. You can set the JVM property, `jaxws.provider.interpretNullAsOneway`, to `true` if you want the JAX-WS runtime environment to interpret this scenario as a request-only operation and not return a response.
3. Understand and apply best practices for exposing methods as operations in SEI-based JAX-WS web services.

   Because of ambiguity across multiple web services specifications regarding which methods are exposed as web services operations for SEI-based endpoints, you can ensure consistent behavior by following best practices, regardless of the JAX-WS implementation that you use.

Results

You have defined the service endpoint implementation that represents the web services application. See the JAX-WS annotations documentation to learn more about the supported JAX-WS annotations.

Sample JavaBeans service endpoint implementation and interface

The following example illustrates a simple explicit JavaBeans service endpoint implementation and the associated service endpoint interface:

```
/** This is an excerpt from the service implementation file, EchoServicePortTypeImpl.java.
package com.ibm.was.wssample.echo;
import java.io.ByteArrayInputStream;
import java.io.ByteArrayOutputStream;

import javax.xml.bind.JAXBContext;
import javax.xml.bind.Marshaller;
import javax.xml.bind.Unmarshaller;
import javax.xml.transform.stream.StreamSource;

@javax.jws.WebService(serviceName = "EchoService", endpointInterface =
"com.ibm.was.wssample.echo.EchoServicePortType", targetNamespace="http://com/ibm/was/wssample/echo/",
portName="EchoServicePort")
public class EchoServicePortTypeImpl implements EchoServicePortType {

                public EchoServicePortTypeImpl() {
                }

                public String echo(String obj) {
                        String str;
                        ....
                        str = obj;
                        ....

                        return str;

                }

}
/**  This is a sample EchoServicePortType.java service interface. */

import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.xml.ws.*;

@WebService(name = "EchoServicePortType", targetNamespace = "http://com/ibm/was/wssample/echo/",
wsdlLocation="WEB-INF/wsdl/Echo.wsdl")
public interface EchoServicePortType {

    /** ...the method process ...*/
        @WebMethod

}
```

The following example illustrates a simple Provider service endpoint interface for a Java class:

```
package jaxws.provider.source;

import javax.xml.ws.Provider;
import javax.xml.ws.WebServiceProvider;
import javax.xml.transform.Source;

@WebServiceProvider()
public class SourceProvider implements Provider<Source> {

    public Source echo(Source data) {
        return data;
    }
}
```

In the Provider implementation example, the `javax.xml.transform.Source` type is specified in the generic `<Source>` method. The generic `<Source>` method specifies that both the input and output types are `Source` objects.

What to do next

Develop Java artifacts for JAX-WS applications from JavaBeans. To learn more, see the generating Java artifacts for JAX-WS applications information.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root
: Refers to the top directory for a WebSphere Application Server node.

  The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

  The default varies based on node type. Common defaults are *configuration_root*`/AppServer` and *configuration_root*`/DeploymentManager`.

configuration_root
: Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

  The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

  The default is `/wasv8config/`*cell_name*`/`*node_name*.

plug-ins_root
: Refers to the installation root directory for Web Server Plug-ins.

profile_root
: Refers to the home directory for a particular instantiated WebSphere Application Server profile.

  Corresponding product variables are *server.root* and *user.install.root.*

  In general, this is the same as *app_server_root*`/profiles/`*profile_name*. On z/OS, this will always be *app_server_root*`/profiles/default` because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root
: Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

  The corresponding product variable is *smpe.install.root*.

  The default is `/usr/lpp/zWebSphere/V8R5`.

Exposing methods in SEI-based JAX-WS web services

You can use the @WebService and @WebMethod annotations on a service endpoint implementation to specify Java methods that you want to expose as Java API for XML-Based Web Services (JAX-WS) web services.

Before you begin

JAX-WS technology enables the implementation of web services based on both the standard service endpoint interface and a Provider interface. When developing a JAX-WS web service starting from existing

Java classes, known as the bottom-up approach, you must annotate the class with either the @WebService or @WebServiceProvider annotation to initially define the class as a web service.

Using the Provider interface is the dynamic approach to defining your JAX-WS services. To use the Provider interface, your class must implement the javax.xml.ws.Provider interface, and contain the @WebServiceProvider annotation. The Provider interface has one method, the invoke method, which uses generics in the Java programming language to control both the input and output types when working with various messages or message payloads.

In contrast, this topic describes how you can use Java annotations to describe your web services using the service endpoint interface (SEI) approach.

About this task

To initially define a web service, annotate the Java class with the @WebService annotation. You can also selectively annotate individual methods with the @WebMethod annotation to control their exposure as web services operations.

Because of ambiguities across multiple web services specifications regarding how methods are exposed as operations, use the following guidelines to help ensure consistent behavior regardless of the JAX-WS implementation that you use.

- To define a basic web service, annotate the implementation class with the @WebService annotation.
- To define your web services using an explicit SEI, explicitly reference a Java interface class using the endpointInterface attribute of the @WebService annotation.
- Provide a reference to a WSDL file in the wsdlLocation attribute of the @WebService annotation. By specifying a pre-defined WSDL file, performance is improved. Also, discrepancies between the WSDL file and the annotations are reported to you by the runtime environment.
- When you use an explicit SEI, all public methods in the SEI and inherited classes are always exposed. You only need to add @WebMethod annotations if you want to further customize the methods that are already exposed.
- Providing a reference in the @WebService annotation to an explicit SEI or to an existing WSDL file helps to remove possible ambiguities when exposing methods.
- If you do not use an explicit SEI, follow these rules to ensure that your methods are exposed consistently:
  - Add an @WebService annotation to your implementation class and all its superclasses that contain methods that you want to expose. Adding an @WebService annotation to a class exposes all public methods in that class that are not static or final.
  - If you want more granular control to expose only certain methods, use the @WebMethod annotation on selected methods. To ensure that a method is exposed, annotate it with the @WebMethod annotation. If you want to make sure that a method is not exposed, annotate it with the @WebMethod(exclude=true) annotation.

Note:

Behavior change for exposing methods that are not annotated:

The behavior of JAX-WS has changed regarding exposing methods as web services operations. This complies with recent clarifications to JAX-WS specifications.

Applications without an explicit SEI or WSDL that are migrated from prior versions might have additional operations exposed as shown below. You can set a property so the JAX-WS runtime environment uses the legacy behavior. You might need this when migrating applications without a WSDL or an SEI so that additional methods are not exposed.

```
@WebService
public class Foo {
 @WebMethod
 public void a() {} // exposed now, exposed before
 public void b() {} // exposed now, not exposed before
}
```

Using the new interpretation, public methods in an implementation class and its superclasses are only exposed under the following conditions:

- The containing class has an @WebService annotation.
- The method does not have an @WebMethod(exclude=true) annotation.

Using the legacy interpretation, a method in an implementation class and its superclasses are only exposed under the following conditions:

- The containing class has an @WebService annotation.
- The method has no @WebMethod annotations AND no other methods have @WebMethod annotations.
- The method has an @WebMethod or @WebMethod(exclude=false) annotation.

To specify that the JAX-WS runtime environment use the legacy @WebMethod behavior, configure the `jaxws.runtime.legacyWebMethod=true` property. You can configure this property as a Java Virtual Machine (JVM) system property or as a property in the `META-INF/MANIFEST.MF` file of a web application archive (WAR) file. By default, this property is set to `false` and the application server uses the new behavior.

You might encounter a WSWS7054E error message if all of the following conditions are true:

- Your web service application consists of unannotated methods.
- The methods are not meant to be mapped to a web service operation.
- Your application does not reference an SEI nor package a WSDL file.

The error message contains information that is similar to the following text:

```
javax.xml.ws.WebServiceException: WSWS7054E:
 The Web Services Description Language (WSDL) file could not be generated for the XXXX Web service implementation
 class because of the following error: javax.xml.ws.WebServiceException: Unable to create JAXBContext
```

The JAX-WS tooling complies with the JAX-WS specification with respect to @WebMethod mapping principles. This change might affect applications that have been dependent on previously non-compliant default behavior. If your applications package and reference WSDL or an SEI and have ALL methods correctly annotated with the @WebMethod exclude flag in the SEI implementation, then this change does not affect you. However, if you are affected, add explicit annotations to your methods to ensure that they are excluded in WSDL generation. For example: @WebMethod(exclude=true) Also, you can package a WSDL with your application to eliminate the need for the run time to generate a WSDL on your behalf.

Behavior change for exposing static and final methods:

Static or final methods in a service without an explicit SEI are no longer exposed as web services operations. To expose them, package the WSDL with the application and set `jaxws.runtime.legacyWebMethod=true`.

Procedure

1. Identify the methods that you want to expose as web services operations.
2. Review the rules for exposing methods as operations on classes annotated with the @WebService annotation.
3. Use the best practices for applying the @WebMethod and @WebService annotations in applications without SEIs to appropriately expose methods as operations within your web services.

Results

You have used the @WebMethod annotation to specify which methods to expose as web services operations.

Note:

If you have upgraded your application server environment and you are experiencing problems, review the following troubleshooting information.

Client errors indicate a mismatch between the WSDL file and portType when using a JAX-WS tooling version 2.1.6 or higher environment

You might receive a client-side error message like the following message:

```
javax.xml.ws.WebServiceException: The Endpoint validation failed to validate due to the following errors:
:: Invalid Endpoint Interface ::
:: The number of operations in the WSDL portType does not match the number of methods in the SEI or web service
 implementation class.  wsdl operations = [...] dispatch operations = [....]
```

To correct this problem, you must regenerate client artifacts to match the WSDL file.

Note: Be sure to regenerate your client side artifacts any time you receive an updated WSDL file.

Clients that perform a ?WSDL operation on web services have non-dispatchable operations

After performing a ?WSDL operation, you might receive a WSDL file that contains more operations than the JAX-WS runtime environment can dispatch. If the client tries to invoke any of the non-dispatchable operations, the client receives an error like the following message:

```
The endpoint reference (EPR) for the Operation not found is http://localhost:9086/example/BeanImpl2Service and the WSA
Action = <WSA_action_from_server>. If this EPR was previously reachable, contact the server administrator.
```

Clients must only access the operations that the web service intends to expose. You can correct this problem in one of the following ways:

- Modify the @WebMethod annotations in the web services application so that the resulting WSDL file exposes the correct set of operations.
- Set the `jaxws.runtime.legacyWebMethod` property to `false` to ensure that all operations in the WSDL are dispatched.

What to do next

Develop Java artifacts for JAX-WS applications from JavaBeans.

JAX-WS annotations

Java API for XML-Based Web Services (JAX-WS) relies on the use of annotations to specify metadata associated with web services implementations and to simplify the development of web services. Annotations describe how a server-side service implementation is accessed as a web service or how a client-side Java class accesses web services.

The JAX-WS programming standard introduces support for annotating Java classes with metadata that is used to define a service endpoint application as a web service and how a client can access the web service. JAX-WS supports the use of annotations based on the Metadata Facility for the Java Programming Language (Java Specification Request (JSR) 175) specification, the Web Services Metadata for the Java Platform (JSR 181) specification and annotations defined by the JAX-WS 2.0 and later (JSR 224) specification which includes JAXB annotations. Using annotations from the JSR 181 standard, you can simply annotate the service implementation class or the service interface and now the application is enabled as a web service. Using annotations within the Java source simplifies development and

deployment of web services by defining some of the additional information that is typically obtained from deployment descriptor files, WSDL files, or mapping metadata from XML and WSDL into the source artifacts.

Use annotations to configure bindings, handler chains, set names of portType, service and other WSDL parameters. Annotations are used in mapping Java to WSDL and schema, and at runtime to control how the JAX-WS runtime processes and responds to web service invocations.

For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (Web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations.

In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre- Java Platform, Enterprise Edition (Java EE) 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatability with the feature pack from previous releases, you must configure one of the following properties:

- You can set the `UseWSFEP61ScanPolicy` property in the META-INF/MANIFEST.MF of a WAR file or EJB module to `true`. For example:

```
Manifest-Version: 1.0
UseWSFEP61ScanPolicy: true
```

  When this property is set to `true` in the META-INF/MANIFEST.MF file of the module, the module is scanned for JAX-WS annotations regardless of the Java EE version of the module. The default value is `false` and when the default value is in effect, JAX-WS annotations are only supported in modules whose version is Java EE 5 or later.
- You can set the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` custom Java virtual machine (JVM) property using the administrative console. See the JVM custom properties documentation for the correct navigation path to use. To request annotation scanning in all modules regardless of their Java EE version, set the custom property `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` to `true`. You must change the setting on each server that requires a change in the default behavior.

If the property is set within the META-INF/MANIFEST.MF file of the module, this setting takes precedence over the server's custom JVM property. When using either property, you must establish the desired annotation scanning behavior before the application is installed. You cannot dynamically change the scanning behavior once an application is installed. If changes to the behavior are required after your application is installed, you must first uninstall the application, specify the desired scanning behavior using the appropriate property and then install the application again. When federating nodes that have the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` set to `true` in the configuration of the servers contained within the node, this property does not affect the deployment manager. You must set the property to `true` on the deployment manager before the node is federated to preserve the behavior as it was on the node before federation.

Note: If this JVM property is being used on the z/OS platform, it must be set in both the servant and control regions of the server.

Note: When federating nodes that have the `com.ibm.websphere.webservices.UseWSFEP61ScanPolicy` set to `true` in the configuration of the servers contained within the node, this does not affect the deployment manager. You must set the property to `true` on the deployment manager before the node is federated if you wish to preserve the behavior as it was on the node before federation.

Annotations supported by JAX-WS are listed in the table below. The target for annotations is applicable for these Java objects:

- types such as a Java class, enum or interface
- methods
- fields representing local instance variables within a Java class
- parameters within a Java method

Table 125. Web services Metadata Annotations (JSR 181). Describes the supported web services metadata annotations and their associated properties.

Annotation class	Annotation	Properties
`javax.jws. WebService`	The **@WebService** annotation marks a Java class as implementing a Web service or marks a service endpoint interface (SEI) as implementing a web service interface. **Important:** • A Java class that implements a web service must specify either the @WebService or @WebServiceProvider annotation. Both annotations cannot be present. This annotation is applicable on a client or server SEI or a server endpoint implementation class. • If the annotation references an SEI through the `endpointInterface` attribute, the SEI must also be annotated with the @WebService annotation. • See the exposing methods in SEI-based JAX-WS web services information to learn about best practices for using the @WebService and @WebMethod annotations on a service endpoint implementation to specify Java methods that you want to expose as JAX-WS web services.	• Annotation target: Type • Properties: - **`name`** The name of the `wsdl:portType`. The default value is the unqualified name of the Java class or interface. (String) - **`targetNamespace`** Specifies the XML namespace of the WSDL and XML elements generated from the web service. The default value is the namespace mapped from the package name containing the web service. (String) - **`serviceName`** Specifies the service name of the web service: `wsdl:service`. The default value is the simple name of the Java class + *Service*. (String) - **`endpointInterface`** Specifies the qualified name of the service endpoint interface that defines the services' abstract web service contract. If specified, the service endpoint interface is used to determine the abstract WSDL contract. (String) - **`portName`** The `wsdl:portName`. The default value is WebService.name +*Port* . (String) - **`wsdlLocation`** Specifies the web address of the WSDL document defining the web service. The web address is either relative or absolute. (String)
`javax.jws. WebMethod`	The **@WebMethod** annotation denotes a method that is a web service operation. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: - **`operationName`** Specifies the name of the `wsdl:operation` matching this method. The default value is the name of Java method. (String) - **`action`** Defines the action for this operation. For SOAP bindings, this value determines the value of the SOAPAction header. The default value is the name of Java method. (String) - **`exclude`** Specifies whether to exclude a method from the web service. The default value is `false`. (Boolean)

Table 125. Web services Metadata Annotations (JSR 181) (continued). Describes the supported web services metadata annotations and their associated properties.

Annotation class	Annotation	Properties
`javax.jws. Oneway`	The **@Oneway** annotation denotes a method as a web service one-way operation that only has an input message and no output message. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • There are no properties on the Oneway annotation.
`javax.jws. WebParam`	The **@WebParam** annotation customizes the mapping of an individual parameter to a web service message part and XML element. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Parameter • Properties: **- name** The name of the parameter. If the operation is remote procedure call (RPC) style and the `partName` attribute is not specified, then this is the name of the `wsdl:part` attribute representing the parameter. If the operation is document style or the parameter maps to a header, then `-name` is the local name of the XML element representing the parameter. This attribute is required if the operation is document style, the parameter style is `BARE`, and the mode is `OUT` or `INOUT`. (String) **- partName** Defines the name of `wsdl:part` attribute representing this parameter. This is only used if the operation is RPC style, or the operation is document style and the parameter style is `BARE`. (String) **- targetNamespace** Specifies the XML namespace of the XML element for the parameter. Applies only for document bindings when the attribute maps to an XML element. The default value is the `targetNamespace` for the web service. (String) **- mode** The value represents the direction the parameter flows for this method. Valid values are `IN`, `INOUT`, and `OUT`. (String) **- header** Specifies whether the parameter is in a message header rather than a message body. The default value is `false`. (Boolean)

Table 125. Web services Metadata Annotations (JSR 181) (continued). Describes the supported web services metadata annotations and their associated properties.

Annotation class	Annotation	Properties
`javax.jws. WebResult`	The **@WebResult** annotation customizes the mapping of a return value to a WSDL part or XML element. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: **- name** Specifies the name of the return value as it is listed in the WSDL file and found in messages on the wire. For RPC bindings, this is the name of the `wsdl:part` attribute representing the return value. For document bindings, the `-name` parameter is the local name of the XML element representing the return value. The default value is `return` for RPC and DOCUMENT/WRAPPED bindings. The default value is the method name + `Response` for DOCUMENT/BARE bindings. (String) **- targetNamespace** Specifies the XML namespace for the return value. This parameter is only used if the operation is RPC style or if the operation is DOCUMENT style and the parameter style is BARE. (String) **- header** Specifies whether the result is carried in a header. The default value is `false`. (Boolean) **- partName** Specifies the part name for the result with RPC or DOCUMENT/BARE operations. The default value is `@WebResult.name`. (String)
`javax.jws. HandlerChain`	The **@HandlerChain** annotation associates the web service with an externally defined handler chain. You can only configure the server side handler by using the @HandlerChain annotation on the Service Endpoint Interface (SEI) or the server endpoint implementation class. Use one of several ways to configure a client side handler. You can configure a client side handler by using the @HandlerChain annotation on the generated service class or SEI. Additionally, you can programmatically register your own implementation of the HandlerResolver interface on the Service, or programmatically set the handler chain on the Binding object.	• Annotation target: Type • Properties: **- file** Specifies the location of the handler chain file. The file location is either an absolute java.net.URL in external form or a relative path from the class file. (String) **- name** Specifies the name of the handler chain in the configuration file. (String)

Table 125. Web services Metadata Annotations (JSR 181) (continued). Describes the supported web services metadata annotations and their associated properties.

Annotation class	Annotation	Properties
`javax.jws. SOAPBinding`	The **@SOAPBinding** annotation specifies the mapping of the web service onto the SOAP message protocol. Apply this annotation to a type or methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class. The method level annotation is limited in what it can specify and is only used if the `style` property is `DOCUMENT`. If the method level annotation is not specified, the **@SOAPBinding** behavior from the type is used.	• Annotation target: Type or Method • Properties: **- `style`** Defines encoding style for messages sent to and from the web service. The valid values are `DOCUMENT` and `RPC`. The default value is `DOCUMENT`. (String) **- `use`** Defines the formatting used for messages sent to and from the web service. The default value is `LITERAL`. `ENCODED` is not supported. (String) **- `parameterStyle`** Determines whether the method's parameters represent the entire message body or whether parameters are elements wrapped inside a top-level element named after the operation. Valid values are `WRAPPED` or `BARE`. You can only use the `BARE` value with `DOCUMENT` style bindings. The default value is `WRAPPED`. (String)

Table 126. JAX-WS Annotations (JSR 224). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
`javax.xml.ws. Action`	The **@Action** annotation specifies the WS-Addressing action that is associated with a web service operation. When you use this annotation with a particular method, and generate the corresponding WSDL document, the WS-Addressing Action extension attribute is added to the input and output elements of the WSDL operation that corresponds to that method. To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.	• Annotation target: Method • Properties: **- fault** Specifies the array of `FaultAction` for the `wsdl:fault` of the operation. (String) **- input** Specifies the action for the`wsdl:input` of the operation. (String) **- output** Specifies the action for the`wsdl:output` of the operation. (String)
`javax.xml.ws. BindingType`	The **@BindingType** annotation specifies the binding to use when publishing an endpoint of this type. Apply this annotation to a server endpoint implementation class. **Important:** You can use the @BindingType annotation on the JavaBeans endpoint implementation class to enable MTOM by specifying either `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_MTOM_BINDING` or `javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_MTOM_BINDING` as the value for the annotation.	• Annotation target: Type • Properties: **- value** Indicates the binding identifier web address. Valid values are `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING`, `javax.xml.ws.soap.SOAPBinding.SOAP12HTTP_BINDING`, and `javax.xml.ws.http.HTTPBinding.HTTP2HTTP_BINDING`. The default value is `javax.xml.ws.soap.SOAPBinding.SOAP11HTTP_BINDING`. (String)
`javax.xml.ws. FaultAction`	The **@FaultAction** annotation specifies the WS-Addressing action that is added to a fault response. This annotation must be contained within an @Action annotation. When you use this annotation with a particular method, the WS-Addressing FaultAction extension attribute is added to the fault element of the WSDL operation that corresponds to that method. To add this attribute to the WSDL operation, you must also specify the @Addressing annotation on the server endpoint implementation class. If you do not want to use the @Addressing annotation you can supply your own WSDL document with the Action attribute already defined.	• Annotation target: Method • Properties: **- value** Specifies the action of the `wsdl:fault` of the operation. (String) **- output** Specifies the name of the exception class. (String) **- className** Specifies the name of the class representing the request wrapper. (String)

Table 126. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
`javax.xml.ws. RequestWrapper`	The **@RequestWrapper** annotation supplies the JAXB generated request wrapper bean, the element name, and the namespace for serialization and deserialization with the request wrapper bean that is used at runtime. When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the `className` attribute is required in this case. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: - **`localName`** Specifies the local name of the XML schema element representing the request wrapper. The default value is the `operationName` as defined in javax.jws.WebMethod annotation. (String) - **`targetNamespace`** Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String) - **`className`** Specifies the name of the class representing the request wrapper. (String) - **`partName`** Specifies the name of the wsdl:part attribute that represents the XML schema element for the RequestWrapper class. This property is applicable for JAX-WS 2.2 and later. (String)
`javax.xml.ws. ResponseWrapper`	The **@ResponseWrapper** annotation supplies the JAXB generated response wrapper bean, the element name, and the namespace for serialization and deserialization with the response wrapper bean that is used at runtime. When starting with a Java object, this element is used to resolve overloading conflicts in document literal mode. Only the `className` attribute is required in this case. Apply this annotation to methods on a client or server Service Endpoint Interface (SEI) or a server endpoint implementation class.	• Annotation target: Method • Properties: - **`localName`** Specifies the local name of the XML schema element representing the request wrapper. The default value is the `operationName` + *Response*. `operationName` is defined in javax.jws.WebMethod annotation. (String) - **`targetNamespace`** Specifies the XML namespace of the request wrapper method. The default value is the target namespace of the SEI. (String) - **`className`** Specifies the name of the class representing the response wrapper. (String) - **`partName`** Specifies the name of the wsdl:part attribute that represents the XML schema element for the ResponseWrapper class. This property is applicable for JAX-WS 2.2 and later. (String)

Table 126. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
`javax.xml.ws. RespectBinding`	The **@RespectBinding** annotation specifies whether the JAX-WS implementation must use the contents of the `wsdl:binding` for an endpoint. When this annotation is specified, a check is performed to ensure all required WSDL extensibility elements with the enabled attribute set to `true` are supported. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Method • Properties: **- enabled** Specifies whether the `wsdl:binding` must be used or not. The default value is `true`. (Boolean)
`javax.xml.ws. ServiceMode`	The **@ServiceMode** annotation specifies whether a service provider needs to have access to an entire protocol message or just the message payload. **Important:** The @ServiceMode annotation is only supported on classes that are annotated with the @WebServiceProvider annotation.	• Annotation target: Type • Properties: **- value** Indicates whether the provider class accepts the payload of the message, `PAYLOAD` or the entire message `MESSAGE`. The default value is `PAYLOAD`. (String)
`javax.xml.ws. soap.Addressing`	The **@Addressing** annotation specifies that this service wants to enable WS-Addressing support. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Type • Properties: **- enabled** Specifies if WS-Addressing is enabled or not. The default value is `true`. (Boolean) **- required** Specifies that WS-Addressing headers must be present on incoming messages. The default value is `false`. (Boolean) **- responses** Specifies the message exchange pattern to use. The default value is `Responses.ALL`. This property is applicable for JAX-WS 2.2 and later. (String)

Table 126. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
`javax.xml.ws. soap.MTOM`	The **@MTOM** annotation specifies whether binary content in the body of a SOAP message is sent using MTOM. Apply this annotation to a service endpoint implementation class.	• Annotation target: Class • Properties: - **`enabled`** Specifies if MTOM is enabled for the JAX-WS endpoint. The default value is `true`. (Boolean) - **`threshold`** Specifies the minimum size for messages that are sent using MTOM. When the message size is less than this specified integer, the message is inlined in the XML document as base64 or hexBinary data. (integer)
`javax.xml.ws. WebFault`	The **@WebFault** annotation maps WSDL faults to Java exceptions. It is used to capture the name of the fault during the serialization of the JAXB type that is generated from a global element referenced by a WSDL fault message. It can also be used to customize the mapping of service specific exceptions to WSDL faults. This annotation can only be applied to a fault implementation class on the client or server.	• Annotation target: Type • Properties: - **`name`** Specifies the local name of the XML element that represents the corresponding fault in the WSDL file. The actual value must be specified. (String) - **`targetNamespace`** Specifies the namespace of the XML element that represents the corresponding fault in the WSDL file. (String) - **`faultBean`** Specifies the name of the fault bean class. (String) - **`messageName`** Specifies the name of the wsdl:message attribute that represents the corresponding fault in the WSDL file. This property is applicable for JAX-WS 2.2 and later. (String)

Table 126. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
`javax.xml.ws. WebServiceProvider`	The **@WebServiceProvider** annotation denotes that a class satisfies requirements for a JAX-WS Provider implementation class. **Important:** • A Java class that implements a web service must specify either the @WebService or @WebServiceProvider annotation. Both annotations cannot be present. • The @WebServiceProvider annotation is only supported on the service implementation class. Any class with the @WebServiceProvider annotation must implement the javax.xml.ws.Provider interface.	• Annotation target: Type • Properties: - **`targetNamespace`** Specifies the XML namespace of the WSDL and XML elements generated from the web service. The default value is the namespace mapped from the package name containing the web service. (String) - **`serviceName`** Specifies the service name of the web service: `wsdl:service`. The default value is the simple name of the Java class + *Service*. (String) - **`portName`** The `wsdl:portName`. The default value is the name of the class + *Port*. (String) - **`wsdlLocation`** The web address of the WSDL document defining the web service. This attribute is required. (String)

Table 126. JAX-WS Annotations (JSR 224) (continued). Describes the supported JAX-WS annotations and their associated properties.

Annotation class	Annotation	Properties
`javax.xml.ws. WebServiceRef`	The **@WebServiceRef** annotation defines a reference to a web service invoked by the client. **Note:** • The @WebServiceRef annotation can be used to inject instances of JAX-WS services and ports. • The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types.	• Annotation target: Type, Field or Method • Properties: **- name** Specifies the JNDI name of the resource. The field name is the default for field annotations. The JavaBeans property name that corresponds to the method is the default for method annotations. You must specify a value for class annotations as there is no default. (String) **- type** Indicates the Java type of the resource. The field type is the default for field annotations. The type of the JavaBeans property is the default for method annotations. You must specify a value for class annotations as there is no default. (Class) **- mappedName** Specifies the name to map this resource to. (String) **- value** Indicates the value of the service class and it is a type that extends `javax.xml.ws.Service`. This attribute is required when the type of the reference is a service endpoint interface. (Class) **- wsdlLocation** The web address of the WSDL document defining the web service. This attribute is required. (String) **- lookup** Specifies the JNDI lookup name for the target web service. This property is applicable for JAX-WS 2.2 and later. (String)
`javax.xml.ws. WebServiceRefs`	The **@WebServiceRefs** annotation associates multiple @WebServiceRef annotations with a specific class. **Note:** The @WebServiceRef annotation is only supported in certain class types. Examples are JAX-WS endpoint implementation classes, JAX-WS handler classes, Enterprise JavaBeans classes, and servlet classes. This annotation is supported in the same class types as the @Resource annotation. See the Java Platform, Enterprise Edition (Java EE) 5 specification for a complete list of supported class types.	• Annotation target: Type • Properties: **- value** Specifies an array for multiple web service reference declarations. This attribute is required.

Table 127. JAX-WS Common Annotations (JSR 250). Describes the supported JAX-WS common annotations and their associated properties.

Annotation class	Annotation	Properties
`javax.annotation. Resource`	The **@Resource** annotation marks a WebServiceContext resource needed by the application. **Note:** Applying this annotation to a WebServiceContext type field on the server endpoint implementation class for a JavaBeans endpoint or a Provider endpoint results in the container injecting an instance of the WebServiceContext into the specified field. When this annotation is used in place of the @WebServiceRef annotation, the rules described for the @WebServiceRef annotation apply.	• Annotation target: Field or Method • Properties: **- type** Indicates the Java type of the resource. You are required to use the default, `java.lang.Object` or `javax.xml.ws.Web ServiceContext` value. If the type is the default, the resource must be injected into a field or a method. In this case, the type of the field or the type of the JavaBeans property defined by the method must be `javax.xml.ws.WebServiceContext`. (Class) If you are using this annotation to inject a web service, see the description of the @WebServiceRef `type` attribute.
`javax.annotation. Resources`	The **@Resources** annotation associates multiple @Resource annotations with a specific class and serves as a container for multiple resource declarations.	• Annotation target: Field or Method • Properties: **- value** Specifies an array for multiple @Resource annotations. This attribute is required.
`javax.annotation. PostConstruct`	The **@PostConstruct** annotation marks a method that needs to run after dependency injection is performed on the class. Apply this annotation to a JAX-WS application handler, a server endpoint implementation class.	• Annotation target: Method
`javax.annotation. PreDestroy`	The **@PreDestroy** annotation marks a method that must be run when the instance is in the process of being removed by the container. Apply this annotation to a JAX-WS application handler or a server endpoint implementation class.	• Annotation target: Method

Table 128. IBM proprietary annotations. Describes the supported IBM proprietary annotations and their associated properties.

Annotation class	Annotation	Properties
`com.ibm.websphere. wsaddressing. jaxws21. SubmissionAddressing`	The **@SubmissionAddressing** annotation specifies that this service wants to enable WS-Addressing support for the 2004/08 WS-Addressing specification. This annotation is part of the IBM implementation of the JAX-WS 2.1 specification. Apply this annotation to methods on a server endpoint implementation class.	• Annotation target: Type • Properties: - **`enabled`** Specifies if WS-Addressing is enabled or not. The default value is `true`. (Boolean) - **`required`** Specifies that WS-Addressing headers must be present on incoming messages. The default value is `false`. (Boolean)

Generating Java artifacts for JAX-WS applications

Use Java API for XML-Based Web Services (JAX-WS) tools to generate the necessary JAX-WS and Java Architecture for XML Binding (JAXB) Java artifacts that are needed for JAX-WS web services applications when starting from JavaBeans or enterprise beans components.

Before you begin

To develop a Java API for XML-Based Web Services (JAX-WS) web service application, you must first develop a service endpoint interface (SEI) implementation that explicitly or implicitly describes the SEI.

About this task

When using a bottom-up approach to develop JAX-WS web services, use the **wsgen** command-line tool on the existing service endpoint implementation. The **wsgen** tool processes a compiled service endpoint implementation class as input and generates the following portable artifacts:

- Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents.
- a Web Services Description Language (WSDL) file if the optional *-wsdl* argument is specified.

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

You are not required to develop a WSDL file when developing JAX-WS Web services using the bottom-up approach of starting with JavaBeans. The use of annotations provides all of the WSDL information necessary to configure the service endpoint or the client. The application server supports WSDL 1.1 documents that comply with Web Services-Interoperability (WS-I) Basic Profile 1.1 specifications and are either Document/Literal style documents or RPC/Literal style documents. Additionally, WSDL documents with bindings that declare a `USE` attribute of value `LITERAL` are supported while the value, `ENCODED`, is not supported. For WSDL documents that implement a Document/Literal wrapped pattern, a root element is declared in the XML schema and is used as an operation wrapper for a message flow. Separate wrapper element definitions exist for both the request and the response.

To ensure the **wsgen** command does not miss inherited methods on a service endpoint implementation bean, you must either add the @WebService annotation to the desired superclass or you can override the inherited method in the implementation class with a call to the superclass method.

Although a WSDL file is typically optional when developing a JAX-WS service implementation bean, it is required if your JAX-WS endpoints are exposed using the SOAP over JMS transport and you are publishing your WSDL file. If you are developing an enterprise JavaBeans service implementation bean that is invoked using the SOAP over JMS transport, and you want to publish the WSDL so that the

published WSDL file contains the fully resolved JMS endpoint URL, then have **wsgen** tool generate the WSDL file by specifying the *-wsdl* argument. In this scenario, you must package the WSDL file with your web service application.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsGen` Ant task from within the Ant build environment to invoke the wsgen tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

Procedure

1. Locate your service endpoint implementation class file.
2. Run the **wsgen** command to generate the portable artifacts. The **wsgen** tool is located in the *app_server_root*/bin/ directory.

   (Optional) Use the following options with the **wsgen** command:
   - Use the **-verbose** option to see a list of generated files along with additional informational messages.
   - Use the **-keep** option to keep generated Java files.
   - Use the **-wsdl** option to generate a WSDL file. If you are developing a service implementation bean that will be invoked using the HTTP transport, then the WSDL file generated by the **wsgen** command-line tool during this step is optional. However, if you are developing a service implementation bean that will be invoked using the SOAP over JMS transport, then the WSDL file generated by the **wsgen** tool during this step is required in subsequent developing JAX-WS applications steps, so it is not optional.

   Read about **wsgen** to learn more about this command and additional options that you can specify.

Results

You have the required Java artifacts to create a JAX-WS web service.

Note: The **wsgen** command does not differentiate the XML namespace between multiple XMLType annotations that have the same @XMLType name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates that you have classes or @XMLType.name values that have the same name, but exist within different Java packages. To prevent this error, add the @XML.Type.namespace class to the existing @XMLType annotation to differentiate between the XML types.

With JAX-WS applications, the **wsgen** command-line tool might not locate shared class files. You can specify the location of these class files using the com.ibm.websphere.webservices.wsdl_generation_extra_classpath custom property. For more information, see the documentation about the Java virtual machine custom properties.

Example

The following example demonstrates how to use the **wsgen** command to process the service endpoint implementation class to generate JAX-WS artifacts. This example EchoService service implementation class uses an explicit JavaBeans service endpoint.

1. Copy the sample `EchoServicePortTypeImpl` service implementation class file and the associated `EchoServicePortType` service interface class file into a directory. The directory must contain a directory tree structure that corresponds to the `com.ibm.was.wssample.echo` package name for the class file.

```
/* This is a sample EchoServicePortTypeImpl.java file.    */
package com.ibm.was.wssample.echo;
```

```
@javax.jws.WebService(serviceName = "EchoService", endpointInterface =
"com.ibm.was.wssample.echo.EchoServicePortType",
targetNamespace="http://com/ibm/was/wssample/echo/",
portName="EchoServicePort")

public class EchoServicePortTypeImpl implements EchoServicePortType {

 public EchoServicePortTypeImpl() {
 }

 public String invoke(String obj) {
  System.out.println(">> JAXB Provider Service:
Request received.\n");
  String str = "Failed";
  if (obj != null) {
   try {
    str = obj;
   } catch (Exception e) {
    e.printStackTrace();
   }
  }
  return str;

 }

}
```

```
/* This is a sample EchoServicePortType.java file.    */
package com.ibm.was.wssample.echo;

import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.xml.ws.RequestWrapper;
import javax.xml.ws.ResponseWrapper;

@WebService(name = "EchoServicePortType", targetNamespace =
"http://com/ibm/was/wssample/echo/",
 wsdlLocation="WEB-INF/wsdl/Echo.wsdl")

public interface EchoServicePortType {

    /**
     *
     * @param arg0
     * @return
     *     returns java.lang.String
     */
    @WebMethod
    @WebResult(name = "response", targetNamespace =
    "http://com/ibm/was/wssample/echo/")
    @RequestWrapper(localName = "invoke", targetNamespace =
    "http://com/ibm/was/wssample/echo/",
     className = "com.ibm.was.wssample.echo.Invoke")
    @ResponseWrapper(localName = "echoStringResponse",
     targetNamespace = "http://com/ibm/was/wssample/echo/",
     className = "com.ibm.was.wssample.echo.EchoStringResponse")
    public String invoke(
        @WebParam(name = "arg0", targetNamespace =
        "http://com/ibm/was/wssample/echo/")
        String arg0);

}
```

2. Run the **wsgen** command from the *app_server_root*\bin\ directory. The `-cp` option specifies the location of the service implementation class file. The `-s` option specifies the directory for the generated source files. The `-d` option specifies the directory for the generated output files. When using the `-s` or `-d` options, you must first create the directory for the generated output files.

After generating the Java artifacts using the **wsgen** command, the following files are generated:

```
/generated_source/com/ibm/was/wssample/echo/EchoStringResponse.java
/generated_source/com/ibm/was/wssample/echo/Invoke.java
/generated_artifacts/EchoService.wsdl
/generated_artifacts/EchoService_schema1.xsd
/generated_artifacts/com/ibm/was/wssample/echo/EchoStringResponse.class
/generated_artifacts/com/ibm/was/wssample/echo/Invoke.class
```

The EchoStringResponse.java and Invoke.java files are the generated Java class files. The compiled versions of the generated Java files are EchoStringResponse.class and Invoke.class files. The EchoService.wsdl and EchoService_schema1.xsd files are generated because the `-wsdl` option was specified.

What to do next

Complete the implementation of your JAX-WS web service application.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root
: Refers to the top directory for a WebSphere Application Server node.

  The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

  The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root
: Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

  The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

  The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root
: Refers to the installation root directory for Web Server Plug-ins.

profile_root
: Refers to the home directory for a particular instantiated WebSphere Application Server profile.

  Corresponding product variables are *server.root* and *user.install.root.*

  In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root
: Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

  The corresponding product variable is *smpe.install.root*.

  The default is /usr/lpp/zWebSphere/V8R5.

wsgen command for JAX-WS applications

The **wsgen** command-line tool generates the necessary artifacts required for Java API for XML Web Services (JAX-WS) applications when starting from Java code. The generated artifacts are Java 5 compliant, making them portable across different Java versions and platforms.

When using a bottoms-up approach to develop JAX-WS web services and you are starting from a service endpoint implementation, use the **wsgen** tool to generate the required JAX-WS artifacts.

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

The **wsgen** tool accepts a properly annotated service endpoint implementation using the @WebService annotation as input and generates the following artifacts:

- any additional Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents.
- a WSDL file if the optional `-wsdl` argument is specified. The **wsgen** tool does not automatically generate the WSDL file.

When using JAX-WS V2.2 tools, java.lang.RuntimeException and java.rmi.RemoteException references and their subclasses are no longer mapped in the WSDL file. This behavior change complies with the JAX-WS V2.1 specification conformance rule that is described in section 3.7 of the specification. This conformance rule specifies that the java.lang.RuntimeException and java.rmi.RemoteException classes and their subclasses cannot be treated as service-specific exceptions and mapped in the WSDL file.

In addition to using the tools from the command line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsGen` Ant task from within the Ant build environment to invoke the wsgen tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

Note: The **wsgen** command does not differentiate the XML namespace between multiple XMLType annotations that have the same @XMLType name defined within different Java packages. When this scenario occurs, the following error is produced:

```
Error: Two classes have the same XML type name ....
Use @XmlType.name and @XmlType.namespace to assign different names to them...
```

This error indicates you have class names or @XMLType.name values that have the same name, but exist within different Java packages. To prevent this error, add the @XML.Type.namespace class to the existing @XMLType annotation to differentiate between the XML types.

With JAX-WS applications, the **wsgen** command-line tool might not locate shared class files. You can specify the location of these class files using the com.ibm.websphere.webservices.wsdl_generation_extra_classpath custom property. For more information, see the documentation about the Java virtual machine custom properties.

Syntax

The command-line syntax is:

Parameters

The *service_implementation_class* name is the only parameter that is required. The following parameters are optional for the **wsgen** command:

-classpath <path>
Specifies the location of the service implementation class.

-cp <path>
Specifies the location of the service implementation class. This parameter is the same as *-classpath <path>*.

-d <directory>
Specifies where to place the generated output files.

-extension
Specifies whether to enable custom extensions for functionality not specified by the JAX-WS specification. Use of the extensions can result in applications that are not portable or do not interoperate with other implementations.

-help
Displays the help menu.

-keep
Specifies whether to keep the generated source files.

-r <directory>
This parameter is only used with the `-wsdl` parameter. Specifies where to place the generated WSDL file.

-s <directory>
Specifies the directory to place the generated source files.

-verbose
Specifies to output messages about what the compiler is doing.

-version
Prints the version information. If you specify this option, only the version information is output and normal command processing does not occur.

-wsdl [:protocol]
By default, the **wsgen** tool does not generate a WSDL file. This optional parameter causes **wsgen** to generate a WSDL file and is typically only used to enable a developer to review a WSDL file before the endpoint is deployed. The `protocol` is optional and specifies the protocol used in the `wsdl:binding`. Valid values for `protocol` are `soap 1.1` and `Xsoap 1.2`. The default value is `soap 1.1`. The `Xsoap 1.2` value is not standard and is only used with the *-extension* option.

-servicename <name>
This parameter is only used with the `-wsdl` option. Specifies a `wsdl:service` name to be generated in the WSDL file. For example,

```
-service name "{http://mynamespace/}MyService"
```

-portname
This parameter is only used with the `-wsdl` option. Specifies a `wsdl:port` name to be generated in the WSDL file. For example,

```
-portname "{http://mynamespace/}MyPort"
```

Mapping between Java language, WSDL and XML for JAX-WS applications

Data for Java API for XML Web Services (JAX-WS) applications flows as extensible Markup Language (XML). JAX-WS applications use mappings to describe the data conversion between the Java language and extensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP that are supported by the application server.

For web services based on the JAX-WS programming model, mappings between the Java language and XML are specified by the JAX-WS specification and the Java Architecture for XML Binding (JAXB) specification for data bindings. JAX-WS leverages the JAXB API and tools as the binding technology for mappings between Java objects and XML documents. JAX-WS tooling relies on JAXB tooling for default data binding for two-way mappings between Java objects and XML documents.

The JAX-WS specification describes the mapping between Web Services Description Language (WSDL) files and the Java language. The supported mappings include WSDL-to-Java mappings and Java-to-WSDL mappings. WSDL 1.1 is required by the JAX-WS 2.0 specification. You can use annotations to customize the mapping from Java artifacts to their associated WSDL components. Refer to the JAX-WS specification for details describing the WSDL-to-Java mappings and Java-to-WSDL mappings.

Data binding mappings used by the JAX-WS programming model are described by the JAXB specification. Refer to the JAXB specification for details that describe the JAXB mappings for the Java representation of XML content, including the default and custom bindings between XML schema to Java representations.

Enabling MTOM for JAX-WS web services

With Java API for XML-Based Web Services (JAX-WS), you can send binary attachments such as images or files along with web services requests. JAX-WS adds support for optimized transmission of binary data as specified by the SOAP Message Transmission Optimization Mechanism (MTOM) specification.

About this task

JAX-WS supports the use of SOAP Message Transmission Optimized Mechanism (MTOM) for sending binary attachment data. By enabling MTOM, you can send and receive binary data optimally without incurring the cost of data encoding needed to embed the binary data in an XML document.

The application server supports sending attachments using MTOM only for JAX-WS applications. This product also provides the ability to provide attachments with Web Services Security SOAP messages by using the new MTOM and XOP standards.

JAX-WS applications can send binary data as base64 or hexBinary encoded data contained within the XML document. However, to take advantage of the optimizations provided by MTOM, enable MTOM to send binary base64 data as attachments contained outside the XML document. MTOM optimization is not enabled by default. JAX-WS applications require separate configuration of both the client and the server artifacts to enable MTOM support.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes an XML schema or Web Services Description Language (WSDL) file that represents your web services application data that includes a binary attachment.
   a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the wsimport command to generate the required JAX-WS portable artifacts.
   b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and optionally generate a WSDL file using the wsgen command. The XML schema or WSDL file includes a `xsd:base64Binary` or `xsd:hexBinary` element definition for the binary data.
   c. You can also include the `xmime:expectedContentTypes` attribute on the element to affect the mapping by JAXB.
2. Enable MTOM on your endpoint implementation class using one of the following methods:
   - Use the @MTOM annotation on the endpoint.

     To enable MTOM on an endpoint, use the @MTOM (javax.xml.ws.soap.MTOM) annotation on the endpoint. The @MTOM annotation has two parameters, `enabled` and `threshold`. The `enabled` parameter has a boolean value and indicates if MTOM is enabled for the JAX-WS endpoint. The `threshold` parameter has an integer value, that must be greater than or equal to zero. When MTOM is enabled, any binary data whose size, in bytes, exceeds the threshold value is XML-binary Optimized Packaging (XOP) encoded or sent as an attachment. When the message size is less than the threshold value, the message is inlined in the XML document as either base64 or hexBinary data.

The following example snippet illustrates adding the @MTOM annotation so that MTOM is enabled for the JAX-WS `MyServiceImpl` endpoint and specifies a threshold value of 2048 bytes:

```
@MTOM(enabled=true, threshold=2048)
@WebService
public class MyServiceImpl {
...
}
```

Additionally, you can use the @BindingType (javax.xml.ws.BindingType) annotation on an endpoint implementation class to specify that the endpoint supports one of the MTOM binding types so that the response messages are MTOM-enabled. The javax.xml.ws.SOAPBinding class defines two different constants, `SOAP11HTTP_MTOM_BINDING` and `SOAP12HTTP_MTOM_BINDING` that you can use for the value of the @BindingType annotation; for example:

```
// This example is for SOAP version 1.1.
@BindingType(value = SOAPBinding.SOAP11HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
...
}
```

```
// This example is for SOAP version 1.2.
@BindingType(value = SOAPBinding.SOAP12HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
...
}
```

The presence and value of an @MTOM annotation overrides the value of the @BindingType annotation. For example, if the @BindingType indicates MTOM is enabled, but an @MTOM annotation is present with an `enabled` value of `false`, then MTOM is not enabled.

- Use the `<enable-mtom>` and `<mtom-threshold>` deployment descriptor elements.

  You can use the `<enable-mtom>` and `<mtom-threshold>` elements within the `<port-component>` element in the webservices.xml deployment descriptor as an alternative to using the @MTOM annotation on the service endpoint implementation class; for example:

```
<port-component>
   <port-component-name>MyPort1</port-component-name>
   <enable-mtom>true</enable-mtom>
   <mtom-threshold>2048</mtom-threshold>
   <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
   </service-impl-bean>
</port-component>
```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but the `<enable-mtom>` element is set to `false` in the `webservices.xml` file, MTOM is not enabled for the corresponding endpoint.

3. Enable MTOM on your client to optimize the binary messages that are sent from the client to the server. Use one of the following methods to enable MTOM on your client:

   - Enable MTOM on a Dispatch client.

     The following examples use SOAP version 1.1.

     The first method uses SOAPBinding.setMTOMEnabled(); for example:

```
SOAPBinding binding = (SOAPBinding)dispatch.getBinding();
    binding.setMTOMEnabled(true);
```

     The second method uses Service.addPort; for example:

```
    Service svc = Service.create(serviceName);
    svc.addPort(portName,SOAPBinding.SOAP11HTTP_MTOM_BINDING,endpointUrl);
```

     The third method uses MTOMFeature; for example:

```
   MTOMFeature mtom = new MTOMFeature(true, 2048);
    Service svc = Service.create(serviceName);
    svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
    Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, mtom);
```

   - Enable MTOM on a Dynamic Proxy client.

```
// Create a BindingProvider bp from a proxy port.
  Service svc = Service.create(serviceName);
  MtomSample proxy = svc.getPort(portName, MtomSample.class);
  BindingProvider bp = (BindingProvider) proxy;
```

```
  //Enable MTOM using the SOAPBinding.
  MtomSample proxy = svc.getPort(portName, MtomSample.class);
  BindingProvider bp = (BindingProvider) proxy;
  SOAPBinding binding = (SOAPBinding) bp.getBinding();
  binding.setMTOMEnabled(true);

  //Or, you can enable MTOM with the MTOMFeature.
  MTOMFeature mtom = new MTOMFeature();
  MtomSample proxy = svc.getPort(portName, MtomSample.class, mtom);
```

- Enable MTOM on your client using the @MTOM annotation; for example:

```
public class MyClientApplication {

    // Enable MTOM for a port-comonent-ref resource injection.
     @MTOM(enabled=true, threshold=1024)
     @WebServiceRef(MyService.class)
     private MyPortType myPort;
    ...
}
```

- Enable MTOM on your client using deployment descriptor elements within a port-component-ref element; for example:

```
<service-ref>
    <service-ref-name>service/MyPortComponentRef</service-ref-name>
    <service-interface>com.example.MyService</service-ref-interface>
    <port-component-ref>
        <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
        <enable-mtom>true</enable-mtom>
        <mtom-threshold>1024</mtom-threshold>
    </port-component-ref>
</service-ref>
```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but the `<enable-mtom>` element is set to `false` in the deployment descriptor entry for the service-ref of the client, MTOM is not enabled for that service reference.

Results

You have developed a JAX-WS web services server and client application that optimally sends and receives binary data using MTOM.

Example

The following example illustrates enabling MTOM support on both the web services client and server endpoint when starting with an WSDL file.

1. Locate the WSDL file containing an `xsd:base64Binary` element. The following example is a portion of a WSDL file that contains an `xsd:base64Binary` element.

```
  <types>
    ........
    <xs:complexType name="ImageDepot">
        <xs:sequence>
            <xs:element name="imageData"
                        type="xs:base64Binary"
                        xmime:expectedContentTypes="image/jpeg"/>

        </xs:sequence>
    </xs:complexType>
    ........
</types>
```

2. Run the **wsimport** command from the *app_server_root*\bin\ directory against the WSDL file to generate a set of JAX-WS portable artifacts.

   Depending on the `expectedContentTypes` value contained in the WSDL file, the JAXB artifacts generated are in the Java type as described in the following table:

Table 129. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.

MIME Type	Java Type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String

Table 129. Mapping of MIME type and Java type (continued). Describes the mapping between MIME types and Java types.

MIME Type	Java Type
text/xml	javax.xml.transform.Source
application/xml	javax.xml.transform.Source
/	javax.activation.DataHandler

3. Use the JAXB artifacts in the same manner as in any other JAX-WS application. Use these beans to send binary data from both the Dispatch and the Dynamic Proxy client APIs.
4. Enable MTOM on a Dispatch client.

```
//Create the Dispatch instance.
        JAXBContext jbc = JAXBContext.newInstance("org.apache.axis2.jaxws.sample.mtom");
        Dispatch<Object> dispatch = svc.createDispatch(portName, jbc, Service.Mode.PAYLOAD);

//Enable MTOM.
        SOAPBinding binding = (SOAPBinding) dispatch.getBinding();
        binding.setMTOMEnabled(true);
```

5. Enable MTOM on a Dynamic Proxy client.

```
//Create the Dynamic Proxy instance.
        Service svc = Service.create(serviceName);
        MtomSample proxy = svc.getPort(portName, MtomSample.class);

//Enable MTOM.
        BindingProvider bp = (BindingProvider) proxy;
        SOAPBinding binding = (SOAPBinding) bp.getBinding();
        binding.setMTOMEnabled(true);
```

   Now that you have enabled the JAX-WS client for MTOM, messages sent to the server have MTOM enabled. However, for the server to respond back to the client using MTOM, you must enable MTOM on the endpoint.
6. Enable MTOM on the endpoint implementation class.

```
@MTOM(enabled, threshold=4096)
@WebService (endpointInterface="org.apache.axis2.jaxws.sample.mtom.MtomSample")

public class MtomSampleService implements MtomSample {
   ....
}
```

   The `jaxax.xml.ws.SOAPBinding` class has a static member for each of the supported binding types. Include either the `SOAP11HTTP_MTOM_BINDING` or the `SOAP12HTTP_MTOM_BINDING` as the value for the `@BindingType` annotation. This value enables all server responses to have MTOM enabled.

When you enable MTOM on the server and the client, the binary data that represents the attachment is included as a Multipurpose Internet Mail Extensions (MIME) attachment to the SOAP message. Without MTOM, the same data is encoded in the format that describes the XML schema, either base64 or hexadecimal encoding, and included inline in the XML document.

This example illustrates an MTOM enabled SOAP version 1.1 message with an attachment. The `type` and `content-type` attributes both have the value, `application/xop+xml`, which indicates that the message was successfully optimized using XML-binary Optimized packaging (XOP) when MTOM was enabled. This example demonstrates how the optimized message looks on the wire with MTOM enabled.

```
... other transport headers ...
Content-Type: multipart/related; boundary=MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812;
type="application/xop+xml"; start="
<0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>"; start-info="text/xml"; charset=UTF-8

--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: application/xop+xml; charset=UTF-8; type="text/xml";
content-transfer-encoding: binary
content-id:
   <0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>

<?xml version="1.0" encoding="UTF-8"?>
         <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
            <soapenv:Header/>
            <soapenv:Body>
               <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
                  <input>
```

```
                    <imageData>
                       <xop:Include xmlns:xop="http://www.w3.org/2004/08/xop/include"
href="cid:1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org"/>
                    </imageData>
                 </input>
              </sendImage>
           </soapenv:Body>
        </soapenv:Envelope>
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: text/plain
content-transfer-encoding: binary
content-id:
        <1.urn:uuid:0FE43E4D025F0BF3DC115824676468l1@apache.org>

... binary data goes here ...
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812--
```

In contrast, this example demonstrates a SOAP version 1.1 message on the wire without MTOM enabled. The binary data is included in the body of the SOAP message, and the SOAP message is not optimized.

```
... other transport headers ...
Content-Type: text/xml; charset=UTF-8

<?xml version="1.0" encoding="UTF-8"?>
   <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
      <soapenv:Header/>
      <soapenv:Body>
         <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
            <input>
               <imageData>R0lGAD1 ... more base64 encoded data ... KTJk8giAAA7</imageData>
            </input>
         </sendImage>
      </soapenv:Body>
   </soapenv:Envelope>
```

For additional information, refer to the Samples section of the Information Center which includes a sample that demonstrates the use of MTOM with JAX-WS web services.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root

Refers to the top directory for a WebSphere Application Server node.

The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root

Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root

Refers to the installation root directory for Web Server Plug-ins.

profile_root

Refers to the home directory for a particular instantiated WebSphere Application Server profile.

Corresponding product variables are *server.root* and *user.install.root.*

In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root
Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

The corresponding product variable is *smpe.install.root*.

The default is /usr/lpp/zWebSphere/V8R5.

Enforcing adherence to WSDL bindings in JAX-WS web services

Java API for XML-Based Web Services (JAX-WS) Version 2.1 introduced the concept of *features* as a way to programmatically control specific functions and behaviors. The RespectBindingFeature is one of the supported standard features. You can use the RespectBindingFeature to control whether a JAX-WS implementation is required to respect the contents of a Web Services Description Language (WSDL) binding that is associated with an endpoint.

About this task

While WSDL documents are often used during the development process, the actual enforcement of the use of the WSDL document specifications, when they are provided, at run time has not been well defined in versions of the JAX-WS specification previous to Version 2.1. The JAX-WS Version 2.1 specification added the feature, RespectBindingFeature, to clarify the impact of the wsdl:binding in a JAX-WS runtime environment.

Enabling the feature, RespectBindingFeature, causes the JAX-WS runtime environment to inspect the wsdl:binding for an endpoint at run time to ensure that the binding of service endpoint interface (SEI) parameters and return values is respected. Additionally, this feature ensures that all required wsdl:binding extensions are either understood and used by the runtime environment, or the extensions have been explicitly disabled by the application. Your JAX-WS application can disable a specific wsdl:binding extension that has a defined WebServiceFeature interface by using the appropriate annotation that is associated with that feature, using an API that accepts the javax.xml.ws.WebServiceFeature interface, or configuring the deployment descriptors.

When the RespectBindingFeature feature is not enabled, which is the default, the runtime environment can choose whether any part of the wsdl:binding is enforced.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes a Web Services Description Language (WSDL) file that represents your web services application.
   a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the wsimport command to generate the required JAX-WS portable artifacts.
   b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and generate a WSDL file using the wsgen command.
2. If you want to enable RespectBindingFeature on your endpoint implementation class, use one of the following methods:
   - Use the @RespectBinding annotation on the endpoint.

     To enable RespectBinding on an endpoint, use the @RespectBinding (javax.xml.ws.RespectBinding) annotation on the endpoint. The @RespectBinding annotation has only one parameter, enabled. This parameter is optional. The enabled parameter has a Boolean value and indicates if RespectBindingFeature is enabled for the JAX-WS endpoint.

     The following example snippet illustrates adding the @RespectBinding annotation for the JAX-WS MyServiceImpl endpoint:

```
@RespectBinding(enabled=true))
@WebService
public class MyServiceImpl {
...
}
```

- Use the <respect-binding> deployment descriptor element.

  You can use the <respect-binding> element within the <port-component> element in the webservices.xml deployment descriptor as an alternative to using the @RespectBinding annotation on the service endpoint implementation class; for example:

```
<port-component>
     <port-component-name>MyPort1</port-component-name>
     <respect-binding>
         <enabled>true</enabled>
     </respect-binding>
     <service-impl-bean>
         <servlet-link>MyPort1ImplBean</servlet-link>
     </service-impl-bean>
</port-component>
```

3. If you want to enable RespectBindingFeature on your client, use one of the following methods:
   - Enable RespectBindingFeature on a dispatch client; for example:

```
RespectBindingFeature respectBinding = new RespectBindingFeature();
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, respectBinding);
```

   - Enable RespectBindingFeature on a dynamic proxy client; for example:

```
// Create a dynamic proxy with RespectBinding enabled.
  Service svc = Service.create(serviceName);
  RespectBindingFeature respectBinding = new RespectBindingFeature();
  RespectBindingSample proxy = svc.getPort(portName, RespectBindingSample.class, respectBinding);
```

   - Enable RespectBindingFeature on your client using the @RespectBinding annotation; for example:

```
public class MyClientApplication {

               // Enable RespectBinding for a port-component-ref resource injection.
                   @RespectBinding(enabled=true)
                   @WebServiceRef(MyService.class)
                   private MyPortType myPort;
               ...
}
```

   - Enable RespectBindingFeature on your client using deployment descriptor elements within a port-component-ref element; for example:

```
<service-ref>
    <service-ref-name>service/MyPortComponentRef</service-ref-name>
    <service-interface>com.example.MyService</service-ref-interface>
    <port-component-ref>
        <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
        <respect-binding>
            <enabled>true</enabled>
        </respect-binding>
    </port-component-ref>
</service-ref>
```

Results

By implementing the feature, RespectBindingFeature, you have specified to enforce adherence of the contents of a WSDL binding that is associated with an endpoint for your JAX-WS application.

Developing a webservices.xml deployment descriptor for JAX-WS applications

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. You can optionally use the webservices.xml deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services.

About this task

Similar to Java API for XML-based RPC (JAX-RPC) Web services, you can use deployment descriptors to describe JAX-WS web services. For JAX-WS web services, the use of the webservices.xml deployment

descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

A JAX-WS web service requires that you annotate your Java class with the `javax.jws.WebService` annotation or the `javax.jws.WebServiceProvider` annotation for Provider endpoints. You can use server-side deployment descriptors to override corresponding attributes of the annotation or to enhance information in annotations. There is a defined relationship between the deployment descriptor elements and the @WebService and @WebServiceProvider annotations. Refer to section 5.3 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification, Version 1.2 for detailed information regarding the deployment descriptor elements and the mapping to the @WebService and @WebServiceProvider annotation attributes. There are also elements in the `webservice.xml` deployment descriptor that map to other annotations. For example, the deployment descriptor element <protocol-binding> maps to the @BindingType annotation, and the deployment descriptor element <enable-mtom> maps to the @MTOM annotation. For more information regarding the web services deployment descriptor elements, see section 7.1 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

Procedure

Use assembly tools to generate the `webservice.xml` deployment descriptor.

Results

You have deployment descriptor templates that you can use to override JAX-WS annotation attributes or specify attributes that are not defined by the annotation.

Example

In the following example, the service implementation class for a JAX-WS web service includes the @WebService annotation:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

The associated `webservices.xml` deployment descriptor specifies a different filename for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

The value that is specified in the deployment descriptor, `META-INF/wsdl/ExampleService.wsdl`, overrides the annotation value.

What to do next

Configure the `webservice.xml` deployment descriptor. After you configure the deployment descriptors, you must assemble the Web services application for deployment.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root
: Refers to the top directory for a WebSphere Application Server node.

The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root
Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root
Refers to the installation root directory for Web Server Plug-ins.

profile_root
Refers to the home directory for a particular instantiated WebSphere Application Server profile.

Corresponding product variables are *server.root* and *user.install.root.*

In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root
Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

The corresponding product variable is *smpe.install.root*.

The default is /usr/lpp/zWebSphere/V8R5.

Completing the JavaBeans implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the JavaBeans implementation to assemble a web application archive (WAR) file. The resulting WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Write the JavaBeans implementation. The JavaBeans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your JavaBeans implementation to complete your web service application.

What to do next

After completing the JavaBeans implementation, assemble your web services application.

Completing the EJB implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file. The resulting JAR file contains the Enterprise JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Write the enterprise beans implementation. The enterprise beans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your enterprise beans implementation to complete your web service application.

What to do next

After completing the enterprise beans implementation, assemble your web services application.

Developing JAX-WS web services with WSDL files (top-down)

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

1. Set up the environment.

   Run the **setupCmdLine** script from the */profile_root/<application_server>/bin* directory.
2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:

```
set PATH=%WAS_PATH%;%PATH%
```

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Generating Java artifacts for JAX-WS applications from a WSDL file

Use JAX-WS tools to generate the Java artifacts that are needed to develop JAX-WS web services when starting with a Web Services Description Language (WSDL) file.

Before you begin

When using a top-down development approach to developing Java API for XML-Based Web Services (JAX-WS) web services by starting with a Web Services Description Language (WSDL) file, you must obtain the Uniform Resource Locator (URL) of the WSDL file.

If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

About this task

You can use the JAX-WS tool, **wsimport**, to process a WSDL file and generate portable Java artifacts that are used to create a web service. The portable Java artifacts created using the **wsimport** tool are:

- Service endpoint interface (SEI)
- Service class
- Exception class that is mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To

take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build environment to invoke the wsimport tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

Procedure

Run the wsimport command to generate the portable client artifacts. The **wsimport** tool is located in the *app_server_root*\bin\ directory.
(Optional) Use the following options with the **wsimport** command:

- Use the **-verbose** option to see a list of generated files when you run the command.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdlLocation** option to specify the location of the WSDL file.

  Note: A best practice for ensuring that you produce a JAX-WS web services client enterprise archive (EAR) file that is portable to other systems is to package the WSDL document within the application module such as a web services client Java archive (JAR) file or a web application archive (WAR) file. You can specify a relative URI for the location of your WSDL file by using the `-wsdllocation` annotation attribute. For example, if your `MyService.wsdl` file is located in the `META-INF/wsdl/` directory, then run the **wsimport** tool and use the `-wsdllocation` option to specify the value to be used for the location of the WSDL file. This ensures that the generated artifacts contain the correct `-wsdllocation` information needed when the application is loaded into the administrative console; for example:

```
wsimport -keep -wsdllocation=META-INF/wsdl/MyService.wsdl
```

- Use the **-b** option if you are using WSDL or schema customizations to specify external binding files that contain your customizations.

  You can customize the bindings in your WSDL file to enable asynchronous mappings or attachments. To generate asynchronous interfaces, add the client-side only customization `enableAsyncMapping` binding declaration to the `wsdl:definitions` element or in an external binding file that is defined in the WSDL file. Use the `enableMIMEContent` binding declaration in your custom client or server binding file to enable or disable the default mime:content mapping rules. For additional information on custom binding declarations, see chapter 8 the JAX-WS specification.

Read about the **wsimport** command to learn more about this command and additional options that you can specify.

Results

You have the required Java artifacts to create a JAX-WS web service. To learn more about the usage, syntax, and parameters for the **wsimport** command, see the **wsimport** command for JAX-WS applications documentation.

Example

The following example illustrates how the **wsimport** command is used to process the sample Ping WSDL file to generate portable artifacts.

1. Copy the following `ping.wsdl` WSDL file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--
 * This program can be used, run, copied, modified and distributed
 * without royalty for the purpose of developing, using, marketing, or distributing.
 -->
<wsdl:definitions xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
```

```
xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
xmlns:tns="http://com/ibm/was/wssample/sei/ping/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="PingService"
targetNamespace="http://com/ibm/was/wssample/sei/ping/">
<wsdl:types>
 <xsd:schema
  targetNamespace="http://com/ibm/was/wssample/sei/ping/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">

  <xsd:element name="pingStringInput">
   <xsd:complexType>
    <xsd:sequence>
     <xsd:element name="pingInput" type="xsd:string" />
    </xsd:sequence>
   </xsd:complexType>
  </xsd:element>
 </xsd:schema>
</wsdl:types>
<wsdl:message name="pingOperationRequest">
 <wsdl:part element="tns:pingStringInput" name="parameter" />
</wsdl:message>
<wsdl:portType name="PingServicePortType">
 <wsdl:operation name="pingOperation">
  <wsdl:input message="tns:pingOperationRequest" />

 </wsdl:operation>
</wsdl:portType>
<wsdl:binding name="PingSOAP" type="tns:PingServicePortType">
 <soap:binding style="document"
  transport="http://schemas.xmlsoap.org/soap/http" />
 <wsdl:operation name="pingOperation">
  <soap:operation soapAction="pingOperation" style="document" />
  <wsdl:input>
   <soap:body use="literal" />
  </wsdl:input>
 </wsdl:operation>
</wsdl:binding>
<wsdl:service name="PingService">
 <wsdl:port binding="tns:PingSOAP" name="PingServicePort">
  <soap:address
   location="http://localhost:9080/WSSampleSei/PingService" />
 </wsdl:port>
</wsdl:service>
</wsdl:definitions>
```

2. Run the **wsimport** command from the *app_server_root*\bin\ directory.

After generating the template files using the **wsimport** command, the following files are generated:

```
com\ibm\was\wssample\sei\ping\ObjectFactory.java
com\ibm\was\wssample\sei\ping\package-info.java
com\ibm\was\wssample\sei\ping\PingServicePortType.java
com\ibm\was\wssample\sei\ping\PingStringInput.java
com\ibm\was\wssample\sei\ping\PingService.java
```

The `ObjectFactory.java` file contains factory methods for each Java content interface and Java element interface generated in the associated ping package. The `package-info.java` file takes the targetNamespace value and creates the directory structure. The `PingServicePortType.java` file is the generated service endpoint interface (SEI) class that contains the `ping` method definition. The `PinStringInput.java` file contains the JAXB generated type values which are Java classes mapped from XML schema types. The `PingService.java` file is the generated service provider class file that is used by the JAX-WS client.

What to do next

Complete the implementation of your web service application by completing the JavaBeans or enterprise beans implementation.

wsimport command for JAX-WS applications

The wsimport command-line tool processes an existing Web Services Description Language (WSDL) file and generates the required artifacts for developing Java API for XML-Based Web Services (JAX-WS) web service applications. The generated artifacts are Java 5 compliant, making them portable across different Java versions and platforms.

The **wsimport** command-line tool supports the top-down approach to developing JAX-WS web services. When you start with an existing WSDL file, use the **wsimport** command-line tool to generate the required JAX-WS artifacts.

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

The **wsimport** tool reads an existing WSDL file and generates the following artifacts:

- Service Endpoint Interface (SEI) - The SEI is the annotated Java representation of the WSDL file for the web service. This interface is used for implementing JavaBeans endpoints or creating dynamic proxy client instances.
- `javax.xml.ws.Service` extension class - This is a generated class that extends the `javax.xml.ws.Service` class. This class is used to configure and create both dynamic proxy and dispatch instances.
- required data beans, including any Java Architecture for XML Binding (JAXB) beans that are required to model the web service data.

You can package the generated artifacts in a web application archive (WAR) file with the WSDL file and schema documents along with the endpoint implementation to be deployed.

Note: To correctly use the **wsimport** tool, you must adhere to the following requirements:

- You must define all your services within the main WSDL file. Services that are defined within an imported WSDL file are not processed by the **wsimport** tool.
- If you run the **wsimport** tool on a WSDL file that implements a Document or Literal style pattern, the complexTypes elements that define the input and output types must be composed of unique names to prevent naming conflicts in the parameter list for the operation..
- If you run the **wsimport** tool and pass a `?wsdl` Uniform Resource Identifier (URI) as a parameter for a WSDL file, ensure that you are using the actual resolved WSDL URI. The **wsimport** tool correctly resolves the `?wsdl` URI, but other relative URIs that are referenced might not resolve correctly.

In addition to using the tools from the command line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build environment to invoke the wsimport tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

Syntax

The command-line syntax is:

Parameters

The *WSDL_URI* is the only parameter that is required. The following parameters are optional for the **wsimport** command:

-b <path>
Specifies the external JAX-WS or JAXB binding files. You can specify multiple JAX-WS and JAXB binding files by using the `-b` option; however, each file must be specified with its own `-b` option.

-B <jaxbOption>
Specifies to pass this option to the JAXB schema compiler.

-catalog
Specifies the catalog file to resolve external entity references. It supports the TR9401, XCatalog, and the OASIS XML Catalog formats

-d <directory>
Specifies where to place the generated output files.

-extension
Specifies whether to accept custom extensions for functionality that are not specified by the JAX-WS specification. The use of custom extensions can result in applications that are not portable or do not interoperate with other implementations.

-help
Displays the help menu.

-httpproxy:<host>:<port>
Specifies an HTTP proxy. The default port value is 8080.

-keep
Specifies whether to keep the generated source files.

-p <package_name>
Specifies a target package with this command-line option and overrides any WSDL file and schema binding customization for the package name and the default package name algorithm defined in the JAX-WS specification.

-quiet
Specifies to suppress the **wsimport** output.

-s <directory>
Specifies the directory to place the generated source files.

-target <version>>
Specifies to generate code that is compliant with a specific JAX-WS specification level. Specify version `2.0` or `2.1` to generate code that is compliant with the JAX-WS 2.0 or JAX-WS 2.1 specification respectively. Specifying version `2.1` indicates to generate code that is compliant with the JAX-WS 2.1 specification. The default value is version `2.2` and generates compliant code for the JAXB 2.2 specification.

-verbose
Specifies to output messages about what the compiler is doing.

-version
Prints the version information. If you specify this option, only the version information is included in the output and normal command processing does not occur.

-wsdlLocation
Specifies the `@WebServiceClient.wsdlLocation` value.

Note: The **wsimport** tool does not set the `@WebService.wsdlLocation` value either by default or when the -wsdlLocation attribute is specified. The **wsimport** command-line tool updates the @WebServiceClient.wsdlLocation annotation only. You can manually update the @WebService.wsdlLocation annotation with a relative URL that specifies the location of the Web Services Description Language (WSDL) file. If the @WebService.wsdlLocation annotation is present on an endpoint implementation class, then the value must be a relative URL and the WSDL document that it references must be packaged with the application.

Note: If you specify an HTTPS URL for the -wsdlLocation parameter, the **wsimport** tool generates a service class with a no-argument constructor that is not valid. Avoid using the no-argument service constructor to instantiate your service. Instead, pass the HTTPS URL to one of the service class constructors that takes a WSDL URL for an argument; for example:

```
MyService("https://example.ibm.com/My?wsdl");
```

Enabling MTOM for JAX-WS web services

With Java API for XML-Based Web Services (JAX-WS), you can send binary attachments such as images or files along with web services requests. JAX-WS adds support for optimized transmission of binary data as specified by the SOAP Message Transmission Optimization Mechanism (MTOM) specification.

About this task

JAX-WS supports the use of SOAP Message Transmission Optimized Mechanism (MTOM) for sending binary attachment data. By enabling MTOM, you can send and receive binary data optimally without incurring the cost of data encoding needed to embed the binary data in an XML document.

The application server supports sending attachments using MTOM only for JAX-WS applications. This product also provides the ability to provide attachments with Web Services Security SOAP messages by using the new MTOM and XOP standards.

JAX-WS applications can send binary data as base64 or hexBinary encoded data contained within the XML document. However, to take advantage of the optimizations provided by MTOM, enable MTOM to send binary base64 data as attachments contained outside the XML document. MTOM optimization is not enabled by default. JAX-WS applications require separate configuration of both the client and the server artifacts to enable MTOM support.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes an XML schema or Web Services Description Language (WSDL) file that represents your web services application data that includes a binary attachment.
   a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the wsimport command to generate the required JAX-WS portable artifacts.
   b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and optionally generate a WSDL file using the wsgen command. The XML schema or WSDL file includes a `xsd:base64Binary` or `xsd:hexBinary` element definition for the binary data.
   c. You can also include the `xmime:expectedContentTypes` attribute on the element to affect the mapping by JAXB.
2. Enable MTOM on your endpoint implementation class using one of the following methods:
   - Use the @MTOM annotation on the endpoint.

     To enable MTOM on an endpoint, use the @MTOM (javax.xml.ws.soap.MTOM) annotation on the endpoint. The @MTOM annotation has two parameters, `enabled` and `threshold`. The `enabled` parameter has a boolean value and indicates if MTOM is enabled for the JAX-WS endpoint. The

threshold parameter has an integer value, that must be greater than or equal to zero. When MTOM is enabled, any binary data whose size, in bytes, exceeds the threshold value is XML-binary Optimized Packaging (XOP) encoded or sent as an attachment. When the message size is less than the threshold value, the message is inlined in the XML document as either base64 or hexBinary data.

The following example snippet illustrates adding the @MTOM annotation so that MTOM is enabled for the JAX-WS MyServiceImpl endpoint and specifies a threshold value of 2048 bytes:

```
@MTOM(enabled=true, threshold=2048)
@WebService
public class MyServiceImpl {
...
}
```

Additionally, you can use the @BindingType (javax.xml.ws.BindingType) annotation on an endpoint implementation class to specify that the endpoint supports one of the MTOM binding types so that the response messages are MTOM-enabled. The javax.xml.ws.SOAPBinding class defines two different constants, SOAP11HTTP_MTOM_BINDING and SOAP12HTTP_MTOM_BINDING that you can use for the value of the @BindingType annotation; for example:

```
// This example is for SOAP version 1.1.
@BindingType(value = SOAPBinding.SOAP11HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
...
}

// This example is for SOAP version 1.2.
@BindingType(value = SOAPBinding.SOAP12HTTP_MTOM_BINDING)
@WebService
public class MyServiceImpl {
...
}
```

The presence and value of an @MTOM annotation overrides the value of the @BindingType annotation. For example, if the @BindingType indicates MTOM is enabled, but an @MTOM annotation is present with an enabled value of false, then MTOM is not enabled.

- Use the <enable-mtom> and <mtom-threshold> deployment descriptor elements.

  You can use the <enable-mtom> and <mtom-threshold> elements within the <port-component> element in the webservices.xml deployment descriptor as an alternative to using the @MTOM annotation on the service endpoint implementation class; for example:

```
<port-component>
   <port-component-name>MyPort1</port-component-name>
   <enable-mtom>true</enable-mtom>
   <mtom-threshold>2048</mtom-threshold>
   <service-impl-bean>
    <servlet-link>MyPort1ImplBean</servlet-link>
   </service-impl-bean>
</port-component>
```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the enabled attribute is set to true in the annotation, but the <enable-mtom> element is set to false in the webservices.xml file, MTOM is not enabled for the corresponding endpoint.

3. Enable MTOM on your client to optimize the binary messages that are sent from the client to the server. Use one of the following methods to enable MTOM on your client:

   - Enable MTOM on a Dispatch client.

     The following examples use SOAP version 1.1.

     The first method uses SOAPBinding.setMTOMEnabled(); for example:

```
SOAPBinding binding = (SOAPBinding)dispatch.getBinding();
    binding.setMTOMEnabled(true);
```

     The second method uses Service.addPort; for example:

```
    Service svc = Service.create(serviceName);
    svc.addPort(portName,SOAPBinding.SOAP11HTTP_MTOM_BINDING,endpointUrl);
```

     The third method uses MTOMFeature; for example:

```
   MTOMFeature mtom = new MTOMFeature(true, 2048);
    Service svc = Service.create(serviceName);
    svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
    Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, mtom);
```

- Enable MTOM on a Dynamic Proxy client.

```
// Create a BindingProvider bp from a proxy port.
  Service svc = Service.create(serviceName);
  MtomSample proxy = svc.getPort(portName, MtomSample.class);
  BindingProvider bp = (BindingProvider) proxy;

  //Enable MTOM using the SOAPBinding.
  MtomSample proxy = svc.getPort(portName, MtomSample.class);
  BindingProvider bp = (BindingProvider) proxy;
  SOAPBinding binding = (SOAPBinding) bp.getBinding();
  binding.setMTOMEnabled(true);

  //Or, you can enable MTOM with the MTOMFeature.
  MTOMFeature mtom = new MTOMFeature();
  MtomSample proxy = svc.getPort(portName, MtomSample.class, mtom);
```

- Enable MTOM on your client using the @MTOM annotation; for example:

```
public class MyClientApplication {

    // Enable MTOM for a port-comonent-ref resource injection.
     @MTOM(enabled=true, threshold=1024)
     @WebServiceRef(MyService.class)
     private MyPortType myPort;
    ...
}
```

- Enable MTOM on your client using deployment descriptor elements within a port-component-ref element; for example:

```
<service-ref>
    <service-ref-name>service/MyPortComponentRef</service-ref-name>
    <service-interface>com.example.MyService</service-ref-interface>
    <port-component-ref>
        <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
        <enable-mtom>true</enable-mtom>
        <mtom-threshold>1024</mtom-threshold>
    </port-component-ref>
</service-ref>
```

Note: The deployment descriptor elements take precedence over the corresponding attributes in the MTOM annotation. For example, if the `enabled` attribute is set to `true` in the annotation, but the `<enable-mtom>` element is set to `false` in the deployment descriptor entry for the service-ref of the client, MTOM is not enabled for that service reference.

Results

You have developed a JAX-WS web services server and client application that optimally sends and receives binary data using MTOM.

Example

The following example illustrates enabling MTOM support on both the web services client and server endpoint when starting with an WSDL file.

1. Locate the WSDL file containing an `xsd:base64Binary` element. The following example is a portion of a WSDL file that contains an `xsd:base64Binary` element.

```
  <types>
    ........
    <xs:complexType name="ImageDepot">
        <xs:sequence>
            <xs:element name="imageData"
                        type="xs:base64Binary"
                        xmime:expectedContentTypes="image/jpeg"/>

        </xs:sequence>
    </xs:complexType>
    ........
</types>
```

2. Run the **wsimport** command from the *app_server_root*\bin\ directory against the WSDL file to generate a set of JAX-WS portable artifacts.

   Depending on the `expectedContentTypes` value contained in the WSDL file, the JAXB artifacts generated are in the Java type as described in the following table:

Table 130. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.

MIME Type	Java Type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String
text/xml	javax.xml.transform.Source
application/xml	javax.xml.transform.Source
/	javax.activation.DataHandler

3. Use the JAXB artifacts in the same manner as in any other JAX-WS application. Use these beans to send binary data from both the Dispatch and the Dynamic Proxy client APIs.
4. Enable MTOM on a Dispatch client.

```
//Create the Dispatch instance.
        JAXBContext jbc = JAXBContext.newInstance("org.apache.axis2.jaxws.sample.mtom");
        Dispatch<Object> dispatch = svc.createDispatch(portName, jbc, Service.Mode.PAYLOAD);

//Enable MTOM.
        SOAPBinding binding = (SOAPBinding) dispatch.getBinding();
        binding.setMTOMEnabled(true);
```

5. Enable MTOM on a Dynamic Proxy client.

```
//Create the Dynamic Proxy instance.
        Service svc = Service.create(serviceName);
        MtomSample proxy = svc.getPort(portName, MtomSample.class);

//Enable MTOM.
        BindingProvider bp = (BindingProvider) proxy;
        SOAPBinding binding = (SOAPBinding) bp.getBinding();
        binding.setMTOMEnabled(true);
```

   Now that you have enabled the JAX-WS client for MTOM, messages sent to the server have MTOM enabled. However, for the server to respond back to the client using MTOM, you must enable MTOM on the endpoint.

6. Enable MTOM on the endpoint implementation class.

```
@MTOM(enabled, threshold=4096)
@WebService (endpointInterface="org.apache.axis2.jaxws.sample.mtom.MtomSample")

public class MtomSampleService implements MtomSample {
   ....
}
```

   The `jaxax.xml.ws.SOAPBinding` class has a static member for each of the supported binding types. Include either the `SOAP11HTTP_MTOM_BINDING` or the `SOAP12HTTP_MTOM_BINDING` as the value for the `@BindingType` annotation. This value enables all server responses to have MTOM enabled.

When you enable MTOM on the server and the client, the binary data that represents the attachment is included as a Multipurpose Internet Mail Extensions (MIME) attachment to the SOAP message. Without MTOM, the same data is encoded in the format that describes the XML schema, either base64 or hexadecimal encoding, and included inline in the XML document.

This example illustrates an MTOM enabled SOAP version 1.1 message with an attachment. The `type` and `content-type` attributes both have the value, `application/xop+xml`, which indicates that the message was successfully optimized using XML-binary Optimized packaging (XOP) when MTOM was enabled. This example demonstrates how the optimized message looks on the wire with MTOM enabled.

```
... other transport headers ...
Content-Type: multipart/related; boundary=MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812;
type="application/xop+xml"; start="
<0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>"; start-info="text/xml"; charset=UTF-8

--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: application/xop+xml; charset=UTF-8; type="text/xml";
content-transfer-encoding: binary
content-id:
   <0.urn:uuid:0FE43E4D025F0BF3DC11582467646813@apache.org>

<?xml version="1.0" encoding="UTF-8"?>
         <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
```

```
            <soapenv:Header/>
            <soapenv:Body>
               <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
                  <input>
                     <imageData>
                        <xop:Include xmlns:xop="http://www.w3.org/2004/08/xop/include"
href="cid:1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org"/>
                     </imageData>
                  </input>
               </sendImage>
            </soapenv:Body>
         </soapenv:Envelope>
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812
content-type: text/plain
content-transfer-encoding: binary
content-id:
         <1.urn:uuid:0FE43E4D025F0BF3DC11582467646811@apache.org>

... binary data goes here ...
--MIMEBoundaryurn_uuid_0FE43E4D025F0BF3DC11582467646812--
```

In contrast, this example demonstrates a SOAP version 1.1 message on the wire without MTOM enabled. The binary data is included in the body of the SOAP message, and the SOAP message is not optimized.

```
... other transport headers ...
Content-Type: text/xml; charset=UTF-8

<?xml version="1.0" encoding="UTF-8"?>
   <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
      <soapenv:Header/>
      <soapenv:Body>
         <sendImage xmlns="http://org/apache/axis2/jaxws/sample/mtom">
            <input>
               <imageData>R0lGAD1 ... more base64 encoded data ... KTJk8giAAA7</imageData>
            </input>
         </sendImage>
      </soapenv:Body>
   </soapenv:Envelope>
```

For additional information, refer to the Samples section of the Information Center which includes a sample that demonstrates the use of MTOM with JAX-WS web services.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root

Refers to the top directory for a WebSphere Application Server node.

The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root

Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root

Refers to the installation root directory for Web Server Plug-ins.

profile_root

Refers to the home directory for a particular instantiated WebSphere Application Server profile.

Corresponding product variables are *server.root* and *user.install.root.*

In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root

Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

The corresponding product variable is *smpe.install.root*.

The default is /usr/lpp/zWebSphere/V8R5.

Enforcing adherence to WSDL bindings in JAX-WS web services

Java API for XML-Based Web Services (JAX-WS) Version 2.1 introduced the concept of *features* as a way to programmatically control specific functions and behaviors. The RespectBindingFeature is one of the supported standard features. You can use the RespectBindingFeature to control whether a JAX-WS implementation is required to respect the contents of a Web Services Description Language (WSDL) binding that is associated with an endpoint.

About this task

While WSDL documents are often used during the development process, the actual enforcement of the use of the WSDL document specifications, when they are provided, at run time has not been well defined in versions of the JAX-WS specification previous to Version 2.1. The JAX-WS Version 2.1 specification added the feature, RespectBindingFeature, to clarify the impact of the wsdl:binding in a JAX-WS runtime environment.

Enabling the feature, RespectBindingFeature, causes the JAX-WS runtime environment to inspect the wsdl:binding for an endpoint at run time to ensure that the binding of service endpoint interface (SEI) parameters and return values is respected. Additionally, this feature ensures that all required wsdl:binding extensions are either understood and used by the runtime environment, or the extensions have been explicitly disabled by the application. Your JAX-WS application can disable a specific wsdl:binding extension that has a defined WebServiceFeature interface by using the appropriate annotation that is associated with that feature, using an API that accepts the javax.xml.ws.WebServiceFeature interface, or configuring the deployment descriptors.

When the RespectBindingFeature feature is not enabled, which is the default, the runtime environment can choose whether any part of the wsdl:binding is enforced.

Procedure

1. Develop Java artifacts for your JAX-WS application that includes a Web Services Description Language (WSDL) file that represents your web services application.
   a. If you are starting with a WSDL file, develop Java artifacts from a WSDL file by using the wsimport command to generate the required JAX-WS portable artifacts.
   b. If you are starting with JavaBeans components, develop Java artifacts for JAX-WS applications and generate a WSDL file using the wsgen command.
2. If you want to enable RespectBindingFeature on your endpoint implementation class, use one of the following methods:
   - Use the @RespectBinding annotation on the endpoint.

     To enable RespectBinding on an endpoint, use the @RespectBinding (javax.xml.ws.RespectBinding) annotation on the endpoint. The @RespectBinding annotation has only one parameter, enabled. This parameter is optional. The enabled parameter has a Boolean value and indicates if RespectBindingFeature is enabled for the JAX-WS endpoint.

     The following example snippet illustrates adding the @RespectBinding annotation for the JAX-WS MyServiceImpl endpoint:

```
@RespectBinding(enabled=true))
@WebService
public class MyServiceImpl {
...
}
```

- Use the <respect-binding> deployment descriptor element.

  You can use the <respect-binding> element within the <port-component> element in the webservices.xml deployment descriptor as an alternative to using the @RespectBinding annotation on the service endpoint implementation class; for example:

```
<port-component>
     <port-component-name>MyPort1</port-component-name>
     <respect-binding>
         <enabled>true</enabled>
     </respect-binding>
     <service-impl-bean>
         <servlet-link>MyPort1ImplBean</servlet-link>
     </service-impl-bean>
</port-component>
```

3. If you want to enable RespectBindingFeature on your client, use one of the following methods:
   - Enable RespectBindingFeature on a dispatch client; for example:

```
RespectBindingFeature respectBinding = new RespectBindingFeature();
Service svc = Service.create(serviceName);
svc.addPort(portName, SOAPBinding.SOAP11_HTTP_BINDING, endpointUrl);
Dispatch<Source> dsp = svc.createDispatch(portName, Source.class, Service.Mode.PAYLOAD, respectBinding);
```

   - Enable RespectBindingFeature on a dynamic proxy client; for example:

```
// Create a dynamic proxy with RespectBinding enabled.
  Service svc = Service.create(serviceName);
  RespectBindingFeature respectBinding = new RespectBindingFeature();
  RespectBindingSample proxy = svc.getPort(portName, RespectBindingSample.class, respectBinding);
```

   - Enable RespectBindingFeature on your client using the @RespectBinding annotation; for example:

```
public class MyClientApplication {

               // Enable RespectBinding for a port-component-ref resource injection.
                   @RespectBinding(enabled=true)
                   @WebServiceRef(MyService.class)
                   private MyPortType myPort;
               ...
}
```

   - Enable RespectBindingFeature on your client using deployment descriptor elements within a port-component-ref element; for example:

```
<service-ref>
    <service-ref-name>service/MyPortComponentRef</service-ref-name>
    <service-interface>com.example.MyService</service-ref-interface>
    <port-component-ref>
        <service-endpoint-interface>com.example.MyPortType</service-endpoint-interface>
        <respect-binding>
            <enabled>true</enabled>
        </respect-binding>
    </port-component-ref>
</service-ref>
```

Results

By implementing the feature, RespectBindingFeature, you have specified to enforce adherence of the contents of a WSDL binding that is associated with an endpoint for your JAX-WS application.

Developing a webservices.xml deployment descriptor for JAX-WS applications

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. You can optionally use the webservices.xml deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services.

About this task

Similar to Java API for XML-based RPC (JAX-RPC) Web services, you can use deployment descriptors to describe JAX-WS web services. For JAX-WS web services, the use of the webservices.xml deployment

descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

A JAX-WS web service requires that you annotate your Java class with the `javax.jws.WebService` annotation or the `javax.jws.WebServiceProvider` annotation for Provider endpoints. You can use server-side deployment descriptors to override corresponding attributes of the annotation or to enhance information in annotations. There is a defined relationship between the deployment descriptor elements and the @WebService and @WebServiceProvider annotations. Refer to section 5.3 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification, Version 1.2 for detailed information regarding the deployment descriptor elements and the mapping to the @WebService and @WebServiceProvider annotation attributes. There are also elements in the `webservice.xml` deployment descriptor that map to other annotations. For example, the deployment descriptor element <protocol-binding> maps to the @BindingType annotation, and the deployment descriptor element <enable-mtom> maps to the @MTOM annotation. For more information regarding the web services deployment descriptor elements, see section 7.1 in the Web Services for Java Platform, Enterprise Edition (Java EE) specification.

Procedure

Use assembly tools to generate the `webservice.xml` deployment descriptor.

Results

You have deployment descriptor templates that you can use to override JAX-WS annotation attributes or specify attributes that are not defined by the annotation.

Example

In the following example, the service implementation class for a JAX-WS web service includes the @WebService annotation:

```
@WebService(wsdlLocation="http://myhost.com/location/of/the/wsdl/ExampleService.wsdl")
```

The associated `webservices.xml` deployment descriptor specifies a different filename for the WSDL document as follows:

```
<webservices>
<webservice-description>
<webservice-description-name>ExampleService</webservice-description-name>
<wsdl-file>META-INF/wsdl/ExampleService.wsdl</wsdl-file>
...
</webservice-description>
</webservices>
```

The value that is specified in the deployment descriptor, `META-INF/wsdl/ExampleService.wsdl`, overrides the annotation value.

What to do next

Configure the `webservice.xml` deployment descriptor. After you configure the deployment descriptors, you must assemble the Web services application for deployment.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This article describes the conventions in use for WebSphere Application Server.

Default product locations - z/OS

app_server_root
: Refers to the top directory for a WebSphere Application Server node.

The node may be of any type—application server, deployment manager, or unmanaged for example. Each node has its own *app_server_root*. Corresponding product variables are *was.install.root* and *WAS_HOME*.

The default varies based on node type. Common defaults are *configuration_root*/AppServer and *configuration_root*/DeploymentManager.

configuration_root
Refers to the mount point for the configuration file system (formerly, the configuration HFS) in WebSphere Application Server for z/OS.

The *configuration_root* contains the various *app_server_root* directories and certain symbolic links associated with them. Each different node type under the *configuration_root* requires its own cataloged procedures under z/OS.

The default is /wasv8config/*cell_name*/*node_name*.

plug-ins_root
Refers to the installation root directory for Web Server Plug-ins.

profile_root
Refers to the home directory for a particular instantiated WebSphere Application Server profile.

Corresponding product variables are *server.root* and *user.install.root.*

In general, this is the same as *app_server_root*/profiles/*profile_name*. On z/OS, this will always be *app_server_root*/profiles/default because only the profile name "default" is used in WebSphere Application Server for z/OS.

smpe_root
Refers to the root directory for product code installed with SMP/E or IBM Installation Manager.

The corresponding product variable is *smpe.install.root*.

The default is /usr/lpp/zWebSphere/V8R5.

Completing the JavaBeans implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the JavaBeans implementation to assemble a web application archive (WAR) file. The resulting WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Write the JavaBeans implementation. The JavaBeans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your JavaBeans implementation to complete your web service application.

What to do next

After completing the JavaBeans implementation, assemble your web services application.

Completing the EJB implementation for JAX-WS applications

After you have developed the Java artifacts necessary to develop a Java API for XML-Based Web Services (JAX-WS) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file. The resulting JAR file contains the Enterprise JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Generate Java artifacts for JAX-WS applications and optionally generate a WSDL file using the **wsgen** command-line tool. You can also optionally use deployment descriptors to augment or override binding information contained in annotations for JAX-WS web services.

About this task

For JAX-WS applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Write the enterprise beans implementation. The enterprise beans implementation is not generated by JAX-WS tooling.
2. Compile all the Java classes.

Results

You have now written your enterprise beans implementation to complete your web service application.

What to do next

After completing the enterprise beans implementation, assemble your web services application.

Developing JAX-WS clients

Developing a JAX-WS client from a WSDL file

Java API for XML-Based Web Services (JAX-WS) tooling supports generating Java artifacts you need to develop static JAX-WS web services clients when starting with a Web Services Description Language (WSDL) file.

Before you begin

When you use a top-down development approach to developing JAX-WS web services by starting with a WSDL file, you must obtain the Uniform Resource Locator (URL) for the WSDL file.

If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

About this task

The static client programming model for JAX-WS is the called the dynamic proxy client. The dynamic proxy client invokes a web service based on a service endpoint interface that is provided. After you create

the proxy, the client application can invoke methods on the proxy just like a standard implementation of those interfaces. For JAX-WS web service clients using the dynamic proxy programming model, use the JAX-WS tool, **wsimport**, to process a WSDL file and generate portable Java artifacts that are used to create a web service client. Create the following portable Java artifacts using the **wsimport** tool:

- Service endpoint interface (SEI)
- Service class
- Exception class that is mapped from the wsdl:fault class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

Note: The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform. Read about these command-line tools for JAX-WS applications to learn more about these tools.

Note: WebSphere Application Server provides Java API for XML-Based Web Services (JAX-WS) and Java Architecture for XML Binding (JAXB) tooling. The **wsimport**, **wsgen**, **schemagen** and **xjc** command-line tools are located in the *app_server_root*\bin\ directory. Similar tooling is provided by the Java SE Development Kit (JDK) 6. On some occasions, the artifacts generated by both the tooling provided by WebSphere Application Server and the JDK support the same levels of the specifications. In general, the artifacts generated by the JDK tools are portable across other compliant runtime environments. However, it is a best practice to use the tools provided with this product to achieve seamless integration within the WebSphere Application Server environment and to take advantage of the features that may be only supported in WebSphere Application Server. To take advantage of JAX-WS and JAXB V2.2 tooling, use the tools provided with the application server that are located in the *app_server_root*\bin\ directory.

In addition to using the tools from the command-line, you can invoke these JAX-WS tools from within the Ant build environments. Use the `com.sun.tools.ws.ant.WsImport` Ant task from within the Ant build environment to invoke the wsimport tool. To function properly, this Ant task requires that you invoke Ant using the ws_ant script.

Procedure

Run the wsimport command to generate the portable client artifacts. The **wsimport** tool is located in the *app_server_root*\bin\ directory.
(Optional) Use the following options with the **wsimport** command:

- Use the **-verbose** option to see a list of generated files when you run the command.
- Use the **-keep** option to keep generated Java files.
- Use the **-wsdlLocation** option to specify the location of the WSDL file.

  Note: A best practice for ensuring that you produce a JAX-WS web services client enterprise archive (EAR) file that is portable to other systems is to package the WSDL document within the application module such as a web services client Java archive (JAR) file or a web application archive (WAR) file. You can specify a relative URI for the location of your WSDL file by using the `-wsdllocation` annotation attribute. For example, if your `MyService.wsdl` file is located in the `META-INF/wsdl/ directory`, then run the **wsimport** tool and use the `-wsdllocation` option to specify the value to be used for the location of the WSDL file. This ensures that the generated artifacts contain the correct `-wsdllocation` information needed when the application is loaded into the administrative console; for example:

```
wsimport -keep -wsdllocation /META-INF/wsdl/MyService.wsdl
```

- Use the **-b** option if you are using WSDL or schema customizations to specify external binding files that contain your customizations.

You can customize the bindings in your WSDL file to enable asynchronous mappings or attachment files. To generate asynchronous interfaces, add the client-side only customization `enableAsyncMapping` binding declaration to the `wsdl:definitions` element or in an external binding file that is defined in the WSDL file. Use the `enableMIMEContent` binding declaration in your custom client or server binding file to enable or disable the default mime:content mapping rules. For additional information on custom binding declarations, see chapter 8 the JAX-WS specification.

Read about the **wsimport** command to learn more about this command and additional options that you can specify.

Results

You have the generated Java artifacts to create a JAX-WS client that can invoke JAX-WS web services. To learn more about the usage, syntax, and parameters for the **wsimport** command, see the **wsimport** command for JAX-WS applications documentation.

Example

The following example illustrates how the **wsimport** command is used to process the sample `ping.wsdl` file to generate portable artifacts.

1. Copy the following `ping.wsdl` file to a temporary directory.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--
 * This program can be used, run, copied, modified and distributed
 * without royalty for the purpose of developing, using, marketing, or distributing.
 -->
<wsdl:definitions xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
 xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:tns="http://com/ibm/was/wssample/sei/ping/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema" name="PingService"
 targetNamespace="http://com/ibm/was/wssample/sei/ping/">
 <wsdl:types>
  <xsd:schema
   targetNamespace="http://com/ibm/was/wssample/sei/ping/"
   xmlns:xsd="http://www.w3.org/2001/XMLSchema">

   <xsd:element name="pingStringInput">
    <xsd:complexType>
     <xsd:sequence>
      <xsd:element name="pingInput" type="xsd:string" />
     </xsd:sequence>
    </xsd:complexType>
   </xsd:element>
  </xsd:schema>
 </wsdl:types>
 <wsdl:message name="pingOperationRequest">
  <wsdl:part element="tns:pingStringInput" name="parameter" />
 </wsdl:message>
 <wsdl:portType name="PingServicePortType">
  <wsdl:operation name="pingOperation">
   <wsdl:input message="tns:pingOperationRequest" />

  </wsdl:operation>
 </wsdl:portType>
 <wsdl:binding name="PingSOAP" type="tns:PingServicePortType">
  <soap:binding style="document"
   transport="http://schemas.xmlsoap.org/soap/http" />
  <wsdl:operation name="pingOperation">
   <soap:operation soapAction="pingOperation" style="document" />
   <wsdl:input>
    <soap:body use="literal" />
   </wsdl:input>
  </wsdl:operation>
 </wsdl:binding>
 <wsdl:service name="PingService">
  <wsdl:port binding="tns:PingSOAP" name="PingServicePort">
   <soap:address
```

```
    location="http://localhost:9080/WSSampleSei/PingService" />
  </wsdl:port>
 </wsdl:service>
</wsdl:definitions>
```

2. Run the **wsimport** command from the *app_server_root*\bin\ directory.

After generating the template files from the **wsimport** command, the following files are generated:

```
com\ibm\was\wssample\sei\ping\ObjectFactory.java
com\ibm\was\wssample\sei\ping\package-info.java
com\ibm\was\wssample\sei\ping\PingServicePortType.java
com\ibm\was\wssample\sei\ping\PingService.java
com\ibm\was\wssample\sei\ping\PingStringInput.java
```

The `ObjectFactory.java`, `PingService.java`, and `PingServicePortType.java` files are the generated Java class files to use when you package the Java artifacts with your client implementation inside a Java archive (JAR) or a web application archive (WAR) file.

What to do next

Complete the client implementation.

Developing deployment descriptors for a JAX-WS client

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. You can optionally use the Web Services for Java Platform, Enterprise Edition (Java EE) specification (JSR 109) service reference deployment descriptor to augment or override application metadata specified in annotations within Java API for XML-Based Web Services (JAX-WS) web services client.

Before you begin

You must first generate the web services client artifacts from a Web Services Description Language (WSDL) file using the **wsimport** command.

About this task

You can add `service-ref` entries within the `application-client.xml`, `web.xml`, or `ejb-jar.xml` Java EE deployment descriptors. A `service-ref` entry represents a reference to a web service that is used by a Java EE component in Web, Enterprise JavaBeans (EJB) or application client containers. A `service-ref` entry has a JNDI name that is used to lookup the service. Specifying the `service-ref` entry enables the client applications to locate the service using a JNDI lookup and you can also use these service references for resource injection.

For each `service-ref` entry found in one of the deployment descriptors, the corresponding service object is bound into the JNDI namespace and the port information is included, if specified. The JAX-WS client can now perform a JNDI lookup to retrieve either a JAX-WS service or port instance.

When defining a `service-ref` that represents a JAX-WS service, use the `javax.xml.ws.Service` subclass that is generated by the **wsimport** tool as the `service-interface` value. This is the class that contains the @WebServiceClient annotation. When defining a `service-ref` that represents a JAX-WS port, the `service-interface` value is still the javax.xml.ws.Service subclass generated by the **wsimport** tool, and the `service-ref-type` value specifies the service endpoint interface (SEI) class used by the port. The SEI class is also generated by **wsimport**, and it is annotated with the @WebService annotation.

Procedure

1. Define the `service-ref` entry in your `application-client.xml`, `web.xml`, or `ejb-jar.xml` deployment descriptors.

For example, suppose a web application archive (WAR) file contains a `WEB-INF/web.xml` deployment descriptor that includes the following `service-ref` entries:

```
<service-ref>
  <service-ref-name>service/ExampleService</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
</service-ref>

<service-ref>
  <service-ref-name>service/ExamplePort</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExamplePort</service-ref-type>
</service-ref>

<service-ref>
  <service-ref-name>service/ExamplePortInjected</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExamplePort</service-ref-type>

  <injection-target>
    <injection-target-class>com.ibm.sample.J2EEClient</injection-target-class>
    <injection-target-name>injectedPort</injection-target-name>
  </injection-target>
</service-ref>
```

In this example, `com.ibm.sample.ExampleService` is a generated JAX-WS service class and this class must be a subclass of javax.xml.ws.Service. Additionally, the `ExampleService.getPort()` method returns an instance of `com.ibm.sample.ExamplePort`.

2. Use the deployment descriptors within your web services client application to customize your application. The following code fragments are examples of how your client application can use the `service-ref` entries within the WAR module:

```
import javax.xml.ws.Service;
import com.ibm.sample.ExampleService;
import com.ibm.sample.ExamplePort;

// Create an InitialContext object for doing JNDI lookups.
InitialContext ic = new InitialContext();

// Client obtains an instance of the generic service class using JNDI.
Service genericService =
(Service) ic.lookup("java:comp/env/service/ExampleService");

// Client obtains an instance of the generated service class using JNDI.
ExampleService exampleService =
(ExampleService) ic.lookup("java:comp/env/service/ExampleService");

// Client obtains an instance of the port using JNDI.
ExamplePort ExamplePort =
(ExamplePort) ic.lookup("java:comp/env/service/ExamplePort");

// The container injects an instance of ExamplePort based on the client deployment descriptor
private ExamplePort injectedPort;
```

Results

You can now use the service references that were defined in the deployment descriptor within your client application. Additionally, you can use deployment descriptors to augment or override information specified by `@WebServiceRef` or `@Resource` annotations.

The `<lookup-name>` deployment descriptor element is new in Java EE 6, and is used to indirectly refer to an already-defined service reference. When the `<lookup-name>` element is used, only the `<service-ref-name>` element may also be specified, and no other child elements of `<service-ref>` may be defined.

The following example shows a `service-ref` entry within a `WEB-INF/web.xml` file which defines a reference to a JAX-WS service, as well as a `service-ref` entry within the same `web.xml` file which defines an indirect reference to the first `service-ref`:

```
<service-ref>
  <service-ref-name>service/ExampleService</service-ref-name>
  <service-interface>com.ibm.sample.ExampleService</service-interface>
  <service-ref-type>com.ibm.sample.ExampleServicePortType</service-ref-type>
  <wsdl-file>WEB-INF/wsdl/ExampleService.wsdl</wsdl-file>
</service-ref>
```

```
<service-ref>
  <service-ref-name>service/ExampleService2</service-ref>
  <lookup-name>java:comp/env/service/ExampleService</lookup-name>
</service-ref>
```

Assuming the above `service-ref`s are defined in the `WEB-INF/web.xml` file, the client application could perform a JNDI lookup using the name `java:comp/env/service/ExampleService2`, and the result would be a reference to the `ExampleService` service defined in the WSDL document `WEB-INF/wsdl/ExampleService.wsdl`, as defined in the first `service-ref`.

What to do next

Complete the client implementation by writing your client application code that is used to invoke the web service.

Developing a dynamic client using JAX-WS APIs

Java API for XML-Based Web Services (JAX-WS) provides support for the dynamic invocation of service endpoint operations.

About this task

JAX-WS provides a new dynamic Dispatch client API that is more generic and offers more flexibility than the existing Java API for XML-based RPC (JAX-RPC)-based Dynamic Invocation Interface (DII). The Dispatch client interface, javax.xml.ws.Dispatch, is an XML messaging oriented client that is intended for advanced XML developers who prefer to work at the XML level using XML constructs. To write a Dispatch client, you must have expertise with the Dispatch client APIs, the supported object types, and knowledge of the message representations for the associated Web Services Description Language (WSDL) file.

The Dispatch API can send data in either `PAYLOAD` or `MESSAGE` mode. When using the `PAYLOAD` mode, the Dispatch client is only responsible for providing the contents of the <soap:Body> and JAX-WS includes the input payload in a <soap:Envelope> element. When using the `MESSAGE` mode, the Dispatch client is responsible for providing the entire SOAP envelope.

The Dispatch client API requires application clients to construct messages or payloads as XML and requires a detailed knowledge of the message or message payload. The Dispatch client can use HTTP bindings when using Source objects, Java Architecture for XML Binding (JAXB) objects, or data source objects. The Dispatch client supports the following types of objects:

- javax.xml.transform.Source: Use Source objects to enable clients to use XML APIs directly. You can use Source objects with SOAP and HTTP bindings.
- JAXB objects: Use JAXB objects so that clients can use JAXB objects that are generated from an XML schema to create and manipulate XML with JAX-WS applications. JAXB objects can only be used with SOAP and HTTP bindings.
- javax.xml.soap.SOAPMessage: Use SOAPMessage objects so that clients can work with SOAP messages. You can only use SOAPMessage objects with SOAP version 1.1 or SOAP version 1.2 bindings.
- javax.activation.DataSource: Use DataSource objects so that clients can work with Multipurpose Internet Mail Extension (MIME) messages. Use DataSource only with HTTP bindings.

The Dispatch API uses the concept of generics that are introduced in Java SE Runtime Environment (JRE) 6. For each of the `invoke()` methods on the Dispatch interface, generics are used to determine the return type.

Procedure

1. Determine if you want your dynamic client to send data in `PAYLOAD` or `MESSAGE` mode.
2. Create a service instance and add at least one port to it. The port carries the protocol binding and service endpoint address information.

3. Create a Dispatch<T> object using either the Service.Mode.PAYLOAD method or the Service.Mode.MESSAGE method.
4. Configure the request context properties on the javax.xml.ws.BindingProvider interface. Use the request context to specify additional properties such as enabling HTTP authentication or specifying the endpoint address.
5. Optional: Set the jaxws.response.throwExceptionIfSOAPFault property on the RequestContext option for the Dispatch API to `Boolean.TRUE` if you do not want the JAX-WS runtime to throw a SOAPFaultException.

   The following example illustrates how to specify this property on the RequestContext option for the Dispatch API

```
Dispatch<OMElement> dispatch = service.createDispatch(
portName, OMElement.class, Mode.MESSAGE);
BindingProvider bp = (BindingProvider)dispatch;
bp.getRequestContext().put(
"jaxws.response.throwExceptionIfSOAPFault", Boolean.FALSE);
```

6. Compose the client request message for the dynamic client.
7. Invoke the service endpoint with the Dispatch client either synchronously or asynchronously.
8. Process the response message from the service.

Results

You have developed a dynamic JAX-WS client using the Dispatch API. Refer to Chapter 4, section 3 of the JAX-WS 2.0 specification for more information on using a Dispatch client.

JAX-WS dynamic ports, which are those added using the service method addPort, might have additional memory requirements starting in WebSphere Application Server Version 8.0. In previous releases, a single instance of a dynamic port could be shared across multiple service instances. In version 8.x, dynamic ports are now scoped to the instance of the service that added them. If a JAX-WS client has multiple service instances which refer to a dynamic port of the same name, those instances are no longer shared. This can potentially increase the memory requirements for that client. The memory used by dynamic ports is released when the service instance goes out of scope. However, if you encounter issues related to increased memory usage, it is possible to revert the behavior so that dynamic ports are again shared across service instances. To do this, set the system property `jaxws.share.dynamic.ports.enable` to the value `true`. However, note that doing so can cause some other issues, such as having policy set attachments incorrectly applied across shared dynamic ports. If you set this flag to `true` and encounter some of these issues, then you should remove the flag setting. In previous releases, if a SOAP Action was not provided by the Dispatch client application, the correct SOAP Action was not sent on the outbound message. Instead, the SOAP action was set to an anonymous operation. Starting in WebSphere Application Server Version 8, if the SOAP Action is not provided by the Dispatch client application, the JAX-WS runtime environment parses the outgoing message. It determines the operation being invoked and uses that information to determine the appropriate value for the SOAP Action. The operation resolution of the outbound message is based on the SOAP Body and the message encoding, for example, Doc/Lit/Bare, Doc/Lit/Wrapped. Since this parsing can be expensive, a property can be set. To always disable the parsing, set the property at the System level. To disable parsing on a per-message basis, set the property on the JAX-WS Request Message Context. The property is defined as a constant `org.apache.axis2.jaxws.Constants.DISPATCH_CLIENT_OUTBOUND_RESOLUTION` with a String value of `jaxws.dispatch.outbound.operation.resolution.enable`. The default value of the property is null which is interpreted as the String `true`, which enables the outbound operation resolution. Setting the property to `false` disables the outbound operation resolution. If parsing is disabled, then the SOAP Action in the outbound message is set to an anonymous operation as in previous releases. If the client provides a SOAP Action through the JAX-WS `javax.xml.ws.BindingProvider` properties, `SOAPACTION_USE_PROPERTY` and `SOAPACTION_URI_PROPERTY`, then that SOAP Action is used. Therefore, parsing of the outbound message does not occur regardless of the setting of the property. Setting a SOAP Action explicitly by the client is considered a best practice, particularly for performance on the service-provider. This practice prevents the inbound message from being parsed, to be routed to the correct endpoint operation.

Example

The following example illustrates the steps to create a Dispatch client and invoke a sample EchoService service endpoint.

```
String endpointUrl = ...;

QName serviceName = new QName("http://com/ibm/was/wssample/echo/",
 "EchoService");
QName portName = new QName("http://com/ibm/was/wssample/echo/",
 "EchoServicePort");

/** Create a service and add at least one port to it. **/
Service service = Service.create(serviceName);
service.addPort(portName, SOAPBinding.SOAP11HTTP_BINDING, endpointUrl);

/** Create a Dispatch instance from a service.**/
Dispatch<SOAPMessage> dispatch = service.createDispatch(portName,
SOAPMessage.class, Service.Mode.MESSAGE);

/** Create SOAPMessage request. **/
// compose a request message
MessageFactory mf = MessageFactory.newInstance(SOAPConstants.SOAP_1_1_PROTOCOL);

// Create a message.  This example works with the SOAPPART.
SOAPMessage request = mf.createMessage();
SOAPPart part = request.getSOAPPart();

// Obtain the SOAPEnvelope and header and body elements.
SOAPEnvelope env = part.getEnvelope();
SOAPHeader header = env.getHeader();
SOAPBody body = env.getBody();

// Construct the message payload.
SOAPElement operation = body.addChildElement("invoke", "ns1",
 "http://com/ibm/was/wssample/echo/");
SOAPElement value = operation.addChildElement("arg0");
value.addTextNode("ping");
request.saveChanges();

/** Invoke the service endpoint. **/
SOAPMessage response = dispatch.invoke(request);

/** Process the response. **/
```

Invoking JAX-WS web services asynchronously

Java API for XML-Based Web Services (JAX-WS) provides support for invoking web services using an asynchronous client invocation. JAX-WS provides support for both a callback and polling model when calling web services asynchronously. Both the callback model and the polling model are available on the Dispatch client and the Dynamic Proxy client.

Before you begin

Develop a JAX-WS Dynamic Proxy or Dispatch client. When developing Dynamic Proxy clients, after you generate the portable client artifacts from a Web Services Description Language (WSDL) file using the **wsimport** command, the generated service endpoint interface (SEI) does not have asynchronous methods included in the interface. Use JAX-WS bindings to add the asynchronous callback or polling methods on the interface for the Dynamic Proxy client. To enable asynchronous mappings, you can add the `jaxws:enableAsyncMapping` binding declaration to the WSDL file. For more information on adding binding customizations to generate an asynchronous interface, see chapter 8 of the JAX-WS specification.

Note: When you run the **wsimport** tool and enable asynchronous invocation through the use of the JAX-WS enableAsyncMapping binding declaration, ensure that the corresponding response message your WSDL file does not contain parts. When a response message does not contain parts, the request acts as a two-way request, but the actual response that is sent back is empty. The **wsimport** tool does not correctly handle a void response. To avoid this scenario, you can remove the output message from the operation which makes your operation a one-way operation or you can add a `<wsdl:part>` to your message. For more information on the usage, syntax and parameters for the **wsimport** tool, see the wsimport command for JAX-WS applications documentation.

About this task

An asynchronous invocation of a web service sends a request to the service endpoint and then immediately returns control to the client program without waiting for the response to return from the service. JAX-WS asynchronous web service clients consume web services using either the callback approach or the polling approach. Using a polling model, a client can issue a request and receive a response object that is polled to determine if the server has responded. When the server responds, the actual response is retrieved. Using the callback model, the client provides a callback handler to accept and process the inbound response object. The `handleResponse()` method of the handler is called when the result is available. Both the polling and callback models enable the client to focus on continuing to process work without waiting for a response to return, while providing for a more dynamic and efficient model to invoke web services. Polling invocations are valid from Enterprise JavaBeans (EJB) clients or Java Platform, Enterprise Edition (Java EE) application clients. Callback invocations are valid only from Java EE application clients.

Using the callback asynchronous invocation model

To implement an asynchronous invocation that uses the callback model, the client provides an `AsyncHandler` callback handler to accept and process the inbound response object. The client callback handler implements the `javax.xml.ws.AsyncHandler` interface, which contains the application code that is run when an asynchronous response is received from the server. The `javax.xml.ws.AsyncHandler` interface contains the `handleResponse(java.xml.ws.Response)` method that is called after the run time has received and processed the asynchronous response from the server. The response is delivered to the callback handler in the form of a `javax.xml.ws.Response` object. The response object returns the response content when the `get()` method is called. Additionally, if an error was received, then an exception is returned to the client during that call. The response method is then invoked according to the threading model used by the executor method, `java.util.concurrent.Executor` on the client's `java.xml.ws.Service` instance that was used to create the Dynamic Proxy or Dispatch client instance. The executor is used to invoke any asynchronous callbacks registered by the application. Use the `setExecutor` and `getExecutor` methods to modify and retrieve the executor configured for your service.

Using the polling asynchronous invocation model

Using the polling model, a client can issue a request and receive a response object that can subsequently be polled to determine if the server has responded. When the server responds, the actual response can then be retrieved. The response object returns the response content when the `get()` method is called. The client receives an object of type `javax.xml.ws.Response` from the `invokeAsync` method. That Response object is used to monitor the status of the request to the server, determine when the operation has completed, and to retrieve the response results.

Using an asynchronous message exchange

By default, asynchronous client invocations do not have asynchronous behavior of the message exchange pattern on the wire. The programming model is asynchronous; however, the exchange of request or response messages with the server is not asynchronous. To use an asynchronous message exchange, the `com.ibm.websphere.webservices.use.async.mep` property must be set on the client request context with a boolean value of `true`. When this property is enabled, the messages exchanged between the client and server are different from messages exchanged synchronously. With an asynchronous exchange, the request and response messages have WS-Addressing headers added that provide additional routing information for the messages. Another major difference between asynchronous and synchronous message exchange is that the response is delivered to an asynchronous listener that then delivers that response back to the client. For asynchronous exchanges, there is no timeout that is sent to notify the client to stop listening for a response. To force the client to stop waiting for a response, issue a `Response.cancel()` method on the object returned from a polling invocation or a `Future.cancel()` method on the object returned from a callback invocation. The cancel response does not affect the server when processing a request.

Procedure

1. Determine if you want to implement the callback method or the polling method for the client to asynchronously invoke the web service.
2. (Optional) Configure the client request context. Add the

```
com.ibm.websphere.webservices.use.async.mep
```

   property to the request context to enable asynchronous messaging for the web services client. Using this property requires that the service endpoint supports WS-Addressing which is supported by default for the application server. The following example demonstrates how to set this property:

```
Map<String, Object> rc = ((BindingProvider) port).getRequestContext();
 rc.put("com.ibm.websphere.webservices.use.async.mep", Boolean.TRUE);
```

3. To implement the asynchronous callback method, perform the following steps.
   a. Find the asynchronous callback method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has one more parameter than the synchronous method of type `javax.xml.ws.AsyncHandler`. The `invokeAsync(Object, AsyncHandler)` method is the one that is used on the Dispatch interface.
   b. (Optional) Add the `service.setExecutor` methods to the client application. Adding the executor methods gives the client control of the scheduling methods for processing the response. You can also choose to use the `java.current.Executors` class factory to obtain packaged executors or implement your own executor class. See the JAX-WS specification for more information on using executor class methods with your client.
   c. Implement the `javax.xml.ws.AsyncHandler` interface. The `javax.xml.ws.AsyncHandler` interface only has the `handleResponse(javax.xml.ws.Response)` method. The method must contain the logic for processing the response or possibly an exception. The method is called after the client run time has received and processed the asynchronous response from the server.
   d. Invoke the asynchronous callback method with the parameter data and the callback handler.
   e. The `handleResponse(Response)` method is invoked on the callback object when the response is available. The `Response.get()` method is called within this method to deliver the response.
4. To implement the polling method,
   a. Find the asynchronous polling method on the SEI or `javax.xml.ws.Dispatch` interface. For an SEI, the method name ends in *Async* and has a return type of `javax.xml.ws.Response`. The `invokeAsync(Object)` method is used on the Dispatch interface.
   b. Invoke the asynchronous polling method with the parameter data.
   c. The client receives the object type, `javax.xml.ws.Response`, that is used to monitor the status of the request to the server. The `isDone()` method indicates whether the invocation has completed. When the `isDone()` method returns a value of `true`, call the `get()` method to retrieve the response object.
5. Use the `cancel()` method for the callback or polling method if the client needs to stop waiting for a response from the service. If the `cancel()` method is invoked by the client, the endpoint continues to process the request. However, the wait and response processing for the client is stopped.

Results

You have enabled your JAX-WS web service client to asynchronously invoke and consume web services. See the JAX-WS specification for additional information regarding the asynchronous client APIs.

Example

The following example illustrates a web service interface with methods for asynchronous requests from the client.

```
@WebService

public interface CreditRatingService {
       // Synchronous operation.
       Score getCreditScore(Customer     customer);
```

```
        // Asynchronous operation with polling.
        Response<Score> getCreditScoreAsync(Customer customer);
        // Asynchronous operation with callback.
        Future<?> getQuoteAsync(Customer customer,
               AsyncHandler<Score> handler);
}
```

Using the callback method

The callback method requires a callback handler that is shown in the following example. When using the callback procedure, after a request is made, the callback handler is responsible for handling the response. The response value is a response or possibly an exception. The `Future<?>` method represents the result of an asynchronous computation and is checked to see if the computation is complete. When you want the application to find out if the request is completed, invoke the `Future.isDone()` method. Note that the `Future.get()` method does not provide a meaningful response and is not similar to the `Response.get()` method.

```
CreditRatingService svc = ...;

Future<?> invocation = svc.getCreditScoreAsync(customerTom,
        new AsyncHandler<Score>() {
               public void handleResponse (
                      Response<Score> response)
                   {
                      score = response.get();
                      // process the request...
                   }
    }
);
```

Using the polling method

The following example illustrates an asynchronous polling client:

```
CreditRatingService svc = ...;
Response<Score> response = svc.getCreditScoreAsync(customerTom);

while (!response.isDone()) {
        // Do something while we wait.
}

score = response.get();
```

Implementing extensions to JAX-WS web services clients

WebSphere Application Server provides extensions to web services clients using the Java API for XML-based Web Services (JAX-WS) programming model.

About this task

You can customize web services by using the following extensions to the JAX-WS client programming model.

Procedure

- Set the **JAXWS_OUTBOUND_SOAP_HEADERS** and **JAXWS_INBOUND_SOAP_HEADERS** properties on the request context of the Dispatch or Proxy object to enable a JAX-WS web services client to send or retrieve implicit SOAP headers.

  An implicit SOAP header is a SOAP header that is not explicitly defined in the WSDL file. An implicit SOAP header file fits one of the following descriptions:

  – A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.

  – An element that is not contained in the WSDL file.

  Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

  To learn how to modify your client code to send or retrieve transport headers, see the information on sending implicit SOAP headers with JAX-WS or receiving implicit SOAP headers with JAX-WS.

- Set the **REQUEST_TRANSPORT_PROPERTIES** and **RESPONSE_TRANSPORT_PROPERTIES** properties to enable a web services client to send or retrieve transport headers.

Set the properties on the BindingProvider instance.

By modifying your client code to send or retrieve transport headers, you can send or receive specific information within the transport headers of outgoing requests or incoming responses from the server. For requests or responses that use the HTTP transport, the information is sent or retrieved in an HTTP header. Similarly, for a request or response that uses the Java Message Service (JMS) transport, the information is sent or retrieved in a JMS message property.

To learn how to modify your client code to send or retrieve transport headers, see the information on sending transport headers with JAX-WS or retrieving transport headers with JAX-WS.

To learn how to enable a web services client to send or retrieve transport headers, see the transport header properties best practices information.

Example: Using JAX-WS properties to manipulate SOAP headers in a JAX-WS handler

WebSphere Application Server provides extensions to the Java API for XML-Based Web Services (JAX-WS) and Web Services for Java Platform, Enterprise Edition (Java EE) client programming models, including the jaxws.binding.soap.headers.outbound and jaxws.binding.soap.headers.inbound properties. This example shows how to use these two properties to manipulate SOAP headers in a JAX-WS handler.

The following programming example illustrates how to set two request SOAP headers and retrieve one response SOAP header within a JAX-WS handler context:

```
1  //Create the hashmaps for the outbound soap headers
2  Map<QName, List<String>> outboundHeaders=messageContext.get("jaxws.binding.soap.headers.outbound");
3
4  //Add "AtmUuid1" and "AtmUuid2" to the outbound map
5  List<String> list1 = new ArrayList<String>();
6  list1.add("<AtmUuid1 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
7  List<String> list2 = new ArrayList<String>();
8  list2.add("<AtmUuid2 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid2>"
9  outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid1"), list1);
10 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid2"), list2);
11 // Set the outbound map on the MessageContext object, which is passed into the JAX-WS handler method
12 messageContext.put("jaxws.binding.soap.headers.outbound", outboundHeaders);
```

On line 2, retrieve the outbound SOAP header map from the MessageContext parameter, which is passed into the JAX-WS handler method.

On lines 5-10, the AtmUuid1 and AtmUuid2 headers elements are added to the outbound map.

On line 12, the outbound map is set on the JAX-WS handler context, which causes the AtmUuid1 and AtmUuid2 headers to be added to the request message. This code is not necessary because the outboundHeaders map is a live map.

JAX-WS handler methods might also retrieve specific headers from the map and remove headers or entire lists of headers, if desired.

Sending implicit SOAP headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to send values in implicit SOAP headers. By modifying your client code to send implicit SOAP headers, you can send specific information within an outgoing web service request.

Before you begin

To complete this task, you need a web services client that you can enable to send implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

Using JAX-WS, there is no restriction on types of headers that you can manipulate.

About this task

The client application sets properties on the Dispatch or Proxy object to send and receive implicit SOAP headers.

Procedure

1. Create a `java.util.HashMap<QName, List<String>>` object.
2. Add an entry to the HashMap object for each implicit SOAP header that the client wants to send. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is a `List<String>` object, and each String is the XML text of the entire SOAP header element. By using `List<String>` object, you can add multiple SOAP header elements that each have the same QName object.
3. Set the HashMap object as a property on the request context of the Dispatch or Proxy object. The property name is com.ibm.wsspi.websvcs.Constants.JAXWS_OUTBOUND_SOAP_HEADERS. The value of the property is the HashMap.
4. Issue the remote method calls using the Dispatch or Proxy object. The headers within the HashMap object are sent in the outgoing message.

   A WebServiceException error can occur if any of the following are true:

   - The HashMap object contains a key that is not a QName object or if the HashMap object contains a value that is not a `List<String>` object.
   - The String representing an SOAP header is not a compliant XML message.
   - The HashMap contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-WS web services client that is configured to send implicit SOAP headers.

Example

The following programming example illustrates how to set two request SOAP headers and retrieve one response SOAP header within a JAX-WS web services request and response context:

```
1  //Create the hashmaps for the outbound soap headers
2  Map<QName, List<String>> outboundHeaders=new HashMap<QName, List<String>>();
3
4  //Add "AtmUuid1" and "AtmUuid2" to the outbound map
5  List<String> list1 = new ArrayList<String>();
6  list1.add("<AtmUuid1 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
7  List<String> list2 = new ArrayList<String>();
8  list2.add("<AtmUuid2 xmlns=\"com.rotbank.security\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid2>"
9  outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid1"), list1);
10 outboundHeaders.put(new QName("com.rotbank.security", "AtmUuid2"), list2);
11 // Set the outbound map on the request context
12 dispatch.getRequestContext().put("jaxws.binding.soap.headers.outbound");
13 // Invoke the remote operation
14 dispatch.invoke(parm1);
15 // Get the inbound header map from the response context
16 Map<QName,List<String>> inboundMap = dispatch.getResponseContext().get("jaxws.binding.soap.headers.outbound");
17 List<String> serverUuidList = inboundMap.get(new QName("com.rotbank.security","ServerUuid"));
18 String text = serverUiidList.get(0);
19 //Note: text now equals a XML object that contains a SOAP header:
21//"<y:ServerUuid xmlns:y=\"com.rotbank.security\"><:uuid>ROTB-0A03519322FSA01
22  </y:uuid></y:ServerUuid.");
```

On line 2, create the outbound SOAP header map.

On lines 5-10, the AtmUuid1 and AtmUuid2 headers elements are added to the outbound map.

On line 12, the outbound map is set on the request context, which causes the AtmUuid1 and AtmUuid2 headers to be added to the request message when the operation is invoked.

On line 14, invoke the remote operation.

On line 15, obtain the outbound header map.

On lines 17-18, the ServerUuid header is retrieved from the response Map. The Map accesses the SOAP header from the response message.

Receiving implicit SOAP headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to receive values from implicit SOAP headers. By modifying your client code to receive implicit SOAP headers, you can receive specific information within an incoming web service response.

Before you begin

To complete this task, you need a web services client that you can enable to receive implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

Using JAX-WS, there is no restriction on types of headers that you can manipulate.

About this task

The client application sets properties on the Dispatch or Proxy object to send and receive implicit SOAP headers.

Procedure

1. Issue a remote method call with the Dispatch or Proxy object.
2. Using the property name, `com.ibm.wsspi.websvcs.Constants.JAXWS_INBOUND_SOAP_HEADERS`, retrieve the `Map<QName, List<String>>` from the ResponseContext of the Dispatch or Proxy object.
3. From the `Map<QName, List<String>>` value, retrieve a `List<String>` using the QName of the SOAP header. If the `List<String>` value is present, that value contains zero or more String objects that contain the XML text of the SOAP headers for the corresponding QName.

Results

You have a JAX-WS web services client that can receive values from implicit SOAP headers.

Transport header properties best practices

You can set the REQUEST_TRANSPORT_PROPERTIES property and RESPONSE_TRANSPORT_PROPERTIES property on a Java API for XML-based RPC (JAX-RPC) client Stub, a Call instance, or a Java API for XML-Based Web services (JAX-WS) BindingProvider's RequestContext instance to enable a web services client to send or retrieve transport headers.

Note: Use these best practices to enable a Web services client to send or retrieve transport headers.

REQUEST_TRANSPORT_PROPERTIES best practices

Some transport headers such as the HTTP Cookie header and the Cookie2 header contain multiple embedded values. For headers that contain multiple values, the header value must be written in the following way:

- Each name=value pair embedded within the header value must be separated by a semi-colon (;).
- Each *name* and its value must be separated by an equal (=) sign.

The following is an example of how the header value must be written:

```
name1=value1;name2=value2;name3=value3
```

The values contained in the user's Map might be parsed before being added to the outgoing request if the outgoing request already contains a header identifier that matches one in the Map. For certain transport headers that contain multiple embedded values, the header values in the Map are parsed into individual name=value components. A semi-colon (;) separates the components, for example, name1=value1;name2=value2. Each name=value is appended to the outgoing header unless:

- The outgoing request header contains a *name* value.

  In this case, the name=value from the Map is silently ignored, preventing a client from overwriting or modifying values for the *name* value that are already set in the outgoing request header by either the server or the web services engine.
- The user's header value contains multiple *name* values.

  When the user's header value contains multiple *name* values, the first occurrence of the *name* value is used and the others are silently ignored. For example, if the user's header value contains name1=value1;name2=value2;name1=value3, where there are two occurrences of name1, the first value, name1=value1, is used. The other value, name1=value3, is silently ignored.

RESPONSE_TRANSPORT_PROPERTIES best practices

Only the Map keys are used; the Map values are ignored. The values are filled in this Map by retrieving the transport headers, which correspond to the Map keys from the incoming response message. An empty Map causes all of the transport headers and the associated values to be retrieved from the incoming response message.

HTTP headers that are processed under special consideration

The following are HTTP headers that are given special consideration when sending and retrieving HTTP responses and requests.

The values in these headers can be set in a variety of ways. For example, some header values are sent based on settings in a deployment descriptor or binding file. In these cases, the value set through REQUEST_TRANSPORT_PROPERTIES overrides the values set any other way.

Table 131. HTTP request and response header values. Values to specify for HTTP headers when sending and retrieving HTTP responses and requests.

Header	Send request	Retrieve response
Transfer-encoding	• The transfer-encoding header is ignored for HTTP 1.0. • When using HTTP 1.1, the transfer-encoding header is set to `chunked` if the value is `chunked`.	There is no special processing.

Table 131. HTTP request and response header values (continued). Values to specify for HTTP headers when sending and retrieving HTTP responses and requests.

Header	Send request	Retrieve response
Connection	• The connection header is ignored for HTTP 1.0. • When using HTTP 1.1, the following values are set: – The connection header is set to "close" if the value is set to "close". – The connection header is set to "keep-alive" if the value is set to "keep-alive". – All other value settings are ignored.	There is no special processing.
Expect	• The expect header is ignored for HTTP 1.0. • When using HTTP 1.1, the following values are set: – The connection header is set to "100-continue" if the value is set to "100-continue". – All other value settings are ignored.	There is no special processing.
Host	Ignored	There is no special processing.
Content-type	Ignored	There is no special processing.
SOAPAction	Ignored	There is no special processing.
Content-length	Ignored	There is no special processing.
Cookie The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_COOKIE	The value is sent on the header if it is structured correctly. See the information in this article for Header value format and Map values.	There is no special processing.
Cookie2 The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_COOKIE2	See the information in the "Cookie" entry.	There is no special processing.
Set-cookie The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_SET_COOKIE	There is no special processing.	If the property MAINTAIN_SESSION is set to `true`, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information.
Set-cookie2 The following is a String constant: com.ibm.websphere.webservices.Constants .HTTP_HEADER_SET_COOKIE2	There is no special processing.	If the property MAINTAIN_SESSION is set to `true`, the entire value is saved into SessionContext.CONTEXT_PROPERTY and is sent on subsequent requests in the Cookie header. See the Cookie entry in this table for more information.

Example client code

The following is an example of how you can code a web services client to send and retrieve transport header values:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke the web service operation and send and receive transport headers.
    public void invokeService() {

        // Set up the Map that will contain the request headers.
        Map<String, Object>requestHeaders = new HashMap<String, Object>();
        requestHeaders.put("Cookie", "ClientAuthenticationToken=FFEEBBCC");
        requestHeaders.put("MyHeaderFlag", new Boolean(true));
```

```
        // Set the Map as a property on the RequestContext.
        BindingProvider bp = (BindingProvider) port;
        bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES, requestHeaders);

        // Set up the Map to retrieve transport headers from the response message.
        Map<String, Object>responseHeaders = new HashMap<String, Object>();
        responseHeaders.put("Set-Cookie", null);
        responseHeaders.put("MyHeaderFlag, null);

        // Invoke the web services operation.
        String result = port.echoString("Hello, world!");

        // Retrieve the headers from the response.
        String cookieValue = responseHeaders.get("Set-Cookie");
        String headerFlag = responseHeaders.get("MyHeaderFlag");
    }
}
```

Sending transport headers with JAX-WS

You can enable an existing Java API for XML-Based Web Services (JAX-WS) web services client to send application-defined information along with your web services requests by using transport headers. In addition, you can enable a JAX-WS Web services endpoint to send application-defined information along with the Web services response message by using transport headers.

Before you begin

You need a JAX-WS web services client that you can enable to send transport headers.

Sending transport headers is supported in JAX-WS Web services clients, and is supported for the HTTP and JMS transports. The web services client must call the JAX-WS APIs directly and not through any intermediary layers, such as a gateway function.

About this task

When using the JAX-WS programming model, the client must set a property on the BindingProvider's RequestContext object to send values in transport headers with the Web services request message. After you set the property, the values are set in all the requests for subsequent remote method invocations against the BindingProvider object until the associated property is set to `null` or the BindingProvider object is discarded.

To send values in the transport headers on outbound requests from a JAX-WS Web services client application, modify the client code as follows:

Procedure

1. Create a java.util.Map object that contains the transport headers.
2. Add an entry to the Map object for each transport header that you want the client to send.
   a. Set the Map entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made as to the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class.
   b. Set the Map entry value to the value of the transport header. The type of this value can be one of the following data types:
      - java.lang.String
      - java.lang.Integer
      - java.lang.Short
      - java.lang.Long
      - java.lang.Float

- java.lang.Double
- java.lang.Byte
- java.lang.Boolean

3. Set the Map object on the BindingProvider's RequestContext using the com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES property. When the REQUEST_TRANSPORT_PROPERTIES property value is set, that Map is used on subsequent invocations to set the header values in the outgoing requests. If the REQUEST_TRANSPORT_PROPERTIES property value is set to `null`, no transport properties are sent in outgoing requests. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the BindingProvider instance. The headers and the associated values from the Map are added to the outgoing request for each method invocation. If the invocation uses HTTP, then the transport headers are sent as HTTP headers within the HTTP request. If the invocation uses JMS, then the transport headers are sent as JMS message properties.

   If the Constants.REQUEST_TRANSPORT_PROPERTIES property is not set correctly, you might experience API usage errors that result in a WebServiceException error. The following requirements must be met, or the process fails:

   a. The Constants.REQUEST_TRANSPORT_PROPERTIES property value that is set on the BindingProvider's RequestContext must be a java.util.Map object or `null`.
   b. Each key in the Map must be a java.util.String data type.
   c. Each value in the Map must be one of the following data types:
      - java.lang.String
      - java.lang.Integer
      - java.lang.Short
      - java.lang.Long
      - java.lang.Float
      - java.lang.Double
      - java.lang.Byte
      - java.lang.Boolean

Results

You have a JAX-WS web services client that is configured to send transport headers in Web services request messages.

Example

Here is a short programming example that illustrates how request transport headers are sent by a JAX-WS Web services client application:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke  the web service operation and send transport headers on the request.
    public void invokeService() {

        // Set up the Map that will contain the request headers.
        Map<String, Object> requestHeaders = new HashMap<String, Object>();
        requestHeaders.put("MyHeader1", "This is a string value");
        requestHeaders.put("MyHeader2", new Integer(33));
        requestHeaders.put("MyHeader3", new Boolean(true));

        // Set the Map as a property on the RequestContext.
        BindingProvider bp = (BindingProvider) port;
        bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES, requestHeaders);
```

```
        // Invoke the web services operation.
        String result = port.echoString("Hello, world!");
    }
}
```

Sending response transport headers from a JAX-WS endpoint:
Before you begin

You need a JAX-WS Web services endpoint implementation class that you can enable to send transport headers.

Sending response transport headers from a JAX-WS endpoint is similar to sending request transport headers from a JAX-WS client. It is supported for the HTTP and JMS transports.

About this task

When using the JAX-WS programming model, the endpoint implement class must set a property on the MessageContext to send values in transport headers with the Web services response message.

Procedure

1. Create a java.util.Map object that contains the transport headers.
2. Add an entry (key and value) to the Map object for each transport header that you want to send in the response message. This is similar to the procedure for the client above.
3. Retrieve the MessageContext (instance of `javax.xml.ws.handler.MessageContext`) associated with the invocation of the endpoint.
4. Set the Map object on the MessageContext using the com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES property.

Results

You have a JAX-WS Web services endpoint implementation class that is configured to send transport headers in Web services response messages.

Example

Here is a short programming example that illustrates how response transport headers are sent by a JAX-WS Web services endpoint implementation class:

```
@WebService
public class EchoServiceImpl implements EchoServicePortType {

    // Inject an instance of WebServiceContext so we can retrieve
    // the MessageContext for each invocation of this endpoint.
    @Resource
    WebServiceContext ctxt;

    /**
     * Default constructor.
     */
    public EchoServiceImpl() {
        ....
    }

    public String echoString(String input) {
        String result = "Echo result: " + input;

        // Retrieve the MessageContext from the injected WebServiceContext.
        MessageContext mc = ctxt.getMessageContext();

        // Send some headers back in the response message.
        Map<String, Object> responseHeaders = new HashMap<String, Object>();
        responseHeaders.put("MyHeader1", "This is a string response value");
        responseHeaders.put("MyHeader2", new Integer(33));
        responseHeaders.put("MyHeader3", new Boolean(false));
```

```
        // Set the response header Map on the MessageContext.
        mc.put(com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES, responseHeaders);

        return result;
    }
}
```

Retrieving transport headers with JAX-WS

You can enable a Java API for XML-Based Web Services (JAX-WS) web services client to retrieve values from transport headers. For a request that uses HTTP, the transport headers are retrieved from HTTP headers found in the HTTP response message. For a request that uses Java Message Service (JMS), the transport headers are retrieved from the JMS message properties found on the JMS response message.

Before you begin

You need a JAX-WS web services client that you can enable to retrieve transport headers.

Retrieving transport headers is supported only by Web services clients, and is supported for the HTTP and JMS transports. The web services client must call the JAX-WS APIs directly and not through any intermediary layers, such as a gateway function.

About this task

When using the JAX-WS programming model, the client must set a property on the BindingProvider's RequestContext object to retrieve values from the transport headers. After you set the property, values are read from responses for the subsequent method invocations against that BindingProvider object until the associated property is set to `null` or the BindingProvider object is discarded.

To retrieve values from the transport headers on inbound responses, modify the client code as follows:

Procedure

1. Create a java.util.Map object that will hold the transport headers retrieved from the response message. To retrieve all the transport headers from a response message, leave this Map empty.
2. (Optional) Add an entry to the Map for each header that you want to retrieve from the incoming response message.
   a. Set the Map entry key to a string that exactly matches the transport header identifier. You can specify the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made to confirm the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class. The Map entry value is ignored and does not need to be set. An empty Map, for example, one that is non-null, but does not contain any keys, causes all the transport headers in the response to be retrieved.
3. Set the Map object on the BindingProvider's RequestContext using the com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES property. When the Map is set, the RESPONSE_TRANSPORT_PROPERTIES property is used in subsequent invocations to retrieve the headers from the responses. If you set the property to `null`, no headers are retrieved from the response. To learn more about these properties, see the transport header properties documentation.
4. Invoke remote method calls against the BindingProvider instance. The values from the specified transport headers are retrieved from the response message and placed in the Map.

   If the property is not set correctly, you might experience API usage errors that result in a WebServiceException error. The following requirements must be met, or the process fails:

- The Constants.RESPONSE_TRANSPORT_PROPERTIES property value that is set on the BindingProvider's RequestContext instance must be either `null` or an instance of java.util.Map.
- All the Map keys must be of the java.lang.String data type, and the keys must not be null.
- The Map may be empty, which means that it contains no entries at all. In this case, all the transport headers will be retrieved from the response message.

Results

You have a JAX-WS web service that can receive transport headers from incoming response messages.

Example

Here is a short programming example that illustrates how response transport headers are retrieved by a JAX-WS Web services client application:

```
public class MyApplicationClass {
    // Inject an instance of the service's port-type.
    @WebServiceRef(EchoService.class)
    private EchoPortType port;

    // This method will invoke  the web service operation and retrieve transport headers on the request.
    public void invokeService() {

        // Set up the Map to retrieive our response headers.
        Map<String, Object> responseHeaders = new HashMap<String, Object>;
        responseHeaders.put("MyHeader1", null);
        responseHeaders.put("MyHeader2", null);
        responseHeaders.put("MyHeader3", null);

        // Set the Map as a property on the RequestContext.
        BindingProvider bp = (BindingProvider) port;
        bp.getRequestContext().put(com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES, responseHeaders);

        // Invoke the web services operation.
        String result = port.echoString("Hello, world!");

        // Now retrieve our response headers.
        Object header1 = responseHeaders.get("MyHeader1");
        Object header2 = responseHeaders.get("MyHeader2");
        Object header3 = responseHeaders.get("MyHeader3");

    }
}
```

Developing JAX-RPC web services

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

1. Set up the environment.
   Run the **setupCmdLine** script from the */profile_root*/<*application_server*>/bin directory.
2. Configure the path. You can add the WebSphere and Java bin directories to your path by typing:

```
set PATH=%WAS_PATH%;%PATH%
```

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Developing a service endpoint interface from JavaBeans for JAX-RPC applications

You must develop a service endpoint interface if you are developing a JAX-RPC web service from a JavaBeans implementation.

Before you begin

You need to set up a development environment for web services and access an existing Java bean web application archive (WAR) file. See the setting up a development environment for web services information.

About this task

This task is a required step in developing a JAX-RPC Web service from a Java bean.

The service endpoint interface defines the methods for particular Java API for XML-based RPC (JAX-RPC) web services. The JavaBeans implementation must implement methods with the same signature as the methods on the service endpoint interface. A number of restrictions apply on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the JAX-RPC specification.

You can also create a service endpoint interface by using assembly tools.

Develop a service endpoint interface for a JavaBeans implementation by following the actions listed:

Procedure

1. Create a Java interface that contains the methods to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.
   Use the name of the service endpoint interface class in the **javac** command for the class to compile.

Results

You have developed a service endpoint interface that you can use to develop web services.

Example

The following example depicts the AddressBook interface:

```
package addr;
public interface AddressBook {
    /**
     * Retrieve an entry from the AddressBook.
     *
     *@param name the name of the entry to look up.
     *@return the AddressBook entry matching name or null if none.
     *@throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name);
}
```

Use the `AddressBook` interface to create the service endpoint interface:

1. Make a copy of the `AddressBook.java` interface and name it `AddressBook_SEI.java`. Use this copy as a template for the service endpoint interface.
2. Compile the interface.

What to do next

Continue to gather the artifacts that are required to develop a web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a web service. Without a WSDL file, you do not have a web service. See the developing a WSDL file for JAX-RPC applications information.

Developing a service endpoint interface from enterprise beans for JAX-RPC applications

You can develop a service endpoint interface from an Enterprise JavaBeans (EJB) for JAX-RPC web services.

Before you begin

Set up a development environment for web services. To learn more, see the setting up a development environment for web services information.

Set up a development environment for web services.

This task is a required step in developing a Java API for XML-based RPC (JAX-RPC) web service from an enterprise bean.

The service endpoint interface defines the web services methods. The enterprise beans that implements the web service must implement methods having the same signature as the methods of the service endpoint interface. A number of restrictions exist on which types to use as parameters and results of service endpoint interface methods. These restrictions are documented in the Java API for XML-based remote procedure call (JAX-RPC) specification. See the web services specifications and API documentation to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

The easiest method for creating the service endpoint interface for an EJB web service implementation is from the EJB remote interface.

You can also create a service endpoint interface by using assembly tools..

About this task

Develop a service endpoint interface by following the steps provided in this task section.

Procedure

1. Create a Java interface that contains the methods that you want to include in the service endpoint interface. If you start with an existing Java interface, remove any methods that do not conform to the JAX-RPC specification.
2. Compile the interface.

   Use the name of the service endpoint interface class in the **javac** command for the class to compile.

Results

You have a service endpoint interface that you can use to develop a web service.

Example

This example uses the EJB remote interface, `AddressBook_RI`, to create a service endpoint interface for an EJB implementation that is used as a web service. The following code example illustrates the AddressBook_RI remote interface.

```
package addr;
public interface AddressBook_RI extends javax.ejb.EJBObject {
    /**
     * Retrieve an entry from the AddressBook.
     *
     *@param name the name of the entry to look up.
     *@return the AddressBook entry matching name or null if none.
     *@throws java.rmi.RemoteException if communications failure.
     */
    public addr.Address getAddressFromName(java.lang.String name)
     throws java.rmi.RemoteException;
}
```

Use the following steps to create the service endpoint interface with the `AddressBook_RI` remote interface:

1. Locate a remote interface that has already been created, like the `AddressBook_RI.java` remote interface.
2. Make a copy of the `AddressBook.java` remote interface and use it as a template for the service endpoint interface.
3. Compile the `AddressBook.java` service endpoint interface.

What to do next

Continue gathering the artifacts that are required to develop a web service, including the Web Services Description Language (WSDL) file. You need to develop a WSDL file because it is the engine of a web service; without a WSDL file, you have no web service.

Developing a WSDL file for JAX-RPC applications

You can develop a Web Services Description Language (WSDL) file to describe the characteristics of your Java API for XML-based RPC (JAX-RPC) web services application including where the service resides and how to invoke the service using an XML format.

Before you begin

Depending on your development path, develop a service endpoint interface from a JavaBeans implementation or develop a service endpoint interface from an enterprise bean implementation.

About this task

You need a WSDL file to use web services. You can develop your own WSDL file or get one from a web services provider through email, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own.

Develop a WSDL file by following the actions listed:

Procedure

1. Configure the service endpoint interface class and referenced classes into your CLASSPATH variable.
   - On Windows systems, set `CLASSPATH="%CLASSPATH%;<list your application Java archive (JAR) files and classes>"`.
   - On UNIX and Linux systems, export `CLASSPATH="$CLASSPATH:<list your application JAR files and classes>"`.
2. Run the **Java2WSDL** *seiInterface* command. A WSDL file named *seiInterface*`.wsdl` is created.

   Note: The **Java2WSDL** command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product. Read about the **Java2WSDL** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.
   - Move the WSDL file to the `META-INF/wsdl` subdirectory if you are using Enterprise JavaBeans (EJB).
   - Move the WSDL file to the `WEB-INF/wsdl` subdirectory if you are using JavaBeans.
3. Edit the generated WSDL file and inspect the part names. The WSDL parts have names like `arg_0_0`. Modify the WSDL file to use the actual names of the Java parameters.
4. (Optional) Use the **Java2WSDL** command tool to generate the correct part names of WSDL file. You can automatically generate and set the correct part names by using the **Java2WSDL** command tool. Generating and setting the part names is done by providing additional information to the **Java2WSDL** command tool in the form of a Java implementation class that implements the same methods as the service endpoint interface and is compiled with debug information turned on. Parameter names are stored in the `.class` file with the debug information. If your implementation class is compiled with debug on, you can use the `Java2WSDL -implClass` *seiImpl seiInterface* command to generate a WSDL file with the proper part names.

Results

A WSDL file that defines the web services described by the service endpoint interface.

Example

This example uses the JAR file name `AddressBook.jar` that contains a class named `AddressBook.class` class file.

You must add the `AddressBook.jar` file to your CLASSPATH to create the WSDL file. The JAR file contains an EJB implementation class that is compiled with debugging information turned on. Run the `Java2WSDL -implClass addr.AddressBookBean addr.AddressBook` command to create the file, `AddressBook.wsdl`.

What to do next

Depending on your development path, develop web services deployment descriptor templates for JavaBeans or develop web services deployment descriptor templates for an enterprise beans implementation.

Java2WSDL command for JAX-RPC applications

The Java2WSDL command-line tool maps Java classes to a WSDL file for Java API for XML-based RPC (JAX-RPC) applications.

The Java2WSDL command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product.

The **Java2WSDL** command maps a Java class to a Web Services Description Language (WSDL) file by following the Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification.

The **Java2WSDL** command accepts a Java class as input and produces a WSDL file that represents the input class. If a file exists at the output location, it is overwritten. The WSDL file that is generated by the **Java2WSDL** command contains WSDL and XML schema constructs that are automatically derived from the input class. You can override these default values with command-line arguments.

The **Java2WSDL** command is protocol independent; when you run the **Java2WSDL** command, you can specify command-line options that generate both SOAP and non-SOAP protocol bindings in the WSDL file. For each binding that can be generated, the **Java2WSDL** command has a binding generator to generate the WSDL for that binding.

Command line syntax and arguments

The command line syntax is:

```
Java2WSDL [argument...] class
```

The following command-line arguments are supported:

Required arguments

- class

  Represents the fully qualified name of one of the following Java classes:
  - Stateless session Enterprise JavaBeans (EJB) remote interface that extends the javax.ejb.EJBObject class
  - Service endpoint interface that extends the java.rmi.Remote class
  - Java beans

  The **Java2WSDL** command locates the class in the CLASSPATH variable.

Important arguments

- -location *location*

  Provides the published location or the Uniform Resource Locator (URL) of the service. If this information is not provided, a warning is issued that indicates that the final published location is not determined yet. The service location is typically overridden when the web service is deployed.

  The name after the last backslash is the name of the service port, unless the name is overridden by the -servicePortName argument. The service port address location attribute is assigned the specified value. Multiple endpoint addresses can be specified. Using the -location option is recommended only if a single binding type is required. If multiple binding types are requested, protocol binding-specific location properties are passed over the command line using the -x flag.

  The following example illustrates how to produce both SOAP over HTTP, and SOAP over Java Message Service (JMS) bindings :

```
java2wsdl -bindingTypes http,jms \
  -x http.location=http://your.server.name:9080/StockQuoteService/services/StockQuote \
  -x jms.location= \
 jms:/queue?destination=jms/MyQueue&connectionFactory=jms/MyCF&targetService=StockQuote
```

  Use the -location option to determine to which port the -location option value applies by requiring the endpoint URLs to be specified through the binding-specific property values.
- -output *wsdl-uri*

  Indicates the path and file name of the output WSDL file. If not specified, the default `class.wsdl` file is written into the current directory.
- -input *wsdl-uri*

  Specifies the input WSDL file that is used to build an output WSDL file. Information from an existing WSDL file, is specified in this option and is used with the input Java class to generate the output.
- -bindingTypes

Specifies the list of binding types write to the output WSDL file. Each binding generator in the **Java2WSDL** command supports specific binding types. The valid binding type values are `http` (SOAP over HTTP), `jms` (SOAP over JMS) and `ejb` (local or remote EJB invocation). For example, the following command can be used to generate SOAP over HTTP, EJB bindings for the my.pkg.MySEI Service Endpoint Interface and the my.pkg.MyEJBClass implementation class :

```
java2wsdl -bindingTypes http,ejb -implClass my.pkg.MyEJBClass my.pkg.MySEI
```

The following command is an example of using the -bindingTypes option to generate SOAP over HTTP and SOAP over JMS bindings:

```
java2wsdl -bindingTypes http,jms -implClass my.pkg.MyEJBClass my.pkg.MySEI
```

- -style RPC | DOCUMENT

  Specifies the WSDL style to use in the generated WSDL file. To learn more, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information. This argument is used with the -use argument.

  If RPC is specified with -use ENCODED, a `style=rpc/use=encoded` WSDL file is generated. If RPC is specified with the -use LITERAL option, a `style=rpc/use=literal` WSDL file is generated. If DOCUMENT is specified with the -use LITERAL option, a `style=document/use=literal` WSDL file is generated.
- -use LITERAL | ENCODED

  Specifies which style and use combinations are generated into the WSDL file when used with the -style argument. The combinations are rpc and encoded, rpc and literal, or doc and literal. This setting applies to all SOAP bindings. To learn more, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information.
- -transport http | jms

  Generates SOAP bindings for either HTTP (default) or JMS. If JMS is specified, the characters `jms` are appended to the WSDL file name to prevent overwriting an existing WSDL file for another transport. The transport option can be specified only once.

  This option is deprecated. The -bindingTypes option replaces the -transport option, so that you can generate bindings that are non-SOAP specific.
- -portTypeName *name*

  Specifies the name to use for the portType element. If not specified, the binding name is the port type name.
- -bindingName *name*

  Specifies the name to use for the binding element. If not specified, the binding name is the port type name.
- -serviceElementName *name*

  Specifies the name of the service element.
- -servicePortName *name*

  Specifies the name of the service. If not specified, the service name is derived from the -location argument.
- -namespace *targetNamespace*

  Indicates the target namespace for the WSDL file being generated. To learn about the algorithm that is used to obtain the default namespace, see the Mapping between Java language, WSDL and XML for JAX-RPC applications information.
- -PkgtoNS *package namespace*

  Specifies the mapping of a Java package to a namespace. If a package does not have a namespace, the **Java2WSDL** command generates a namespace name. You can repeat the -PkgtoNS argument to specify mappings for multiple packages.
- -extraClasses *classes*

  Specifies other classes that are represented in the WSDL file.
- -implClass *impl-class*

  The **Java2WSDL** command uses method parameter names to construct the WSDL file message part names. The command automatically obtains the message names from the debug information in the

class. If the class is compiled without debug information, or if the class is an interface, the method parameter names are not available. In this case, you can use the -implClass argument to provide an alternative class from which to obtain method parameter names. The impl-class does not need to implement the class if the class is an interface, but it must implement the same methods as the class.

- -verbose

  Displays verbose messages.
- -help

  Displays the help message.
- -helpX

  Displays the help message for extended options and for various options that are supported by binding generators.

Other arguments

- -wrapped *boolean*

  Specifies whether to generate the WSDL file according to wrapped rules. This option is valid if `use` is literal only. The option defaults to `true`.
- -stopClasses *parent* [, *parent*]

  The **Java2WSDL** command searches inherited classes and interfaces to construct the list of methods for WSDL file operations if the -all argument is specified.

  The **Java2WSDL** command searches inherited classes and interfaces when generating extended complexTypes. The search stops when a class or an interface is found within a package that begins with `java` or `javax`. You can use the -stopClasses argument to define additional classes that cause the search to stop.
- -methods *argument*

  Specifies a list of method names from the Service Endpoint Interface that must be exposed in the output WSDL file. The list is separated by spaces or commas.
- -soapAction

  Valid arguments are:
  - DEFAULT

    Sets the soapAction field according to the deployment information.
  - NONE

    Sets the soapAction field to double quotes ("").
  - OPERATION

    Sets the soapAction field to the operation name.
- -outputImpl *impl-wsdl*

  Specifies if you want an interface and implementation WSDL file emitted.
- -locationImport *location-uri*

  Specifies the location of the interface WSDL file if you use the -outputImpl argument.
- -namespaceImpl *namespace*

  Specifies the target namespace for the implementation WSDL file, if you use the -outputImpl argument.
- -MIMEStyle <*style*>

  Specifies the Multipurpose Internet Mail Extensions (MIME)- type used to map to Web Services-Interoperability (WS-I) SOAP with attachments reference (wsi:swaRef) for the binding element.

  <*style*> can be one of the following:
  - WSDL11 (default): Exclusively map MIME types using WSDL 1.1 standards. If the MIME type cannot map to WSDL 1.1 standards, the command fails.
  - AXIS: Map MIME types using AXIS standards, for example image becomes axis:image.
  - swaRef: Map MIME types using WSDL 1.1 standards with two caveats:
    - DataHandler maps to the wsi:swaRef element instead of an application and octet-stream

- If mapping is illegal through WSDL 1.1, map to the wsi:swaRef element

- -propertiesFile *argument*

  Sets existing options, such as -extraClasses, with a properties file instead of with a command line. The following example illustrates the use of this argument:

```
extraClasses=com.ibm.Class1, com.sun.Class2,org.apache.Class3
```

- -voidReturn

  Valid arguments are:
  – ONEWAY

    Methods with void returns are one-way. This argument is the default for a JMS transport.
  – TWOWAY

    Methods with void returns are two-way. This argument is the default for an HTTP transport.

- -debug

  Displays debug messages.

- -property or -x

  You can use the -x option to pass command-line options to various binding generators. Use the -x option multiple times on the command line to specify a set of property values to pass to each binding generator method called by the **Java2WSDL** command. You can also use a single -x option to specify multiple properties by separating them with a comma, for example:

```
java2wsdl -x prop1=value1 -x prop2=value2
```

  is equivalent to:

```
java2wsdl -x prop1=value1,prop2=value2
```

  The -x option provides flexibility to specify each command-line option for each binding generator individually, if required. The value specified in the -x option overrides the value that is specified in the equivalent command-line option if both are specified.

Mapping between Java language, WSDL and XML for JAX-RPC applications

Data for Java API for XML-based Remote Procedure Call (JAX-RPC) applications flows as extensible Markup Language (XML). JAX-RPC applications use mappings to describe the data conversion between the Java language and extensible Markup Language (XML) technologies, including XML Schema, Web Services Description Language (WSDL) and SOAP that are supported by the application server.

For JAX-RPC applications, most of the mappings between the Java language and XML are specified by the JAX-RPC specification. Some mappings that are optional or unspecified in JAX-RPC are also supported. Review the JAX-RPC specification for a complete list of APIs. For a complete list of the supported standards and specifications, see the web services specifications and API documentation.

Notational conventions

Table 132. Namespace conventions. Describes the namespace prefixes and the corresponding namespace used in namespace conventions.

Namespace prefix	Namespace
xsd	http://www.w3.org/2001/XMLSchema
xsi	http://www.w3.org/2001/XMLSchema-instance
soapenc	http://schemas.xmlsoap.org/soap/encoding/
wsdl	http://schemas.xmlsoap.org/wsdl/
wsdlsoap	http://schemas.xmlsoap.org/wsdl/soap/
ns	user-defined namespace
apache	http://xml.apache.org/xml-soap
wasws	http://websphere.ibm.com/webservices/

Detailed mapping information

The following sections identify the supported mappings, including:
- Java-to-WSDL mapping
- WSDL-to-Java mapping
- Mapping between WSDL and SOAP messages

Java-to-WSDL mapping

This section summarizes the Java-to-WSDL mapping rules. The Java-to-WSDL mapping rules are used by the **Java2WSDL** command for *bottom-up processing*. In bottom-up processing, an existing Java service implementation is used to create a WSDL file defining the web service. The generated WSDL file can require additional manual editing for the following reasons:
- Not all Java classes and constructs have mappings to WSDL files. For example, Java classes that do not comply with the Java bean specification rules might not map to a WSDL construct.
- Some Java classes and constructs have multiple mappings to a WSDL file. For example, a java.lang.String class can map to either an xsd:string or soapenc:string construct. The **Java2WSDL** command chooses one of these mappings, but you must edit the WSDL file if a different mapping is required.
- Multiple ways exist to generate WSDL constructs. For example, you can generate the wsdl:part in wsdl:message with a type or element attribute. The **Java2WSDL** command makes an informed choice based on the -style and -use option settings.
- The WSDL file describes the instance data elements sent in the SOAP message. If you want to modify the names or format used in the message, the WSDL file must be edited. For example, the **Java2WSDL** command maps a Java bean property as an XML element. In some circumstances, you might want to change the WSDL file to map the Java bean property as an XML attribute.
- The WSDL file requires editing if header or attachment support is desired.
- The WSDL file requires editing if a multipart WSDL file, using the wsdl:import construct, is desired.

For simple services, the generated WSDL file is sufficient. For complicated services, the generated WSDL file is a good starting point. Read about the Java2WSDL command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

General issues

- Package to namespace mapping:

  The JAX-RPC specification does not indicate the default mapping of Java package names to XML namespaces. The JAX-RPC specification does specify that each Java package must map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm is provided that constructs the namespace by reversing the names of the Java package and adding an `http://` prefix. For example, a package named, com.ibm.webservice, is mapped to the XML namespace `http://webservice.ibm.com`.

  You can override the default mapping between XML namespaces and Java package names by using the -NStoPkg and -PkgtoNS options of the **WSDL2Java** and **Java2WSDL** commands.
- Identifier mapping :

  Java identifiers are mapped directly to WSDL and XML identifiers.

  Java bean property names are mapped to XML identifiers. For example, a Java bean, with getInfo and setInfo methods, maps to an XML construct with the name, `info`.

  The service endpoint interface method parameter names, if available, are mapped directly to the WSDL and XML identifiers. See the information for the WSDL2Java command -implClass option to learn more.
- WSDL construction summary:

Table 133. Mapping of Java to WSDL or an XML construct. Describes the mapping from a Java construct to the related WSDL and XML construct.

Java construct	WSDL and XML construct
Service endpoint interface	wsdl:portType

Table 133. Mapping of Java to WSDL or an XML construct (continued). Describes the mapping from a Java construct to the related WSDL and XML construct.

Java construct	WSDL and XML construct
Method	wsdl:operation
Parameters	wsdl:input, wsdl:message, wsdl:part
Return	wsdl:output, wsdl:message, wsdl:part
Throws	wsdl:fault, wsdl:message, wsdl:part
Primitive types	xsd and soapenc simple types
Java beans	xsd:complexType
Java bean properties	Nested xsd:elements of xsd:complexType
Arrays	JAX-RPC defined xsd:complexType or xsd:element with a maxOccurs="unbounded" attribute
User defined exceptions	`xsd:complexType`

- **Binding** and **service** construction

  A wsdl:binding that conforms to the generated wsdl:portType is generated. A wsdl:service containing a port that references the generated wsdl:binding is generated. The names of the binding and service are controlled by the **Java2WSDL** command.
- **Style** and **use**

  Use the -style and -use options to generate different kinds of WSDL files. The four supported combinations are:
  – -style DOCUMENT -use LITERAL
  – -style RPC -use LITERAL
  – -style DOCUMENT -use LITERAL -wrapped false
  – -style RPC -use ENCODED

  The following is a brief description of each combination.
  – DOCUMENT LITERAL:

    The **Java2WSDL** command generates a Web Services - Interoperability (WS-I) specification compliant document-literal WSDL file. The wsdl:binding is generated with embedded style="document" and use="literal" attributes. An xsd:element is generated for each service endpoint interface method to describe the request message. A similar xsd:element is generated for each service endpoint interface method to describe the response message.
  – RPC LITERAL:

    The **Java2WSDL** command generates a WS-I compliant rpc-literal WSDL file. The wsdl:binding is generated with embedded style="rpc" and use="literal" attributes. The wsdl:message constructs are generated for the inputs and outputs of each service endpoint interface method. The parameters of the method are described by the part elements within the wsdl:message constructs.
  – DOCUMENT LITERAL not wrapped:

    The **Java2WSDL** command generates a document-literal WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with .NET. The main difference between DOCUMENT LITERAL and DOCUMENT LITERAL not wrapped is the use of wsdl:message constructs to define the request and response messages.
  – RPC ENCODED:

    The **Java2WSDL** command generates an rpc-encoded WSDL file according to the JAX-RPC specification. This WSDL file is not compliant with the WS-I specification. The wsdl:binding is generated with embedded style="rpc" and use="encoded" attributes. Certain soapenc mappings are used to represent types and arrays.

  Many Java types map directly to standard XML types. For example, a java.lang.String maps to an xsd:string. These mappings are described in the JAX-RPC specification.

  Java types that cannot be mapped directly to standard XML types are generated in the `wsdl:types` section. A Java class that matches the Java bean pattern is mapped to an `xsd:complexType`. Review the JAX-RPC specification for a description of all the mapping rules. The following example illustrates the mapping for a sample base and derived Java classes.

Java:

```
public abstract class Base {
     public Base() {}
     public int a;                          // mapped
     private int b;                         // mapped via setter/getter
     private int c;                         // not mapped
     private int[] d;                       // mapped via indexed setter/getter

     public int getB() { return b;}         // map property b
     public void setB(int b) {this.b = b;}

     public int[] getD() { return d;}       // map indexed property d
     public void setD(int[] d) {this.d = d;}
     public int getD(int index) { return d[index];}
     public void setB(int index, int value) {this.d[index] = value;}

     public void someMethod() {...}         // not mapped
  }

  public class Derived extends Base {
     public int x;                          // mapped
     private int y;                         // not mapped
  }
```

Mapped to:

```
<xsd:complexType name="Base" abstract="true">
 <xsd:sequence>
  <xsd:element name="a" type="xsd:int"/>
  <xsd:element name="b" type="xsd:int"/>
  <xsd:element name="d" minOccurs="0" maxOccurs="unbounded" type="xsd:int"/>
 </xsd:sequence>
</xsd:complexType>

<xsd:complexType name="Derived">
 <xsd:complexContent>
  <xsd:extension base="ns:Base">
   <xsd:sequence>
    <xsd:element name="x" type="xsd:int"/>
   </xsd:sequence>
  </xsd:extension>
 </xsd:complexContent>
</xsd:complexType>
```

- Unsupported classes:

  If a class cannot be mapped to an XML type, the **Java2WSDL** command issues a message and an xsd:anyType reference is generated in the WSDL file. In these situations, modify the web service implementation to use the JAX-RPC compliant classes.

WSDL-to-Java mapping

The **WSDL2Java** command generates Java classes using information described in the WSDL file.

General issues:

- Mapping of a namespace to a package:

  JAX-RPC does not specify the mapping of XML namespaces to Java package names. JAX-RPC does specify that each Java package map to a single XML namespace. Likewise, each XML namespace must map to a single Java package. A default mapping algorithm omits any protocol from the XML namespace and reverses the names. For example, an XML namespace `http://websphere.ibm.com` becomes a Java package with the name com.ibm.websphere.

  The default mapping of an XML namespace to a Java package disregards the context-root. If two namespaces are the same up to the first slash, they map to the same Java package. For example, the XML namespaces `http://websphere.ibm.com/foo` and `http://websphere.ibm.com/bar` map to the com.ibm.websphere Java package. You can override the default mapping between XML namespaces and Java package names by using the -NStoPkg and -PkgtoNS options of the **WSDL2Java** and **Java2WSDL** commands.

  XML names are much richer than Java identifiers. They can include characters that are not permitted in Java identifiers. See Appendix 20 of the JAX-RPC specification for the rules to map an XML name to a Java identifier.

- Java construction summary:

The following table summarizes the XML to Java construction. See the JAX-RPC specification for a description of these mappings.

Table 134. Mapping of a WSDL or an XML construct to Java. Describes the mapping between constructions for XML and Java.

WSDL and XML construction	Java construction
xsd:complexType	Java bean class, Java exception class, or Java array
nested xsd:element/xsd:attribute	Java bean property
xsd:simpleType (enumeration)	JAX-RPC enumeration class
wsdl:message The method parameter signature typically is determined by the wsdl:message.	Service endpoint interface method signature
wsdl:portType	Service endpoint interface
wsdl:operation	Service endpoint interface method
wsdl:binding	Stub
wsdl:service	Service interface
wsdl:port	Port accessor method in Service interface

- Mapping standard XML types:
  - JAX-RPC simple XML types mapping:

    Many XML types are mapped directly to Java types. See the JAX-RPC specification for a description of these mappings.

    The **WSDL2Java** command generates Java types for the XML schema constructs that are defined in the wsdl:types section. The XML schema language is broader than the required or optional subset defined in the JAX-RPC specification. The **WSDL2Java** command supports the required mappings and most of the optional mappings, as well as some XML schema mappings that are not included in the JAX-RPC specification. The **WSDL2Java** command ignores some constructs that it does not support. For example, the command does not support the default attribute. If an xsd:element is defined with the default attribute, the default attribute is ignored. In some cases, the command maps unsupported constructs to the Java interface, javax.xml.soap.SOAPElement.

    The standard Java bean mapping is defined in section 4.2.3 of the JAX-RPC specification. The xsd:complexType defines the type. The nested xsd:elements within the xsd:sequence or xsd:all groups are mapped to Java bean properties. For example:

XML:

```
<xsd:complexType name="Sample">
  <xsd:sequence>
  <xsd:element name="a" type="xsd:string"/>
  <xsd:element name="b" maxOccurs="unbounded" type="xsd:string"/>
 </xsd:sequence>
</xsd:complexType>
```

Java:

```
public class Sample {
     // ..
     public Sample() {}

     // Bean Property a
     public String getA()             {...}
     public void   setA(String value) {...}

     // Indexed Bean Property b
     public String[] getB()           {...}
     public String   getB(int index)  {...}
     public void     setB(String[] values) {...}
     public void     setB(int index, String value) {...}

  }
```

  - Mapping of the wsdl:portType construct:

    The wsdl:portType construct is mapped to the service endpoint interface. The name of the wsdl:portType construct is mapped to the name of the class of the service endpoint interface.
  - Mapping of the wsdl:operation construct:

A wsdl:operation construct within a wsdl:portType is mapped to a method of the service endpoint interface. The name of the wsdl:operation is mapped to the name of the method. The wsdl:operation contains wsdl:input and wsdl:output elements that reference the request and response wsdl:message constructs using the message attribute. The wsdl:operation can contain a wsdl:fault element that references a wsdl:message describing the fault. These faults are mapped to Java classes that extend the exception, java.lang.Exception as discussed in section 4.3.6 of the JAX-RPC specification.

- Effect of document literal wrapped format:

  If the WSDL file uses the document literal wrapped format, the method parameters are mapped from the wrapper xsd:element. The document literal wrapped and literal format is automatically detected by the **WSDL2Java** command. The following criteria must be met:
  - The WSDL file must have style="document" in its wsdl:binding construct.
  - The input and output constructs of the operations within the wsdl:binding must contain soap:body elements that contain use="literal".
  - The wsdl:message referenced by the wsdl:operation input construct must have a single part.
  - The part must use the element attribute to reference an xsd:element.
  - The referenced xsd:element, or wrapper element, must have the same name as the wsdl:operation.
  - The wrapper element must not contain any xsd:attributes.

  In such cases, each parameter name is mapped from a nested xsd:element contained within wrapper element. The type of the parameter is mapped from the type of the nested xsd:element. For example:

WSDL:

```
<xsd:element name="myMethod">
 <xsd:complexType>
  <xsd:sequence>
   <xsd:element name="param1" type="xsd:string"/>
   <xsd:element name="param2" type="xsd:int"/>
  </xsd:sequence>
 </xsd:complexType>
</xsd:element>
...
<wsdl:message name="response"/>
 <part name="parameters" element="ns:myMethod"/>
</wsdl:message name="response"/>

<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod">
 <input name="input" message="request"/>
 <output name="output" message="response"/>
</wsdl:operation>
```

Java:

```
void myMethod(String param1, int param2) ...
```

- Parameter mapping:

  If the document and literal wrapped format is not detected, the parameter mapping follows the normal JAX-RPC mapping rules set in section 4.3.4 of the JAX-RPC specification.

  Each parameter is defined by a wsdl:message part referenced from the input and output elements.
  - A wsdl:part in the request wsdl:message is mapped to an input parameter.
  - A wsdl:part in the response wsdl:message is mapped to the return value. If multiple wsdl:parts exist in the response message, they are mapped to output parameters.
    - A Holder class is generated for each output parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
  - A wsdl:part that is both the request and response wsdl:message is mapped to an inout parameter.
    - A Holder class is generated for each inout parameter, as discussed in section 4.3.5 of the JAX-RPC specification.
    - The wsdl:operation parameterOrder attribute defines the order of the parameters.

XML:

```
<wsdl:message name="request">
 <part name="param1" type="xsd:string"/>
```

```
 <part name="param2" type="xsd:int"/>
</wsdl:message name="response"/>

<wsdl:message name="response"/>
...
<wsdl:operation name="myMethod" parameterOrder="param1, param2">
 <input name="input" message="request"/>
 <output name="output" message="response"/>
</wsdl:operation>
```

Java:

```
void myMethod(String param1, int param2) ...
```

– Mapping of wsdl:binding:

The **WSDL2Java** command uses the wsdl:binding information to generate an implementation-specific client-side stub. WebSphere Application Server uses the wsdl:binding information on the server side to properly deserialize the request, invoke the web service, and serialize the response. The information in the wsdl:binding does not affect the generation of the service endpoint interface, except when the document and literal wrapped format is used, or when MIME attachments are present.

- MIME attachments:

  For a WSDL 1.1-compliant WSDL file, the part of an operation message, that is defined in the binding as a MIME attachment, becomes a parameter of the type of the attachment regardless of the part declared. For example:

XML:

```
<wsdl:types>
 <schema ...>
  <complexType name="ArrayOfBinary">
   <restriction base="soapenc:Array">
     <attribute ref="soapenc:arrayType" wsdl:arrayType="xsd:binary[]"/>
   </restriction>
  </complexType>
 </schema>
</wsdl:types>

<wsdl:message name="request">
 <part name="param1" type="ns:ArrayOfBinary"/>
<wsdl:message name="response"/>

<wsdl:message name="response"/>
 ...

 <wsdl:operation name="myMethod">
  <input name="input" message="request"/>
  <output name="output" message="response"/>
 </wsdl:operation>
  ...

<binding ...
 <wsdl:operation name="myMethod">
  <input>
   <mime:multipartRelated>
    <mime:part>
     <mime:content part="param1" type="image/jpeg"/>
    </mime:part>
   </mime:multipartRelated>
  </input>
   ...
 </wsdl:operation>
```

Java:

```
void myMethod(java.awt.Image param1) ...
```

The JAX-RPC specification requires support for the following MIME types:

Table 135. Mapping of MIME type and Java type. Describes the mapping between MIME types and Java types.

MIME type	Java type
image/gif	java.awt.Image
image/jpeg	java.awt.Image
text/plain	java.lang.String
multipart/*	javax.mail.internet.MimeMultipart
text/xml	javax.xml.transform.Source

Table 135. Mapping of MIME type and Java type (continued). Describes the mapping between MIME types and Java types.

MIME type	Java type
application/xml	javax.xml.transform.Source

– Mapping of wsdl:service:

  The wsdl:service element is mapped to a generated service interface. The generated service interface contains methods to access each of the ports in the wsdl:service element. The generated service interface is discussed in sections 4.3.9, 4.3.10, and 4.3.11 of the JAX-RPC specification.

  In addition, the wsdl:service element is mapped to the implementation-specific ServiceLocator class, which is an implementation of the generated service interface.

Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

Mapping between WSDL and SOAP messages

The WSDL file defines the format of the SOAP message that are transmitted through network connections. The **WSDL2Java** command and the WebSphere Application Server runtime use the information in the WSDL file to ensure that the SOAP message is properly serialized and deserialized.

If a wsdl:binding element indicates that a message is sent using an RPC format, the SOAP message contains an element defining the operation. If a wsdl:binding element indicates that the message is sent using a document format, the SOAP message does not contain the operation element.

If the wsdl:part element is defined using the type attribute, the name and type of the part are used in the message. If the wsdl:part element is defined using the element attribute, the name and type of the element are used in the message. The element attribute is not supported by the JAX-RPC specification when use="encoded".

If a wsdl:binding element indicates that a message is encoded, the values in the message are sent with xsi:type information. If a wsdl:binding element indicates that a message is literal, the values in the message are typically not sent with xsi:type information. For example:

DOCUMENT/LITERAL
WSDL:

```
<xsd:element name="c" type="xsd:int"/>
<xsd:element name="method">
 <xsd:complexType>
  <xsd:sequence>
   <xsd:element name="a" type="xsd:string"/>
   <xsd:element ref="ns:c"/>
  </xsd:sequence>
 </xsd:complexType>
</xsd:element>
...
  <wsdl:message name="request">
    <part name="parameters" element="ns:method"/>
  </wsdl:message>
 ...
 <wsdl:operation name="method">
  <input message="request"/>
 ...
```

Message:

```
<soap:body>
  <ns:method>
   <a>ABC</a>
   <c>123</a>
  <ns:method>
</soap:body>
```

RPC/ENCODED
WSDL:

```
<xsd:element name="c" type="xsd:int"/>

...
  <wsdl:message name="request">
    <part name="a" type="xsd:string"/>
```

```
    <part name="b" element="ns:c"/>
  </wsdl:message>
 ...
 <wsdl:operation name="method">
    <input message="request"/>
 ...

Message:
<soap:body>
  <ns:method>
   <a xsi:type="xsd:string">ABC</a>
   <element attribute is not permitted in rpc/encoded mode>
  </ns:method>
 </soap:body>
DOCUMENT/LITERAL  not wrapped
WSDL:
<xsd:element name="c" type="xsd:int"/>

...
  <wsdl:message name="request">
    <part name="a" type="xsd:string"/>
    <part name="b" element="ns:c"/>
  </wsdl:message>
 ...
 <wsdl:operation name="method">
    <input message="request"/>

...

Message:
<soap:body>
  <a>ABC</a>
  <c>123</a>
</soap:body>
```

Developing JAX-RPC web services deployment descriptor templates for a JavaBeans implementation

Deployment descriptors are standard text files, formatted using XML and packaged in a web services application. Deployment descriptors are required to deploy Java API for XML-based RPC (JAX-RPC) web services that are developed using Web Services for Java Platform, Enterprise Edition (Java EE) technology.

Before you begin

Develop a Web Services Description Language (WSDL) file.

You need a WSDL file to use web services. You can develop your own WSDL file or get one from a web services provider through email, downloading, or through a Uniform Resource Locator (URL). This documentation assumes you are creating your own. See the developing a WSDL file for JAX-RPC applications information.

About this task

Completing this task creates the deployment descriptors used to describe how to map the service implementation to a JavaBeans component for Java API for XML-based RPC (JAX-RPC) applications.

To develop the deployment descriptor templates from a WSDL file, you must obtain the web address of the WSDL file.

If the WSDL file is a local file and you are running on the Windows platform, the web address looks like this example: `file:drive:\path\file_name.wsdl`. If you are using the Linux or Unix platform, the Web address looks like this example: `file:/path/file_name.wsdl`. You can also specify local files using the absolute or relative file system path.

When the web service is a JavaBeans implementation in a web module, the `webservices.xml`,`ibm-webservices-bnd.xmi` and `ibm-webservices.ext.xmi` deployment descriptors and the JAX-RPC mapping file are generated in the `WEB-INF` subdirectory.

Procedure

Run the **WSDL2Java -verbose -role develop-server -container web -genJava no *wsdlURL*** command to generate the server deployment descriptor templates and mapping file into the `WEB-INF` subdirectory. If the **-verbose** option is specified, a list of all the generated files is displayed when the command runs.

Note: The **WSDL2Java** command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product. Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

Results

You have deployment descriptor templates that are required to implement or use JAX-RPC web services.

Example

The following example uses a WSDL file named `AddressBookJ2WB.wsdl`:

Generate the template files:

```
WSDL2Java -verbose -role develop-server -container web -genJava no AddressBookJ2WB.wsdl
```

The deployment descriptor templates and mapping file are generated into the `WEB-INF` subdirectory:

```
Parsing XML file: AddressBookJ2WB.wsdl
Generating: WEB-INF\webservices.xml
Generating: WEB-INF\ibm-webservices-bnd.xmi
Generating: WEB-INF\ibm-webservices-ext.xmi
Generating: WEB-INF\AddressBookJ2WB_mapping.xml
```

What to do next

Now, you need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that application server can process the incoming web services. After you configure the deployment descriptors, you must assemble the web services application for deployment. See the information on configuring the `webservices.xml` deployment descriptor for JAX-RPC web services and configuring the `ibm-webservices-bnd.xmi` deployment descriptor for JAX-RPC web services.

WSDL2Java command for JAX-RPC applications:

Run the **WSDL2Java** command-line tool against the WSDL file to create Java APIs and deployment descriptor templates.

The WSDL2Java command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with WebSphere Application Server running on the z/OS platform.

A Web Services Description Language (WSDL) file describes a Web service. The Java API for XML-based Remote Procedure Call (JAX-RPC) 1.1 specification defines a Java API mapping that interacts with the web service. The Web Services for Java Platform, Enterprise Edition (Java EE) specification defines deployment descriptors that deploy a web service in a Java EE environment. The **WSDL2Java** command is run against the WSDL file to create Java APIs and deployment descriptor templates according to these specifications.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the **WSDL2Java** tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. However,

if you have an established WSDL or schema that relies on relative namespaces, under specific conditions you can use the `allowRelativeNamespace` property to disable the relative namespace restrictions in the **WSDL2Java** tool. For additional information, see the property description.

You can convert any relative namespaces to absolute namespaces. The following is an example of a relative namespace:

```
targetNamespace="MyRelNamespace"
```

. You can change the relative namespace in this example to an absolute namespace by adding the protocol and base URI information:

```
targetNamespace="http://www.sample.com/MyRelNamespace"
```

Command-line syntax

The command-line syntax is:

```
WSDL2Java [arguments] WSDL-URI
```

Required arguments

- WSDL-URI

  Specifies the location of the input WSDL file using a Universal Resource Identifier (URI). You can also use a regular file path if the WSDL file is on the local file system.

Important arguments

- -role *Java EE role*

  Specifies the Java EE development role that identifies which files to generate. Valid arguments include:
  - client

    A combination of the develop-client and deploy-client arguments.
  - deploy-client

    Generates binding files for client deployment.
  - deploy-server

    Generates binding files for server deployment.
  - develop-client (default)

    Generates files for client development.
  - develop-server

    Generates files for server development.
  - server

    A combination of the develop-server and deploy-server arguments.
- -container *Java EE-container*

  Indicates the Java EE container to use. Valid arguments include:
  - client

    Indicates client container.
  - ejb

    Indicates an Enterprise JavaBeans (EJB) container.
  - none

    Indicates no container.
  - web

    Indicates a web container.

  For client roles (see the -role option), the default argument is `none`. For server roles, the container must be `ejb` or `web`. The same container option must be used for both development and deployment.
- -output *directory*

  Sets the root directory for emitted files.
- -inputMappingFile mapping file

Specifies the file name of the Web Services for Java EE mapping file.

- -introspect

  Uses existing Java beans with a new web service API.

  In some scenarios, it is good to use existing Java classes instead of generating new classes. The -introspect option directs the **WSDL2Java** command to examine existing Java classes when generating classes. The existing classes are validated against the JAX-RPC specification. For example:

  Suppose you have an existing Java bean

```
public class Bean {
 public Date x;
}
```

  The WSDL file defines *x* as `xsd:dateTime`. Without the -introspect option, the **WSDL2Java** command generates a Java bean that is similar to the following example:

```
public class Bean {
 private Calendar x;
 public void setx(Calendar value) (x=value;)
 public Calendar getX() { return x;)
}
```

  The **WSDL2Java** command uses the -introspect option to examine the original Java bean and to generate classes that are compatible with existing Java beans.

- -classpath *paths*

  Defines an alternative class path to search for Java classes.

- -noDataBinding

  Disables the binding of XML types to Java types. Instead, each XML type is mapped to a `javax.xml.soap.SOAPElement` interface defined by the SOAP with Attachments API for Java (SAAJ) specification.

  The Java API for XML Web Services (JAX-WS) programming model supports SAAJ 1.2 and 1.3.

  The JAX-RPC programming model supports SAAJ 1.2.

  The Java programming models define Java mappings for a subset of XML types. Several XML types cannot be mapped to Java beans or primitives. In this situation, the **WSDL2Java** command maps the type to an SAAJ `SOAPElement`. A SAAJ SOAPElement is a generic representation of the element in the message. The methods on the `SOAPElement` can be used to examine the element and its children.

  In some scenarios, it might be more appropriate to use the generic `SOAPElement` mapping exclusively. To learn more about the use of `SOAPElement`, see the information on SOAP with Attachments API for Java interface and custom data binders for JAX-RPC applications.

  For a complete list of the supported standards and specifications, see the web services specifications and API documentation.

- -help

  Displays a help message and exits.

- -helpX

  Displays a help message for extended options. The options include:

- -verbose

  Displays processing information, including the names of the generated files.

- -NStoPkg *namespace=package*

  By default, package names are automatically derived from the namespace strings in the WSDL file. For example, if the namespace is of the form *http://x.y.com* or *urn:x.y.com*, the corresponding package is *com.y.x*.

  You can provide your own mapping by using the -NStoPkg argument, which you can repeat as often as necessary, once for each unique namespace mapping. For example, if a namespace in the WSDL file is called `urn:AddressFetcher2`, and you want files generated from the objects in this namespace to reside in the samples.addr package, provide the -NStoPkg "http://urn:AddressFetcher2/"=samples.addr argument to the **WSDL2Java** command.

- -timeout *seconds*

Specifies how long the **WSDL2Java** command waits, in seconds, for the WSDL-URI to respond before giving up. The default is 45 seconds; -1 disables the timeout.

- -genResolver

  Generates an absolute-import resolver class. The purpose of this class is to record the contents of the imported WSDL files that are used by the WSDL URI. This class is used by the run time and can also be used for future **WSDL2Java** command runs. This flexibility is desirable when the imported WSDL files are remote and possibly inaccessible. When an import resolver is used, the possibility that a remote WSDL file has different contents at run time that it did during development is eliminated. The generated class is named `_AbsoluteImportResolver.java`. Compile and package this class with the other Java classes that are generated by the **WSDL2Java** command.
- -useResolver *resolver-class*

  Specifies an absolute-import resolver class to use during parsing. This class must be created during a previous run of the **WSDL2Java** command that uses the -genResolver option. The class must be available in the CLASSPATH variable.
- -deployScope *argument*

  Indicates how to deploy the server implementation. Valid arguments include:
  - Application

    Uses one instance of the implementation class for all requests.
  - Request

    Creates a new instance of the implementation class for each request.
  - Session

    Creates a new instance of the implementation class for each session.

Other arguments

- -user *id*

  Specifies the login user name to access the WSDL URI.
- -password *password*

  Specifies the login user password to access the WSDL URI.
- -all

  Generates Java files for all types, even those that are not referenced.
- -allowRelativeNamespace *true or false*

  Specifies whether to disable the relative namespace restrictions. If you specify `-allowRelativeNamespace=true`, the relative namespace restrictions are disabled.

  Note: Only use this property if you have an established WSDL file or schema that relies on a relative namespaces and you are seeking to interoperate with a defined set of vendors that permit the use of relative namespaces.
- -debug

  Prints debugging information.
- -genJava *argument*

  Generates Java files. Valid arguments include:
  - IfNotExists, default
  - Overwrite
  - No
- -javaSearch *argument*

  The -javaSearch option is used with the -genJava option. If the -genJava IfNotExists, use the -javaSearch option to determine how file existence is detected.
  - File (default): Looks for a file in the output directory
  - Classpath: Looks for a class in the CLASSPATH variable
  - Both: Looks for a file in the output directory or in a class in the CLASSPATH variable

- -genXML *argument*

  Generates the `.xml` and `.xmi` files. Valid arguments are:
  - IfNotExists, default
  - Overwrite
  - No
- -genImplSer *true or false*

  Indicates that each generated Java bean implements the java.io.Serializable. The default is `false`.
- -genEquals *true or false*

  Indicates that each generated Java bean have `equals` and `hashCode` methods. The default is false.
- -noWrappedOperations

  Disables wrapped operations detection. Java beans for the request and response messages are generated.
- -noWrappedArrays

  Disables wrapped array detection.
- -fileNStoPkg *file name*

  Specifies the file of the namespace to package mappings. The default is NStoPKG.properties.
- service *wsdl service name*

  Generates files for the installed WSDL service only.
- -testCase

  Generates the template for a JUnit test case for testing web services. JUnit is a simple framework to write repeatable tests.

Developing JAX-RPC web services deployment descriptor templates for an enterprise bean implementation

You can develop deployment descriptor templates for an Enterprise JavaBeans (EJB) implementation that is enabled for Java API for XML-based RPC (JAX-RPC) web services.

Before you begin

You need to create a service endpoint interface and develop a Web Services Description Language (WSDL) file before you can develop the deployment descriptor templates because the service endpoint interface and the WSDL file are artifacts that are used to create the templates.

About this task

Completing this task creates deployment descriptor templates that describe how to map the service implementation to a Enterprise JavaBeans (EJB). This task is a required step in developing a web service from an enterprise bean.

To develop the deployment descriptor templates from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

When the web service implementation contains an enterprise bean in an EJB module, the `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file are generated in the `META-INF` subdirectory.

Procedure

Run the `WSDL2Java -verbose -role develop-server -container ejb -genJava no` *wsdlURL* command to generate the server deployment descriptor templates and mapping file into the `META-INF` subdirectory. If the -verbose option is specified, a list of all generated files displays when the command runs.

Note: The **WSDL2Java** command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly provided with the z/OS version of the product. Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

Results

You have deployment descriptor templates that are required to implement a web service.

Example

The following example uses the `AddressBookJ2WE.wsdl` WSDL file:
1. Generate the template files with the following command syntax:

```
WSDL2Java -verbose -role develop-server -container ejb -genJava no AddressBookJ2WE.wsdl
```

The deployment descriptor templates are generated into the `META-INF` subdirectory as follows:

```
Parsing XML file: AddressBookJ2WE.wsdl
Generating: META-INF\webservices.xml
Generating: META-INF\ibm-webservices-bnd.xmi
Generating: META-INF\ibm-webservices-ext.xmi
Generating: META-INF\AddressBookJ2WE_mapping.xml
```

What to do next

Continue to complete the steps that are necessary to develop a JAX-RPC web service from an enterprise bean. The next step is to complete the EJB implementation. When you complete the EJB implementation, you assemble an enterprise bean Java archive (JAR) file that contains the enterprise bean and supporting classes created from a WSDL file. To learn more, see the completing the EJB implementation for JAX-RPC applications information.

Completing the JavaBeans implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the JavaBeans implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Develop web services deployment descriptor templates for a JavaBeans implementation using the **WSDL2java** command-line tool. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation.

About this task

For JAX-RPC applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Edit the JavaBeans implementation template, *binding*Impl.java. The *binding* is the name of the <wsdl:binding> element in the WSDL file. The JavaBeans implementation is generated by the **WSDL2java** command-line tool.
   a. Complete the implementation of the methods in the template.
   b. (Optional) Make changes if necessary.
   c. (Optional) Change the class name if the binding name is not acceptable.
2. Compile all the Java classes.
3. Assemble a Web archive (WAR) file. Assemble all the Java classes into a WAR file using web module assembly tools. Include all of the classes generated from running the **WSDL2java** command tool for JAX-RPC web service applications when developing implementation templates and bindings from a WSDL file.

Results

You have now enabled the JavaBeans-based business application for JAX-RPC web services. You have a JAR file or a WAR file containing the JavaBeans implementation and supported classes created from the WSDL file.

What to do next

If you are developing a JAX-RPC web services application from JavaBeans, you need to configure the webservices.xml deployment descriptor and configure the ibm-webservices-bnd.xmi deployment descriptor so that the application server can process the incoming web services requests.

Completing the EJB implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the Enterprise JavaBeans (EJB) implementation and the supported classes created from the tooling.

Before you begin

Develop EJB implementation templates and bindings from a WSDL file for JAX-RPC web services using the **wsdl2java** command-line tool. The deployment descriptor templates that are generated from a Web Services Description Language (WSDL) file are required to complete the EJB implementation in the web services development process.

About this task

For JAX-RPC applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Inspect the EJB remote interface template, *portType*_RI.java. If necessary, modify the template. The value *portType* is the name of the <wsdl:portType> element in the WSDL file.
2. Edit the *binding*Impl.java EJB implementation template. Where *binding* is the name of the <wsdl:binding> element in the WSDL file.
3. Complete the implementation of the methods in the template.
4. (Optional) Make changes if necessary.
5. (Optional) Change the class name if the binding name is not acceptable.

6. Compile all the Java classes.
7. Assemble an EJB Java archive (JAR) file. Assemble all the Java classes into an enterprise bean JAR file using assembly tools. Include all of the classes generated from running the **WSDL2Java** command tool when developing implementation templates and bindings from a WSDL file.

Results

You have enabled an enterprise beans business application for JAX-RPC web services. You now have an enterprise bean JAR file containing an EJB and supporting classes created from web services artifacts.

What to do next

Now that you have gathered the required artifacts for developing a JAX-RPC web service with an enterprise bean, you need to, configure the `webservices.xml` deployment descriptor.

Configuring the webservices.xml deployment descriptor for JAX-RPC web services

You can configure the `webservices.xml` deployment descriptor with an assembly tool.

Before you begin

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

For JAX-RPC web services, this task is one of the required steps in developing a web service. You need to configure the deployment descriptors so that the application server can process the incoming web services requests.

If you are developing a web service from JavaBeans, you can develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file. Then, you complete the JavaBeans implementation. To learn more, read about developing JavaBeans deployment descriptor templates from a WSDL file and completing the JavaBeans implementation.

If you are developing a web service from an enterprise bean, you can develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file. Then, you complete the EJB implementation. To learn more, read about developing web services EJB deployment descriptor templates from a WSDL file and completing the EJB implementation.

When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

The assembly tools provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring compliant deployment descriptors for Java Platform, Enterprise Edition (Java EE).

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

You have a `webservices.xml` deployment descriptor that is configured.

What to do next

For JAX-RPC web services, you must configure the `ibm-webservices-bnd.xmi` deployment descriptor. To learn more, see the configuring the `ibm-webservices-bnd.xmi` deployment descriptor for JAX-RPC web services information.

Configuring the webservices.xml deployment descriptor for handler classes

You can use an assembly tool to configure the `webservices.xml` deployment descriptor for user-provided handler classes.

Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

A *handler class* is a class that is written to modify a SOAP message that represents a remote procedure call (RPC) request or response. Handlers can be associated with a web service or a web service client.

Similar to Java API for XML-based RPC (JAX-RPC) web services, you can use deployment descriptors to describe Java API for XML Web Services (JAX-WS) web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

To complete this task, you need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application require configuration. For other handler use, including sending information in the SOAP headers, the client and server applications must be configured with symmetrical handlers.

About this task

The modules in the EAR file contain the handler classes to configure. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java EE specification. See chapter 9 in the JAX-WS specification or chapter 12 in the JAX-RPC specification for additional information on the handler framework for your programming

model. The application modules must contain the webservices.xml deployment descriptor. See the web services specifications and API information to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC web services

Use assembly tools to configure the ibm-webservices-bnd.xml deployment descriptor. This file stores binding information that is associated with the endpoints defined with the webservices.xml deployment descriptor file.

Before you begin

Note: The ibm-webservices-bnd.xmi deployment descriptor is for Java API for XML-based RPC (JAX-RPC) based web services application. It is not used for Java API for XML-Based Web Services (JAX-WS) enabled applications.

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the ibm-webservices-bnd.xml deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

This task is one of the steps in developing a web service. You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming web services requests.

Depending on if you are developing a web service from JavaBeans or an enterprise bean:
- Develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file.
- Develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file.

Then, complete the EJB implementation or complete the JavaBeans implementation. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. These archive files contain the webservices.xml deployment descriptor. The archive files must be assembled before you can configure the webservices.xml deployment descriptor.

Configure the webservices.xml deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

The `ibm-webservices-bnd.xmi` deployment descriptor is configured for the web service implementation module.

What to do next

If you are developing a web service from JavaBeans, assemble a WAR file that is enabled for web services from Java code. See the assembling a WAR file that is enabled for web services from Java code information.

If you are developing a web service from an enterprise bean, assemble a JAR file that is enabled for web services from an enterprise bean. To learn more about assembling the artifacts that are required to enable the EJB module for web services into the JAR file, see the assembling a JAR file that is enabled for web services from an enterprise bean information.

JAX-RPC web services enabled module - deployment descriptor settings (ibm-webservices-bnd.xmi file)

The `ibm-webservices-bnd.xmi` file is a deployment descriptor for a Java API for XML-based RPC (JAX-RPC) web services-enabled web module or an Enterprise JavaBeans (EJB) module. This file contains information for the web services run time that is required by WebSphere Application Server..

You can edit these properties using an assembly tool. See Configuring the `ibm-webservices-bnd.xmi` deployment descriptor for JAX-RPC web services for instructions.

The following user-defined assembly properties are supported:

- **`wsDescNameLink`**

  Attribute of the wsdescBindings element that specifies the link to the corresponding <webservice-description-name> element in the `webservices.xml` file.
- **pc-name-link**

  Attribute of the pcBindings element that specifies the link to the <port-component-name> element in the `webservices.xml` file.
- **scope**

  Attribute of the pcBindings element that specifies when new instances of implementation beans are created. Possible values are request, session, and application.

You can change scope value for a deployed web service using the administrative console. Click **Enterprise Applications** > *application* > **Web modules** or **EJB modules** > *module* > **Web Services Implementation Scope**.

Bindings file examples

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the **WSDL2Java** command, you must confirm that each element has an ID attribute with a unique string value. Review the template xmi files generated by the **WSDL2Java** command for examples of ID strings. Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wsbnd:WSBinding xmi:version="2.0" xmlns:xmi=
"http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wsbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsbnd.xmi">
 <wsdescBindings wsDescNameLink="AddressBookService">
  <pcBindings pcNameLink="AddressBook" scope="Application"/>
 </wsdescBindings>
</com.ibm.etools.webservice.wsbnd:WSBinding>
```

Developing JAX-RPC web services with WSDL files (top-down)

Setting up a development environment for web services

The application server provides command-line tools to develop web services clients and implementations that are based on the Web Services for Java Platform, Enterprise Edition (Java EE) specification. You must set up your development environment before you start developing web services.

Before you begin

Before you can set up a web services development environment within WebSphere Application Server, you must install WebSphere Application Server. For detailed information on installing the application server, read about installing your application server environment.

About this task

Set up a web services development environment by completing the following actions.

Procedure

1. Set up the environment.

   Run the **setupCmdLine** script from the */profile_root/<application_server>/bin* directory.
2. Configure the path. You can add the WebSphere and Java `bin` directories to your path by typing:

```
set PATH=%WAS_PATH%;%PATH%
```

Results

You have set up an environment so that you can develop Web services.

What to do next

Implement web services applications. See the task overview for implementing web services applications information to learn about how to develop and implement a Java EE web service.

Developing Java artifacts for JAX-RPC applications from a WSDL file

You can develop Java artifacts from a Web Services Description Language (WSDL) file for JAX-RPC applications from a WSDL file by using the WSDL2Java command-line tool to create Java implementation templates and bindings.

Before you begin

To develop the JavaBeans implementation templates and bindings from a WSDL file, you must obtain the Uniform Resource Locator (URL) of the WSDL file.

If the WSDL file is a local file, the URL looks like this example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

Implementation templates are generated using the -role develop-server option of the **WSDL2Java** command. The **WSDL2Java** command also generates bindings and deployment descriptors.

The **WSDL2Java** command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product. Read about the WSDL2Java command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

About this task

Develop JavaBeans implementation templates and bindings from a WSDL file by issuing the proper command.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the **WSDL2Java** tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the **WSDL2Java** tool, see the **WSDL2Java** command for JAX-RPC applications documentation.

Procedure

Run the `WSDL2Java -verbose -role develop-server -container web` *wsdlURL* command. Since the -verbose option is specified, a list of all the generated files is displayed when the command runs.

Results

You have templates for the implementation and deployment descriptors required to implement a web service, as well as bindings files. These templates are partially filled with information from the WSDL file.

Example

The following example uses the AddressBook JavaBeans implementation and the `AddressBook.wsdl` WSDL file. After generating the template files from the `WSDL2Java -verbose -role develop-server -container web AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java..
WSWS3282I: Info: Generating WEB-INF\webservices.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating WEB-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating WEB-INF\ibm-webservices-ext.xmi.
```

The `AddressBookSOAPBindingImpl.java` file is the template for the implementation bean. It is named after the port in the WSDL file. Generally, this class is renamed to a more meaningful name.

What to do next

Complete the JavaBeans implementation for JAX-RPC applications.

Developing EJB implementation templates and bindings from a WSDL file for JAX-RPC web services

You can develop Enterprise JavaBeans (EJB) implementation deployment descriptor templates and bindings from a Web Services Description Language (WSDL) file for a JAX-RPC application.

Before you begin

To develop EJB implementation templates and bindings from a WSDL file for a Java API for XML-based RPC (JAX-RPC) web service, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use.

If the WSDL file is a local file, the URL looks like the following example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

About this task

This task is one a required step in developing a web service from an enterprise bean.

Implementation templates are generated using the `-role develop-server` option of the **WSDL2Java** command.

Templates are generated for an EJB implementation for the following components:
- enterprise bean
- EJB remote interface
- EJB Home

The **WSDL2Java** command also generates bindings and deployment descriptors.

The **WSDL2Java** command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product. Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the **WSDL2Java** tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the **WSDL2Java** tool, see the **WSDL2Java** command for JAX-RPC applications documentation.

Procedure

Run the `WSDL2Java -verbose -role develop-server -container ejb` *wsdlURL* command. Because the verbose option is specified, a list of all the generated files is displayed when the command runs.

Results

You have templates for the implementation and deployment descriptors required to implement web services, as well as bindings files. These templates are partially completed with information from the WSDL file.

Example

The following example uses the enterprise bean AddressBook enterprise bean and the `AddressBook.wsdl` file. After generating the template files from the `WSDL2Java -verbose -role develop-server -container EJB AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookSoapBindingImpl.java.
WSWS3282I: Info: Generating addr\AddressBook_RI.java.
WSWS3282I: Info: Generating addr\AddressBookHome.java.
WSWS3282I: Info: Generating META-INF\webservices.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservices-ext.xmi.
```

What to do next

Complete the EJB implementation. When you complete the EJB implementation, an EJB Java archive (JAR) file that contains an EJB and supporting classes is created from a WSDL file.

Completing the JavaBeans implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the JavaBeans implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the JavaBeans implementation and the supported classes created from the tooling.

Before you begin

Develop web services deployment descriptor templates for a JavaBeans implementation using the **WSDL2java** command-line tool. You need to complete this step to create the deployment descriptor templates that are configured to map the service implementation to the JavaBeans implementation.

About this task

For JAX-RPC applications, complete the JavaBeans implementation by writing your business application.

Procedure

1. Edit the JavaBeans implementation template, *binding*`Impl.java`. The *binding* is the name of the <wsdl:binding> element in the WSDL file. The JavaBeans implementation is generated by the **WSDL2java** command-line tool.
   a. Complete the implementation of the methods in the template.
   b. (Optional) Make changes if necessary.
   c. (Optional) Change the class name if the binding name is not acceptable.
2. Compile all the Java classes.
3. Assemble a Web archive (WAR) file. Assemble all the Java classes into a WAR file using web module assembly tools. Include all of the classes generated from running the **WSDL2java** command tool for JAX-RPC web service applications when developing implementation templates and bindings from a WSDL file.

Results

You have now enabled the JavaBeans-based business application for JAX-RPC web services. You have a JAR file or a WAR file containing the JavaBeans implementation and supported classes created from the WSDL file.

What to do next

If you are developing a JAX-RPC web services application from JavaBeans, you need to configure the `webservices.xml` deployment descriptor and configure the `ibm-webservices-bnd.xmi` deployment descriptor so that the application server can process the incoming web services requests.

Completing the EJB implementation for JAX-RPC applications

After you have developed the Java artifacts necessary to develop a Java API for XML-based RPC (JAX-RPC) web service, you must complete the Enterprise JavaBeans (EJB) implementation to assemble a Java archive (JAR) file or a web application archive (WAR) file based on your programming model. The resulting JAR file or WAR file contains the Enterprise JavaBeans (EJB) implementation and the supported classes created from the tooling.

Before you begin

Develop EJB implementation templates and bindings from a WSDL file for JAX-RPC web services using the **wsdl2java** command-line tool. The deployment descriptor templates that are generated from a Web Services Description Language (WSDL) file are required to complete the EJB implementation in the web services development process.

About this task

For JAX-RPC applications, complete the enterprise beans implementation by writing your business application.

Procedure

1. Inspect the EJB remote interface template, *portType*`_RI.java`. If necessary, modify the template. The value *portType* is the name of the `<wsdl:portType>` element in the WSDL file.
2. Edit the *binding*`Impl.java` EJB implementation template. Where *binding* is the name of the `<wsdl:binding>` element in the WSDL file.
3. Complete the implementation of the methods in the template.
4. (Optional) Make changes if necessary.
5. (Optional) Change the class name if the binding name is not acceptable.
6. Compile all the Java classes.
7. Assemble an EJB Java archive (JAR) file. Assemble all the Java classes into an enterprise bean JAR file using assembly tools. Include all of the classes generated from running the **WSDL2Java** command tool when developing implementation templates and bindings from a WSDL file.

Results

You have enabled an enterprise beans business application for JAX-RPC web services. You now have an enterprise bean JAR file containing an EJB and supporting classes created from web services artifacts.

What to do next

Now that you have gathered the required artifacts for developing a JAX-RPC web service with an enterprise bean, you need to, configure the `webservices.xml` deployment descriptor.

Configuring the webservices.xml deployment descriptor for JAX-RPC web services

You can configure the `webservices.xml` deployment descriptor with an assembly tool.

Before you begin

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

For JAX-RPC web services, this task is one of the required steps in developing a web service. You need to configure the deployment descriptors so that the application server can process the incoming web services requests.

If you are developing a web service from JavaBeans, you can develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file. Then, you complete the JavaBeans implementation. To learn more, read about developing JavaBeans deployment descriptor templates from a WSDL file and completing the JavaBeans implementation.

If you are developing a web service from an enterprise bean, you can develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file. Then, you complete the EJB implementation. To learn more, read about developing web services EJB deployment descriptor templates from a WSDL file and completing the EJB implementation.

When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

The assembly tools provide a graphical interface for developing code artifacts, assembling the code artifacts into various archives (modules) and configuring compliant deployment descriptors for Java Platform, Enterprise Edition (Java EE).

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

You have a webservices.xml deployment descriptor that is configured.

What to do next

For JAX-RPC web services, you must configure the ibm-webservices-bnd.xmi deployment descriptor. To learn more, see the configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC web services information.

Configuring the webservices.xml deployment descriptor for handler classes

You can use an assembly tool to configure the webservices.xml deployment descriptor for user-provided handler classes.

Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

A *handler class* is a class that is written to modify a SOAP message that represents a remote procedure call (RPC) request or response. Handlers can be associated with a web service or a web service client.

Similar to Java API for XML-based RPC (JAX-RPC) web services, you can use deployment descriptors to describe Java API for XML Web Services (JAX-WS) web services. For JAX-WS web services, the use of the webservices.xml deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the webservices.xml deployment descriptor overrides any corresponding information that is specified by annotations.

To complete this task, you need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application require configuration. For other handler use, including sending information in the SOAP headers, the client and server applications must be configured with symmetrical handlers.

About this task

The modules in the EAR file contain the handler classes to configure. These classes implement the javax.xml.rpc.handler.Handler interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java EE specification. See chapter 9 in the JAX-WS specification or chapter 12 in the JAX-RPC specification for additional information on the handler framework for your programming model. The application modules must contain the webservices.xml deployment descriptor. See the web services specifications and API information to review the JAX-RPC specification along with a complete list of the supported standards and specifications.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate

files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC web services

Use assembly tools to configure the `ibm-webservices-bnd.xml` deployment descriptor. This file stores binding information that is associated with the endpoints defined with the `webservices.xml` deployment descriptor file.

Before you begin

Note: The `ibm-webservices-bnd.xmi` deployment descriptor is for Java API for XML-based RPC (JAX-RPC) based web services application. It is not used for Java API for XML-Based Web Services (JAX-WS) enabled applications.

To configure the client deployment descriptor, read about the configuring the client deployment descriptor in the Rational Application Developer information.

Before you can configure the `ibm-webservices-bnd.xml` deployment descriptor, you must develop the deployment descriptor templates and complete the implementation.

About this task

This task is one of the steps in developing a web service. You need to configure the deployment descriptors so that WebSphere Application Server can process the incoming web services requests.

Depending on if you are developing a web service from JavaBeans or an enterprise bean:

- Develop web services JavaBeans deployment descriptor templates from a Web Services Description Language (WSDL) file.
- Develop web services Enterprise JavaBeans (EJB) deployment descriptor templates from a WSDL file.

Then, complete the EJB implementation or complete the JavaBeans implementation. When the EJB implementation is complete, the enterprise bean Java archive (JAR) file is assembled. When the JavaBeans implementation is complete, the web module web application archive (WAR) file is assembled. These archive files contain the `webservices.xml` deployment descriptor. The archive files must be assembled before you can configure the `webservices.xml` deployment descriptor.

Configure the `webservices.xml` deployment descriptor by following the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

The ibm-webservices-bnd.xmi deployment descriptor is configured for the web service implementation module.

What to do next

If you are developing a web service from JavaBeans, assemble a WAR file that is enabled for web services from Java code. See the assembling a WAR file that is enabled for web services from Java code information.

If you are developing a web service from an enterprise bean, assemble a JAR file that is enabled for web services from an enterprise bean. To learn more about assembling the artifacts that are required to enable the EJB module for web services into the JAR file, see the assembling a JAR file that is enabled for web services from an enterprise bean information.

JAX-RPC web services enabled module - deployment descriptor settings (ibm-webservices-bnd.xmi file)

The ibm-webservices-bnd.xmi file is a deployment descriptor for a Java API for XML-based RPC (JAX-RPC) web services-enabled web module or an Enterprise JavaBeans (EJB) module. This file contains information for the web services run time that is required by WebSphere Application Server..

You can edit these properties using an assembly tool. See Configuring the ibm-webservices-bnd.xmi deployment descriptor for JAX-RPC web services for instructions.

The following user-defined assembly properties are supported:

- **wsDescNameLink**

  Attribute of the wsdescBindings element that specifies the link to the corresponding <webservice-description-name> element in the webservices.xml file.
- **pc-name-link**

  Attribute of the pcBindings element that specifies the link to the <port-component-name> element in the webservices.xml file.
- **scope**

  Attribute of the pcBindings element that specifies when new instances of implementation beans are created. Possible values are request, session, and application.

You can change scope value for a deployed web service using the administrative console. Click **Enterprise Applications** > *application* > **Web modules** or **EJB modules** > *module* > **Web Services Implementation Scope**.

Bindings file examples

The following examples demonstrate the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the **WSDL2Java** command, you must confirm that each element has an ID attribute with a unique string value. Review the template xmi files generated by the **WSDL2Java** command for examples of ID strings. Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wsbnd:WSBinding xmi:version="2.0" xmlns:xmi=
"http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wsbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wsbnd.xmi">
 <wsdescBindings wsDescNameLink="AddressBookService">
  <pcBindings pcNameLink="AddressBook" scope="Application"/>
 </wsdescBindings>
</com.ibm.etools.webservice.wsbnd:WSBinding>
```

Developing JAX-RPC web services clients

Developing client bindings from a WSDL file for a JAX-RPC Web services client

You can develop client bindings from a Web Services Description (WSDL) file for a JAX-RPC web services client.

Before you begin

To develop the client bindings from a WSDL file for JAX-RPC web service applications, you must obtain the Uniform Resource Locator (URL) of the WSDL file to use. You need bindings and deployment descriptors in order for a client to use a web service.

If the WSDL file is a local file, the URL looks like the following example: file:*drive:**path**file_name*.wsdl.

You can also specify local files using the absolute or relative file system path.

Client bindings are generated using the `-role develop-client` option in combination with the `-container` option of the **WSDL2Java** command. The `-container` option takes the following parameters:

- **-container client**

  Generates bindings and deployment descriptors for a client residing in the application client container.
- **-container ejb**

  Generates bindings and deployment descriptors for a client that is an enterprise bean in the Enterprise JavaBeans (EJB) module.
- **-container web**

  Generates bindings and deployment descriptors for a client residing in the web container.

The **WSDL2Java** command-line tool is not supported on the z/OS platform. This functionality is provided by the assembly tools provided with the z/OS version of the product. Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

About this task

Develop client bindings from a WSDL file by running the appropriate command.

Note: It is a best practice to use absolute namespaces within your WSDL or schema. By default, the **WSDL2Java** tool does not permit the use of relative namespaces. Relative namespaces have been deprecated by the XML Plenary Interest Group and the use of relative namespaces causes the XML Digital Signature to fail as required by the Canonical XML Version 1.0 specification. You can convert any relative namespaces to absolute namespaces. To learn more about the use of namespaces with the **WSDL2Java** tool, see the **WSDL2Java** command for JAX-RPC applications documentation.

Procedure

Run the `WSDL2Java -verbose -role develop-client -container` *type wsdlURL* command, where *type* is **ejb** for an enterprise EJB client, `web` for a JavaBeans client, or `client` for an application client.
You can use the following combinations in the command-line:

- -container `web`
- -container `ejb`
- -container `client`

Because the verbose option is specified, a list of all generated files is displayed when the command runs.

Results

You have the bindings and deployment descriptors needed by a client to use a web service.

Example

The following example uses the AddressBook enterprise bean the `AddressBook.wsdl` WSDL file. After generating the bindings from the `WSDL2Java -verbose -role develop-client -container client AddressBook.wsdl` command, the following files are generated:

```
Parsing XML file:  file:e:/example/app/topdown/step1/AddressBook.wsdl
WSWS3185I: Info: Parsing XML file:  AddressBook.wsdl
WSWS3282I: Info: Generating addr\Address.java.
WSWS3282I: Info: Generating addr\Phone.java.
WSWS3282I: Info: Generating addr\StateType.java.
WSWS3282I: Info: Generating addr\AddressBook.java.
WSWS3282I: Info: Generating addr\AddressBookService.java.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-bnd.xmi.
WSWS3282I: Info: Generating META-INF\AddressBook_mapping.xml.
WSWS3282I: Info: Generating META-INF\ibm-webservicesclient-ext.xmi.
```

What to do next

Complete the client implementation by writing your client application and then assembling the client artifacts.

.

Changing SOAP message encoding to support WSI-Basic Profile

Support for Universal Transformation Format (UTF)-16 encoding is required by the WS-I Basic Profile 1.0. WebSphere Application Server conforms to the WS-I Basic Profile 1.1. UTF-16 is a kind of unicode encoding scheme using 16-bit values to store Universal Character Set (UCS) characters. UTF-8 is the most common encoding that is used on the Internet and UTF-16 encoding is typically used for Java and Windows product applications. You can change the encoding in a SOAP message from UTF-8 to UTF-16.

Before you begin

To learn more about the requirements of the Web Services-Interoperability Basic Profile (WS-I), including UTF-16, see Web Services-Interoperability Basic Profile information.

About this task

Support for UTF-16 encoding is required by WS-I Basic Profile. The application server only supports UTF-8 and UTF-16 encoding of SOAP messages.

You can change the character encoding in one of two ways:

Procedure

- Use a property on the Stub for users to set.

  This choice applies to the client only.

  For a client, the encoding is specified in the SOAP request. The SOAP engine serializes the request and sends it to the web service engine. The web service engine receives the request and deserializes the message to Java objects, which are returned to you in a response.

  When the web service engine on the server receives the serialized request, a raw message in the form of an input stream, is passed to the parser, which understands Byte Order Mark (BOM). BOM is mandatory for UTF-16 encoding and it can be used in UTF-8. The message is deserialized to a Java

objects and a service invocation is made. For two-way invocation, the engine needs to serialize the message using a specific encoding and send it back to the caller. The following example shows you how to use a property on the Stub to change the character set:

```
javax.xml.rpc.Stub stub=service.getPort("MyPortType");
((javax.xml.rpc.Stub)stub).setProperty(com.ibm.wsspi.webservices.Constants.MESSAGE_CHARACTER_SET_ENCODING,"UTF-16");
stub.invokeMethod();
```

In this code example, **com.ibm.wsspi.webservices.Constants.MESSAGE_CHARACTER_SET_ENCODING** = *"com.ibm.wsspi.webservices.xmlcharset";*

- Use a handler to change the character set through SOAP with Attachments API for Java (SAAJ).

  If you are using a handler, the SOAP message is transformed to a SAAJ format from other possible forms, such as an input stream. In such cases as a handleRequest method on the client side and a handleResponse method on the server side, the web services engine transforms from a SAAJ format back to the stream with appropriate character encoding. This transformation or change is called a *roundtrip transformation*. The following is an example of how you can use a handler to specify the character encoding through SAAJ:

```
handleResponse(MessageContext mc) {
 SOAPMessageContext smc = (SOAPMessageContext) context;
 javax.xml.soap.SOAPMessage msg = smc.getMessage();
 msg.setProperty (javax.xml.soap.SOAPMessage.CHARACTER_SET_ENCODING, "UTF-16");
 }
}
```

Results

You have modified the character encoding from UTF-8 to UTF-16 in the web service SOAP message.

Configuring the JAX-RPC web services client deployment descriptor with an assembly tool

You can configure JAX-RPC web services client deployment descriptor with an assembly tool.

Before you begin

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server.

Also, you need an enterprise JavaBeans (EJB) Java archive (JAR) file, web application archive (WAR) file or an application client file that you can import into the assembly tool.

Assemble the client JAR file into an EAR file or assemble the client WAR file into an EAR file. To learn more, see the information on assembling a web services-enabled client JAR file into an EAR file or assembling a web services-enabled client WAR file into an EAR file.

About this task

Complete this task if you are developing a managed client that runs in the Java EE client container. This task is done after you assemble the EJB or web module.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) or Java Archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to assembly tools. To migrate

files, import your WAR or JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

4. Configure the client deployment descriptor. Read about the configuring the client deployment descriptor in the Rational Application Developer information.

Results

You have a client deployment descriptor that is configured.

What to do next

Test the web services client. See the testing web services-enabled clients information to learn more about how to test an unmanaged client Java archive (JAR) file and an unmanaged client application.

Configuring the JAX-RPC client deployment descriptor for handler classes

You can configure the JAX-RPC client deployment descriptor for user-provided handler classes.

Before you begin

You need an enterprise archive (EAR) file for the applications that you want to configure. For some handler use, such as logging or tracing, only the server or client application needs to be configured. For other handler use, including sending information in SOAP headers, the client and server applications must be configured with symmetrical handlers.

The modules in the EAR file should contain the handler classes to configure. These classes implement the `javax.xml.rpc.handler.Handler` interface. For more information on writing handler classes, see chapter 6 of the Web Services for Java Platform, Enterprise Edition (Java EE) specification and chapter 12 of the Java API for XML-based remote procedure call (JAX-RPC) specification. The application modules must contain the `webservices.xml` (for server) and the client deployment descriptors.

For a complete list of the supported standards and specifications, see the web services specifications and API documentation.

About this task

Configure a handler in the client deployment descriptor by following the steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer information.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer information.
3. Migrate the web application archive (WAR) or Java archive (JAR) files that are created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. Read about importing WAR or JAR files using an assembly tool in the Rational Application Developer information.
4. Configure the client deployment descriptor. Read about creating web services handlers in the Rational Application Developer information.

Results

You have a client deployment descriptor that is configured.

What to do next

Test the web services client. See the testing web services-enabled clients information to learn more about how to test an unmanaged client Java archive (JAR) file and an unmanaged client application.

Handler class properties with JAX-RPC

This article describes handler class properties using Java API for XML-based RPC (JAX-RPC).

You can configure the following handler class properties with assembly tools provided with WebSphere Application Server. See Configuring the `webservices.xml` deployment descriptor for Handler classes or Configuring the client deployment descriptors for Handler classes for instructions on how to configure the properties.

You can configure the following handler class properties with assembly tools provided with WebSphere Application Server. For instructions on how to configure the handler class properties, read about configuring the `webservices.xml` deployment descriptor for handler classes or configuring the client deployment descriptors for handler classes.

Description:

Standard Java Platform, Enterprise Edition (Java EE) technology descriptor field.

Display name:

Standard Java EE technology descriptor field.

Small icon:

Standard Java EE technology descriptor field.

Large icon:

Standard Java EE technology descriptor field.

Handler name:

The name of the handler. This name must be unique within the module.

Handler class:

The fully qualified name of the handler class. Initially, it is set by an assembly tool.

Initial parameters:

Property names and values available to the handler.

SOAP headers:

Qualified names (Qnames) of the SOAP headers that are processed by this handler.

See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through the web services specifications and APIs information, for more information about setting this property.

SOAP roles:

URIs containing the SOAP actor names for which the handler acts in the role.

See section 12.2.2 of the Java API for XML-based remote procedure call (JAX-RPC) specification, available through the web services specifications and APIs information, for more information about setting this property.

Example: Configuring handler classes for web services deployment descriptors

This scenario explains how to add a client and server handler class to a sample application, `WebServicesSamples.ear`. The handler classes display messages when given a request or response to handle.

The code for the client handler class is illustrated in the following example:

```
package samples;

public class ClientHandler implements javax.xml.rpc.handler.Handler {
    public ClientHandler() { }

public boolean handleRequest(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ClientHandler: In handleRequest");
    return true; }

public boolean handleResponse(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ClientHandler: In handleResponse");
    return true; }

public boolean handleFault(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ClientHandler: In handleFault");
    return true;  }

public void init(javax.xml.rpc.handler.HandlerInfo config) {}

public void destroy() {}

public javax.xml.namespace.QName[] getHeaders() {
    return null; }
}
```

The code for the server handler class is illustrated in the following example:

```
package sample;
public class ServerHandler implements javax.xml.rpc.handler.Handler {
    public ServerHandler() { }

public boolean handleRequest(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ServerHandler: In handleRequest");
    return true; }

public boolean handleResponse(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ServerHandler: In handleResponse");
    return true; }

public boolean handleFault(javax.xml.rpc.handler.MessageContext context) {
    System.out.println("ServerHandler: In handleFault");
    return true; }

public void init(javax.xml.rpc.handler.HandlerInfo config) {}

public void destroy() {}

public javax.xml.namespace.QName[] getHeaders() {
    return null;  }
}
```

1. Compile these classes using:
2. Open an assembly tool and import the two sample enterprise archive (EAR) files:
   -
   -
3. Import the compiled handler classes into the projects for the sample modules:
   - Import sample.ClientHandler into the **appClientModule** directory of the **AddressBookClient** project.
   - Import sample.ServerHandler into the **ejbModule** directory of the **AddressBookW2JE** project.
4. Configure the client deployment descriptor for handler classes.

This topic explains how to configure the client deployment descriptor for user-provided handler classes.

5. Configure the webservices.xml deployment descriptor for handler classes.

   This topic explains how to configure the `webservices.xml` deployment descriptor for user-provided handler classes.

6. Save your changes and export the EAR files.
7. Uninstall the `WebServicesSamples.ear` application from your server if it is already installed.
8. Install the new `WebServicesSamples.ear` application.
9. Start the server.
10. Run the client:

    ```
    launchClient ApplicationClients.ear -CCjar=AddressBookClient.jar
    ```

    When the client runs, the console output looks like the following example. The messages from the handlers are shown in bold.

```
IBM WebSphere Application Server

com.ibm.websphere.samples.webservices.addr.AddressBookClient
>> Querying address for 'Purdue Boilermaker' using port
AddressBookW2JE
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
       1 University Drive
       West Lafayette, IN 47907
       Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WE
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
       2 University Drive
       West Lafayette, IN 47907
       Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port
AddressBookJ2WB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
       3 University Drive
       West Lafayette, IN 47907
       Phone: (765) 555-4900
>> Querying address for 'Purdue Boilermaker' using port AddressBookW2JB
ClientHandler: In handleRequest
ClientHandler: In handleResponse
>> Response is:
       4 University Drive
       West Lafayette, IN 47907
       Phone: (765) 555-4900
```

    For the client, the handler class is configured for each service reference, not for each port. The AddressBook sample has four ports, but only one service reference, therefore the ClientHandler handles requests and responses on all ports.

When the server log file is examined, it contains the following data:

```
[9/24/03 16:39:22:661 CDT] 4deec1c6 WebGroup      I SRVE0180I:
[HTTP router for AddressBookW2JE.jar] [/AddressBookW2JE] [Servlet.LOG]:
AddressBook: init
[9/24/03 16:39:23:161 CDT] 4deec1c6 SystemOut     O ServerHandler: In handleRequest
[9/24/03 16:39:23:211 CDT] 4deec1c6 SystemOut     O ServerHandler: In handleResponse
```

Results

The deployment descriptors for handler classes are configured. Deployment descriptors are required so that so that WebSphere Application Server can process the incoming web services requests.

What to do next

Deploy the EAR file that has been configured and enabled for web services. Then you can test the application to make sure it runs within the WebSphere Application Server environment.

Configuring the JAX-RPC web services client bindings in the ibm-webservicesclient-bnd.xmi deployment descriptor

You can configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor file with assembly tools.

Before you begin

You can configure deployment descriptors with assembly tools provided with the application server.

You must configure the assembly tool before you can use it. Read about configuring the assembly tool in the Rational Application Developer documentation.

About this task

Now that you have assembled the client module, complete this step to configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor. Deployment descriptors are required so that so that WebSphere Application Server can process the incoming web services requests.

Configure the `ibm-webservicesclient-bnd.xmi` deployment descriptor file with the following steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. Switch to the Java EE Perspective.
   a. Click **Window** > **Open Perspective** > **Other** > **Java EE**.
3. Open the Project Explorer.
   a. Click **Window** > **Show View** > **Other** > **Project Explorer**.
4. Locate the deployment descriptor file for the module. Hint: Deployment Descriptor: *<module>*
5. Double-click the deployment descriptor file to open the Deployment Descriptor editor.
   a. Select the **WS Binding** tab at the bottom of the editor window to open the Web Services Client Bindings editor.
6. Verify the serviceRefLink element settings.
   a. Open the **Web Services Client Bindings** editor.
   b. Click the **Services References** tab.
   c. Click **Add**.
   d. Select the service references defined in the client deployment descriptor file from the list.
7. Verify the deployedWSDLFile element settings.
   a. Open the **Web Services Client Bindings** editor.
   b. Select the service reference.
   c. Expand the **Service Reference Details** section.
   d. Click **Browse** that is located to the right of the Deployed WSDL file field.

e. Select the new Web Services Description Language (WSDL) file.
f. Click **OK**.

You can also change the deployedWSDLFile element of a deployed web service using the administrative console. Click **Enterprise Applications** > ***application*** > **Web module or EJB module** > ***module*** > **Web services client bindings**.

8. Verify the `defaultMappings` element settings.
   a. Open the **Web services client bindings** editor.
   b. Click **Default mappings**.
   c. Click **Add**.
   d. Edit the entries in the newly added row to establish a mapping between a *portType* and a *port* in the WSDL file. Only one entry is supported for each *portType*.
   e. Click **OK**.

   You can also change the defaultMappings element of a deployed web service using the administrative console. Click **Enterprise Applications** > ***application*** > **Web module or EJB module** > ***module*** > **Web services client bindings**.
9. Access the web services client Port bindings editor through the **Port qualified name binding details** section at the bottom of the editor pane.
10. Verify the syncTimeout element settings.
    a. Create a Port qualified name bindings for the port.
    b. Open the **Web services client bindings** editor.
    c. Confirm that a service reference is selected in either the **Component-scoped references** or the **Service references** section.
    d. Expand the **Port qualified name binding** section.
    e. Click **Add**. The **Add port qualified name binding** dialog opens.
    f. Type the *namespace* of the WSDL file port you want to configure, in the **Port namespace link** field.
    g. Type the *local_name* of the WSDL file port you want to configure in the **Port local name link** field. The name displayed in the **Port qualified name binding** list is the local name of the WSDL file port.
    h. Click **OK**.
    a. Configure the syncTimeout property by locating the Synchronization timeout field and enter the desired value. The default is 300 seconds.
11. Verify the basicAuth element settings.
    a. Locate the **HTTP basic authentication** field in the **Port qualified name binding details** section.
    b. Type the desired value in the User ID and Password fields.
    c. Click **OK**.
12. Verify the sslConfig element settings.
    a. Locate the **SSL configuration** field in the **Port qualified name binding details** section.
    b. Type the desired value in the **Name** field.
    c. Click **OK**.
13. After editing the properties, type `ctrl-s` on your keyboard to save the changes.

Results

You have configured the `ibm-webservicesclient-bnd.xmi` deployment descriptor. If you have configured all of the client deployment descriptors, test the web services client. If you have not configured all of the client deployment descriptors, complete the configurations and then test the web services client.

ibm-webservicesclient-bnd.xmi assembly properties for JAX applications

The ibm-webservicesclient-bnd.xmi deployment descriptor file contains information for the web services run time that is WebSphere product-specific. This deployment descriptor file is used with Java API for XML-based web services.

You can configure deployment descriptors with assembly tools provided with WebSphere Application Server. Read about configuring the JAX-RPC web services client bindings in the ibm-webservicesclient-bnd.xmi deployment descriptor to learn more about configuring this deployment descriptor.

Assembly properties

The following list is a collection of supported properties and attributes that you can define for your applications.

Note: The overriddenEndpointURI property is the only property that is applicable for Java API for XML-Based Web Services (JAX-WS) Web services.

componentNameLink
An attribute of the componentScopedRefs element. When a web service is implemented by an Enterprise JavaBeans (EJB) implementation, each <componentScopedRefs> element contains assembly properties for an individual enterprise bean. The componentNameLink attribute of the <componentScopedRefs> element identifies the enterprise bean that the assembly properties apply to by specifying the <ejb-name>. This property is used only when the web service client is an enterprise bean.

serviceRefLink
An attribute of the serviceRefs element. Specifies the link to the <service-ref-name> in the <service-ref> element in the client deployment descriptor. The client deployment descriptor is either `ejb-jar.xml`, `web.xml` or `application-client.xml`.

deployedWSDLFile
An attribute of the serviceRefs element is optional. Permits an alternate Web Services Description Language (WSDL) file to use other than that specified in the <wsdl-file> element of the <service-ref> element in the client deployment descriptor. If an attribute is specified, the alternate WSDL file must be packaged in the same module and must be compatible with the development WSDL file. The deployedWSDLFile property supplies a new WSDL file containing a different endpoint web address than the original WSDL file.

defaultMappings
An element that identifies which port to use for a given portType when one is not selected by the client. This element has the following attributes: portTypeNamespace, portTypeLocalName, portNamespace, portLocalName. These attributes identify which wsdl:port is used for a wsdl:portType.

syncTimeout
An attribute of the portQnameBindings element. Specifies how long, in seconds, to wait for a response from a synchronous call. The default is 300 seconds.

basicAuth
An element of the portQnameBindings element. Authenticates a service client to the service endpoint, independent of the underlying transport that includes, HTTP, HTTPS, and Java Message Service (JMS). Set the user ID and password attributes as needed.

sslConfig
An element of the portQnameBindings element. Specifies the Secure Sockets Layer (SSL) configuration of an HTTPS outbound request. The name attribute is the name of an SSL configuration entry or alias that is defined in the SSL configuration repertoire. This attribute is used only when the client is running in the WebSphere Application Server.

For WebSphere Application Server for z/OS, some digital certificate and keyring management is required. To learn more, see the creating Secure Sockets Layer digital certificates and System Authorization Facility keyrings that applications can use to initiate HTTPS requests information.

overriddenEndpointURI
A property that specifies the final URL to which requests will be sent. When the client is run to invoke the web service, the request is sent to this property's URL, which takes precedence over the address given in the WSDL file and the client code. This property is the only property in the ibm-webservicesclient-bnd.xmi file which is applicable to JAX-WS services.

A bindings file example

The following example demonstrates the spelling and position of the various attributes. You cannot cut and paste these examples because they do not contain the required ID attributes. If you add elements to a binding file template generated by the **WSDL2Java** command, you must confirm that each element has an ID attribute whose value is a unique string. Review the template `xmi` files generated by the **WSDL2Java** command for examples of ID strings. Read about the **WSDL2Java** command-line tool for Java API for XML-based Remote Procedure Call (JAX-RPC) applications to learn more about this tool.

```
<com.ibm.etools.webservice.wscbnd:ClientBinding xmi:version="2.0"
xmlns:xmi="http://www.omg.org/XMI" xmlns:com.ibm.etools.webservice.wscbnd=
"http://www.ibm.com/websphere/appserver/schemas/5.0.2/wscbnd.xmi">

 <componentScopedRefs componentNameLink="myComponent ref"/>

 <serviceRefs serviceRefLink="myService ref" deployedWSDLFile="META-INF/wsdl/alternate.wsdl">
  <defaultMappings portTypeLocalName="AddressBook" portTypeNamespace="http://www.com.ibm"
portLocalName="AddressBookPort" portNamespace="http://www.com.ibm"/>
   <portQnameBindings portQnameNamespaceLink="http://www.com.ibm"
portQnameLocalNameLink="AddressBookPort" syncTimeout="99">
    <basicAuth userid="myId" password="myPassword"/>
    <sslConfig name="mynode/DefaultSSLSettings"/>
   </portQnameBindings>
  </serviceRefs>
 </com.ibm.etools.webservice.wscbnd:ClientBinding>
```

Implementing extensions to JAX-RPC web services clients

WebSphere Application Server provides extensions to web services clients using the Java API for XML-based RPC (JAX-RPC) programming model.

About this task

You can customize web services by using the following extensions to the JAX-RPC client programming model.

Procedure

- Set the **REQUEST_SOAP_HEADERS** and **RESPONSE_SOAP_HEADERS** properties in a JAX-RPC client Stub to enable a web services client to send or retrieve implicit SOAP headers.

  An implicit SOAP header is a SOAP header that is not explicitly defined in the WSDL file. An implicit SOAP header file fits one of the following descriptions:

  – A message part that is declared as a SOAP header in the binding in the WSDL file, but the message definition is not referenced by a portType within a WSDL file.
  – An element that is not contained in the WSDL file.

  Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

  To learn how to modify your client code to send or retrieve transport headers, see the information on sending implicit SOAP headers with JAX-RPC or receiving implicit SOAP headers with JAX-RPC.
- Set the **REQUEST_TRANSPORT_PROPERTIES** and **RESPONSE_TRANSPORT_PROPERTIES** properties to enable a web services client to send or retrieve transport headers.

Set the properties on the Stub or Call object.

By modifying your client code to send or retrieve transport headers, you can send or receive specific information within the transport headers of outgoing requests or incoming responses from the server. For requests or responses that use the HTTP transport, the information is sent or retrieved in an HTTP header. Similarly, for a request or response that uses the Java Message Service (JMS) transport, the information is sent or retrieved in a JMS message property.

To learn how to modify your client code to send or retrieve transport headers, see the information on sending transport headers with JAX-RPC or retrieving transport headers with JAX-RPC.

To learn how to enable a Web services client to send or retrieve transport headers, see the transport header properties best practices information.

- Implement support for `javax.xml.rpc.ServiceFactory.loadService()` methods.

  The loadService methods create an instance of the generated service implementation class in an implementation-specific manner. The loadService methods are new for JAX-RPC 1.1 and include three signatures:

  – **public.javax.xml.rpc.Service loadService (Class serviceInterface)**

    As documented in the JAX-RPC specification, this method returns the generated service implementation for the service interface. See the web services specifications and API documentation to review the JAX-RPC specification.

  – **public.javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, Class serviceInterface, Properties properties)**

    This method behaves like the loadService (Class serviceInterface) because the following parameters are ignored:

    - wsdlDocumentLocation
    - properties

  – **public.javax.xml.rpc.Service loadService (URL wsdlDocumentLocation, QName serviceName, Properties properties)**

    This method returns the generated service implementation for the specified service by using optional namespace-to-package mapping information.

    - wsdlDocumentLocation - ignored
    - serviceName - QName (namespace, localpart) of the service
    - properties - If this parameter is non-null, it contains namespace-to-package mapping entries. Each Property entry key is a String corresponding to the namespace. Each Property entry value is a String corresponding to the Java package name.

      If the properties argument contains an entry with a key (namespace) that matches the namespace portion of the QName serviceName argument, the entry value (`javaPackage`) is used as the package name when trying to locate the service implementation.

  For more information on these methods, see the JAX-RPC specification.

- Implement the `CustomBinder` interface to provide concrete custom data binders for a specific XML schema type **(JAX-RPC applications only)**.

  Custom data binders are used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification. WebSphere Application Server provides an extension to the Web Services for Java Platform, Enterprise Edition (Java EE) programming model called the CustomBinder interface that implements these custom bindings for a specific XML schema type. The CustomBinder interface has three properties, in addition to deserialize and serialize methods:

  – QName for the XML schema type

  – QName scope

  – Java type

  The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the runtime system and interacts with the

web services runtime using a SOAPElement. They are added to the runtime by using custom binding providers. Read about the custom data binders and the custom binding provider to learn more. See the CustomBinder interface documentation to learn more about how you can implement this interface to provide concrete custom data binders for a specific XML schema type.

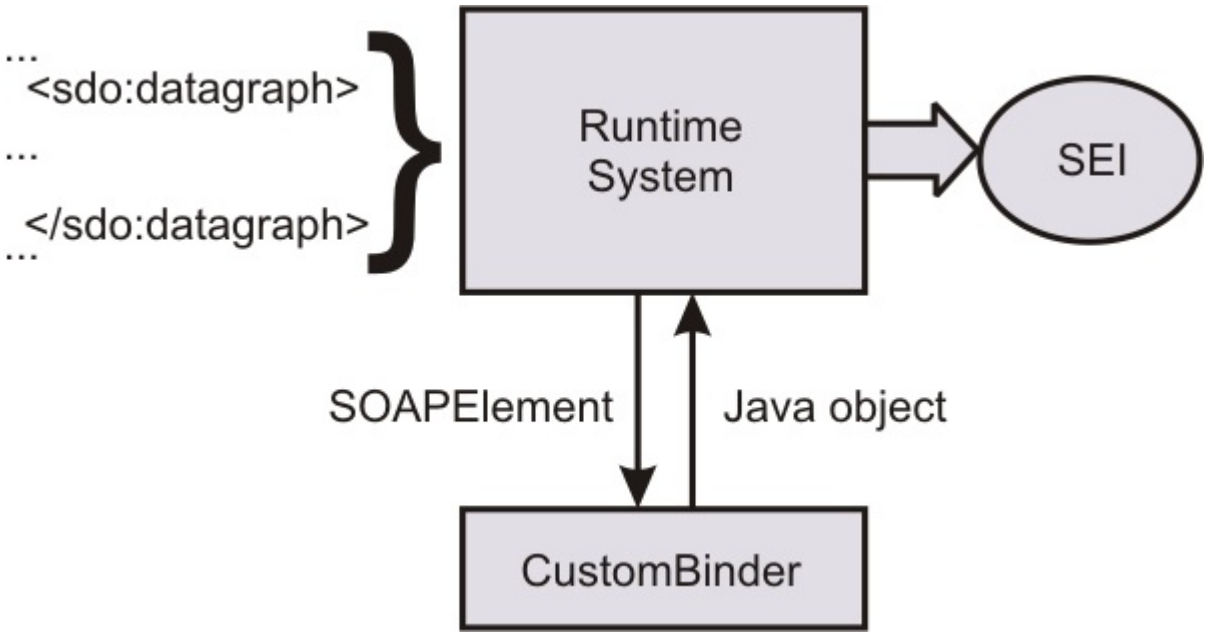
Custom data binders for JAX-RPC applications

A *custom data binder* is used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification.

The custom data binder defines serialize and deserialize methods to convert between a Java object and a SOAPElement interface. A custom data binder is added to the runtime system and interacts with the web services run time using a SOAPElement. Unlike conventional deserializers, custom data binders do not rely on the low-level parsing events from the run time to build the Java object, such as Simple API for XML (SAX). Instead, the run time builds the custom data binder by rendering the incoming SOAP message into a SOAPElement. The SOAPElement that contains the message is passed to the customer data binder. For example, if the incoming message contains a Service Data Object (SDO) datagraph, the runtime system processes as follows:

1. The runtime system recognizes the `<sdo:Datagraph>` code.
2. The run time queries the type mapping system to locate the custom data binder for the datagraph data, for example SDOCustomBinder.
3. A SOAPElement is created that represents the incoming SDO datagraph.
4. The run time passes the SOAPElement to the SDOCustomBinder.

Within the deserialized method, the SDOCustomBinder extracts the content from the SOAPElement and builds a concrete DataGraph object with a `commonj.sdo.DataGraph` type.



When a Java object is serialized, a similar process occurs. The run time locates a custom data binder and converts the Java object to a SOAPElement. The runtime serializes the SOAPElement to the raw message that is transported in the output stream.

The following is an example of an XML schema that is defined by the SDO specification:

```
<xsd:schema
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:sdo="commonj.sdo"
  targetNamespace="commonj.sdo">

  <xsd:element name="datagraph" type="sdo:DataGraphType"/>

  <xsd:complexType name="DataGraphType">
  <xsd:complexContent>
    <xsd:extension base="sdo:BaseDataGraphType">
      <xsd:sequence>
        <xsd:any minOccurs="0" maxOccurs="1"
                 namespace="##other" processContents="lax"/>
      </xsd:sequence>
    </xsd:extension>
  </xsd:complexContent>
  </xsd:complexType>

  <xsd:complexType name="BaseDataGraphType" abstract="true">
  <xsd:sequence>
    <xsd:element name="models" type="sdo:ModelsType" minOccurs="0"/>
    <xsd:element name="xsd" type="sdo:XSDType" minOccurs="0"/>
    <xsd:element name="changeSummary"
                 type="sdo:ChangeSummaryType" minOccurs="0"/>
   </xsd:sequence>
  <xsd:anyAttribute namespace="##other" processContents="lax"/>
  </xsd:complexType>

  <xsd:complexType name="ModelsType">
  <xsd:sequence>
    <xsd:any minOccurs="0" maxOccurs="unbounded"
             namespace="##other" processContents="lax"/>
  </xsd:sequence>
  </xsd:complexType>

  <xsd:complexType name="XSDType">
  <xsd:sequence>
    <xsd:any minOccurs="0" maxOccurs="unbounded"
        namespace="http://www.w3.org/2001/XMLSchema" processContents="lax"/>
  </xsd:sequence>
  </xsd:complexType>

  <xsd:complexType name="ChangeSummaryType">
  <xsd:sequence>
    <xsd:any minOccurs="0" maxOccurs="unbounded"
             namespace="##any" processContents="lax"/>
  </xsd:sequence>
  <xsd:attribute name="create" type="xsd:string"/>
  <xsd:attribute name="delete" type="xsd:string"/>
  </xsd:complexType>

</xsd:schema>
```

WebSphere Application Server defines the CustomBinder interface that implements concrete custom bindings for a specific XML schema type.

The custom binding provider is used to import the custom bindings into the run time. To learn how to plug your custom data binders into the **WSDL2Java** command-line tool for development, read about custom binding providers. You can also read about usage patterns for deploying custom data binders to learn more about how to deploy the provider package to your runtime, as well as the roles involved in the custom binding process.

Custom binding providers for JAX-RPC applications

A *custom binding provider* is the packaging of custom data binder classes with a declarative metadata file. The main purpose of a custom binding provider is to aggregate related custom data binders to support particular user scenarios. The custom binding provider is used to plug the custom data binders into the emitter tools and the run time system so that the emitter tools can generate the appropriate artifacts and the run time system can augment its existing type mapping system to reflect the applied custom data binders and invoke them.

A custom binding provider works with a specific XML schema type, while applications involve a few related XML schema types. You need a mechanism to aggregate and declare various custom data binders to provide a complete binding solution. The concept of the custom binding provider defines a declarative model that can be used to plug in a set of custom data binders to either emitter tools or the run time system.

See the custom data binders information and the information on the CustomBinder interface to learn more about custom data binders and the CustomBinder API included in WebSphere Application Server to define the custom data binders. After you have defined the custom data binders, you are ready to deploy the custom binder package. To learn how to deploy this package, see the information on usage patterns for deploying custom data binders for JAX-RPC applications.

The declarative metadata file, `CustomBindingProvider.xml`, is an XML file that is packaged with the custom provider classes in a single Java archive (JAR) file and located in the `/META-INF/services/directory`. Once a provider JAR file is packaged, the binary information and the metadata file located in the JAR file can be used by the **WSDL2Java** command-line tool and the run time system.

The following example is the XML schema for the `CustomBindingProvider.xml` file. The top-level type is the providerType that contains a list of mapping elements. Each mapping element defines the associated custom data binder and properties, including xmlQName, javaName and qnameScope. You can read more about these properties in the information for CustomBinder interface for JAX-RPC applications. The providerType also has an attribute called scope that has a value of *server*, *application* or *module*. The scope attribute is used by the server deployment to resolve the conflict and to realize a custom binding hierarchy.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema
    targetNamespace=
       "http://www.ibm.com/webservices/customdatabinding/2004/06"
    xmlns:customdatabinding=
        "http://www.ibm.com/webservices/customdatabinding/2004/06"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    elementFormDefault="qualified" attributeFormDefault="qualified">

   <xsd:element name="provider" type="customdatabinding:providerType"/>

   <xsd:complexType name="providerType">
   <xsd:sequence>
     <xsd:element name="description" type="xsd:string" minOccurs="0"/>
     <xsd:element name="mapping" minOccurs="0" maxOccurs="unbounded">
      <xsd:complexType>
        <xsd:sequence>
          <xsd:element name="description" type="xsd:string" minOccurs="0"/>
          <xsd:element name="xmlQName" type="xsd:QName"/>
          <xsd:element name="javaName" type="xsd:string"/>
          <xsd:element name="qnameScope"
                       type="customdatabinding:qnameScopeType"/>
          <xsd:element name="binder" type="xsd:string"/>
        </xsd:sequence>
       /xsd:complexType>
      </xsd:element>
       <xsd:attribute name="scope"
            type="customdatabinding:ProviderScopeType" default="module"/>
      </xsd:sequence>
   </xsd:complexType

  <xsd:simpleType name="qnameScopeType">
      <xsd:restriction base="xsd:string">
         <xsd:enumeration value="simpleType"/>
         <xsd:enumeration value="complexType"/>
         <xsd:enumeration value="element"/>
      </xsd:restriction>
  </xsd:simpleType>

  <xsd:simpleType name="ProviderScopeType">
     <xsd:restriction base="xsd:string">
         <xsd:enumeration value="server"/>
         <xsd:enumeration value="application"/>
```

```
        <xsd:enumeration value="module"/>
    </xsd:restriction>
  </xsd:simpleType>
</xsd:schema>
```

The following is an example of the `CustomBindingProvider.xml` file for the SDO DataGraph schema that was introduced in CustomBinder interface. The example displays the mapping between a schema type, DataGraphType, and a Java type, commonj.sdo.DataGraph. The binder that represents this mapping is called `test.sdo.SDODataGraphBinder`.

```
<cdb:provider
 xmlns:cdb="http://www.ibm.com/webservices/customdatabinding/2004/06"
   xmlns:sdo="commonj.sdo">
   <cdb:mapping>
     <cdb:xmlQName>sdo:DataGraphType</cdb:xmlQName>
     <cdb:javaName>commonj.sdo.DataGraph</cdb:javaName>
     <cdb:qnameScope>complexType</cdb:qnameScope>
     <cdb:binder>test.sdo.SDODataGraphBinder</cdb:binder>
   </cdb:mapping>
</cdb:provider>
```

You need to import your custom data binders into the **WSDL2Java** command-line tool for development purposes. The custom data binders affect how the development artifacts, including the Service Endpoint Interface and the JSR 109 mapping data, are generated from the Web Services Description Language (WSDL) file. The **WSDL2Java** command-line tool ships with WebSphere Application Server and uses the custom binder Java archive file, or custom binder package, to generate these the development artifacts.

The following example is a WSDL file that references the SDO DataGraph schema that is introduced in the CustomBinder interface topic.

```
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions targetNamespace="http://sdo.test"
   xmlns:impl="http://sdo.test"
   xmlns:intf="http://sdo.test"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
   xmlns:wsdlsoap="http://schemas.xmlsoap.org/wsdl/soap/"
   xmlns:xsd="http://www.w3.org/2001/XMLSchema"
   xmlns:sdo="commonj.sdo">

 <wsdl:types>
  <schema elementFormDefault="qualified" targetNamespace="http://sdo.test"
       xmlns="http://www.w3.org/2001/XMLSchema" xmlns:sdo="commonj.sdo">
   <import namespace="commonj.sdo" schemaLocation="sdo.xsd"/>
  </schema>
 </wsdl:types>

 <wsdl:message name="echoResponse">
  <wsdl:part element="sdo:datagraph" name="return"/>
 </wsdl:message>

 <wsdl:message name="echoRequest">
   <wsdl:part element="sdo:datagraph" name="parameter"/>
 </wsdl:message>

 <wsdl:portType name="EchoService">
   <wsdl:operation name="echo">
     <wsdl:input message="impl:echoRequest" name="echoRequest"/>
     <wsdl:output message="impl:echoResponse" name="echoResponse"/>
    </wsdl:operation>
 </wsdl:portType>

 <wsdl:binding name="EchoServiceSoapBinding" type="impl:EchoService">
   <wsdlsoap:binding style="document"
                    transport="http://schemas.xmlsoap.org/soap/http"/>
     <wsdl:operation name="echo">
        <wsdlsoap:operation soapAction=""/>
        <wsdl:input name="echoRequest">
         <wsdlsoap:body use="literal"/>
        </wsdl:input>

       <wsdl:output name="echoResponse">
          <wsdlsoap:body use="literal"/>
       </wsdl:output>
    </wsdl:operation>
```

```
  </wsdl:binding>

  <wsdl:service name="EchoServiceService">
     <wsdl:port binding="impl:EchoServiceSoapBinding" name="EchoService">
       <wsdlsoap:address location="http://<uri>"/>
    </wsdl:port>
  </wsdl:service>

</wsdl:definitions>
```

If you run the **WSDL2Java** command without the custom data binding package, the following Service Endpoint Interface is generated with a parameter type, as dictated by the JAX-RPC specification:

```
public interface EchoService extends java.rmi.Remote {
  public javax.xml.soap.SOAPElement
   echo(javax.xml.soap.SOAPElement parameter)
    throws java.rmi.RemoteException;
}
```

When you run the **WSDL2Java** command with the custom data binding package, the custom data binders are used to generate the parameter types. To apply the custom data binders, use the `-classpath` option on the WSDL2Java tool. The tool searches its classpath to locate all the files with the same file path of `/META-INF/services/CustomBindingProvider.xml`. The following is an example how you can use the command to generate a Service Endpoint Interface with the parameter type of `commonj.sdo.Datagraph`:

```
WSDL2Java -role develop-server -container web classpath sdobinder.jar echo.wsdl
```

The Service Endpoint Interface that is generated looks like the following:

```
public interface EchoService extends java.rmi.Remote {
  public commonj.sdo.DataGraph
   echo(commonj.sdo.DataGraph parameter)
    throws java.rmi.RemoteException;
}
```

The custom binder packaged JAR file has to be made available at runtime to make sure the web service client is invoked, regardless if it is a stub-based client or a Dynamic Invocation Interface (DII) client. The same applies to the service.

CustomBinder interface for JAX-RPC applications

WebSphere Application Server defines a CustomBinder interface that you can implement for Java API for XML-based Remote Call Procedure (JAX-RPC) applications to provide concrete custom data binders for a specific XML schema type.

The CustomBinder interface has three properties, in addition to deserialize and serialize methods. These properties are QName for the XML schema type, the QName scope, and the Java type that the schema type maps to. The properties are accessible through the corresponding getter methods.

getQName

The getQName method returns the QName of the target XML schema type. Custom data binders only work with the root level schema type.

For anonymous types, the getQName method returns the QName of the containing element.

For named types, the getQName method returns the QName of the complexType or the simpleType.

getQNameScope

The getQNameScope method returns the binder qnameScope property that indicates whether the schema type is a named type or an anonymous type. The qnameScope property value can be *complexType* for an <xsd:complexType>, *simpleType* for an <xsd:simpleType> or *element* for an <xsd:element> that is defined with an anonymous type.

In the following schema, data1 is an element that is defined with an anonymous type. The element, data2, is defined using the named type, data2Type.

```
<xsd:element name="data1">
 <xsd:complexType>
  ...
 </xsd:complexType>
</xsd:element>

<xsd:element name= "data2" type="data2Type"/>
<xsd:complexType name="data2Type">
 ...
</xsd:complexType>
```

The anonymous type, data1, has a qNameScope of element and a qName of data1. The type, data2Type, has a qNameScope of complexType and a qName of data2Type.

The element, data2, is not represented in the custom data binder. The custom data binder only processes types and not elements.

getJavaName

The getJavaName method returns the fully-qualified class name for the Java type that is mapped to the named or anonymous type. The class can be an interface or a concrete class. The object returned from the deserialize method has a type that is compatible with the Java type that is returned by the getJavaName method.

serialize

The serialize method returns the SOAPElement that the custom data binder builds from the Java object. The Java object is passed from the run time system and is expected to match what is returned from the getJavaName method. The SOAPElement parameter does not have child elements, but it does have a valid QName. This parameter is a reference for the binder to create the final SOAPElement.

In most cases, the binder implementation appends the child elements to the root SOAPElement. The run time system guarantees that the SOAPElement QName is correct. Therefore, the custom data binder for named types keeps the QName of the root element because the binder does not know the enclosing element. The binder implementation for an anonymous type should always include the QName in the returned SOAPElement that matches the defined schema type. WebSphere Application Server does not have concrete methods in the CustomBindingContext parameter.

deserialize

The deserialize method returns a Java object that the custom data binder builds from the passed root SOAPElement. The object type of the returned Java object must match what is returned from the getJavaName method. Unlike the parameter serialize method, the passed SOAPElement contains the original XML data with the necessary namespace declarations.

The following is an example of an implementation of the SDO DataGraph binder, where the convertToSDO and convertToSAAJ utility methods convert between SOAPElement and an SDO object.

```
package test.sdo.binder;

import javax.xml.namespace.QName;
import javax.xml.soap.SOAPElement;

import com.ibm.wsspi.webservices.binding.CustomBinder;
import com.ibm.wsspi.webservices.binding.CustomBindingContext;

public class DataGraphBinder implements CustomBinder {
 public QName getQName() {
  return new QName("commonj.sdo", "DataGraphyType");
}
public String getJavaName() {
```

```
 return CustomBinder.QNAME_SCOPE_COMPLEXTYPE;
}
public String getJavaName() {
 return commonj.sdo.DataGraph.class.getName();
}
public javax.xml.soap.SOAPElement serialize(
  Object bean,
  SOAPElement rootNode,
  CustomBindingContext context)
  throws javax,xml.soap.SOAPException {
 // convertToSAAJ is a utility method to convert
 // the SDO DataGraph to the SOAPElement
 return convertToSAAJ(bean, rootNode);

public Object deserialize(
  SOAPElement source,
  CustomBindingContext context)
  throws javax.xml.soap.SOAPException {
  // convertToSDO is a utility method to convert
  // the SOAPElement to the SDO DataGraph
  return convertToSDO(source);
 }
}
```

To learn more about custom data binders, see the custom data binders for JAX-RPC applications information. To learn how to plug your custom data binders into the **WSDL2Java** command-line tool for development, see the custom binding providers for JAX-RPC applications information.

Usage patterns for deploying custom data binders for JAX-RPC applications

Custom data binders are used to map XML schema types with Java objects. Custom data binders provide bindings for XML schema types that are not supported by the current Java API for XML-based Remote Call Procedure (JAX-RPC) specification. WebSphere Application Server provides an extension to the Web Services for Java Platform, Enterprise Edition (Java EE) programming model called the CustomBinder interface that implements these custom bindings for a specific XML schema type. The custom binding provider is the package for the custom data binders that is imported into the runtime.

To learn more about the CustomBinder API, see the CustomBinder interface for JAX-RPC applications information. For general information about custom binders, see the custom data binders for JAX-RPC applications information. See the custom binding providers for JAX-RPC applications information to review how custom binding providers are packaged for development.

This usage pattern reviews how to deploy the provider package to your runtime, as well as the roles involved in the custom binding process.

Roles involved in custom data binding

Four roles are involved with custom data binding. These roles that are defined by the Web Services for Java Platform, Enterprise Edition (Java EE) specification are as follows:

- **Custom binding provider** is responsible for implementing the required custom data binders, declaring these binders in a `CustomBindingProvider.xml` file and packaging the binding classes into a Java archive (JAR) file.
- **Application developer** is responsible for applying the custom binding provider JAR file and generating the development artifacts.
- **Application assembler** needs to understand the application requirements in terms of the custom data binding and decides how to package the custom provider JAR file as a part of the application.
- **Application deployer** configures the shared libraries to make custom data binding support available to the applications. This needs to be done if the custom provider JAR file is not packaged with the application. If the application is not deployed, the deployer has to run the web services deployment tools after the application is installed.

Common usage patterns

The custom binder provider package can be deployed in various ways to provide flexibility beyond the standard JAX-RPC mapping standards. Three primary deployment usage patterns are as follows:

- **Deploy the custom data binders at the server level**

  This pattern ensures that all the applications that are running on the server are affected by the custom data binders and is useful if fundamental XML types are introduced but are not supported by the standard JAX-RPC mapping rules.

  This type of situation occurs frequently for new web services specifications that define new schema types. For example, the WS-Addressing specification defines an EndpointReferenceType schema type that is not supported by the JAX-RPC mapping rules. Because this pattern requires augmenting the server classpath, it has a significant impact on the server runtime and affects the installed applications. This pattern is most suitable for WebSphere Application Server internal components.
- **Deploy the custom binders for one or more application**

  Use this pattern if you only want specified applications to be affected by the custom data binders and if relevant XML schema types apply to a set of applications. You can share the custom data binders within a set of applications while achieving isolation between different sets of applications.
- **Deploy the custom binders for a specific web module within an application**

  Using this pattern ensures that a specific Web module is affected by the deployed custom data binders. This pattern is useful when fine granularity for custom binding is required. You cannot use this pattern with EJB modules because the module and its referenced library belong to the entire application.

Usage patterns

This section reviews deploying custom data binders using one of the three patterns:

- **Server level deployment**

  If you deploy the custom data binders at the server level, you need to set the scope attribute of the declared binding provider as *server*. Setting the value to *server* guarantees a higher priority for declared binders if there are conflicts between the server and applications. The custom binding provider JAR file needs to be in the appropriate place to be picked up by the server runtime. Configure the server path and make the custom binding provider JAR file a part of the server classpath. To learn about values used in configuring the server classpath, see the Java virtual machine settings information.
- **Deploying custom data binders for one or more applications**

  To deploy custom data binders for one or more applications, set the scope attribute of the declared custom binding provider as *application*. Setting the value to application guarantees higher priority binders in case of conflicts between the application and the module. If the custom data binders are used by more than one application, configure a shared library for the applications to reference. To learn about values used in configuring the shared libraries path, see the managing shared libraries information.
- **Deploy the custom data binders for a specific web module within an application**

  To deploy custom data binders for a specific web module within an application, set the scope attribute of the declared custom binding provider to the value *module*. The only way to apply the custom data binder for this pattern is to pre-package the custom binding provider JAR file with the web module, for example, place the JAR file in the `/WEB-INF/lib` directory.

Sending implicit SOAP headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to send values in implicit SOAP headers. By modifying your client code to send implicit SOAP headers, you can send specific information within an outgoing web service request.

Before you begin

To complete this task, you need a web services client that you can enable to send implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception occurs if you try to manipulate protected SOAP headers.

About this task

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers.

Procedure

1. Create a java.util.HashMap object.
2. Add an entry to the HashMap object for each implicit SOAP header that the client wants to send. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is either an SAAJ SOAPElement object or a String that contains the XML text of the entire SOAP header element.
3. Set the HashMap object as a property on the Stub or Call object. The property name is com.ibm.websphere.webservices.Constants.REQUEST_SOAP_HEADERS. The value of the property is the HashMap.
4. Issue the remote method calls using the Stub or Call object. The headers within the HashMap object are sent in the outgoing message.

   A `JAXRPCException` error can occur if any of the following are true:

   - The HashMap object contains a key that is not a QName object or if the HashMap object contains a value that is not a String or a SOAPElement object.
   - The HashMap object contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-RPC web services client that is configured to send implicit SOAP headers.

Example

The following programming example illustrates how to send two request SOAP headers and receive one response SOAP header within a web services request and response:

```
1 //Create the request and response hashmaps.
2 HashMap requestHeaders=new HashMap();
3 HashMap responseHeaders=new HashMap();
4
5 //Add "AtmUuid1" and "AtmUuid2" to the request hashmap.
6 requestHeaders.put(new QName("com.rotbank.security", "AtmUuid1"),
7   "<AtmUuid1 xmlns=\"><uuid>ROTB-0A01254385FCA09</uuid></AtmUuid1>");
8 requestHeaders.put(new QName("com.rotbank.security", "AtmUuid2"),
9  ((IBMSOAPFactory)SOAPFactory.newInstance()).createElementFromXMLString(
10   "x:AtmUuid2 xmlns:x=\"com.rotbank.security\"><x:uuid>ROTB-0A01254385FCA09
```

```
    </x:uuid><x:AtmUuid2>"));
11
12 //Add "ServerUuid" to the response hashmap.
13 //If "responseHeaders" is empty, all the SOAP headers are
14 //extracted from the response message.
15 responseHeaders.put(new QName("com.rotbank.security","ServerUuid"), null);
16
17 //Set the properties on the Stub object.
18 stub.setProperty(Constants.REQUEST_SOAP_HEADERS.requestHeaders);
19 stub.setProperty(Constants.RESPONSE_SOAP_HEADERS.responseHeaders);
20
21 //Call the operationon the Stub.
22 stub.foo(parm2, parm2);
23
24 //Retrieve "ServerUuid" from the response hashmap.
25 SOAPElement serverUuid =
26   (SOAPElement) responseHeaders.get(new QName("com.rotbank.security","ServerUuid"));
27
28 //Note: "serverUuid" now equals a SOAPElement object that represents the
29 //following code:
30//"<y:ServerUuid xmlns:y=\"com.rotbank.security\"><:uuid>ROTB-0A03519322FSA01
   </y:uuid></y:ServerUuid.");
```

On lines 2-3, new HashMaps are created that are used for the request and response SOAP headers.

On lines 6-10, the AtmUuid1 and AtmUuid2 headers elements are added to the request HashMap.

On line 15, the ServerUuid header element name, along with a null value, is added to the response HashMap.

On line 18, the request HashMap is set as a property on the Stub object. This causes the AtmUuid1 and AtmUuid2 headers to be added to each request message that is associated with an operation that is invoked on the Stub object.

On line 19, the response HashMap is set as a property on the Stub object. This causes the ServerUuid header to be extracted from each response message that is associated with an operation that is invoked on the Stub object.

On line 22, the web service operation is invoked on the Stub object.

On lines 25-26, the ServerUuid header is retrieved from the response HashMap. The header was extracted from the response message and inserted into the HashMap by the web services engine.

Receiving implicit SOAP headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to receive values from implicit SOAP headers. By modifying your client code to receive implicit SOAP headers, you can receive specific information within an incoming web service response.

Before you begin

To complete this task, you need a web services client that you can enable to receive implicit SOAP headers.

An *implicit SOAP header* is a SOAP header that fits one of the following descriptions:

- A message part that is declared as a SOAP header in the binding in the Web Services Description Language (WSDL) file, but the message definition is not referenced by a portType element within a WSDL file.
- An element that is not contained in the WSDL file.

Handlers and service endpoints can manipulate implicit or explicit SOAP headers using the SOAP with Attachments API for Java (SAAJ) data model.

You cannot manipulate protected SOAP headers. A SOAP header that is declared protected by its owning component, for example, Web Services Security, is not accessible to client applications. An exception occurs if you try to manipulate protected SOAP headers.

About this task

The client application sets properties on the Stub or Call object to send and receive implicit SOAP headers.

Procedure

1. Create a java.util.HashMap object
2. Add an entry to the HashMap object for each implicit SOAP header that the client wants to receive. The HashMap entry key is the QName of the SOAP header. The HashMap entry value is `null`.
3. Set the HashMap entry on the Stub or Call object. The property name is com.ibm.websphere.webservices.Constants.RESPONSE_SOAP_HEADERS. The value of the property is the HashMap.
4. Issue remote method calls against the Stub or Call object. The web services engine extracts the specified response headers from the web services response message and inserts them into the HashMap. After the remote method returns, the response headers are accessible from the HashMap object.

   A `JAXRPCException` error can occur if any of the following are true:
   - The HashMap contains a key that is not a QName.
   - The HashMap contains a key that represents a SOAP header that is declared protected by the owning component.

Results

You have a JAX-RPC web services client that can receive values from implicit SOAP headers.

Sending transport headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to send application-defined information along with your Web services requests by using transport headers.

Before you begin

You need a JAX-RPC web services client that you can enable to send transport headers.

Sending transport headers is supported only by web services clients, and only supported for the HTTP and JMS transports. The web services client must call the JAX-RPC APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the web services server is done through non-web services APIs.

About this task

When using the JAX-RPC programming model, the client must set a property on the Stub or Call object to send values in transport headers. After you set the property, the values are set in all the requests for subsequent remote method invocations against that Stub or Call object until the associated property is set to `null` or the Stub or Call object is discarded.

To send values in the transport headers on outbound requests, modify the client code as follows:

Procedure

1. Create a java.util.HashMap object that contains the transport header identifiers.
2. Add an entry to the HashMap object for each transport header that you want the client to send.

a. Set the HashMap entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made as to the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class.

b. Set the HashMap entry value to a string that contains the value of the transport header.

3. Set the HashMap entry on the Stub or Call object using the `com.ibm.websphere.webservices.Constants.REQUEST_TRANSPORT_PROPERTIES` property. When the REQUEST_TRANSPORT_PROPERTIES property value is set, that HashMap is used on subsequent invocations to set the header values in the outgoing requests. If the REQUEST_TRANSPORT_PROPERTIES property value is set to `null`, no HashMap is used on subsequent invocations to set header values in outgoing requests. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the Stub or Call object. The headers and the associated values from the HashMap are added to the outgoing request for each method invocation. If the invocation uses HTTP, then the transport headers are sent as HTTP headers within the HTTP request. If the invocation uses JMS, then the transport headers are sent as JMS message properties.

   If the property is not set correctly, you might experience API usage errors that result in a JAXRPCException error. The following requirements must be met, or the process fails:

   - The property value that is set on the Stub or Call object must be a HashMap object or `null`.
   - The HashMap must not be empty.
   - Each key in the HashMap must be a String object.
   - Each value in the HashMap must be a String object.

Results

You have a JAX-RPC web services client that is configured to send transport headers.

Retrieving transport headers with JAX-RPC

You can enable an existing Java API for XML-based RPC (JAX-RPC) Web services client to retrieve values from transport headers. For a request that uses HTTP, the transport headers are retrieved from HTTP headers found in the HTTP response message. For a request that uses Java Message Service (JMS), the transport headers are retrieved from the JMS message properties found on the JMS response message.

Before you begin

You need a web services client that you can enable to retrieve transport headers.

Retrieving transport headers is supported only by web services clients, and only supported for the HTTP and JMS transports. The web services client must call the JAX-RPC APIs directly and not through any intermediary layers, such as a gateway function. Sending and retrieving transport headers on the web services server is done through non-web services APIs.

About this task

When using the JAX-RPC programming model, the client must set a property on the Stub or Call object in order to retrieve values from the transport headers. After you set the property, values are read from responses for the subsequent method invocations against that Stub or Call instance until the associated property is set to `null` or the Stub or Call object is discarded.

To retrieve values from the transport headers on inbound responses, modify the client code.

Procedure

1. Create a java.util.HashMap object that contains the names of the transport headers to be retrieved from incoming response messages.
2. Add an entry to the HashMap for each header that you want to retrieve a value from every incoming response message.
   a. Set the HashMap entry key to a string that exactly matches the transport header identifier. You can define the header identifier with a reserved header name, such as Cookie in the case of HTTP, or the header identifier can be user-defined, such as `MyTransportHeader`. Certain header identifiers are processed in a unique manner, but no other checks are made to confirm the header identifier value. To learn more about the HTTP header identifiers that have unique consideration, read about transport header properties best practices. You can find common header identifier string constants, such as HTTP_HEADER_SET_COOKIE in the com.ibm.websphere.webservices.Constants class. The HashMap entry value is ignored and does not need to be set. An empty HashMap, for example, one that is non-null, but does not contain any keys, causes all the transport headers in the response to be retrieved.
3. Set the HashMap entry on the Stub or Call object using the com.ibm.websphere.webservices.Constants.RESPONSE_TRANSPORT_PROPERTIES property. When the HashMap is set, the RESPONSE_TRANSPORT_PROPERTIES property is used in subsequent invocations to retrieve the headers from the responses. If you set the property to `null`, no headers are retrieved from the response. To learn more about these properties, see the transport header properties documentation.
4. Issue remote method calls against the Stub or Call object. The values from the specified transport headers are retrieved from the response message and placed in the HashMap.

   If the property is not set correctly, you might experience API usage errors that result in a JAXRPCException error. The following requirements must be met, or the process fails:
   - The property value that is set on the Stub or Call object must be either `null` or an instance of a HashMap.
   - All the HashMap keys must be a string data type, and the keys must not be null.

Results

You have a JAX-RPC web service that can receive transport headers from incoming response messages.

Assembling web services applications

Assembling web services applications

You can assemble Java-based web services applications using assembly tools.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with the application server.

About this task

After you develop your web service application, you are now ready to assemble the application. Assembling a web service application consists of creating the Java Platform, Enterprise Edition (Java EE) modules that you can deploy onto application servers. The modules are created from code artifacts such as web application archives (WAR) files for JavaBeans applications or enterprise beans Java archive (JAR) files for enterprise beans applications. This packaging and configuring of code artifacts into enterprise application modules (EAR files) or standalone web modules is necessary for deploying the modules onto an application server.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. Assemble your web services enabled bean into the appropriate module.
   - For JavaBeans enabled as web services:
     a. “Assembling a WAR file that is enabled for web services from Java code” on page 1294.
     b. “Assembling a web services-enabled WAR file from a WSDL file” on page 1295.
   - For enterprise beans enabled as web services:
     a. “Assembling a JAR file that is enabled for web services from an enterprise bean.”
     b. “Assembling a web services-enabled enterprise bean JAR file from a WSDL file” on page 1292.

   Note: This product supports packaging enterprise beans in WAR files. If you include a web services-enabled enterprise bean JAR file into a WAR file, you must merge any information in the webservices.xml deployment descriptor files that are in the JAR files into the webservices.xml deployment descriptor in the WEB-INF directory of the WAR file. To learn more, see the EJB content in WAR modules information.

   Note: When developing faults for a JAX-WS application, it is a best practice to always include the fault bean that is generated by the JAX-WS tooling in the packaging of your JAX-WS application. However if your application does not use the fault bean classes that are generated by the JAX-WS tooling (that is, you use a bottom-up development approach starting from Java and you choose not to package the fault bean classes), the application server runtime environment dynamically generates the fault beans. Even so, it is a best practice to always package the fault bean.
3. Assemble the web services enabled module into an enterprise archive (EAR) file.
   - “Assembling a web services-enabled WAR into an EAR file” on page 1297.
   - “Assembling an enterprise bean JAR file into an EAR file” on page 1296.
4. Enable the EAR file for EJB modules that contain web services. When the EAR file contains Enterprise JavaBeans (EJB) modules that contain web services, you must run the **endptEnabler** command-line tool or an assembly tool before deployment to produce a web services endpoint WAR file. This tool is also used to specify whether the web services are exposed using SOAP over Java Message Service (JMS) or SOAP over HTTP.
5. Assemble a web services-enabled WAR file into an EAR file.

Results

You have a web services-enabled EAR file that you can deploy onto the application server.

What to do next

Now you need to deploy the web services-enabled EAR file onto your application server. To learn more, read about deploying web services applications onto application servers

Assembling a JAR file that is enabled for web services from an enterprise bean

You can assemble a web service-enabled enterprise bean Java archive (JAR) file with an assembly tool using artifacts generated from tooling.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

You need the following artifacts that are generated from the **WSDL2Java** command-line tool to complete this task:
- An assembled enterprise bean JAR file that is not enabled for web services
- A compiled Java class for the service endpoint interface
- A Web Services Description Language (WSDL) file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptor, and Java API for XML-based remote procedure call (JAX-RPC) mapping file.

About this task

Assemble a web services-enabled enterprise bean JAR file from Java code by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.

Results

You have the artifacts required to web service-enable an Enterprise JavaBeans (EJB) module for web services. The artifacts are added to the JAR file. Now you need to configure the deployment descriptors so that you can deploy the web service into the application server run time environment.

Example

The `AddressBook.jar` JAR file contains the following files after assembly. The files added in this task are in bold. These files include the WSDL file, the deployment descriptors, and the JAX-RPC mapping file.

```
META-INF/MANIFEST.MF
META-INF/ejb-jar.xml
addr/Address.class
addr/AddressBook_RI.class
addr/AddressBookBean.class
addr/AddressBookHome.class
addr/Phone.class
addr/StateType.class
addr/AddressBook.class
META-INF/wsdl/AddressBook.wsdl
META-INF/ibm-webservices-bnd.xmi
META-INF/ibm-webservices-ext.xmi
META-INF/webservices.xml
META-INF/AddressBook_mapping.xml
```

What to do next

Assemble the EAR file so that you can deploy the EAR file into WebSphere Application Server.

Assembling a web services-enabled enterprise bean JAR file from a WSDL file

You can assemble a web services-enabled enterprise bean Java archive (JAR) file from a Web Services Description Language (WSDL) file with an assembly tool.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

You need the following artifacts to complete this task:
- An assembled enterprise bean JAR file that contains the Enterprise JavaBeans (EJB) implementation and all classes that generate from the **WSDL2Java** command-line tool when the role argument is `develop-server` and the container argument is `EJB`.
- A WSDL file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi` and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file.

About this task

Assemble a web services-enabled enterprise bean JAR file from a WSDL file by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.

Results

You have the artifacts required to web service-enable an EJB module for web services. The artifacts are added to the JAR file. Now you need to configure the deployment descriptors so that you can deploy the web service into the application server runtime environment.

Example

The `AddressBook.jar` JAR file contains the following files after assembly. The files added in this task are in bold. These files include the WSDL file, the deployment descriptors, and the JAX-RPC mapping file.

```
META-INF/MANIFEST.MF
META-INF/ejb-jar.xml
addr/Address.class
addr/AddressBook_RI.class
addr/AddressBookSoapBindingImpl.class
addr/AddressBookHome.class
addr/Phone.class
addr/StateType.class
addr/AddressBook.class
META-INF/wsdl/AddressBook.wsdl
META-INF/ibm-webservices-bnd.xmi
META-INF/ibm-webservices-ext.xmi
META-INF/webservices.xml
META-INF/AddressBook_mapping.xml
```

What to do next

For JAX-RPC web services, configure the `webservices.xml` deployment descriptor . You need to configure the deployment descriptors for the web service so that WebSphere Application Server can process the incoming web services requests.

Assembling a WAR file that is enabled for web services from Java code

You can assemble a web application archive (WAR) file that is enabled for web services from Java code with an assembly tool.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the **wsgen** command-line tool when starting from a service endpoint implementation to complete this task. The **wsgen** tool processes a compiled service endpoint implementation class as input and generates the following portable artifacts:

- any additional Java Architecture for XML Binding (JAXB) classes that are required to marshal and unmarshal the message contents. The additional classes include classes that are represented by the @RequestWrapper annotation and the @ResponseWrapper annotation for a wrapped method.
- a WSDL file if the optional *-wsdl* argument is specified. The **wsgen** command does not automatically generate the WSDL file. The WSDL file is automatically generated when you deploy the service endpoint.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated by the **WSDL2Java** command-line tool to complete this task:

- An assembled WAR file that contains the `web.xml` file, but is not enabled for web services.
- The Java class for the service endpoint interface
- A Web Services Description Language (WSDL) file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file classes that are generated by the **WSDL2Java** command.

About this task

Assemble a web services-enabled WAR file from Java code by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the JavaBeans implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

Results

The artifacts required to enable the web module for web services are added to the WAR file.

What to do next

Now you can assemble the WAR file that is enabled for Web services into an EAR file. To learn more, read about assembling a web services-enabled WAR into an EAR file.

Assembling a web services-enabled WAR file from a WSDL file

You can assemble a web application archive (WAR) file from a Web Services Description Language (WSDL) file that is enabled for web services.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the **wsimport** command-line tool when starting from a WSDL file to complete this task. The **wsimport** tool processes a WSDL file as input and generates the following portable artifacts:

- Service Endpoint Interface (SEI)
- Service class
- Exception classes that are mapped from the `wsdl:fault` class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

You can package the generated artifacts in a web application archive (WAR) file with the WSDL file and schema documents along with the endpoint implementation that you plan to deploy.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated by the **WSDL2Java** command-line tool to complete this task:

- An assembled WAR file that contains the Enterprise JavaBeans (EJB) implementation, all the classes that generate from the **WSDL2Java** command-line tool and the `web.xml` deployment descriptor file.
- A WSDL file
- The complete `webservices.xml`, `ibm-webservices-bnd.xmi`, and `ibm-webservices-ext.xmi` deployment descriptors, and the Java API for XML-based remote procedure call (JAX-RPC) mapping file.

About this task

Assemble a web services-enabled WAR file from a WSDL file by following the actions in the steps for this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the JavaBeans implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate JAR files created with the Assembly Toolkit, Application Assembly Tool or a different tool to the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer information.

Results

The artifacts required to enable the web module for web services is added to the WAR file.

What to do next

Now you can assemble the WAR file that is enabled for Web services into an EAR file. To learn more, read about assembling a web services-enabled WAR into an EAR file.

Assembling an enterprise bean JAR file into an EAR file

You can assemble an enterprise bean Java archive (JAR) file into an enterprise archive (EAR) file with an assembly tool. Assembling the JAR file, and now the EAR file, are required tasks to enable Java code for web services.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

Before assembling a web services-enabled EAR file you must assemble an enterprise bean JAR file that you want to enable for Web services. To learn more about the artifacts that are needed for the assembly of the enterprise bean JAR file, see the information on assembling an enterprise bean JAR file from Java code that is enabled for web services.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

To assemble a web services-enabled EAR file:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Assemble the web services-enabled JAR file into an EAR file. The EAR file can contain an enterprise bean or application client JAR files, WAR files, web applications, and metadata describing the applications or `application.xml` files.

Results

A web services-enabled EAR file.

Example

In the following example, there is an `application.xml` deployment descriptor packaged with a web services-enabled JAR file called `AddressBook.jar` that is packaged into an EAR file called `AddressBook.ear`. The EAR file contains:

```
META-INF/MANIFEST.MF
META-INF/application.xml
AddressBook.jar
```

An example of the `application.xml` deployment descriptor is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE application PUBLIC "-//Sun Microsystems, Inc.//DTD J2EE Application 1.3//EN"
"http://java.sun.com/dtd/application_1_3.dtd">
 <application id="Application_ID">
  <display-name>AddressBookJ2WEE</display-name>
  <description>AddressBook EJB Example from Java</description>
  <module id="EjbModule_1">
   <ejb>AddressBook.jar</ejb>
  </module>
 </application>
```

What to do next

You can enable an EAR file for EJB modules that contain web services. Then, deploy the EAR file into WebSphere Application Server.

Assembling a web services-enabled WAR into an EAR file

You can assemble a web services-enabled web application archive (WAR) file into an enterprise archive (EAR) file with an assembly tool.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

Assemble a web services-enabled WAR file into an EAR file using the steps provided in this task section.

Procedure

1. Start an assembly tool. Read about starting the assembly tool in theRational Application Developer documentation.
2. Assemble the web services-enabled WAR file into an EAR file. Assemble the EAR file that contains the JAR or WAR files. The EAR file can contain an enterprise bean or application client JAR files; web applications or WAR files; and metadata describing the applications or `application.xml` files. To learn more about how to assemble the WAR file, see the assembling applications documentation.

Results

A web services-enabled EAR file.

Example

In the following example, there is an `application.xml` deployment descriptor packaged with a web services-enabled JAR file called `AddressBook.jar` that is packaged into an EAR file called `AddressBook.ear`. The EAR file contains:

```
META-INF/MANIFEST.MF
META-INF/application.xml
AddressBook.war
```

An example of the `application.xml` deployment descriptor is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE application PUBLIC "-//Sun Microsystems, Inc.//DTD J2EE Application 1.3//EN"
"http://java.sun.com/dtd/application_1_3.dtd">
 <application id="Application_ID">
  <display-name>AddressBook</display-name>
  <description>AddressBook Example from Java bean</description>
  <module id="WebModule_1">
   <web>
    <web-uri>AddressBook.war</web-uri>
    <context-root>/AddressBook</context-root>
   </web>
  </module>
 </application>
```

What to do next

Deploy your web services.

Enabling an EAR file for EJB modules that contain web services

When your enterprise archive (EAR) file contains enterprise JavaBeans (EJB) modules that contain Web services, you must run the **endptEnabler** command-line tool or an assembly tool before deployment to produce a web services endpoint web application archive (WAR) fiile.

Before you begin

Assemble an enterprise Java archive (JAR) file that is enabled for web services from an enterprise bean. The enterprise JAR file is an artifact that is required to build the EAR file.

About this task

You can add router modules to your application that is enabled for web services with either the **endptEnabler** command-line tool or with assembly tools provided with WebSphere Application Server. The tool that you choose to use for this task depends on your preference to work with a command-line tool or a graphical user interface. See the assembly tools documentation to learn how to use assembly tool to accomplish this task.

These tools add one or more router modules to the EAR file for each web service-enabled enterprise JavaBeans (EJB) module contained in the EAR file. A router module provides an endpoint for the web service in a particular EJB module.

You should not modify the contents of the EJB module or the web module that was generated using the **endptEnabler**command-line tool. If you do, an error occurs during run time. The following is an example of the error that displays:

```
"Error]- WSWS3142E: Error: Could not find web services engine.]: javax.servlet.ServletException: WSWS3142E:
Error: Could not find web services engine."
```

Each router module supports a specific transport such as HTTP or Java Message Service (JMS). If no enterprise bean JAR modules are located in the EAR file, it is not necessary to use these tools.

Procedure

Enable an EAR file with the **endptEnabler** command-line tool. In its interactive mode, the **endptEnabler** command guides you through the required steps to enable one or more services within an application.

What to do next

Deploy the EAR file into WebSphere Application Server. An assembled EAR file that is enabled for web services is required for deployment.

Enabling an EAR file for web services with the endptEnabler command:

Use the **endptEnabler** command-line tool to enable an enterprise archive (EAR) file for Enterprise JavaBeans (EJB) modules that contain web services and to specify whether the web services are exposed using SOAP over Java Message Service (JMS) or SOAP over HTTP.

Before you begin

Before doing this task, you need to assemble a web services-enabled enterprise Java archive (JAR) into an EAR file.

About this task

The **endptEnabler** command-line tool adds one or more router modules to the EAR file for each Java API for XML Web Services (JAX-WS) or Java API for XML-based RPC (JAX-RPC) based Web service-enabled enterprise bean Java archive (JAR) module within the EAR file. A router module provides an endpoint for the web services in a particular enterprise bean JAR module.

Each router module supports a specific transport such as HTTP or JMS. An HTTP router module is a web application archive (WAR) module that provides an HTTP endpoint for each of the web services contained within a particular enterprise bean JAR module. Likewise, a JMS router module is an enterprise bean JAR module that contains a Message Driven Bean (MDB) that serves as the message listener for requests intended for the web service endpoints.

If no enterprise bean JAR modules exist in the EAR file, it is not necessary to use this tool.

Procedure

1. Invoke the **endptEnabler** command.

   Invoke the **endptEnabler** command from the *install_root*/bin directory.
2. Enter the name of the EAR file, when prompted.
3. Enter various input values as requested by the **endptEnabler** command. You are prompted for various input values for each enterprise bean JAR module that is enabled for web services in the EAR file. Typically, you accept the defaults for each prompt. To learn about the properties of this command, see the **endptEnabler** command documentation.
   a. Specify an HTTP router module to transport your EJB-based web service. Use the `-transport http` option to indicate the web service is available using HTTP. One router module is created for each enterprise bean JAR file that contains either JAX-WS or JAX-RPC web services.
   b. Specify an JMS router module to transport your EJB-based web service. Use the `-transport jms` option to indicate the web service is available using JMS. One router module is created for each enterprise bean JAR file that contains either JAX-WS or JAX-RPC web services.

Results

An HTTP or JMS router module is added to the EAR file for each enterprise bean JAR module within the EAR file that contains web services endpoints. For HTTP, a context-root is configured for the application so that the web service can be invoked through a Web address. The web address used to invoke the web service is:

`http://host[:port]/<context-root>/services/<port-component-name>`

Ensure that you install the HTTP or Java Message Service (JMS) router module that you generated with the **endptEnabler** command onto the same target as your web services enterprise bean JAR files. These HTTP or JMS router modules are included in your web services application and they need to use the runtime libraries of the application server.

What to do next

Deploy the EAR file onto your application server. An assembled EAR file that is enabled for web services is required for deployment.

If you are using JMS as a transport for your web service requests, define the various JMS objects such as queues, topics, or connection factories, that will be used by your application prior to installing the application.

endptEnabler command:

The **endptEnabler** command is used to enable a set of web services within an enterprise archive (EAR) file. The **endptEnabler** command must run on EAR files containing Enterprise JavaBeans (EJB) modules that are enabled for web services.

Each router module provides a web service endpoint for a particular transport. For example, you can add a HTTP router module so that the web service can receive requests over the HTTP transport. Or, you can add a Java Message Service (JMS) router module so that the web service can receive requests from a JMS queue or topic.

In its interactive mode, the **endptEnabler** command guides you through the required steps to enable one or more services within an application. The **endptEnabler** command makes a backup copy of your original EAR file in the event that you need to remove or add services at a later time. If your EAR file contains an enterprise bean Java archive (JAR) file that is enabled for web services, you must run the **endptEnabler** command before the EAR file is deployed. Otherwise, you do not need to run the command.

endptEnabler usage syntax

Invoke the **endptEnabler** command from the WebSphere Application Server `bin` directory. The command syntax is presented in the following example:

```
endptEnabler
    [-verbose|-v]
    [-quiet|-q]
    [-help|-h|-?]
    [-properties|-p properties-filename]
    [-transport|-t default-transports]
    [-enableHttpRouterSecurity]
    [-enableClientCertSecurity]
    [ear-filename]
    [-classpath|-cp]
```

All parameters are optional and described in the following list:

-verbose, -v
This parameter details and displays progress messages as the endptEnabler tool processes the EAR file. This command-line option is mapped to the verbose global property.

-quiet, -q
This parameter makes sure that there are no displays of per-module progress messages as the endptEnabler tool processes the EAR file. This command-line option is mapped to the quiet global property.

-help, -h, -?
This parameter displays a brief help message that explains the various options.

-properties, -p <properties-filename>
This parameter reads properties from the *properties-filename* properties and controls the behavior of the endptEnabler tool.

-transport, -t <default-transports>
This parameter specifies the default list of transports for which router modules are created for each enterprise bean JAR file contained in the EAR file. This command-line option is mapped to the *defaultTransports* global property. The following are examples of this parameter:

```
-transport http (the default)
-transport jms
-t http,jms
```

-enableHttpRouterSecurity
This parameter enables you to add a security policy for all authenticated users to protect the HTTP router module if all the EJB modules are secured in the enterprise bean JAR file. This command-line option is mapped to the `http.enableRouterSecurity` global property.

-enableClientCertSecurity
This parameter enables you to add the following login-config stanza to the `web.xml` file for certificate authentication, instead of basic-auth or form-login. This command-line option is mapped to the `http.enableClientCertSecurity` global property.

```
<login-config>
  <auth-method>CLIENT-CERT</auth-method>
</login-config>
```

Note: Use the -enableClientCertSecurity parameter with the -enableHttpRouterSecurity parameter.

<ear-filename>
This parameter specifies the name of the EAR file to be processed.

If the **ear-filename** parameter is not entered on the command line, the interactive mode is used. In the interactive mode, you are prompted for the EAR file name, the router module names and other important values as the processing occurs. The following dialog is an example of the endptEnabler interactive mode.

In this dialog, the user input is in fixed width font and the endptEnabler output is in bold.

```
endptEnabler<enter>
WSWS2004I: IBM WebSphere Application Server Release 5
WSWS2005I: Web Services Enterprise Archive Endpoint Enabler Tool.
WSWS2007I: (C) COPYRIGHT International Business Machines Corp. 1997, 2003
WSWS2006I: Please enter the name of your EAR file: AddressBook.ear<enter>

WSWS2003I: Backing up EAR file to: AddressBook.ear~

WSWS2016I: Loading EAR file: AddressBook.ear
WSWS2017I: Found EJB Module: AddressBookEJB.jar

WSWS2029I: Enter http router name for EJB Module AddressBookEJB
[AddressBookEJB_HTTPRouter.war]:<enter>
WSWS2030I: Enter http context root for EJB Module AddressBookEJB
[/AddressBookEJB]:<enter>
WSWS2024I: Adding http router for EJB Module AddressBookEJB.jar.
WSWS2036I: Saving EAR file AddressBook.ear...
WSWS2037I: Finished saving the EAR file.
WSWS2018I: Finished processing EAR file AddressBook.ear.
```

If the **ear-filename** parameter is entered on the command-line, the non-interactive mode is used. In the non-interactive mode, the router module names and other important values are determined from the user-specified properties or default values.

-classpath, -cp
This parameter enables you to specify separate JAR files in the class path for the **endptEnabler** command. Use this parameter if the EJB file references Java types in separate JAR files that do not exist within the EAR file. You can specify multiple values for this parameter. For example:

```
endptEnabler -classpath C:\MyWork\Utility.jar;D:\SharedFiles\Hello.zip;HelloWorld.jar
```

When you do not specify this parameter, you might encounter an error that is similar to the following message:

```
WSWS2021I: Skipping the enterprise bean module module_name
because it contains no web services.
```

endptEnabler properties

With the **endptEnabler** command you can control its runtime behavior by specifying a set of properties with the -properties command-line option. These properties are organized in one of two ways: global and per-module. Global properties affect the overall behavior of the tool as it processes multiple enterprise bean JAR modules within the EAR file. Per-module properties affect the processing of a particular enterprise bean JAR module.

Table 136. Global properties for the **endptEnabler** *command. Use these global properties of the endptEnabler command when enabling a set of web services within an enterprise archive (EAR) file.*

Property name	Description	Default value
verbose	Displays detailed progress messages.	False
quiet	Displays only brief progress messages.	False
http.enableRouterSecurity	Enables you to add a security policy for all authenticated users to protect the HTTP router module if all the EJB modules are secured in the enterprise bean JAR file.	False

http.enableClientCertSecurity	Enables you to add the following login-config stanza to the `web.xml` file for certificate authentication, instead of basic-auth or form-login:
	`<login-config>`
	`  <auth-method>CLIENT-CERT</auth-method>`
	`</login-config>`
		False

http.routerModuleNameSuffix	Specifies the suffix used to construct default HTTP router module names. The `.war` extension is added by the **endptEnabler** command.	_HTTPRouter
jms.routerModuleNameSuffix	Specifies the suffix used to construct default JMS router module names. The `.jar` extension is added by the **endptEnabler** command.	_JMSRouter
jms.defaultDestinationType	Specifies the default destination type to use for all JMS router modules that are added to the EAR file. This type is either queue or topic.	queue
defaultTransports	Specifies the default list of transports for which router modules are created. The list can contain the values `http` and `jms`. Multiple values are separated by a comma. Examples are: `http, jms` and `http,jms`.	http

The following table describes the per-module properties supported by the **endptEnabler** command. The *ejbJarName* variable refers to the name of an enterprise bean JAR module within the EAR file, without the `.jar` extension.

Table 137. Per-module properties for the **endptEnabler** *command. Use these properties of the* **endptEnabler** *command that affect the processing of a particular enterprise bean JAR module.*

Property name	Description	Default value
`<ejbJarName>.transports`	Lists the transports for which router modules are created for a particular enterprise bean JAR file. The list can contain the values `http` and `jms`. Multiple values are separated by a comma. Examples are: `http, jms` and `http,jms`.	http
`<ejbJarName>.http.skip`	Specifies the flag which bypasses the addition of an HTTP router module, even if it otherwise is added based on other properties. Valid values are `true` and `false`.	false
`<ejbJarName>` `.http.routerModuleName`	Specifies the name of the HTTP router module for a particular enterprise bean JAR file.	*ejbJarName*_HTTPRouter
`<ejbJarName>.http.contextRoot`	Specifies the context root associated with the HTTP router module for a particular enterprise bean JAR file.	/*ejbJarName*
`<ejbJarName>.jms.skip`	Specifies the flag that bypasses the addition of an JMS router module even if it otherwise is added based on other properties. Valid values are `true` and `false`.	false
`<ejbJarName>.jms.` `routerModuleName`	Specifies the name of the JMS router module for a particular enterprise bean JAR file.	*ejbJarName*_JMSRouter
`<ejbJarName>.jms.` `activationSpecJndiName`	Specifies the Java Naming and Directory Interface (JNDI) name of the activation specification that is configured for the Message Driven Bean (MDB) within the JMS router module.	null

Table 137. Per-module properties for the **endptEnabler** *command (continued). Use these properties of the* **endptEnabler** *command that affect the processing of a particular enterprise bean JAR module.*

Property name	Description	Default value
<ejbJarName>.jms. listenerInputPortName	Specifies the name of the listener port to configure for the MDB within the JMS router module. The listener port is configured only if an activationSpecJndiName property is not specified.	null
<ejbJarName>.jms.destinationType	Specifies the JMS destination type associated with the MDB within the JMS router. Valid values are queue and topic.	queue
<ejbJarName>.<port_local_name> .http.urlPattern= <url_pattern_name>	Specifies the URL pattern for ports. If you have EJB module with the indicated name that has a port with the indicated local name, you can specify the HTTP URL pattern with this property. This property only applies to HTTP router modules. It has no affect on JMS router modules.	null

Properties example

Suppose an EAR file contains an enterprise bean JAR file named, StockQuoteEJB.jar that contains web services. The following set of properties can be used to control the **endptEnabler** command runtime behavior as it processes the EAR file:

```
StockQuoteEJB.transports=http,jms

StockQuoteEJB.http.routerModuleName=StockQuoteEJB_HTTP

StockQuoteEJB.http.contextRoot=/StockQuote

StockQuoteEJB.jms.routerModuleName=StockQuoteEJB_JMS

StockQuoteEJB.jms.destinationType=queue
```

endptEnabler examples

The following commands are examples of how the **endptEnabler** command can be used:

```
endptEnabler MyApp.ear

endptEnabler -t jms,http MyApp.ear

endptEnabler -v -properties MyApp.props MyApp.ear

endptEnabler -q -t jms MyApp.ear

endptEnabler -v -t http,jms
```

Assembling web services-enabled clients

Assembling a web services-enabled client JAR file into an EAR file

Now that you have generated your application artifacts, you need to assemble these artifacts to create an enterprise archive (EAR) file that is used in the web services application.

Before you begin

For Java API for XML-Based Web Services (JAX-WS) web service applications, you need the portable artifacts that are generated by the **wsimport** command-line tool when starting from a WSDL file to complete this task. The **wsimport** tool processes a WSDL file as input and generates the following portable artifacts:

- Service Endpoint Interface (SEI)
- Service class
- Exception classes that are mapped from the wsdl:fault class (if any)
- Java Architecture for XML Binding (JAXB) generated type values which are Java classes mapped from XML schema types

- An assembled client module that contains the implementation, all of the classes generated by the **wsimport** command-line tool and the `ejb-jar.xml` deployment descriptor or the `application-client.xml` deployment descriptor. This module can be:
  - An application client module that contains the `META-INF/application-client.xml` file.
  - An Enterprise JavaBeans (EJB) module that contains the `META-INF/ejb-jar.xml` file.

For Java API for XML-based RPC (JAX-RPC) web service applications, you need the following artifacts that are generated from the **WSDL2Java** command-line tool to complete this task:
- An assembled client module that contains the implementation, all of the classes generated by the **WSDL2Java** command-line tool and the `ejb-jar.xml` deployment descriptor or the `application-client.xml` deployment descriptor. This module can be:
  - An application client module that contains the `META-INF/application-client.xml` file.
  - An Enterprise JavaBeans (EJB) module that contains the `META-INF/ejb-jar.xml` file.
- The WSDL file that you used to develop the client.
- The templates for the `ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` deployment descriptor, if used.
- A generated Java API for XML-based remote procedure call (JAX-RPC) mapping deployment descriptor.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

You can use assembly tools included with WebSphere Application Server to assemble web services-enabled client applications.

Assemble the client code and artifacts that enable the application client to access a web service with steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.
3. Import the client implementation and the artifacts generated by the command-line tooling into the assembly tool.
4. Migrate JAR files created with the Rational Application Developer assembly tool. To migrate files, import your JAR files to the assembly tool. Read about migrating code artifacts to an assembly tool in the Rational Application Developer documentation.
5. Assemble the JAR file into an enterprise archive (EAR) file using typical assembly techniques if the client runs in a container.

Results

You have assembled the artifacts required to enable the client application for web services into an EAR file.

Example

This example of the assembly process uses the `AddressBookClient.jar` JAR file the `AddressBookClient.ear` EAR file:

```
META-INF/MANIFEST.MF
META-INF/application-client.xml
META-INF/wsdl/AddressBook.wsdl
META-INF/AddressBook_mapping.xml

com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...
```

After assembling the `AddressBookClient.jar` file into the `AddressBookClient.ear` file, the `AddressBookClient.ear` file contains the following files:

```
META-INF/MANIFEST.MF
AddressBookClient.jar
META-INF/application.xml
```

What to do next

For Java API for XML-Based Web Services (JAX-WS) applications, you are ready to deploy the web services client application.

For Java API for XML-based RPC (JAX-RPC) applications, you need to configure the client deployment descriptor bindings with an assembly tool so that the client can communicate with a web service that is deployed on a server.

Assembling a web services-enabled client WAR file into an EAR file

Now that you have generated your application artifacts, you need to assemble these artifacts to create an enterprise archive (EAR) file that is used in the web services application.

Before you begin

You can assemble Java-based web services modules with assembly tools provided with WebSphere Application Server.

Restriction: Do not include a pound sign (#) in the name of files that are packaged within an application archive. Due to internal processing, the application server fails to correctly deploy the application when a pound sign is included in a file name within the application archive. When this failure occurs, an exception might occur when the application is being processed. Also, parts of the application might be missing after the application is deployed. To address this issue, rename any file names within the application archive so that they do not contain a pound sign.

About this task

Assemble the client code and artifacts that enable the application client to access a web service with steps provided:

Procedure

1. Start an assembly tool. Read about starting the assembly tool in the Rational Application Developer documentation.
2. If you have not done so already, configure the assembly tool so that it works on Java EE modules. You need to make sure that the **Java EE** and **Web** categories are enabled. Read about configuring the assembly tool in the Rational Application Developer documentation.

3. Migrate WAR files created with the Assembly Toolkit, Application Assembly Tool (AAT) or a different tool to the Rational Application Developer assembly tool. To migrate files, import your WAR files to an assembly tool. Read about importing web application archive (WAR) files using an assembly tool in the Rational Application Developer documentation.

Results

You have assembled the artifacts required to enable the client application for web services into an EAR file.

Example

This example of the assembly process uses the `AddressBookWeb.war` WAR file and the `AddressBook.ear` EAR file:

```
WEB-INF/MANIFEST.MF
WEB-INF/web.xml
WEB-INF/wsdl/AddressBook.wsdl
WEB-INF/AddressBook_mapping.xml
WEB-INF/ibm-webservicesclient-ext.xmi (optional)
WEB-INF/ibm-webservicesclient-bnd.xmi
com/ibm/websphere/samples/webservices/addr/Address.class
com/ibm/websphere/samples/webservices/addr/AddressBook.class
com/ibm/websphere/samples/webservices/addr/AddressBookClient.class
com/ibm/websphere/samples/webservices/addr/AddressBookService.class
...other generated classes...
```

After assembling the `AddressBookWeb.war` file into the `AddressBook.ear` file, the `AddressBook.ear` file contains the following files:

```
META-INF/MANIFEST.MF
AddressBookWeb.war
META-INF/application.xml
```

What to do next

For Java API for XML-Based Web Services (JAX-WS) applications, you are ready to deploy the web services client application.

For Java API for XML-based RPC (JAX-RPC) applications, you need to configure the client deployment descriptor bindings with an assembly tool so that the client can communicate with a web service that is deployed on a server.

Chapter 29. Developing web services - Addressing (WS-Addressing)

The Web Services Addressing (WS-Addressing) support in this product provides the environment for web services that use the World Wide Web Consortium (W3C) WS-Addressing specifications. This family of specifications provide transport-neutral mechanisms to address web services and to facilitate end-to-end addressing.

Using the Web Services Addressing APIs: Creating an application that uses endpoint references

This product provides application programming interfaces for applications that have to create endpoint references and use those endpoint references to target web service endpoints.

Before you begin

The steps described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Complete this task if you are a web service developer who needs to create endpoint references within an application, and then use these references to target web service resource instances. For example, a WSRF application developer.

Procedure

1. Create a web service that is referenced by an endpoint reference, and a client that accesses the web service. For JAX-WS applications, use the instructions in “Creating a JAX-WS web service application that uses Web Services Addressing.” For JAX-RPC applications, use the instructions in “Creating a JAX-RPC web service application that uses Web Services Addressing” on page 1312
2. Optional: You can extend the application that you created in the previous step so that it conforms to the Web Services Resource Framework (WSRF) specifications, by following the instructions in Creating stateful web services by using the Web Services Resource Framework.

Creating a JAX-WS web service application that uses Web Services Addressing

Web Services Addressing (WS-Addressing) aids interoperability between web services by defining a standard way to address web services and provide addressing information in messages. This task describes the steps that are required to create a JAX-WS web service that is accessed using a WS-Addressing endpoint reference. The task also describes the extra steps that are required to use stateful resources as part of the web service.

Before you begin

The steps that are described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Complete this task if you are creating a JAX-WS web service that uses the WS-Addressing specification. This task uses the JAX-WS WS-Addressing APIs to create the required endpoint reference. Alternatively, you can create endpoint references by using the IBM proprietary WS-Addressing API, and convert them into JAX-WS API objects for use with the rest of the application.

Procedure

1. Provide a web service interface that returns an endpoint reference to the target service.

   The interface must return an endpoint reference, which it can do by using a factory operation or a separate factory service. The target service can front a resource instance, for example a shopping cart.
2. Implement the web service created in the previous step. For the WS-Addressing portion of the implementation, complete the following steps:
   a. Optional: Include annotations to specify WS-Addressing behavior. See “Web Services Addressing annotations” on page 1359 for more details.
   b. Optional: If your interface involves a web service that fronts a resource instance, create or look up the resource instance.
   c. Optional: If you are using a resource instance, obtain the identifier of the resource. The resource identifier is application dependent and might be generated during the creation of the resource instance.

      Attention: Do not put sensitive information in the resource identifier, because the identifier is propagated in the SOAP message.
   d. Create an endpoint reference that references the web service by following the instructions in “Creating endpoint references by using the JAX-WS Web Services Addressing API” on page 1310. If you are using a resource instance, pass in the resource identifier as a parameter.
   e. Return the endpoint reference.
3. If your web service uses resource instances, extend the implementation to match incoming messages to the appropriate resource instances. Because you associated the resource identifier with the endpoint reference that you created earlier, any incoming messages targeted at that endpoint reference contain the resource identifier information as a reference parameter in the SOAP header of the message. Because the resource identifier is passed in the SOAP header, you do not have to expose it on the web service interface. When WebSphere Application Server receives the message, it puts this information into the message context on the thread. Extend the implementation to undertake the following actions:
   a. Obtain the resource instance identifier from the message context.
      - If you are using the 2005/08 WS-Addressing namespace, use the REFERENCE_PARAMETERS property of the MessageContext class.
      - If you are using the 2004/08 WS-Addressing namespace, you must use the IBM WS-Addressing API, specifically the EndpointReferenceManager.getReferenceParameterFrom MessageContext(QName resource_id) method.

      Use the following method for the 2005/08 namespace:

```
...
List resourceIDList = (List)getContext().getMessageContext().get(MessageContext.REFERENCE_PARAMETERS);
...
```

      Use the following method for the 2004/08 namespace:

```
...

String resource_identifier =
        EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);
...
```

   b. Forward the message to the appropriate resource instance.
4. Optional: Configure a proxy client to communicate with the service.
   a. Use the wsimport or xjc tool to generate the artifacts required by the client.

      Note: If you want to use the 2004/08 WS-Addressing specification, specify the provided binding file, *app_server_root*/util/SubmissionEndpointReference.xjb, as the -b parameter of the tool. This parameter tells the tool to generate endpoint reference objects by using the SubmissionEndpointReference class that is part of the IBM implementation of the standard JAX-WS API. If you do not specify this bindings file, the resulting endpoint reference objects will not work with the standard JAX-WS API.

b. In the client code, create an instance of the service class.

c. Obtain a proxy object from the service class. There are several ways to use the JAX-WS API to obtain proxy objects. For example, there are several getPort methods on the Service class and one on the EndpointReference class. For more information, refer to the API documentation.

d. Optional: Use the Addressing or SubmissionAddressing feature to enable WS-Addressing support. For example, create a proxy by using a getPort method that accepts web service features as a parameter. If you prefer, you can enable WS-Addressing support by using another method, such as policy sets. For more information see “Enabling Web Services Addressing support for JAX-WS applications” on page 1324.

e. Use the proxy object to invoke the service method that returns the endpoint reference.

The following sample code shows a client invoking a web service to add two numbers together. The web service issues a ticket (the resource identifier) to the client, and requires the client to use this ticket when invoking the web service.

The client creates two proxies. The first proxy obtains the ticket as an endpoint reference from the service. The second proxy uses the AddressingFeature class to enable WS-Addressing for the 2005/08 specification, and invokes the service to add the two numbers together.

```
...
CalculatorService service = new CalculatorService();
// Create the first proxy
Calculator port1 = service.getCalculatorServicePort();
// Obtain the ticket as an endpoint reference from the service
W3CEndpointReference epr = port1.getTicket();

// Create the second proxy, using an addressing feature to enable WS-Addressing
Calculator port2 = epr.getPort(Calculator.class, new AddressingFeature());
// Invoke the service to add the numbers
int answer = port2.add(value0, value1);
System.out.println("The answer is: " + answer);
...
```

Note: If the metadata of the endpoint reference conflicts with the information already associated with the outbound message, for example if the proxy object is configured to represent a different interface, a javax.xml.ws.WebServiceException exception is thrown on attempts to invoke the endpoint.

If you want to set message-addressing properties, such as a reply to endpoint, you must use the IBM proprietary WS-Addressing SPI and the BindingProvider class, as described in “Specifying and acquiring message-addressing properties by using the IBM proprietary Web Services Addressing SPIs” on page 1321.

5. Optional: Configure a Dispatch client to communicate with the service. You can configure a client in different ways; the following steps describe one example.

   a. Create an instance of the service.

   b. Add a port to the service object.

   c. Create an instance of the Dispatch class, passing in the endpoint reference.

   d. Create a Dispatch<T> object. Use the Service.createDispatch method with the following parameters:

      - The endpoint reference returned by the service, which represents the resource to forward messages to.
      - An array of web service features. Include one or more WS-Addressing features to enable WS-Addressing. See “Enabling Web Services Addressing support for JAX-WS applications” on page 1324 for more details.

      There are several variations of the Service.createDispatch method; see the API documentation for more details.

   e. Compose the client request message.

   f. Invoke the service endpoint with the Dispatch client.

   The following code shows an example fragment of a Dispatch client that enables 2004/08 WS-Addressing.

```
...
CalculatorService service = new CalculatorService();
Dispatch(<SOAPMessage> dispatch = service.createDispatch(
    endpointReference,
    SOAPMessage.class,
    Service.Mode.MESSAGE,
    new SubmissionAddressingFeature(true));
...
```

Results

The web service and client are configured to use endpoint references through the WS-Addressing support. For a detailed example that includes code, see “Example: Creating a web service that uses the JAX-WS Web Services Addressing API to access a generic web service resource instance” on page 1318.

What to do next

- Refer to “Web Services Addressing security” on page 1361 for information about security with WS-Addressing.
- Deploy the application. If you used WS-Addressing annotations or features in the code, you do not have to take any additional steps to enable WS-Addressing support. For more information and for other scenarios that might require additional steps, for example enabling WS-Addressing support by using policy sets, see “Enabling Web Services Addressing support for JAX-WS applications” on page 1324.

Creating endpoint references by using the JAX-WS Web Services Addressing API

Endpoint references are a primary concept of the Web Services Addressing (WS-Addressing) interoperability protocol, and provide a standard mechanism to encapsulate information about specific web service endpoints. This product provides interfaces for you to create endpoint references by using the standard JAX-WS API.

About this task

This task is a subtask of “Creating a JAX-WS web service application that uses Web Services Addressing” on page 1307.

Complete this task if you are writing an application that uses the standard JAX-WS WS-Addressing API. Such applications require endpoint references to target web service endpoints. The standard JAX-WS API is designed to create only simple endpoint references, and therefore has the following restrictions:

- You cannot create highly available or workload managed endpoint references.
- You cannot create endpoint references that represent stateful session beans.
- You cannot use classes that are created by using the JAX-WS API with the IBM proprietary WS-Addressing SPI.

You can overcome these restrictions by using the IBM proprietary WS-Addressing API to create the endpoint references and then converting them into standard JAX-WS endpoint references that can be used by the rest of the application.

Procedure

- If an endpoint needs to create an endpoint reference that represents itself, use the getEndpointReference method of the web service context object, passing in an Element object representing the reference parameters to be associated with the endpoint reference (or a null object if you do not want to specify any reference parameters).

  By default, this method creates a W3CEndpointReference object. If you want to create a SubmissionEndpointReference object, representing an endpoint that conforms to the 2004/08 WS-Addressing specification, pass the endpoint reference type as a parameter. For example, the following code fragment uses the getEndpointReference method to return a W3CEndpointRerence object that has a ticket ID associated with it:

```
...
@WebService(name="Calculator",
            targetNamespace="http://calculator.org")

public class Calculator {
    @Resource
    WebServiceContext wsc;

    ...
    // Create the ticket id
    element = document.createElementNS(
                      "http://calculator.jaxws.axis2.apache.org", "TicketId");
    element.appendChild( document.createTextNode("123456789") );
    ...

    public W3CEndpointReference getEPR() {
        // Get the endpoint reference and associate the ticket id
        // with it as a reference parameter
        W3CEndpointReference epr = (W3CEndpointReference)wsc.getEndpointReference(element);

        return epr;
    }
...
```

The following line of code shows how to create a 2004/08 endpoint reference for the preceding sample:

```
SubmissionEndpointReference epr = (SubmissionEndpointReference)
       wsc.getEndpointReference(SubmissionEndpointReference.class, element);
```

- If an endpoint needs to create an endpoint reference that represents a different endpoint, use either the W3CEndpointReferenceBuilder class or the SubmissionEndpointReferenceBuilder class, depending on the namespace that you want to use.
  1. Create an instance of the appropriate builder class. Use the W3CEndpointReferenceBuilder class if you want to create an endpoint reference that complies with the 2005/08 WS-Addressing specification. Use the SubmissionEndpointReferenceBuilder class if you want to create an endpoint reference that complies with the 2004/08 WS-Addressing specification.
  2. Set the following property or properties of the builder instance according to the location of the endpoint.
     - If the endpoint is in another module in this application, set the serviceName and endpointName properties to appropriate values. You must set the serviceName property before you set the endpointName property, otherwise the application throws an error. The endpoint reference that is returned contains a suitable address for the endpoint, as determined by the implementation.

       Note: This behavior differs from the IBM WS-Addressing API, in that creating an endpoint reference using the com.ibm.websphere.wsaddressing.EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName) method is not restricted to endpoints in the same application.
     - If the endpoint is in another Java EE application, set the address property to point to the endpoint.
  3. Optional: Set other properties of the builder instance as required. For example, if the web service is used to access a resource instance, use the referenceParameter property to associate the identifier of the resource with the endpoint reference. For more information on the properties that you can set, see the API documentation.
  4. Invoke the build method on the builder instance to obtain the endpoint reference.

  For example, the following code fragment uses the W3CEndpointReferenceBuilder class to obtain an endpoint reference that complies with the 2005/08 specification, and points to an endpoint that is in another application:

```
...
@WebService(name="Calculator", targetNamespace="http://calculator.org")
public class Calculator {

    public W3CEndpointReference getEPR() {
        ...
        // Create the builder object
        W3CEndpointReferenceBuilder builder = new
                           W3CEndpointReferenceBuilder();
```

```
        // Modify builder properties
        builder.address(otherServiceURI);

        // Create the endpoint reference from the builder object
        W3CEndpointReference epr = builder.build();
        return epr;
    }
...
```

The following code fragment uses the SubmissionEndpointReferenceBuilder class to obtain an endpoint reference that complies with the 2004/08 specification, and points to an endpoint that is in another module in this application:

```
...
@WebService(name="Calculator", targetNamespace="http://calculator.org")
public class Calculator {

    public W3CEndpointReference getEPR() {
        ...
        // Create the builder object
        SubmissionEndpointReferenceBuilder builder = new
                        SubmissionEndpointReferenceBuilder();

        // Modify builder properties
        builder.serviceName(calculatorService);
        builder.endpointName(calculatorPort);

        // Create the endpoint reference from the builder object
        SubmissionEndpointReference epr = builder.build();
        return epr;
    }
...
```

Results

You created an endpoint reference for use by your application.

What to do next

1. If required, convert the endpoint reference to an instance of the com.ibm.websphere.wsaddressing.EndpointReference class, by using the createIBMEndpointReference method. For example, on a client you might want to set the FaultTo message addressing property for outbound messages. You cannot set this property by using the JAX-WS API, so you must convert the endpoint reference representing the FaultTo endpoint to an instance of the com.ibm.websphere.wsaddressing.EndpointReference class, before setting it as a property on the BindingProvider object.
2. Continue with “Creating a JAX-WS web service application that uses Web Services Addressing” on page 1307.

Creating a JAX-RPC web service application that uses Web Services Addressing

Web Services Addressing (WS-Addressing) aids interoperability between web services by defining a standard way to address web services and provide addressing information in messages. This task describes the steps that are required to create a JAX-RPC web service that is accessed by using a WS-Addressing endpoint reference. The task also describes the extra steps that are required to use stateful resources as part of the web service.

Before you begin

The steps that are described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Complete this task if you are creating a web service that uses the WS-Addressing specification.

Procedure

1. Provide a web service interface, by creating or generating a Web Services Description Language (WSDL) document for the web service, that returns an endpoint reference to the target service. The interface must return an endpoint reference, which it can do by using a factory operation or a separate factory service. The target service can front a resource instance, for example a shopping cart.
2. Implement the web service created in the previous step. For the WS-Addressing portion of the implementation, complete the following steps:
   a. Create an endpoint reference that references the web service, by following the instructions in "Creating endpoint references by using the IBM proprietary Web Services Addressing API" on page 1316.
   b. Optional: If your interface involves a web service that fronts a resource instance, create or look up the resource instance.
   c. Optional: If you are using a resource instance, obtain the identifier of the resource and associate it with the endpoint reference as a reference parameter, by using the EndpointReference.setReferenceParameter(QName resource_id_name, String value) method. The resource identifier is application-dependent and might be generated during the creation of the resource instance.

      Attention: Do not put sensitive information in the resource identifier, because the identifier is propagated in the SOAP message.
      The endpoint reference now targets the resource.
   d. Return the endpoint reference.
3. If your web service uses resource instances, extend the implementation to match incoming messages to the appropriate resource instances. Because you associated the resource identifier with the endpoint reference that you created earlier, any incoming messages targeted at that endpoint reference contain the resource identifier information as a reference parameter in the SOAP header of the message. Because the resource identifier is passed in the SOAP header, you do not have to expose it on the web service interface. When WebSphere Application Server receives the message, it puts this information into the message context on the thread. Extend the implementation to undertake the following actions:
   a. Obtain the resource instance identifier from the message context, by using the EndpointReferenceManager.getReferenceParameterFromMessageContext(QName resource_id_name) method.
   b. Forward the message to the appropriate resource instance.
4. To configure a client to communicate with the service, use the endpoint reference that is produced by the service in the first step to send messages to the endpoint.
   a. Obtain a Stub object (by looking up the service in the Java Naming and Directory Interface (JNDI)), or create an empty Call object.
   b. Associate the endpoint reference with the proxy object. Use the setProperty(String property_name, Object value) method of the Stub or Call object. Use the WS-Addressing constant WSADDRESSING_DESTINATION_EPR as the property name, and the endpoint reference as the value.

      This procedure automatically configures the Stub or Call object, to represent the web service (or resource instance if your interface uses a web service that fronts a resource instance) of the endpoint reference. For Call objects, this process includes the configuration of the interface and endpoint metadata (portType and port elements) that are associated with the endpoint reference.

      Note: If the metadata of the endpoint reference conflicts with the information already associated with the outbound message, for example if the Stub object is configured to represent a different interface, a javax.xml.rpc.JAXRPCException exception is thrown on attempts to invoke the endpoint.

   Invocations on the Stub or Call object are now targeted at the web service or resource instance that is defined by the endpoint reference. When an invocation occurs, the product adds appropriate message

addressing properties, such as a reference parameter contained within the endpoint reference that identifies a target resource, to the message header.

Results

The web service and client are configured to use endpoint references through the WS-Addressing support.

Providing a web service interface that returns an endpoint reference to the target service

The following examples correspond to steps 1 to 4 in the procedure. The examples show how an IT organization might use web services to manage a network of printers. The organization might represent each printer as a resource that is addressed through an endpoint reference. The following examples show how to code such a service by using the IBM proprietary Web Services Addressing (WS-Addressing) application programming interfaces (APIs) that are provided by WebSphere Application Server, and JAX-WS.

The IT organization implements a PrinterFactory service that offers a CreatePrinter portType element. This portType element accepts a CreatePrinterRequest message to create a resource that represents a logical printer, and responds with an endpoint reference that is a reference to the resource.

The WSDL definition for such a PrinterFactory service might include the following code:

```
<wsdl:definitions targetNamespace="http://example.org/printer" ...
                  xmlns:pr=" http://example.org/printer">
  <wsdl:types>
    ...
    <xsd:schema...>
      <xsd:element name="CreatePrinterRequest"/>
      <xsd:element name="CreatePrinterResponse"
                   type="wsa:EndpointReferenceType"/>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="CreatePrinterRequest">
    <wsdl:part name="CreatePrinterRequest"
               element="pr:CreatePrinterRequest" />
  </wsdl:message>
  <wsdl:message name="CreatePrinterResponse">
    <wsdl:part name="CreatePrinterResponse"
               element="pr:CreatePrinterResponse" />
  </wsdl:message>
  <wsdl:portType name="CreatePrinter">
    <wsdl:operation name="createPrinter">
      <wsdl:input name="CreatePrinterRequest"
                  message="pr:CreatePrinterRequest" />
      <wsdl:output name="CreatePrinterResponse"
                   message="pr:CreatePrinterResponse" />
    </wsdl:operation>
  </wsdl:portType>
</wsdl:definitions>
```

The CreatePrinter operation in the previous example returns a wsa:EndpointReference object that represents the newly created Printer resource. The client can use this endpoint reference to send messages to the service instance that represents the printer.

The createPrinter method shown in the following example creates an endpoint reference to the Printer service. The operation then obtains the identifier for the individual printer resource instance, and associates it with the endpoint reference. Finally, the createPrinter method converts the EndpointReference object, which now represents the new printer, into a W3CEndpointReference object, and returns the converted endpoint reference.

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
import com.ibm.websphere.wsaddressing.EndpointReference;
import com.ibm.websphere.wsaddressing.jaxws.EndpointReferenceConverter;
import com.ibm.websphere.wsaddressing.jaxws.W3CEndpointReference;

import javax.xml.namespace.QName;

public class MyClass {

    // Create the printer
    ...
```

```
    // Define the printer resource ID as a static constant as it is required in later steps
    public static final QName PRINTER_ID_PARAM_QNAME = new QName("example.printersample",
                                                        "IBM_WSRF_PRINTERID", "ws-rf-pr" );
    public static final QName PRINTER_SERVICE_QNAME = new QName("example.printer.com", "printer", "...");
    public static final String PRINTER_ENDPOINT_NAME = new String("PrinterService");

    public W3CEndpointReference createPrinter(java.lang.Object createPrinterRequest)
    throws Exception {
     // Create an EndpointReference that targets the appropriate WebService URI and port name.
     EndpointReference epr =  EndpointReferenceManager.createEndpointReference(PRINTER_SERVICE_QNAME,
                                                                    PRINTER_ENDPOINT_NAME);

     // Create or lookup the stateful resource and derive a resource
     // identifier string.
     String resource_identifier = "...";

     // Associate this resource identifier with the EndpointReference as
     // a reference parameter.
     // The choice of name is arbitrary, but should be unique
     // to the service.
     epr.setReferenceParameter(PRINTER_ID_PARAM_QNAME,resource_identifier);
     // The endpoint reference now targets the resource rather than the service.
     ...

     return EndpointReferenceConverter.createW3CEndpointReference(epr);
    }
}
```

Because of the web service implementation described previously, the printer resource instance now has a unique identifier embedded in its endpoint reference. This identifier becomes a reference parameter in the SOAP header of subsequent messages that are targeted at the web service, and can be used by the web service to match incoming messages to the appropriate printer.

When a web service receives a message containing WS-Addressing message-addressing properties, the WebSphere Application Server processes these properties before the message is dispatched to the application endpoint, and sets them into the message context on the thread. The Printer web service application accesses the reference parameters that are associated with the target endpoint from the WebServiceContext object, as illustrated in the following example:

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
...
 // Initialize the reference parameter name
 QName name = new QName(..);
 // Extract the String value.
 String resource_identifier =
        EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);
```

The web service implementation can forward messages based on the printer identity acquired from the getReferenceParameterFromMessageContext method to the appropriate printer instances.

The client creates a JAX-WS proxy for the printer, and converts the proxy into a BindingProvider object. The client then associates the EndpointReference object obtained previously with the request context of the BindingProvider object, as illustrated in the following example.

```
import javax.xml.ws.BindingProvider;
...

 javax.xml.ws.Service service= ...;
 Printer myPrinterProxy = service.getPort(portName, Printer.class);

 javax.xml.ws.BindingProvider bp = (javax.xml.ws.BindingProvider)myPrinterProxy;

 // Retrieve the request context for the BindingProvider object
 Map myMap = myBindingProvider.getRequestContext();

 // Associate the endpoint reference that represents the new printer to the request context
 // so that the BindingProvider object now represents a specific printer instance.
 myMap.put(WSADDRESSING_DESTINATION_EPR, destinationEpr);

...
```

The BindingProvider object now represents the new printer resource instance, and can be used by the client to send messages to the printer through the Printer web service. When the client invokes the

BindingProvider object, WebSphere Application Server adds appropriate message-addressing properties to the message header, which in this case is a reference parameter contained within the endpoint reference that identifies the target printer resource.

Alternatively, the client can use a JAX-RPC Stub or Call object, which the client configures to represent the new printer. The use of the Call object is illustrated in the following example.

```
import javax.xml.rpc.Call;
...
 :
 // Associate the endpoint reference that represents the new printer with the call.
 call.setProperty(
        "com.ibm.websphere.wsaddressing.WSAConstants.
                              WSADDRESSING_DESTINATION_EPR ", epr);
```

From the perspective of the client, the endpoint reference is opaque. The client cannot interpret the contents of any endpoint reference parameters and should not try to use them in any way. Clients cannot directly create instances of endpoint references because the reference parameters are private to the service provider; clients must obtain endpoint references from the service provider, for example through a provider factory service, and then use them to direct web service operations to the endpoint that is represented by the endpoint reference, as shown.

What to do next

- Refer to “Web Services Addressing security” on page 1361 for information about security with WS-Addressing.
- Deploy the application. For this scenario, you do not have to take any additional steps to enable the WS-Addressing support in WebSphere Application Server because you specified a WS-Addressing property on the client. For more information, and for other scenarios that might require additional steps, see “Enabling Web Services Addressing support for JAX-RPC applications” on page 1365.

Creating endpoint references by using the IBM proprietary Web Services Addressing API

Endpoint references are a primary concept of the Web Services Addressing (WS-Addressing) interoperability protocol, and provide a standard mechanism to encapsulate information about specific Web service endpoints. This product provides interfaces for you to create endpoint references by using the IBM proprietary implementation of the WS-Addressing standard.

About this task

This task is a subtask of “Creating a JAX-RPC web service application that uses Web Services Addressing” on page 1312.

Complete this task if you are writing an application that uses the IBM proprietary WS-Addressing API. Such applications require endpoint references to target web service endpoints. When you are writing the application, you might not know the address of the endpoint, because the address can change when the application is deployed. By using the IBM proprietary API, you can either specify the endpoint address, or allow the product to generate it for you at run time.

You can also specify the behavior of endpoint references in a cluster environment.

If you want to use endpoint reference objects from the standard JAX-WS API instead of the IBM proprietary equivalents, but want the extra functions provided by the IBM proprietary API, create the endpoint references by using the methods described in this task and then convert them by using the supplied converter classes. For example, you might want to undertake such a conversion if you have a JAX-WS service application and you are creating endpoint references that represent stateful session beans, or that have an affinity to a particular server, or are workload managed. You cannot create such endpoint references by using the JAX-WS API.

Procedure

- To create an endpoint reference with an address that you specify directly, use the WS-Addressing EndpointReferenceManager.createEndpointReference(URI address) method of the system programming interface (SPI) provided. This method is useful in test scenarios, where the address of the service does not change.
- To create an endpoint reference with an address that is automatically generated by the product, complete the following steps:
  1. If you created the web service deployment descriptor file, webservices.xml, manually, ensure that the webservice-description-name in the file is the same as the local part of the Web Services Description Language (WSDL) service name. If you generated the webservices.xml file by using the tools provided, the names match by default. This match is required for the generation of the correct URI for the endpoint reference.
  2. Create the endpoint reference by using the method that is appropriate for the object that the reference will represent.
     - If you are creating an endpoint reference to represent a stateful session bean that maintains in-memory state, create the endpoint reference using the EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName, Remote statefulSessionBean) method of the application programming interface (API) provided. This method ensures that requests are targeted at the specific server that hosts the stateful session bean instance, and are not workload-managed.

       Also, if high availability for stateful session beans is specified, the endpoint reference remains valid even if the stateful session bean is failed over.

       Note: Affinity to stateful session beans that use this method is not supported on the z/OS operating system. If a highly available stateful session bean fails over to another control region, or is passivated from one servant region and reactivated on another servant region in the same control region, the endpoint reference is no longer valid. To achieve affinity with a stateful session bean, run the application in a transaction to use transactional context affinity, or use HTTP session affinity.
     - If you are creating an endpoint reference to represent any other object, create the endpoint reference by using the EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName) method of the API. The combination of service name and endpoint name must be unique in the server. If there is more than one web service application with the same service name and endpoint name, the application server cannot generate a unique URI object for the endpoint. If you cannot ensure that the combination of service name and endpoint name is unique, use an SPI method to create the endpoint reference.

       Because the endpoint reference might be workload-managed at a later date, ensure that the endpoint does not contain any in-memory state. For JAX-WS applications, you can prevent the endpoint reference from being workload-managed by attaching a WS-Addressing policy set to the application and configuring the policy set binding to prevent the workload management of referenced endpoints in clusters.

       Note: You can use the EndpointReferenceManager.createEndpointReference(QName serviceName, String endpointName) method to create an endpoint reference for any endpoint reference in the application server. This behavior differs from that of the JAX-WS API, where creating an endpoint reference by using the service name and endpoint name is restricted to endpoints within the same Java EE application.

     When the application invokes either of the previous two methods, the product generates the address URI for the endpoint reference, and puts the service name and endpoint name into the metadata of the newly created endpoint reference.

     Note: If you configured a virtual host for the server on which the endpoint is created, the URI of the endpoint reference refers to the virtual host of the HTTP server configuration. You can use

the administrative console to override this setting and provide your own HTTP endpoint URL information. The methods described previously will use the overridden value to generate the address URI for the endpoint reference.

Results

You created an endpoint reference for use by your application.

What to do next

1. If you want to convert the endpoint references from IBM proprietary WS-Addressing objects to standard JAX-WS WS-Addressing objects, use one of the following methods of the com.ibm.websphere.wsaddressing.jaxws21.EndpointReferenceConverter class, depending on the namespace of the endpoint reference:
   - createW3CEndpointReference(EndpointReference epr): use this method if the EndpointReference object uses the 2005/08 specification. This method creates a W3CEndpointReference object.
   - createSubmissionEndpointReference(EndpointReference epr): use this method if the EndpointReference object uses the 2004/08 specification. This method creates a SubmissionEndpointReference object.
2. Continue with “Creating a JAX-RPC web service application that uses Web Services Addressing” on page 1312, or if you converted the endpoint reference to the standard JAX-WS API, continue with “Creating a JAX-WS web service application that uses Web Services Addressing” on page 1307.

Example: Creating a web service that uses the JAX-WS Web Services Addressing API to access a generic web service resource instance

Consider an IT organization that has a network of printers that it wants to manage using web services. The organization might represent each printer as a resource that is addressed through an endpoint reference. This example shows how to code such a service by using the JAX-WS Web Services Addressing (WS-Addressing) application programming interfaces (APIs) that are provided by WebSphere Application Server.

Providing a web service interface that returns an endpoint reference to the target service

The IT organization implements a PrinterFactory service that offers a CreatePrinter portType element. This portType element accepts a CreatePrinterRequest message to create a resource that represents a logical printer, and responds with an endpoint reference that is a reference to the resource.

The WSDL definition for such a PrinterFactory service might include the following code:

```
<wsdl:definitions targetNamespace="http://example.org/printer" ...
                  xmlns:pr=" http://example.org/printer">
  <wsdl:types>
    ...
    <xsd:schema...>
      <xsd:element name="CreatePrinterRequest"/>
      <xsd:element name="CreatePrinterResponse"
                   type="wsa:EndpointReferenceType"/>
    </xsd:schema>
  </wsdl:types>
  <wsdl:message name="CreatePrinterRequest">
    <wsdl:part name="CreatePrinterRequest"
               element="pr:CreatePrinterRequest" />
  </wsdl:message>
  <wsdl:message name="CreatePrinterResponse">
    <wsdl:part name="CreatePrinterResponse"
               element="pr:CreatePrinterResponse" />
  </wsdl:message>
  <wsdl:portType name="CreatePrinter">
    <wsdl:operation name="createPrinter">
      <wsdl:input name="CreatePrinterRequest"
                  message="pr:CreatePrinterRequest" />
      <wsdl:output name="CreatePrinterResponse"
```

```
                message="pr:CreatePrinterResponse" />
    </wsdl:operation>
  </wsdl:portType>
</wsdl:definitions>
```

The CreatePrinter operation in the previous example returns a wsa:EndpointReference object that represents the newly created Printer resource. The client can use this endpoint reference to send messages to the service instance that represents the printer.

Implementing the web service interface

The createPrinter method shown in the following example obtains the identifier for the individual printer resource instance. The operation then creates an endpoint reference to the Printer service, and associates the printer ID with the endpoint reference. Finally, the createPrinter method returns the endpoint reference.

```
import javax.xml.ws.wsaddressing.W3CEndpointReference;
import javax.xml.ws.wsaddressing.W3CEndpointReferenceBuilder;

import javax.xml.namespace.QName;

import org.w3c.dom.Document;
import org.w3c.dom.Element;

public class MyClass {

  // Create the printer
  ...

  //Define the printer resource ID as a static constant as it is required in later steps
    public static final QName PRINTER_SERVICE_QNAME = new QName("example.printer.com", "printer", "...");
    public static final QName PRINTER_ENDPOINT_NAME = new QName("example.printer.com", "PrinterService", "...");

    public W3CEndpointReference createPrinter(java.lang.Object createPrinterRequest)
    {
     Document document = ...;

     // Create or lookup the stateful resource and derive a resource
     // identifier string.
     String resource_identifier = "...";

     // Associate this resource identifier with the EndpointReference as
     // a reference parameter.
     // The choice of name is arbitrary, but should be unique
     // to the service.
     Element element = document.createElementNS("example.printersample",
             "IBM_WSRF_PRINTERID");
     element.appendChild( document.createTextNode(resource_identifier) );
     ...

     // Create an EndpointReference that targets the appropriate WebService URI and port name.
     // Alternatively, the getEndpointReference() method of the MessageContext can be used.
     W3CEndpointReferenceBuilder builder = new W3CEndpointReferenceBuilder();
     builder.serviceName(PRINTER_SERVICE_QNAME);
     builder.endpointName(PRINTER_ENDPOINT_NAME);
     builder.referenceParameter(element);

     // The endpoint reference now targets the resource rather than the service.
     return builder.build();
    }
}
```

Extending the target service to match incoming messages to web service resource instances

Because of the web service implementation described previously, the printer resource instance now has a unique identifier embedded in its endpoint reference. This identifier becomes a reference parameter in the SOAP header of subsequent messages that are targeted at the web service, and can be used by the web service to match incoming messages to the appropriate printer.

When a web service receives a message containing WS-Addressing message addressing properties, the WebSphere Application Server processes these properties before the message is dispatched to the application endpoint, and sets them into the message context on the thread. The Printer web service application accesses the reference parameters that are associated with the target endpoint from the WebServiceContext object, as illustrated in the following example:

```
@Resource
private WebServiceContext context;
...
List list = (List) context.getMessageContext().get(MessageContext.REFERENCE_PARAMETERS);
```

If your application uses the 2004/08 version of the WS-Addressing specification, use the IBM proprietary API to retrieve the message parameters, as illustrated in the following example.

```
import com.ibm.websphere.wsaddressing.EndpointReferenceManager;
...
 // Initialize the reference parameter name
 QName name = new QName(..);
 // Extract the String value.
 String resource_identifier =
        EndpointReferenceManager.getReferenceParameterFromMessageContext(PRINTER_ID_PARAM_QNAME);
```

The web service implementation can forward messages based on the printer ID to the appropriate printer instances.

Using endpoint references to send messages to an endpoint

The client uses the endpoint reference returned from the service to create a JAX-WS proxy for the printer, as illustrated in the following example.

```
javax.xml.ws.Service jaxwsServiceObject= ...;
W3CEndpointReference epr = ...;
...
Printer myPrinterProxy = jaxwsServiceObject.getPort(epr, Printer.class, new AddressingFeature());
```

The proxy object now represents the new printer resource instance, and can be used by the client to send messages to the printer through the Printer Web service. When the client invokes the service, WebSphere Application Server adds appropriate message addressing properties to the message header, which in this case is a reference parameter contained within the endpoint reference that identifies the target printer resource.

From the perspective of the client, the endpoint reference is opaque. The client cannot interpret the contents of any endpoint reference parameters and should not try to use them in any way. Clients cannot directly create instances of endpoint references because the reference parameters are private to the service provider; clients must obtain endpoint references from the service provider, for example through a provider factory service, and then use them to direct web service operations to the endpoint that is represented by the endpoint reference, as shown.

Using the IBM proprietary Web Services Addressing SPIs: Performing more advanced Web Services Addressing tasks

This product provides proprietary system programming interfaces for more advanced Web Services Addressing (WS-Addressing) tasks, which involve the WS-Addressing message-addressing properties that are passed in the SOAP header of a web service message. You can also use the SPIs to choose a WS-Addressing specification level other than the default used by the product.

Before you begin

You cannot use the standard JAX-WS API classes with these proprietary SPIs. However, you can convert endpoint references created using the standard JAX-WS API classes to instances of the com.ibm.websphere.wsaddressing.EndpointReference class, by using the com.ibm.websphere.wsaddressing.jaxws21.EndpointReferenceConverter class. You can then use these converted endpoint references with the SPIs.

The steps described in this task apply to servers and clients that run on WebSphere Application Server.

About this task

Complete this task to specify or acquire WS-Addressing message-addressing properties, or if you have an application that needs to interoperate with a client or endpoint that is not using the default WS-Addressing specification supported by this product.

Procedure

- To manipulate message-addressing properties, follow the instructions in "Specifying and acquiring message-addressing properties by using the IBM proprietary Web Services Addressing SPIs"
- To interoperate with the pre-W3C specification of WS-Addressing, with the namespace http://schemas.xmlsoap.org/ws/2004/08/addressing, refer to "Interoperating with Web Services Addressing endpoints that do not support the default specification supported by WebSphere Application Server" on page 1322.

Specifying and acquiring message-addressing properties by using the IBM proprietary Web Services Addressing SPIs

Using the proprietary Web Services Addressing (WS-Addressing) system programming interfaces (SPIs), you can add WS-Addressing message addressing properties (MAPs) to the SOAP headers of an outbound client message, through properties on the JAX-WS BindingProvider request context, or the JAX-RPC Stub or Call object. When the target endpoint receives the message, the SPI enables the endpoint to acquire the MAPs through properties on the message context.

About this task

There are no equivalent SPIs in the JAX-WS standard. If you want to set message-addressing properties in a client that uses JAX-WS endpoint references, you must convert the endpoint references to the IBM proprietary classes, before using them with these SPIs.

Complete this task if you are a web service developer that uses the WS-Addressing support, or a system programmer that uses the IBM proprietary WS-Addressing SPIs to specify message addressing properties, such as fault or reply endpoint references, on web services messages.

The properties that you can set or retrieve are described, with the Java type of property instances, in IBM proprietary Web Services Addressing SPIs. Most properties are of type com.ibm.websphere.wsaddressing.EndpointReference, for example destination, reply, or fault endpoint references. The relationship property is a java.util.Set object that contains instances of the com.ibm.wsspi.wsaddressing.Relationship class. Use relationships when you want to specify an association between messages; for example, in a response message you might want to specify the ID of the message to which you are replying. The action property is an AttributedURI object that identifies a specific method or operation within the target endpoint.

Attention: The destination endpoint reference and action properties are required for the message to be WS-Addressing compliant.

Procedure

1. On the client, obtain the endpoint reference from the service and associate it with your BindingProvider object request context, or your Stub or Call object, as described in "Creating a JAX-RPC web service application that uses Web Services Addressing" on page 1312.
2. Create instances of the required properties. For example, if you want to specify an endpoint reference for the target service to send replies to, create an instance of the com.ibm.websphere.wsaddressing.EndpointReference class, to use as the WSADDRESSING_REPLYTO_EPR property.

3. Set the required properties by associating them with the BindingProvider object request context, or the Stub or Call object. If you are using a Stub or Call object, use the setProperty(String property_name, Object value) method. Note that unlike the endpoint reference required for the first step, these endpoint references do not have to be converted to another type, because they are passed in the header of the SOAP message rather than the body. The following example sets a destination endpoint reference and a reply endpoint reference on a BindingProvider object request context:

```
import javax.xml.ws.BindingProvider;
...
 javax.xml.ws.Service jaxwsServiceObject=...;
 Printer myPrinterProxy = jaxwsServiceObject.getPort(portName, Printer.class);

 javax.xml.ws.BindingProvider myBindingProvider = (javax.xml.ws.BindingProvider)myPrinterProxy;

 // Retrieve the request context for the BindingProvider object
 Map myMap = myBindingProvider.getRequestContext();

 // Associate the endpoint reference for the web service. This property is required for the message
 // to be WS-Addressing compliant.
  myMap.put(WSADDRESSING_DESTINATION_EPR, destinationEpr);

 // Associate the endpoint reference that represents the reply to the request context
 myMap.put(WSADDRESSING_REPLYTO_EPR, replyToEpr);
```

   When an invocation occurs on the BindingProvider, Stub, or Call object, the product adds the appropriate MAPs to the message header.

4. On the server, retrieve the MAPs from the inbound message through the javax.xml.ws.WebServiceContext or javax.xml.rpc.handler.MessageContext object that is currently on the thread. When WebSphere Application Server receives the message, it puts the MAP information into the message context on the thread, making it available to the service. You can retrieve the message context by, for example, using the session context of the endpoint enterprise bean. For more information about message contexts, refer to the JSR-109 standard. The following example retrieves the reply endpoint reference by using the web service context:

```
import javax.xml.ws.handler.MessageContext;
import javax.xml.ws.WebServiceContext;
...

  // Obtain the message context from the WebService context
  private WebServiceContext wsContext;
  MessageContext context = wsContext.getMessageContext();

  // Retrieve the reply endpoint reference
  replyToEpr = context.getProperty(WSADDRESSING_INBOUND_REPLYTO_EPR);
```

Interoperating with Web Services Addressing endpoints that do not support the default specification supported by WebSphere Application Server

A target web service endpoint might not support the same Web Services Addressing (WS-Addressing) namespace as this product. In most cases, you do not have to undertake any extra actions to interoperate with such endpoints, however some scenarios require additional steps in the implementation of your web service.

About this task

WebSphere Application Server supports the default WS-Addressing 2005/08 namespace http://www.w3.org/2005/08/addressing. Complete this task to interoperate with endpoints that support other namespaces. This task specifically describes interoperation with endpoints that are hosted on a node that supports only the 2004/08 namespace: http://schemas.xmlsoap.org/ws/2004/08/addressing.

If you are using the standard JAX-WS API, ensure that you use the appropriate feature, annotation or endpoint reference class for the 2004/08 namespace.

If you are sending to or receiving messages from an endpoint that supports only the 2004/08 namespace, you do not have to undertake any additional steps for interoperability. This product recognizes and understands incoming WS-Addressing messages that conform to the 2004/08 specification, and outbound

messages automatically adhere to the namespace of their destination endpoint reference. If you are sending a request, all WS-Addressing elements, such as reply endpoint or fault endpoint elements, must use the same namespace as the message. Any discrepancy results in a JAX-WS or JAX-RPC configuration error.

If you are interacting in a different way with an endpoint that supports only the 2004/08 namespace, such as exporting endpoint references in the message header or body, and you are not using the JAX-WS standard API, you must undertake additional steps as detailed below.

Procedure

- If you are generating a web service for use by a client that supports only the 2004/08 specification, update the WS-Addressing namespace in the Web Services Description Language (WSDL) document for your web service, by changing `http://www.w3.org/2006/05/addressing/wsdl` to `http://schemas.xmlsoap.org/ws/2004/08/addressing`.

  Note: Only the WS-Addressing WSDL Action extensibility element is recognized by pre-W3C WS-Addressing clients.

- If you are creating endpoint references at run time for export to an endpoint that supports the 2004/08 namespace only, perform the following steps:
  1. Create the endpoint reference to export.
  2. Associate the appropriate namespace with the endpoint reference, by using the setNamespace method. The following example illustrates the association of the 2004/08 namespace with an endpoint reference:

```
import com.ibm.wsspi.wsaddressing.EndpointReference;
import com.ibm.wsspi.wsaddressing.NamespaceNotSupportedException;
import com.ibm.wsspi.wsaddressing.WSAConstants;

:

EndpointReference epr = ...

try
{
    epr.setNamespace(WSAConstants.WSADDRESSING_NAMESPACE_2004_08);
} catch (NamespaceNotSupportedException e)
{
    // Error handling code here
}
```

  When you pass the endpoint reference to the target endpoint, in either the SOAP body or the SOAP header of a message, the endpoint reference is appropriately serialized into SOAP elements according to its namespace.

- To establish the namespace of an inbound request, use the IBM proprietary WS-Addressing system programming interface (SPI) to retrieve the WSADDRESSING_INBOUND_NAMESPACE property from the inbound message context. This property specifies the Core WS-Addressing specification namespace of the incoming message.

  Note: This procedure uses the IBM proprietary WS-Addressing API. There is no equivalent procedure in the JAX-WS API.

  You can retrieve the message context by, for example, using the session context of the endpoint enterprise bean. For more information about message contexts, refer to the JSR-109 specification. The following code example shows how you can establish the namespace of an incoming message on the receiving endpoint:

```
import com.ibm.wsspi.wsaddressing.WSAConstants;
import javax.xml.rpc.handler.MessageContext;

:
  // If the endpoint is implemented as an enterprise bean, you can use its session context
  // to obtain the message context
  private SessionContext sessionContext;
  MessageContext context = sessionContext.getMessageContext();

  try
  {
```

```
    String namespace = (String)msgContext.getProperty(WSAConstants.WSADDRESSING_INBOUND_NAMESPACE);
  } catch (IllegalArgumentException e)
  {
    // Error handling code here
  }
```

Enabling Web Services Addressing support for JAX-WS applications

The Web Services Addressing (WS-Addressing) support provides mechanisms to address web services and provide addressing information in messages. For JAX-WS applications, you can enable WS-Addressing support in several different ways, such as configuring policy sets or using annotations in code.

About this task

Perform this task to enable the WS-Addressing support, either as a service provider or as a client of a service provided by another party.

For service providers, WS-Addressing support is enabled by default, so you do not have to undertake any actions to enable support. However, you can use the enabling mechanisms to modify other WS-Addressing behavior for the service, such as whether WS-Addressing information is required, and what is included in the generated WSDL document.

- Modify the behavior of the WS-Addressing support after the application is deployed by attaching a policy set to the application. Within the policy set, you can configure the WS-Addressing policy type to specify whether WS-Addressing information is required in incoming messages, and whether to use synchronous or asynchronous messaging. You can communicate the WS-Addressing policy configuration to other servers and clients that support WS-Policy, by enabling policy sharing on the server, and by applying the provider policy on the client. This method overrides other methods.
- Use deployment descriptor elements within a `port-component` element.
- Modify the behavior of the WS-Addressing support during development of the service by using the Addressing or SubmissionAddressing annotations in the service code. Within each annotation you can specify whether WS-Addressing is enabled on the server, whether the server requires WS-Addressing information in incoming messages and the message exchange pattern the server will use. The presence of the Addressing annotation in the code adds a UsingAddressing element and a WS-Policy assertion to any WSDL document that is generated for the service.
- Modify the behavior of the WS-Addressing support during development of the service by either adding UsingAddressing elements or WS-Policy assertions into the WSDL document. If you do provide your own WSDL document, instead of relying on the JAX-WS runtime environment to generate one, and your WSDL document is being consumed by non JAX-WS 2.2 clients, you may wish to include the UsingAddressing element as such clients will not process WS-Policy assertions.

For service clients, WS-Addressing support is disabled by default. Use one of the following methods to enable WS-Addressing support. The following list is in descending order of precedence, because you can apply multiple methods. For example the deployment descriptor method overrides the use of annotations or features, but is itself overridden by the use of policy sets.

- Attach a policy set to the client artifact and perform one of the following actions:
  - Specify in the policy that WS-Addressing is mandatory.
  - Apply both client and provider policies. In this situation, WS-Addressing support is enabled on the client only if policy sharing is enabled on the service provider and the policy configuration for the provider specifies that WS-Addressing is mandatory.

  This method overrides other methods.
- Set the **`com.ibm.websphere.webservices.use.async.mep`** property on the client request context.
- Use the IBM proprietary WS-Addressing SPI to add message-addressing properties to the message request context.
- Use deployment descriptor elements within a `port-component-ref` element.

- Use the Addressing annotation in combination with the WebServiceRef annotation in the client code (when you are using an injected Web services proxy reference).
- Use addressing features in the client code. Properties set by using this method override those set in the WSDL document for the service.
- Use WS-Policy assertions in the WSDL document to specify WS-Addressing support. If you add Addressing annotations to your client application code, the generated WSDL document will contain WS-Policy assertions.
- Specify the UsingAddressing element in the WSDL document for the service. If the service uses the Addressing annotation and you generate the WSDL document from the code, the UsingAddressing element already exists.

The following tables summarize the behavior of the WS-Addressing support. Use this table to determine whether a request message is accepted for client settings that do not involve policy configuration.

This is a complex table containing spanned column headings. There is a header column on the left entitled "Client settings" which specifies whether WS-Addressing support is enabled on the client and also which messaging style is configured. The second main column shows the policy settings on the provider, with two sub-columns for whether WS-Addressing is optional or mandatory. Both of these sub-columns are further sub-divided into three sub-columns for messaging style (synchronous, asynchronous, or both). The third main column shows the WSDL settings on the provider, with two sub-columns for whether WS-Addressing is optional or mandatory.

Table 138. How client and provider settings interact to determine whether a request message is accepted. The preceding paragraph describes this table.

	Provider policy settings						**Provider WSDL settings (UsingAddressing `required` attribute)**	
	WS-Addressing is optional			**WS-Addressing is mandatory[1]**				
Client settings	**Synchronous and asynchronous**	**Synchronous only**	**Asynchronous only**	**Synchronous and asynchronous**	**Synchronous only**	**Asynchronous only**	**`false` (WS-Addressing is optional)**	**`true` (WS-Addressing is mandatory[1])**
WS-Addressing support enabled and messaging style synchronous	Message accepted	Message accepted	Fault	Message accepted	Message accepted	Fault	Message accepted	Message accepted
WS-Addressing support enabled and messaging style asynchronous	Message accepted	Fault	Message accepted	Message accepted	Fault	Message accepted	Message accepted	Message accepted
WS-Addressing support not enabled and messaging style synchronous	Message accepted	Message accepted	Message accepted[2]	Fault	Fault	Fault	Message accepted	Fault
WS-Addressing support not enabled and messaging style asynchronous[3]	Fault	Fault	Fault	Fault	Fault	Fault	Fault	Fault

Notes:

1. If WS-Addressing is mandatory, all requests without WS-Addressing headers are rejected.

2. The messaging style is only enforced if WS-Addressing headers are present in the request.
3. Asynchronous messaging is not possible without WS-Addressing headers.

Use the following table to determine whether a request message is accepted when the client and provider both have a WS-Addressing policy configuration; the client has provider and client policies applied; and policy sharing is enabled on the server.

This is a complex table containing spanned column headings. There is a header column on the left entitled "Client settings" which specifies whether WS-Addressing support is optional or mandatory on the client and also which messaging style is configured. The second main column shows the policy settings on the provider, with two sub-columns for whether WS-Addressing is optional or mandatory. Both of these sub-columns are further sub-divided into three sub-columns for messaging style (synchronous and asynchronous, synchronous only, or asynchronous only).

Table 139. How client and provider policy settings interact to determine whether a request message is accepted. The preceding paragraph describes this table.

	Provider policy settings					
	WS-Addressing is optional			**WS-Addressing is mandatory**		
Client policy settings	**Synchronous and asynchronous**	**Synchronous only**	**Asynchronous only**	**Synchronous and asynchronous**	**Synchronous only**	**Asynchronous only**
WS-Addressing optional and messaging style synchronous and asynchronous	Message accepted	Message accepted	Message accepted	Message accepted	Message accepted	Message accepted
WS-Addressing optional and messaging style synchronous only	Message accepted	Message accepted	Message accepted[1]	Message accepted	Message accepted	Fault
WS-Addressing optional and messaging style asynchronous only[2]	Fault	Fault	Fault	Message accepted	Fault	Message accepted
WS-Addressing mandatory and messaging style synchronous and asynchronous	Message accepted	Message accepted	Message accepted	Message accepted	Message accepted	Message accepted
WS-Addressing mandatory and messaging style synchronous only	Message accepted	Message accepted	Fault	Message accepted	Message accepted	Fault
WS-Addressing mandatory and messaging style asynchronous only	Message accepted	Fault	Message accepted	Message accepted	Fault	Message accepted

Notes:

1. The messaging style is only enforced if WS-Addressing headers are present in the request.
2. Asynchronous messaging is not possible without WS-Addressing headers.

If the provider and client policies are not shared, the client does not send WS-Addressing headers (unless you enable WS-Addressing on the client by another method). In this situation, if the provider policy specifies that WS-Addressing is mandatory, the server generates a fault regardless of the messaging style.

Procedure

- To modify the behavior of the WS-Addressing support by creating or modifying policy sets on either the service provider or client, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using policy sets” on page 1327.

- Set the **com.ibm.websphere.webservices.use.async.mep** property on the client request context when using WebSphere Application Server clients to enable WS-Addressing support. See the topic: “Invoking JAX-WS web services asynchronously” on page 1216 for more information.
- To modify the behavior of the WS-Addressing support by using the deployment descriptor of the service or client application, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using deployment descriptors” on page 1354.
- To modify the behavior of the WS-Addressing support programmatically by using addressing annotations in the service application, or on the client with an injected web service proxy reference, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using addressing annotations” on page 1355.
- To enable WS-Addressing support programmatically on the client by creating an instance of an addressing feature class, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using addressing features” on page 1357.
- To modify the behavior of the WS-Addressing support during the development of a client or service application by adding WS-Policy assertions into the WSDL file, see the topic: “Enabling Web Services Addressing support for JAX-WS applications using WS-Policy” on page 1358.

Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

Enabling Web Services Addressing support for JAX-WS applications using policy sets

For JAX-WS applications, you can enable WS-Addressing support after you deploy an application to the server, by creating or modifying policy sets, and attaching those policy sets to either a service or client application.

About this task

You can also configure the WS-Addressing support using other methods, for example in the code of the application, however this method overrides all other methods. Note that WS-Addressing support is enabled by default for service providers.

Procedure

1. Ensure that you have a policy set that contains the WS-Addressing policy type. If you have to create a new policy set, or add the WS-Addressing policy to an existing policy set, refer to Managing policy sets using the administrative console for instructions.
2. Configure the WS-Addressing policy type according to the instructions in “Configuring the WS-Addressing policy” on page 1335. Use the two settings to specify whether WS-Addressing is mandatory, and whether to use a synchronous or asynchronous message exchange pattern. The default settings are that WS-Addressing is not mandatory, and that both synchronous and asynchronous messaging patterns are used.
3. Attach the policy set to a web service provider or client artifact, according to the instructions in “Attaching a policy set to a service artifact” on page 1337.
4. Optional: If you want to communicate the WS-Addressing policy settings to other servers and clients, configure policy sharing as described in “Configuring a service provider to share its policy configuration” on page 1338 or “Configuring the client policy to use a service provider policy” on page 1346. If policy sharing is enabled and the server and client cannot agree a policy, normal WS-Policy behavior applies (a policy error is produced).

Results

WS-Addressing properties are now included in the SOAP message header, and are processed by the server on receipt of the message.

Creating policy sets using the administrative console

You can use the administrative console to either create a policy set by specifying all the necessary information or by copying an existing policy set that you rename. You can use policy sets, or assertions that define services, to simplify your web services configuration because policy sets group security and other web services settings into reusable units.

Before you begin

To create a new policy set, you can either specify the information to create a new policy set or you can copy and rename an existing policy set. Using either method, you need basic information about the policy set that you want to create, such as the name, description, policies to include, policy details, attachments, and binding configurations. If you are creating a policy set by copying an existing policy set, then you should also view the existing policy sets to choose one with properties that are most similar to the one you plan to create.

About this task

Whether you choose to create a new policy set or copy and rename an existing one, start from the Applications policy sets collection in the administrative console.

Procedure

1. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. If the policy set you are creating is:
   - a new policy set, then click **New**.
   - an existing policy set to be copied and renamed, click the **Select** box beside the name of the policy set to be copied in the **Name** column and click **Copy**.

   Using either method, this action opens the Policy set settings view to specify the required information about the policy set being created or copied.
3. Enter the name of the policy set that you want to create or copy in the **Name** field.
4. Enter a brief description of the policy set in the **Description** field. This is the description that displays in the Application policy sets or the System policy set collection, so it must be meaningful to you and other potential users of this policy set.

   Note: If you created a new policy set, it does not contain policies to edit until you add them to the policy set. The policy set is initially empty.

Results

You have provided the basic information to create a policy set.

Example

After you have looked at your web services, you might decide that the WS-I RSP default policy set most closely meets your needs. You would go to the administrative console and click **Services > Policy sets > Application policy sets** to access the Application policy sets collection. Locate the WS-I RSP default in the **Name** column of the table and click the box beside it (in the **Select** column). Click **Copy**. This opens the Policy set settings window. You might want to name your policy set by your company or division so you could provide a name like `ABC WS-I RSP` in the Name field. Because you know others in your

organization might access and use it, you've chosen a name that is meaningful to those people too. You want to be sure everyone knows exactly what this copy of the WS-I RSP policy is used for, so you add a description in the **Description** field describing it. Now you want to customize the policy set so you edit the policy information by clicking the name of a policy to edit it.

When you identify the requirements of your web service, you might decide that none of the default policy sets meet your needs closely enough to use them as a template so you might decide to create your own policy set. You would first create the policy set with the name you choose to give it. As if you were reusing an existing template, you would go to the administrative console and click **Services > Policy sets > Application policy sets** and click **New**. The Policy set settings window opens but note that the Policy set name field is blank and there are not yet any associated policies in the table. Enter the name and add any policies necessary.

When you add policies to a policy set, the policies are set to their default values. You can then edit the policies to modify any attribute values that need to be changed and save the settings.

What to do next

If you are creating a new policy set without copying an existing policy set, you need to specify the policy information. If you are copying an existing policy set, you can either accept the default policies associated with the policy set or you can change the policies.

WS-I RSP default policy sets:

The Reliable Asynchronous Message Profile (WS-I RSP) default policy sets are based on the Reliable Asynchronous Message Profile specification. The WS-I RSP default policy sets include the WS-I RSP default policy set, the Lightweight Third-Party Authentication (LTPA) WS-I RSP default policy set and the Username WS-I RSP default policy set. You can use these policy sets to simplify your web services configuration.

The WS-I RSP default policy sets are composed of a set of policies to provide reliable and secure web services. The WS-I RSP default policy sets use the WS-Addressing, WS-ReliableMessaging, and WS-Security specifications. Use the WS-I RSP default policy set, the LTPA WS-I RSP default policy set, or the Username WS-Security WS-I RSP default policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-I RSP default policy sets include the following policies:

WS-Addressing policy
: You can use the WS-Addressing policy to enable the addressing capability of the WS-Addressing specification.

WS-ReliableMessaging policy
: You can use the WS-ReliableMessaging policy to specify the quality of service for reliable delivery.

WS-Security policy
: The WS-Security policy in the WS-I RSP default policy set provides the following security:
  - Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
  - Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.
  - Traditional RSA cryptography is used to secure a request to a Trust Server to obtain a Secure Context Token (SCT). Thereafter, the conversation is secured using symmetric keys derived from the SCT.

The application server provides additional policy sets that you can use or customize. To use the following default policy sets, you must import the policy sets from the default repository. Read about importing policy sets using the administrative console for more information.

The following WS-I RSP default policy sets exist:

WS-I RSP default
This policy set provides:

- Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging.
- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.

LTPA WS-I RSP default
This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username WS-I RSP default
This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

SecureConversation default policy sets:

The SecureConversation default policy sets are based on the Web Services Secure Conversation Language (SecureConversation) standard that establishes a secure context, based on shared keys for the client and server to use for a series of messages. This standard provides a framework to define how to secure the message exchange across organizations. The SecureConversation default policy sets include the SecureConversation policy set, the Lightweight Third-Party Authentication (LTPA) SecureConversation policy set, and the Username SecureConversation policy set.

The SecureConversation default policy sets are based on the WS-SecureConversation, the WS-Security, and the WS-Addressing specifications. Use the SecureConversation policy set, the LTPA SecureConversation policy set, or the Username SecureConversation policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-SecureConversation specification alone does not provide a complete security solution. The WS-SecureConversation is built on the WS-Security and WS-Trust specifications to provide secure communication across one or more messages. Specifically, this specification defines mechanisms for establishing and sharing security contexts, and deriving keys from established security contexts or any shared secret.

WS-Security focuses on the message authentication model but not in a security context. The WS-SecureConversation specification defines mechanisms for establishing and sharing security contexts, and deriving keys from security contexts, to enable a secure conversation. By using the SOAP extensibility model, modular SOAP-based specifications are designed to be composed with each other to provide a rich messaging environment.

The following SecureConversation default policy sets exist:

SecureConversation
This policy set provides:

- Message integrity by digital signature that includes signing the body, timestamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications.
- Message confidentiality by encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications.

LTPA SecureConversation
This policy set provides the SecureConversation policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username SecureConversation
This policy set provides the SecureConversation policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

WS-ReliableMessaging default policy sets:

The WS-ReliableMessaging default policy sets are pre-configured to provide reliable message exchange between web services. Two of these policy sets (WS-I RSP and WS-I RSP ND) are immediately available, and the rest are readily available for import from a default repository.

With WS-ReliableMessaging, you can make your SOAP over HTTP-based web services reliable without writing custom code. You can use the provided non-editable default policy sets without change, or you can create customized copies of them.

All the default policy sets that include the WS-ReliableMessaging policy also include the WS-Addressing policy. The WS-ReliableMessaging policy provides the ability to deliver a message reliably to its intended receiver. The WS-Addressing policy provides a transport-neutral way to uniformly address web services and messages, and WS-ReliableMessaging uses WS-Addressing to provide asynchronous request and reply capabilities.

Note: WS-ReliableMessaging Version 1.1 messaging requires WS-Addressing to be mandatory. If you use a policy set that includes WS-ReliableMessaging and WS-Addressing policies, and the WS-Addressing policy is configured as optional, then WebSphere Application Server overrides the WS-Addressing setting and automatically enables WS-Addressing.

The following default policy sets that include the WS-ReliableMessaging policy are immediately available, as described in Viewing policy sets using the administrative console:

WS-I RSP
This policy set enables WS-ReliableMessaging Version 1.1 and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. This quality of service is for single server only and does not work in a cluster. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent. Message integrity is provided by digitally signing the body, the time stamp, and the WS-Addressing headers. Message confidentiality is provided by encrypting the body and the signature. This policy set follows the WS-SecureConversation and WS-Security specifications.

WS-I RSP ND
This is the network deployment version of the WS-I RSP policy set. This policy set provides the WS-I RSP default policy set and adds a *managed non-persistent* quality of service. This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages. This option supports clusters as well as single servers.

The following additional default policy sets that include the WS-ReliableMessaging policy are readily available for import, as described in Importing policy sets using the administrative console:

LTPA WS-I RSP
This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username WS-I RSP
This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

WSReliableMessaging 1_0
This policy set enables both WS-ReliableMessaging Version 1.0 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. This quality of service is for single server only and does not work in a cluster. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

You can use this policy set with .NET-based web services.

WSReliableMessaging default
This policy set enables both WS-ReliableMessaging Version 1.1 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. This quality of service is for single server only and does not work in a cluster. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

WSReliableMessaging persistent
This policy set enables both WS-ReliableMessaging and WS-Addressing and uses the maximum quality of service, *managed persistent*. This quality of service supports asynchronous web service invocations and uses a service integration messaging engine and message store to manage the sequence state. Messages are processed within transactions, are persisted at the web service requester server and at the web service provider server, and are recoverable in the event of server failure. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

Because this policy set specifies managed persistent quality of service, you have to define bindings to the service integration bus and messaging engine that you want to use to manage the WS-ReliableMessaging state. You can attach and bind a WS-ReliableMessaging policy set to a web service application by using the administrative console or the wsadmin tool.

WSAddressing default policy set:

The WSAddressing default policy set provides a transport-neutral way to uniformly address web services and messages.

The WSAddressing default policy set is based on the WS-Addressing specification. The WS-Addressing standard uses endpoint references and message addressing properties to facilitate the addressing of web services in a standard and interoperable way.

Use the WSAddressing default policy set as provided with the application server. To customize the policy set, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

To learn more about the WS-Addressing standard, read about Web Services Addressing support.

Web Services Security default policy sets:

The Web Services Security default policy sets are based on the WS-Security 1.0 and Web Services Addressing (WS-Addressing) specifications. The Web Services Security default policy sets include the WSSecurity default policy set, the Lightweight Third-Party Authentication (LTPA) WSSecurity policy set, the Username WSSecurity policy set, and the Kerberos V5 HTTPS default policy set. These default policy sets are used to build secure web services.

The Web Services Security default policy sets use the WS-Security 1.0 specification enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. Providing quality of protection means to prevent the following potential threats to SOAP messages:

- The message being modified or read by antagonists.
- An antagonist sending messages to a service that are formed correctly, but lack the appropriate security claims to be processed.

The WS-Addressing specification defines XML 1.0 and XML Namespaces elements to identify web services endpoints and to secure end-to-end endpoint identification in messages.

You can use the WSSecurity default policy set, the LTPA WSSecurity policy set, the Username WSSecurity policy set, or the Kerberos V5 HTTPS default policy set as provided with the application server. To customize the other Web Services Security policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

Features and details of the default Web Services Security policy sets are as follows:

Kerberos V5 HTTPS default

This policy set provides message authentication with a Kerberos Version 5 token. Message integrity and confidentiality are provided by Secure Sockets Layer (SSL) transport security. This policy set follows the OASIS Kerberos Token Profile V1.1 and WS-Security specifications.

When you use this policy set, configure the basic authentication data and custom properties such as the com.ibm.wsspi.wssecurity.krbtoken.targetServiceName and com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost custom properties in the client bindings. For more information, see the Authentication generator or consumer token settings and Protection token settings (generator or consumer) topics.

LTPA WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username SecureConversation

This policy set provides:

- Message integrity through digital signature that includes signing the body, time stamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications
- Message confidentiality through encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

Username WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.

WSTransaction default policy sets:

The WSTransaction default policy sets are based on the WS-Transaction specification and provide transactional integrity for web services. The WSTransaction default policy sets include the WSTransaction policy set and the SSL WSTransaction policy set.

You can use the WSTransaction default policy sets to make your SOAP over HTTP-based web services interoperable and coordinate atomic transactions or business activities without writing custom code. Use the WSTransaction policy set or the SSL WSTransaction policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WSTransaction default policy sets are:

WSTransaction

Use this policy set to coordinate distributed transactional work atomically and interoperably, by using the WS-AtomicTransaction specification. Also, use this policy set to coordinate loosely coupled business processes that are distributed across the heterogenous web service environment, with the ability to compensate actions if a failure occurs in the business activity, by using the WS-BusinessActivity specification.

SSL WSTransaction

Use this policy set to coordinate distributed transactional work atomically, interoperably and securely, by using the WS-AtomicTransaction specification and SSL Transport security. Also, use this policy set to coordinate loosely coupled business processes, with the ability to compensate actions if a failure occurs in the business activity, securely, by using the WS-BusinessActivity specification and SSL Transport security.

WSHTTPS default policy set:

The WSHTTPS default policy set provides SSL transport security for the HTTP protocol with web services applications.

The WSHTTPS default policy set is provided with the application server and it contains the HTTP transport policy, the SSL transport policy and the WS-Addressing policy.

You can use the WSHTTPS default policy set as provided with the application server. You cannot edit the WSHTTPS default policy set. You can create a copy of the default policy set and then configure custom policy settings and bindings to meet your needs. Alternatively, you can create a new policy set and specify the policies for it.

Copy of default policy set and bindings settings:

Use this page to copy a policy set that you select from a list of available policy sets.

To view this administrative console page:

1. Click **Services > Policy sets > Application policy sets**.
2. Select the policy set that you want to copy, and click **Copy**.
3. Enter a name for the copy of the policy set in the **Name** field.
4. [Optional] Enter a description for the copy of the policy set in the **Description** field.

Name:

Specifies the name of the policy set. Use this field to enter a name for the copy of the policy set.

Description:

Specifies a description of the policy set that you want to copy.

Transfer attachments:

If the policy set that you want to copy is attached to one or more applications, services, or endpoints, then the check box option for **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations**, is available. The default setting for this check box is cleared. You can perform the following actions:

1. Select the **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations** check box to move the attachments to a new policy set. Selecting the check box detaches the original policy set and attaches the replacement policy set in its place.
2. Select **Copy bindings** if you want to copy the bindings of the policy set that is currently attached.
3. [Optional] Select **Restore default bindings** if you want to restore the default bindings.

Configuring the WS-Addressing policy

When working with policy sets in the administrative console, you can add and configure policies to enable standard addressing of web services.

Before you begin

You can specify policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

About this task

Adding a WS-Addressing policy enables the support for WS-Addressing. This support provides a standard way to address Web services and include addressing information in messages. Adding a WS-Addressing policy is equivalent to configuring the WSDL file for the web service to specify that WS-Addressing should be used.

To specify or configure the policies associated with a policy set, use the administrative console.

Procedure

1. In the navigation pane of the administrative console, click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **[Policies] WS-Addressing**. The WS-Addressing settings pane is displayed.

2. Select **WS-Addressing is mandatory** to specify that WS-Addressing information must be included in SOAP message headers. For servers, this setting means that the server returns a fault if it receives a message that does not contain a WS-Addressing header. For clients, this setting means that WS-Addressing headers are always added to SOAP messages. If you have enabled WS-Policy, this requirement is communicated between servers and clients that support WS-Policy.
3. In the **Messaging style** box, select the message exchange pattern to use:
   - **Synchronous and asynchronous**. The targeting of response messages is not restricted.
   - **Synchronous only**. Response messages must be targeted at the WS-Addressing anonymous URI.
   - **Asynchronous only**. Response messages must not be targeted at the WS-Addressing anonymous URI.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

After you have included the WS-Addressing policy in a policy set, the associated policy set uses this policy to address web services.

WS-Addressing policy settings:

Use this page to define the appropriate WS-Addressing policy assertions for this policy set.

To view this administrative console page, click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **[Policy] WS-Addressing**, when the policy set includes the WS-Addressing policy type.

You can configure the WS-Addressing policy type for both client-side and provider-side policy sets. If you enable WS-Policy, this configuration is communicated between servers and clients that support WS-Policy.

WS-Addressing is mandatory:

Specifies whether a WS-Addressing SOAP header is included on messages.

Information	**Value**
Data type	Check box
Default	Cleared
Range	**Cleared** WS-Addressing is not mandatory. Servers will not generate a fault if they receive a message that does not contain a WS-Addressing header. Clients might not include WS-Addressing headers in SOAP messages, for example, if WS-Policy is enabled and the server does not specify that WS-Addressing is mandatory. **Selected** WS-Addressing is mandatory. Servers return a fault if they receive a message that does not contain a WS-Addressing header. Clients always include WS-Addressing headers in SOAP messages.

Messaging style:

Specifies the messaging style supported by this policy set.

Use the radio buttons to configure the messaging style.

- Select **Synchronous and asynchronous** to specify that there is no restriction on the targeting of response messages.
- Select **Synchronous only** to specify that response messages must be targeted at the WS-Addressing anonymous URI. You might want to use this messaging style in the following situations:
  - The SOAP headers are not signed, and WS-Security is not enabled. Specifying the synchronous message exchange pattern prevents the server sending messages to a third party, thereby preventing the server from potentially taking part in a Denial of Service attack.
  - Clients with a NAT device between themselves and the endpoint. In this configuration, non-anonymous URIs cannot be routed. Use this setting to prevent the client from sending a message containing a ReplyTo endpoint reference with a non-anonymous URI.
- Select **Asynchronous only** to specify that response messages must not be targeted at the WS-Addressing anonymous URI. This setting does not mean that all non-anonymous URIs are supported, therefore a server can return a fault if it receives a response endpoint reference that it cannot process. You might want to use this messaging style if the endpoint has a very long-running invocation time, and you do not want to hold the connection open while waiting for a response.

The following table shows how the messaging style options correspond to WS-Policy assertions.

Table 140. WS-Addressing messaging style and WS-Policy. This table provides a mapping between messaging style options and WS-Policy assertions.

Messaging style	WS-Policy mapping
Synchronous and asynchronous	wsam:AnonymousResponses or wsam:NonAnonymousResponses
Synchronous only	wsam:AnonymousResponses
Asynchronous only	wsam:NonAnonymousResponses

Information	Value
Required	No
Data type	Radio button

Attaching a policy set to a service artifact

Attach a policy set to a service artifact, such as an application, service, endpoint or operation, to define the quality of services that are supported. Policy sets can define the policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport.

Before you begin

Before you can start this task, you must deploy an application containing web services. Also, if none of the default policy sets contain the necessary policy definitions, then you must create a custom policy set with the necessary definitions.

About this task

Develop a web service that contains each of the necessary artifacts, and deploy your web services application into your application server instance. Now you can attach policy sets to your service artifacts, such as an application, service, or endpoint.

To attach a policy set to a service artifact, perform the following steps:

Procedure

1. Open the administrative console.

2. To attach a policy set to a service provider, click **Applications > Enterprise applications** > ***application_name*** > **Service provider policy sets and bindings**.

   To attach a policy set to a service client, click **Applications > Enterprise applications** > ***application_name*** > **Service client policy sets and bindings**.
3. Select the check box for the service artifact.
4. Select **Attach** to display a list of available policy sets to attach. Select a policy set from the list.
5. Click **Save**, to save your changes to the master configuration.
6. [Optional] To see what attachments are defined for a given policy set, select **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **Attached applications**.

Results

When you finish these steps, a policy set is attached to the service artifact.

Example

If you have the application, `app1` and you want to attach the policy set, `WSSecurity default`, then perform the following steps:

1. Locate the `app1` application in the **Applications** > **Enterprise applications** collection.
2. Click the **app1** application.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link.
4. Select the check box for the service artifact where the policy set is to be attached.
5. Click **Attach**. Select **WSSecurity default** policy set.
6. Click **Save**, to save your changes to the master configuration.

What to do next

You can create custom bindings for policy set attachments. Read about creating custom bindings for policy set attachments.

You can configure the service client or service provider to share their policies. Read about using WS-Policy to exchange policies in a standard format.

Configuring a service provider to share its policy configuration

A WebSphere Application Server service provider can share its policy configuration in published Web Services Description Language (WSDL), or WSDL that is obtained by using an HTTP GET request or the Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request.

Before you begin

You have developed a web services service provider that contains all the necessary artifacts and deployed your web services application into your application server instance. You have attached the policy sets and managed the associated bindings.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the topic about learning about WS-Policy.

About this task

You can make the policy configuration of a Java API for XML-Based Web Services (JAX-WS) service endpoint available to share in the following ways:

- Include the policy configuration of the service provider in the WSDL. The WSDL is then available to publish, or to obtain by using an HTTP GET request.
- Enable the Web Services Metadata Exchange (WS-MetadataExchange) protocol so that the policy configuration of the service provider is included in the WSDL and is available to a WS-MetadataExchange GetMetadata request. An advantage of using the WS-MetadataExchange protocol is that you can apply message-level security to WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

If the service provider application uses multipart WSDL, all the WSDL must be local to the web service application. For more information about multipart WSDL, see the topic about WSDL.

You must configure a service provider to share its policy configuration because by default the policy configuration is not available in its WSDL. You can configure the service provider to include the policy configuration in its WSDL, to use WS-MetadataExchange so that the policy configuration is available, or both. This topic describes how to configure a service provider to share its policy configuration by using the administrative console. You can also configure a service provider to share its policy configuration by using wsadmin commands or Rational Application Developer tools.

You can configure a service provider to share its policy configuration at application or service level. The policy configuration that is represented by the policy sets attached to any lower levels will also be shared. Policy sets that are attached at lower levels override the policy set configuration attached at a higher level.

Procedure

1. From the navigation pane of the administrative console, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_provider_application_instance*** > **[Web services properties] Service provider policy sets and bindings**.
2. In the row for the application or service where the provider policy that you want to share is attached, click the link in the Policy sharing column. The link is either **Enabled** or **Disabled**. The Policy Sharing pane is displayed.
3. To include the policy configuration of the service provider in its WSDL so that it can be either published or obtained by using an HTTP GET request, select **Exported WSDL**.
4. To enable WS-MetadataExchange and make the policy configuration of the service provider available to a WS-MetadataExchange GetMetada request, select **WS-MetadataExchange request**.
5. Optional: If you select **WS-MetadataExchange request** and you want to use message-level security, select **Attach a system policy set to the WS-MetadataExchange**, then select a suitable policy set and binding from the drop-down lists. See Configuring security for a WS-MetadataExchange request.
6. Click **OK** and save your changes to the master configuration.

Results

The policy configuration of the service provider is available to its clients. The WSDL of the service provider contains the current policy configuration in WS-PolicyAttachments format so that it is available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification. The link in the Policy Sharing column on the Service provider policy sets and bindings pane changes to **Enabled**.

If the policy configuration cannot be shared, an error that describes the problem is written to the service provider error log, and the following policy is attached to the WSDL of the service provider:

```
<wsp:Policy>
<wsp:ExactlyOne>
</wsp:ExactlyOne>
</wsp:Policy>
```

This policy notifies the client that there is no acceptable policy configuration for the service. Other aspects of the WSDL are unaffected.

A service provider might not be able to share its policy configuration because the configuration cannot be expressed in the standard WS-PolicyAttachments format. One reason might be because multiple incompatible policies are defined for a particular attach point. Another reason might be because there is not enough binding information to generate the standard policy. Policy configuration might include bootstrap policy, for example, the policy to access a WS-Trust service, so the bootstrap policy must also be expressed in WS-PolicyAttachments format.

Configuring a service provider to share its policy configuration using wsadmin scripting:

A WebSphere Application Server service provider can share its policy configuration in published Web Services Description Language (WSDL), or WSDL that is obtained by using an HTTP GET request or the Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request.

Before you begin

You have developed a web services service provider that contains all the necessary artifacts and deployed your web services application into your application server instance. You have attached the policy sets and managed the associated bindings.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the topic about learning about WS-Policy.

About this task

You can make the policy configuration of a Java API for XML-Based Web Services (JAX-WS) service endpoint available to share in the following ways:

- Include the policy configuration of the service provider in the WSDL. The WSDL is then available to publish, or to obtain by using an HTTP GET request.
- Enable the Web Services Metadata Exchange (WS-MetadataExchange) protocol so that the policy configuration of the service provider is included in the WSDL and is available to a WS-MetadataExchange GetMetadata request. An advantage of using the WS-MetadataExchange protocol is that you can apply message-level security to WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

If the service provider application uses multipart WSDL, all the WSDL must be local to the web service application. For more information about multipart WSDL, see the topic about WSDL.

You must configure a service provider to share its policy configuration because by default the policy configuration is not available in its WSDL. You can configure the service provider to include the policy configuration in its WSDL, to use WS-MetadataExchange so that the policy configuration is available, or both. This topic describes how to configure a service provider to share its policy configuration by using wsadmin commands. You can also use the administrative console or Rational Application Developer tools.

You can configure a service provider to share its policy configuration at application or service level. The policy configuration that is represented by the policy sets attached to any lower levels will also be shared. Policy sets that are attached at lower levels override the policy set configuration attached at a higher level.

Procedure

1. Start the wsadmin scripting client if it is not already running.
2. Use the **SetProviderPolicySharingInfo** command. For example:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WebServiceProviderApplication
-resource WebService:/WebServiceProvider.war:{http://example_path/}Service1
-sharePolicyMethods [httpGet ]]')
```

3. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

Results

The policy configuration of the service provider is available to its clients. The WSDL of the service provider contains the current policy configuration in WS-PolicyAttachments format so that it is available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification.

If the policy configuration cannot be shared, an error that describes the problem is written to the service provider error log, and the following policy is attached to the WSDL of the service provider:

```
<wsp:Policy>
<wsp:ExactlyOne>
</wsp:ExactlyOne>
</wsp:Policy>
```

This policy notifies the client that there is no acceptable policy configuration for the service. Other aspects of the WSDL are unaffected.

A service provider might not be able to share its policy configuration because the configuration cannot be expressed in the standard WS-PolicyAttachments format. One reason might be because multiple incompatible policies are defined for a particular attach point. Another reason might be because there is not enough binding information to generate the standard policy. Policy configuration might include bootstrap policy, for example, the policy to access a WS-Trust service, so the bootstrap policy must also be expressed in WS-PolicyAttachments format.

What to do next

Optionally, you can publish the WSDL files.

setProviderPolicySharingInfo command:

Use the **setProviderPolicySharingInfo** command to set how an application or service that is a web service provider can share its policy configuration with other clients, service registries, or services that support the WS-Policy specification. You can set or remove this information about how a provider policy is shared.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the **setProviderPolicySharingInfo** command to set how an application, or a service in an application, shares its policy configuration with clients, service registries, or services that support the WS-Policy specification. The policy configuration is shared in WS-PolicyAttachments format.

The policy configuration of the resource can be shared with clients through a WS-MetadataExchange request, through Web Services Description Language (WSDL) exported by a `?WSDL` HTTP Get request, or through both methods.

Target object

None.

Required parameters

-applicationName
The name of the application for which you want to set how the provider policy is shared. (String)

-resource
The name of the resource for which you want to set how the provider policy is shared. For all resources in an application, specify `WebService:/`. For a service in an application, specify `WebService:/`*`module`*`:{`*`namespace`*`}`*`service_name`*. Endpoints or operations inherit the settings of the parent application or service. (String)

Optional parameters

-sharePolicyMethods
Specifies how the policy configuration of the resource can be shared. (String array)

Enter either or both of the following values:

httpGet
The resource can share its policy configuration through WSDL that is obtained by a `?WSDL` HTTP Get request.

wsMex The resource can share its policy configuration through a WS-MetadataExchange request.

-wsMexProperties
Specifies that message-level security is required for WS-MetadataExchange requests and specifies the settings that provide the message-level security. (Properties)

Enter the following values, following each value with the setting that you require for that value:

wsMexPolicySetName
The name of the system policy set that specifies message-level security when the resource shares its policy configuration through a WS-MetadataExchange request. Specify a system policy set that contains only WS-Security policies, only WS-Addressing policies, or both. The default policy set is `SystemWSSecurityDefault`.

wsMexPolicySetBinding
The name of the general binding for the policy set attachment when the resource shares its policy configuration through a WS-MetadataExchange request. Specify a general binding that is scoped to the global domain, or scoped to the security domain of this service. If you do not specify this property, the default binding is used.

This parameter is valid only when you specify `wsMex` for the **sharePolicyMethods** parameter.

-remove
Specifies whether the information about how the provider policy is shared is removed from the resource. (Boolean)

This parameter takes the following values:

true The information about how the provider policy is shared is removed from the resource.

false This value is the default. The information about how the provider policy is shared is not removed from the resource.

Examples

The following example removes the information about how the provider policy is shared from the WSSampleServices application:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/ -remove true]')
```

The following example enables policy sharing, using WSDL exported by a `?WSDL` HTTP Get request, for the EchoService service in the WSSampleServices application:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/WSSampleServicesSei.war:{http://example_path/}EchoService
-sharePolicyMethods [httpGet ]]')
```

The following example enables policy sharing, using a WS-MetadataExchange request with message-level security, for the WSSampleServices application. Message level security is provided by the SystemWSSecurityDefault policy set and the “Provider sample” general binding.

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/ -sharePolicyMethods [wsMex ]
-wsMexProperties [ [wsMexPolicySetName [SystemWSSecurityDefault]]
[wsMexPolicySetBinding [Provider sample]] ]]')
```

getProviderPolicySharingInfo command:

Use the **getProviderPolicySharingInfo** command to find out whether an application or service that is a web service provider can share its policy configuration, and list the properties that apply to sharing that configuration.

To run the command, use the AdminTask object of the wsadmin scripting client.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the **getProviderPolicySharingInfo** command to find out how a web services application, or a service in a Web services application, shares its policy configuration with clients, service registries, or services that support the WS-Policy specification. The policy configuration is shared in WS-PolicyAttachments format.
